Despite random assignment after the completion of baseline measures and no differences in the way individuals progressed through the trial, there were substantial baseline differences between groups on outcome measures. Accordingly, to examine the effect of the intervention on the outcome measures (MHSS, SSOMI, and GHSQ), ANCOVA using baseline status on the outcome variable as a covariate was chosen as the most appropriate method to adjust for baseline imbalance. Baseline values of each outcome were centered at the whole-sample (intention-to-treat) mean at baseline, so the model parameters for group represent the effect of the intervention at the group mean. The effect of the covariate was allowed to differ postintervention and at follow-up, as was the effect of the intervention itself. Standardized effect sizes were calculated using the difference between groups at the mean and dividing it by the modeled pooled SD for the variable at each time point. Effect sizes (the strengths of the effects demonstrated) were calculated using Cohen *d* estimates of 0.2 for small effect sizes, 0.5 for medium, and 0.8 for large [33].

These analyses were repeated separately for participants with baseline total scores on the DASS-21 of 14 or higher (ie, high mental health distress group) and those with scores below 14 (ie, low mental health distress group) to explore the effectiveness of the intervention in these subgroups.

Qualitative Study

Participants (n=12) were divided into 2 groups based on their levels of current distress to identify potential qualitative differences between individuals with high mental health distress

XSL•FO
RenderX

(total scores>14 on the DASS-21) and low mental health distress (total scores<14 on the DASS-21). Groups consisted of an equal number of participants (n=6). An explanatory sequential design was used to integrate the quantitative and qualitative findings. Quantitative data were collected and analyzed first, followed by qualitative interviews with a subset of participants who volunteered to elaborate on their experiences with the intervention. This approach allowed for a deeper understanding of unexpected or complex results by examining whether participants with high mental health distress responded differently to the intervention compared to those with low mental health distress.

We followed Braun and Clarke's [23] method of reflexive thematic analysis within a contextualist framework, which emphasizes that a person's meaning-making occurs through an interplay between the individual and their environment. In so doing, we used an inductive (bottom-up) approach to identify patterned meanings within the dataset.

One lead researcher conducted all qualitative interviews and transcriptions, immersing themselves in the data. Once completed, participant transcripts were separated into 2 groups ("low mental health distress" or "high mental health distress") and read and reread, with reflexive notes (memos) made relating to notable or recurring observations or concepts. Codes were then applied to each individual transcript, line by line. These codes were discussed during regular meetings with another member of the research team, at which points some codes were modified and reapplied to the transcripts. Given the significant overlap in codes and potential themes, the groups (low and high mental health distress) were combined for subsequent analysis. To identify candidate themes and subthemes, the lead researcher grouped codes together, focusing on semantic features of the data. These initial themes and subthemes were further refined during regular discussions with the broader team, and eventually drawn together into a thematic map. Relevant data, including direct quotes from the transcripts, were collated under the respective themes and subthemes to demonstrate theme or subtheme coherence. The thematic map and the quotes supporting it were reviewed several times with the broader team prior to writing up the results. Consistent with reflexive thematic analysis methodology, we did not focus on data saturation, as we recognize that decisions about sample size and the number of data items collected are inherently subjective and context-dependent, and cannot be fully determined before analysis [23]. Instead, our sampling approach was guided by the concept of "information power" [34] in qualitative research, which considers sample size based on the study aim, sample specificity, theory, data richness, and relevance.

Results

Quantitative Findings

Primary Analyses

Public Stigma

There was a significant difference in mental health public stigma of 0.76 points between the intervention and the active control group postintervention ($F_{1,\ 319}$=8.53, 95% CI 0.25 - 1.27; P=.004). This represented a small effect size (0.18) in favor of the intervention.

Self-Stigma

There was no significant difference between the intervention and active control groups on self-stigma postintervention (modeled mean difference=0.37, SD 6.88; $F_{1,\ 319}$=0.74, 95% CI –0.47 - 1.22; P=.39). However, there was a significant group difference on self-stigma at 1-week follow-up (modeled mean difference=1.55, SD 6.92; $F_{1,\ 166.41}$=5.76, 95% CI 0.27 - 2.82; P=.02, showing a small, beneficial effect size (0.22).

Help-Seeking Intentions: Formal

There was a significant difference of 0.23 points (SD 1.58) between the intervention and the active control group on intentions to seek help from formal sources of help postintervention ($F_{1,\ 319}$=7.78, 95% CI 0.07 - 0.39; P=.006), showing a small effect size (0.15) in favor of the intervention. There was no significant group difference in intentions to seek help from formal sources from baseline to 1-week follow-up (modeled mean difference=0.24, SD 1.53; $F_{1,\ 145.23}$=2.13, 95% CI –0.08 to 0.57; P=.15).

Help-Seeking Intentions: Informal

There were no significant group differences on intentions to seek help from informal sources postintervention (modeled mean difference=–0.07, SD 1.15; $F_{1,\ 319}$=1.72, 95% CI –0.17 to 0.03; P=.19) or at 1-week follow-up (modeled mean difference=–0.20, SD 1.20; $F_{1,\ 139.40}$=2.69, 95% CI –0.44 to 0.04; P=.10).

Exploratory Analyses

Mental Health Distress

Exploratory subgroup post hoc analyses examined the effectiveness of the intervention for individuals with high mental health distress and low mental health distress (Table 2). Those with high mental health distress showed reduced levels of mental health public stigma (modeled mean difference=1.00, SD 4.01; $F_{1,\ 229}$=11.70, 95% CI 0.43 - 1.58; P<.001) immediately following the intervention and were less likely to seek help using informal sources of help (eg, a partner, friend, parent, relative, or family member) at 1-week follow-up (modeled mean difference=0.40, SD 1.16; $F_{1,\ 101.7}$=7.56, 95% CI 0.11 - 0.69; P=.007). This effect of a decrease in intentions to seek help from informal sources, for individuals with high mental health distress was present at follow-up (P=.007), but not immediately following the intervention (P=.06; Figure 2). The effect of informal help-seeking was not significant in participants with low mental health distress postintervention (P=.41) and at 1-week follow-up (P=.07). Instead, participants with low mental health distress reported being more likely to seek help from formal sources of help (eg, a mental health professional, phone helpline, GP, or teacher) following the intervention (modeled mean difference=0.41, SD 1.57; $F_{1,87}$=4.41, 95% CI 0.02 - 0.79; P=.04), but this was not significant at follow-up (P=.09).

XSL•FO
RenderX

Figure 2. Effect of a significant decrease in informal help-seeking at follow-up for individuals with high mental health distress in the intervention group versus the active control group (*P=.007).

For individuals with high mental health distress, there was no significant effect of intentions to seek help from formal sources of help following the intervention (P=.06) or at 1-week follow-up (P=.54). Furthermore, there were no improvements in self-stigma for participants with high mental health distress or low mental health distress, immediately after the intervention (P=.39; P=.85) or at 1-week follow-up (P=.11; P=.18), respectively.

Qualitative Findings

Participant Perceptions of the Contact-Based Intervention

We identified two themes regarding participants' perceptions of the brief digitized contact-based intervention: (1) helpfulness of the intervention and (2) relatability to the speaker (Table 3).

Table . Themes and subthemes for participant perspectives of the contact-based intervention.

Theme	Subtheme
1. Helpfulness of the intervention	• 1.1. Helpful for the participant • 1.2. Helpful for other people • 1.3. Learning something new from the intervention
2. Relatability to the speaker	• 2.1. Understanding how the speaker would be feeling • 2.2. Descriptions of the speaker

Theme 1: Helpfulness of the Intervention

Participant responses varied, with both groups indicating mixed feedback on the helpfulness of the intervention. Participants in the high mental health distress group reported that the intervention was not particularly helpful for themselves (subtheme 1.1), with all participants in that group indicating that they did not learn anything new from the intervention (subtheme 1.3). One participant stated that "the video didn't have a huge impact" and that they "wouldn't say it was helpful" as they have "seen so many videos like that before" (subtheme 1.1). Another participant stated that the video did not increase their awareness, but served to reinforce "how cruel other people can be toward others because they're different" (subtheme 1.3). Notably, this lack of perceived benefit from the video was shared by participants in the low mental health distress group with a history of mental health treatment, who voiced similar responses that the video was not helpful "for someone like me who does know quite a bit about it," and that there was nothing in the video that "I wasn't aware of" (subtheme 1.3). Conversely, those in the low mental health distress group without a history of mental health treatment generally reported that the video was "definitely helpful," "enlightening," or "educational and inspiring" (subtheme 1.1).

While participants in the high mental health distress group reported finding the intervention not helpful for themselves, many indicated that they believed it would be helpful for other people (subtheme 1.2) without their own experiences of mental health difficulties. One participant in the high mental health distress group reported that "for some people, it could be quite helpful, somebody could see it and may be motivated to reach

XSL•FO
RenderX

out to someone" (subtheme 1.2). This view was shared by other participants in the same group, who reported that the video might help other people "find and seek some help" (subtheme 1.2). Relatedly, participants in the low mental health distress group with a history of mental health treatment reported similar thoughts that the video might be more helpful for people who "don't know much about mental health" (subtheme 1.2) or people with higher levels of stigma.

Theme 2: Relatability to the Speaker

Participants also spoke at length about the video speaker and the relatability they felt to either the speaker or their story. Importantly, participants in the high mental health distress group reported finding the speaker and their experience less relatable, although they understood how the speaker would be feeling (subtheme 2.1). Several participants in the high mental health distress group stated that while they did not relate to the speaker's experience or situation, they could relate to the general feeling of having mental health difficulties. For example, one participant stated that they "related to the speaker not in the situation he was in, but in the whole idea of how other people exclude you," while another noted that they could relate "not in terms of their circumstance, but specifically to how they were feeling" (subtheme 2.1).

Consistent with this view, one participant from the low mental health distress group with a history of mental health treatment reported a similar observation, noting that while they "felt pretty different to the speaker," they thought "they would probably understand what it feels like to be a little bit different" (subtheme 2.1). Conversely, other participants in the low mental health distress group reported greater relatability to the speaker, with many stating that they could understand the speaker's situation and relate it to something similar they had previously experienced. Extending on this, one participant in the low mental health distress group stated that they "definitely did relate" and felt "connected" to the speaker, while another participant reported feeling "very empathetic" toward what the speaker was going through (subtheme 2.1).

Furthermore, notable differences arose between groups in descriptions of the speaker (subtheme 2.2). Participants in the low mental health distress group reported feeling strongly about the speaker, often describing them as "real," "sincere," "genuine," "brave," "heartfelt," and "engaging" (subtheme 2.2). Participants in the high mental health distress group referred to the speaker as "interesting," "straightforward," or "easy to understand" (subtheme 2.2).

Discussion

Principal Findings

This study aimed to investigate the effectiveness of a brief digitized contact-based intervention, specifically targeting anxiety and depression, in reducing self-stigma and public stigma and improving help-seeking intentions in young adults. In line with our hypothesis, overall public stigma around mental health and formal help-seeking intentions appeared to improve for those in the intervention group immediately following the intervention. These effects, however, were not sustained at follow-up. Contrary to our hypothesis, the contact-based intervention had a limited impact on improving self-stigma or informal help-seeking intentions across the whole sample. Although immediate improvements in self-stigma were not observed for either group postintervention, individuals who received the intervention demonstrated small improvements in self-stigma 1 week after the intervention. Finally, quantitative and qualitative results showed differing effectiveness of the intervention, with those experiencing high mental health distress responding less positively than those with low mental health distress, contrary to predictions.

Overall, these findings suggest that watching the brief videos can potentially lead to immediate reductions in public stigma and contemporaneous increases in the intentions to seek help from formal sources of help, such as a mental health professional, phone helpline, GP, or teacher. As these effects were not maintained at 1-week follow-up, the intervention's impact on public stigma and help-seeking intentions appears to be short-lived. Conversely, a sleeper effect was observed for self-stigma, with improvements in self-stigma only emerging at follow-up. While previous reviews and meta-analyses have found contact effects to persist at short-term follow-up [7], others have not [8]. These findings may not be surprising given the intervention brevity and the small initial effect. Due to dropout, a lack of power at follow-up due to insufficient sample size may have also influenced the null findings relating to self-stigma and help-seeking from informal sources of help.

Recent meta-analyses of contact interventions yield small to moderate effects; however, the improvement in public stigma in this study was of small effect. It may be the case that the "dose" of the current intervention, at only approximately 8 minutes in duration, influenced the magnitude of the effect. Previously evaluated interventions generally range from 30 minutes to hours in duration [1,7-9]. Although the meta-analysis conducted by Morgan and colleagues [8] did not find that the duration of interventions influenced effectiveness, the review only examined studies targeting severe psychiatric stigma. One consideration in this study that may have contributed to the small effect of the brief digitized contact-based intervention on young adults is the isolated context in which the video was delivered. Typically, the lived experience stories are embedded within a wider batyr@uni program (60 - 90 min in duration), which involves a live debrief discussion on key themes and actionable takeaways from the lived experience stories. While the brief videos used in this study include a prerecorded debrief, perhaps integrating a live facilitator to draw links between the story and discussions around key mental health themes may play a greater role in the intervention's overall impact in the future. Evidence suggests that contact-based interventions are more effective when combined with psychoeducation components to improve mental health literacy [12], including approaches that explicitly target misconceptions regarding treatment-seeking [14], which may be more compelling for young people [14].

Shifting our focus to more nuanced exploratory findings within the subgroups, although both individuals with high and low mental health distress showed improvements in public stigma immediately following the intervention, the findings suggest

XSL•FO
RenderX

that individuals with high mental health distress were less likely to want to seek help from informal sources of help, such as through a partner, friend, parent, relative, or family member, 1 week later. This finding is potentially concerning in the absence of an increase in formal help-seeking intentions in this subgroup, with no significant effect of intentions to seek help from formal sources such as a mental health professional, phone helpline, family doctor, GP, or teacher. It is these formal sources of help that have a higher likelihood, although far from guaranteed, to be evidence-based compared to help that may come from friends and family [35]. In contrast, the findings suggest that individuals with low mental health distress were more likely to use formal sources of help immediately after watching the brief video intervention; however, these effects were not sustained at follow-up. Further caution is warranted when interpreting the results, due to the exploratory and underpowered nature of the subgroup analyses or may reflect the complex interactions with prior mental health experiences. Additionally, the low reliability of the informal help-seeking subscale in the GHSQ suggests that these results should be interpreted with caution. Nonetheless, given that contact-based interventions are designed to increase help-seeking attitudes, particularly for individuals experiencing mental health difficulties who may need it the most, careful consideration in the design of brief digitized interventions is needed and tailoring the videos to target these vulnerable groups and encourage help-seeking would be beneficial.

Furthermore, the sleeper effect observed in improved self-stigma for all those who received the intervention was not evident in the subgroup analyses. No intervention effects at postintervention or follow-up were observed in self-stigma for either those with high or low mental health distress. This is not surprising given the small effect size observed in the whole sample (0.2). An insufficient sample size and subsequent lack of power in the subgroups may have contributed to the null findings for self-stigma. Regardless, these effects may indicate that the current intervention is not sufficiently powerful to shift young adults' perception of their mental health. Future research should focus on replication with a larger sample and enhancing the intervention to allow for more meaningful and long-term shifts in mental health stigma.

Several key themes in the qualitative results were identified, showing differences between the subgroups on topics related to the helpfulness of the intervention and relatability to the speaker in the videos. For instance, individuals with high mental health distress tended to have more negative views about the helpfulness of the intervention and were less likely to be able to relate to the speaker's experience in the videos. On the contrary, individuals with low mental health distress reported more positive responses to the intervention and found the videos educational and helpful. These qualitative findings provide valuable insights into young adults' perceptions of the digitized contact-based intervention. While improvements in public stigma were observed in individuals with high mental health distress, they appeared to respond more negatively toward the contact-based intervention compared to those with low mental health distress. They reported that the intervention provided them with no additional information or learning, that they were familiar with the content conveyed, leaving little impact and negatively reinforced the stereotype that people can be cruel toward individuals with mental health difficulties who are perceived as different. This supports previous research indicating that contact-based interventions are less effective for individuals with prior mental health difficulties, which may be related to preexisting awareness and understanding [22]. A potential explanation may be that these individuals were less likely to see the value in seeking help from and disclosing their mental health to family members or friends following the intervention. These findings add to the growing literature indicating differences in perceptions between those with and without mental health difficulties [1,21,22].

Some participants in this study expressed their belief that the contact-based intervention would be helpful for others. Individuals with low mental health distress reported that they found the intervention helpful, educational, and insightful. A possible interpretation for this positive response may be that individuals with low mental health distress feel more connected and less alone after hearing about other people's lived experiences of mental health difficulties. This is important to consider. If contact-based interventions are less effective for individuals with high mental health distress, future research could focus on alternative interventions or tailoring the content to focus less on education and awareness and more on targeting stigma and feelings of shame and embarrassment, which may be more appropriate to increase and improve help-seeking in young adults. This aligns with previous qualitative research, where individuals with a previous mental health concern were found to identify with themes of shame and embarrassment, compared to those without a previous mental health history [1].

Another factor to consider in designing these interventions pertains to the relatability of the speaker in the contact-based intervention. While the lived experience stories delivered within the batyr@uni program are represented by individuals from diverse backgrounds and experiences, these findings suggest that young adults' relatability to the video speaker differs depending on their levels of mental health distress. Individuals with high mental health distress related less and responded less positively to the speaker. In contrast, participants with low mental health distress spoke more positively, often describing the speaker as highly relatable, genuine, and engaging. This discrepancy may contribute to differences in the effectiveness of the contact-based intervention between groups, suggesting different underlying mechanisms driving change in individuals. Perhaps individuals with high mental health distress experience unique challenges and find the more positive or uplifting aspects of the intervention to be somewhat incongruent with their current mental state. While individuals with low mental health distress may be able to connect more to the positive aspects of the speaker's journey and view the speaker more favorably, and thus are more likely to seek help from formal sources of help as indicated in the quantitative subgroup analysis. Furthermore, the videos and the speaker delivering the intervention were not piloted for likability and perceived relatability prior to the intervention, which are factors shown to influence the effectiveness of antistigma interventions and may potentially account for group differences in perceived helpfulness,

XSL•FO
RenderX

help-seeking intentions, and stigma among the low and high mental health distress groups. These are important aspects to consider when developing and evaluating the effectiveness of stigma-related interventions for young adults with mental health difficulties. Further research is needed to determine whether altering such factors may improve the efficacy of such interventions.

Strengths, Limitations, and Future Directions

This study was the first to investigate whether a brief digitized contact-based intervention (one component of the batyr@uni program) was effective in reducing public stigma, self-stigma, and help-seeking intentions in a young adult university sample using a mixed methods study design. The quantitative and qualitative analyses provide a deeper insight into young adults' perspectives of a brief digitized contact-based intervention targeting anxiety and depression. However, one limitation in this study is the way in which some constructs were measured. For instance, we did not measure actual help-seeking behavior, mental health difficulties, and the construct measurement of self-stigma was more aligned with anticipated self-stigma (ie, future-tense items may reduce sensitivity to change for participants without a current stigmatized identity), which may help explain stability in scores across time points. While help-seeking intentions predict behaviors [29], the relationship is not always strong [36]. Future research should prioritize behavioral measurement of actual help-seeking behavior to better evaluate intervention outcomes of such clinical significance.

Moreover, studies have found that factors such as openness to seeking help, increased mental health literacy, including recognition of disorder symptomology and treatment benefits, predicted help-seeking intentions within an undergraduate sample [12]. Further research is needed to determine whether additional components to contact alone, such as mental health literacy and openness to help-seeking, are needed to bridge the gap between stigma improvement and help-seeking attitudes [12].

In this study, approximately 1 in 5 participants dropped out prior to completing assessments at postintervention, and of those who did, over half did not complete the follow-up assessment. Although there were no differences at baseline or across conditions for dropout, it is difficult to determine whether any systematic factor influenced the dropout rate. As the study was completed online and anonymized, it was not possible to determine the reason for dropout. Such substantial dropout likely influenced the power to detect effects at that time point, possibly accounting for the absence of certain effects persisting over time.

A further limitation is that substantial baseline differences were identified between the intervention and control groups on outcome measures, despite randomization to condition after the completion of baseline measures. Given precision in the identical nature of the procedures between conditions and no differences in the way individuals progressed through the trial, it was concluded that these differences occurred by chance. Nevertheless, this impacted our analysis method and interpretation of results, which involved ANCOVA using baseline status on the outcome variable as a covariate to adjust for the baseline imbalance between groups.

The sample in this study limits the generalizability of findings to other similar groups of young adults. In particular, the small sample size of 12 participants in the qualitative study may not be representative of the perceptions and attitudes of the population from which they were drawn. Participants in this study were majority female undergraduate university students studying psychology, and thus, we might expect lower levels of mental health stigma and greater understanding or awareness when compared to the broader population. Relatedly, for the qualitative study, participants voluntarily expressed their interest in the study and willingness to share their perspectives. The participants involved may have been those more familiar with mental health stigma or those with strongly held opinions that they wished to discuss. Further, the brief contact intervention specifically targeted anxiety and depression in young adults; however, the nature and intensity of mental health stigma can differ across mental disorders, thus the findings may be limited to experiences with common mental disorders. Another limitation is due to the small sample of 6 participants in each group (high vs low mental health distress group). That said, the information elicited from these participants during the in-depth interviews was sufficiently rich to address the study objectives.

Despite these limitations, significant qualitative differences in this study were found among the sample of psychology students, perhaps indicating that greater differences may exist within the broader population. Future research should extend the evaluation of contact-based interventions beyond a university setting to young adults within the community and from different cultural and socioeconomic backgrounds. Social and cultural differences, as well as digital literacy factors, would likely appear more pronounced within diverse community settings and may weigh more heavily on digital intervention efficacy and moderators.

Given the benefits of a digitized and brief intervention in this study for those with low mental health distress, such as cost-effectiveness, accessibility, and convenience, more widespread dissemination of contact-based interventions appears possible. This has implications for when face-to-face dissemination is not feasible, such as government-mandated lockdowns, or for those living in rural and remote regions. Further research on the effectiveness of a digitized and brief intervention in varied populations would be useful.

Conclusions

In conclusion, this study suggests that a brief contact-based video targeting anxiety and depression holds promise as an intervention that could be widely disseminated to reduce young adults' mental health public stigma in the short term; however, further research evaluating its long-term impact is needed. The intervention had a limited effect on self-stigma. Although the intervention changed the way people viewed others with mental health difficulties, it did not change how individuals perceived their own mental health. In fact, there is some evidence that the intervention may lead young people with high mental distress to be less likely to speak to their friends and family. Together, these findings suggest the need for brief digitized contact-based interventions to be adapted to better cater to individuals with

XSL•FO
RenderX

high mental health distress. Factors such as the perceived helpfulness of the intervention and relatability to the speaker in the videos were identified as key themes to consider when developing and disseminating contact-based interventions for young adults. Several study limitations may underlie null effects following the contact intervention for improvements in self-stigma and help-seeking intentions, and limit the extent to which findings may be extrapolated, indicating a need for further research and replication, particularly in more diverse populations. Further research is needed to determine whether tailored alternate strategies or adjunct components, such as individuals' mental health literacy, prior experience with mental health difficulties, perceived likability of speakers delivering the videos, and behavioral measures of help-seeking, could improve outcomes, particularly in self-stigma and help-seeking intentions in those with high mental health distress.

Acknowledgments

The authors would like to acknowledge that this was part of a Master's research project by ND and AE who contributed to the design, evaluation, and implementation of this research trial. We would like to thank all the participants who took the time to take part in the study. We would also like to acknowledge batyr for providing access to the video resources.

Generative artificial intelligence (AI) tools were not used at any stage in the preparation of this manuscript.

Funding

The research team received $5000 from batyr to support personnel for the independent preparation of the results for publication. The authors do not receive any royalties for mental health literacy programs for youth. No other external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article. The design and execution of the research project received no funding.

Data Availability

The data generated and analyzed in this study are highly sensitive and therefore not publicly available. The study's ethical approvals limit data sharing. Recordings include identifiable information and cannot be shared. Deidentified data (excluding recordings) are available from the corresponding author, JH, upon reasonable request.

Authors' Contributions

JH, ND, AE, and EP conceived the study. ND and AE collected the data and executed the research study. AS, JH, AM, and AE analyzed and interpreted the data. AS, ND, AE, JH, and AM wrote the manuscript, and all authors provided critical feedback. All authors contributed to the approved final version of the manuscript for submission.

Conflicts of Interest

The preparation of the publication was partially supported by batyr. batyr were not involved in the design, execution or write-up of the study. batyr supplied the video materials of the intervention and was given a draft of the manuscript to review prior to submission for the purposes of ensuring the accurate description of the program. batyr met with the research team throughout the execution of the project for the purposes of updating progress.

Abstract

Background: Digital health interventions can be effective at changing behavior, but achieving long-term adherence remains a challenge. One psychological barrier to health behavior change is *future discounting*, or the tendency to prefer smaller, short-term rewards over larger, long-term rewards. Episodic Future Thinking (EFT) can disrupt future discounting and is a promising technique for improving health behavior, but such interventions have not been co-designed to address end user needs.

Objective: This study aimed to co-design an app with end users to deliver an EFT intervention aimed at promoting health behavior change in those in the prerisk phase for chronic conditions.

Methods: Community members participated in up to 2 series of face-to-face co-design workshops. A prototype of the app was reviewed, and insights were gathered to understand (1) the optimal characteristics of the app and (2) the concepts of future discounting and EFT. Themes were generated using inductive thematic analysis.

Results: Participants were South Australian adults (n=30) who were predominately affluent women (27/30, 90%) aged 25 - 44 years (mean 36.37, SD 5.65 years). Feedback generated from the first workshop series resulted in 26 suggestions of which 15 informed iterative app development. Higher-level principles were identified and categorized into 5 overarching themes: concept acceptance, triggers and barriers, personalization, gamification, and user-friendly interface.

Conclusions: This study used co-design methodology to develop an app-based EFT intervention. Ongoing engagement with end users and key stakeholders (eg, health care professionals) is needed to ensure that the app meets changing needs. Future work will aim to evaluate its effectiveness in a large-scale clinical trial.

KEYWORDS

Episodic Future Thinking; digital intervention; future discounting; health behavior change; health behaviors; co-design methods; mobile phone

Introduction

Background

Noncommunicable diseases (NCDs), including cardiovascular diseases, diabetes, cancers, and chronic respiratory diseases, account for 75% of deaths each year [1], making them the leading cause of death worldwide [2]. The main risk factors for NCDs are largely preventable and include modifiable lifestyle behaviors such as poor dietary intake, physical inactivity, alcohol consumption, and illicit drug use [3]. Therefore, devising effective lifestyle interventions to reduce NCD risk is an important research priority. The aim of this study was to develop a co-designed smartphone app to deliver a psychological intervention to improve health behaviors in individuals at risk of NCD.

Challenges in Promoting Sustained Health Behavior Change

Despite the well-established health benefits of consuming a nutritious diet and engaging in regular physical activity [4-6], many people find it challenging to adopt and maintain health-promoting behaviors [7]. Indeed, the 2022 Australian National Health Survey found that only 4.2% of Australians met both the fruit and vegetable intake recommendations, while only 23.9% met the physical activity guidelines [8]. Long-term adherence to lifestyle behavior change interventions is an ongoing challenge [7] and may be partly due to underlying psychological barriers. One such barrier is future discounting, namely, the tendency for individuals to devalue rewards as a function of delayed receipt [9], or prioritize behaviors that provide immediate gratification over longer-term benefits [10].

XSL•FO
RenderX

Higher rates of future discounting have been linked with poor health behaviors and obesity [11,12].

In the context of health behaviors, future discounting involves placing less value on the future by engaging in lifestyle behaviors that produce immediate rewards (eg, sedentary behavior and/or consuming discretionary foods high in salt, sugar, and/or fat). Furthermore, such behaviors often lead to the onset of negative, delayed health consequences (ie, chronic disease) in lieu of long-term future rewards (eg, good health). A preference for smaller, immediate rewards over larger, delayed rewards is a transdiagnostic process that has been implicated in health and disease [13]. Future discounting—or delay discounting as it is otherwise known—is typically measured via monetary or domain-specific (eg, food) choice tasks or questionnaires to assess how quickly rewards of varying amounts reduce in value over time. In the eating domain, a meta-analysis found a medium effect size (d=0.43) for the relationship between future discounting for food and monetary rewards and obesity [14]. This suggests that future discounting is a critical target for interventions aiming to modify risky lifestyle behaviors [15].

Episodic Future Thinking Interventions

Episodic Future Thinking (EFT), namely, a form of prospective thought, involves mentally envisioning oneself experiencing specific, personal, and detailed future-oriented events [16]. EFT is a type of psychological intervention that aims to disrupt one's tendency to discount the future by altering the perceived value of delayed outcomes [17]. EFT enables individuals to not only mentally experience upcoming events [18] but also consider both the immediate and extended consequences of their actions [19]. Specifically, EFT encourages individuals to consider the potential future consequences of current behaviors that have a detrimental impact on long-term health [12,20].

EFT is based on several components of interventions of behavior change technique (BCT) specified in the behavior change taxonomy [21] and Ontology [22]. These components include those related to goal-directed BCTs (ie, goal setting and comparing goals with current behavior) and increasing awareness of consequences of BCTs (ie, prompt comparative imaging of future outcomes). Nevertheless, it is important to understand why these techniques are effective by examining the mechanisms by which these intervention components change outcome behaviors [23,24]. The proposed mechanisms of action for EFT are a reduction in present bias or future discounting and an increase in long-term prospective thinking and valuation of future rewards [25,26], which fall under the domain of bodily disposition and, in particular, a mental disposition (ie, a temporal orientation toward the future) [27].

EFT interventions involve pre-experiencing positive, specific, vivid, future events that are either planned to occur or could realistically occur—a technique described as a form of "mental time travel" [28-30]. Specifically, it involves imagining *who* one is with, *what* one is doing, *where* one is, and *how* one is feeling. The process is used to generate a set of episodic cues to prompt participants to repeatedly practice visualization of such events. EFT cues have typically been generated using 2 approaches: interview-guided or survey-guided, with cue delivery methods usually involving text, audio, and/or visual formats [31].

Previous research has shown that EFT is effective for reducing future discounting rates. Three recent, large meta-analyses reported medium-sized effects in clinical and nonclinical populations [32-34]. These analyses showed that intervention effects were stronger when the imagined future events were more positive, vivid, and related to the delayed choice, as well as for those individuals with higher choice impulsivity, such as steeper discounting [33]. Specifically, EFT was more effective at promoting healthier decision-making in samples with higher choice impulsivity, which suggests that such training is more effective for people who are less likely to examine the future health consequences of their actions [35]. Thus, choice impulsivity may be a mechanism underpinning the effectiveness of EFT [36,37]. Furthermore, EFT has been shown to reduce the occurrence of a range of risky health behaviors, including cigarette smoking [38]; consuming less (approximately 300 calories) energy-dense, nutrient-poor food during an ad libitum eating task with adults and children with overweight and obesity [39,40]; and decreasing the consumption of alcoholic beverages in people with alcohol dependence [41].

Although EFT is a promising intervention technique, high variability exists in the specific methodology used. Specifically, previous studies have used various amounts of episodic cues generated, timeframes of future events, frequency of engaging with episodic cues, type of cue delivery (eg, text vs audio formats), and whether personal health goals are linked to the episodic cues. Further discrepancies include the control conditions used as comparators (eg, episodic recent thinking, standardized episodic thinking, and health information thinking) and whether the timeframe of episodic cues matches those of discounting time delays on various tasks and questionnaires used to assess such mechanisms of action [31,34]. Furthermore, studies have differed in intervention length and proximity of cue delivery to engaging in the targeted health behavior. Finally, most studies were conducted in the laboratory or face-to-face, which may warrant concerns regarding daily delivery of EFT cues to enable practice of imagery, as well as future intervention scale-up and implementation in real-world settings. While there is currently no standardized protocol for delivering EFT, it is important to address some of these limitations in developing future interventions. Specifically, it is critical to develop EFT interventions that can be scaled up for delivery in the real world and help people to make sense of and apply EFT in their everyday decisions.

More recent EFT studies have used mobile health (mHealth) and other digital technologies to deliver EFT interventions in real-world settings, with a number of studies using smartphones [15,42-44]. Nevertheless, these previous studies involved generating cues in person with a researcher, which were delivered via text or similar prompts to read daily and practice vividly imaging cues. Prior studies did not use smartphone apps to initially develop cues, nor to deliver them daily via in-built notifications. The independent use of a smartphone app also affords participants more autonomy. Studies using immersive environments such as virtual reality to deliver EFT have also emerged and have found promising results for fostering

XSL•FO
RenderX

future-oriented thinking [45,46]. Additionally, some previous studies have delivered the EFT cues via an audible format, namely, recordings of participants reading their cues [42,43,47]. A recent pilot study using a smartphone app to develop and create audio-based EFT cues reported that such delivery reduces engagement as participants felt uncomfortable listening to their own voice, and it was practically challenging to find somewhere suitable to listen to such recordings [48]. Thus, it may be more acceptable to deliver cues via written format that could be read out loud if preferred, but it is crucial to engage with end users to determine the most acceptable delivery mode. Importantly, no research to date has developed a user-designed comprehensive digital EFT intervention that enables initial cue generation and notifications to foster daily practice.

The Benefits of Co-Design

More broadly, one ongoing criticism of smartphone app development and design, including mHealth apps, is the lack of co-design methodology [49]. Co-design leverages insights from people's lived experiences to foster design-led discovery, innovative ideas, and creative problem-solving, with end users' unique perspectives, values, and needs being placed at the center of the design process [50,51]. The co-design approach also provides a way to ensure that a product, system, or service is suitable for the people for whom it is intended [52], which could mitigate some of the £100 billion (US $134 billion) per annum in research waste [53,54]. Over the last decade, repeated calls have emerged to adopt more participatory approaches to technology design to improve end user engagement [52,55] and to add more precision when tailoring content and interactions to community and individual needs.

This Study

Although previous research has used mHealth technology to deliver EFT interventions, no research to date has used co-design to create an engaging digital intervention with potential end users. Furthermore, prior research examining digitally delivered EFT interventions has focused on laboratory-based testing. More broadly, such limitations likely contribute to the lack of uptake, adoption, and scale-up of digital health interventions in real-world settings [56], which adversely impacts health outcomes [57-59]. Using co-design may help address the evidence to practice gap by enhancing adoption by end users, lowering cost and waste, and boosting behavior change by targeting the appropriate enablers [60]. Using co-design is particularly important for mHealth interventions, given it is the most direct technology-consumer link [61]. Nevertheless, high drop-off rates are common due to design issues as end users' preferences are not often considered [62]. Sustainable use of mHealth interventions could be facilitated using co-design processes [63]. Furthermore, the importance of documenting the co-design process used and how it has influenced the development of digital health intervention is necessary, given the current lack of standardized measures to assess impact [64] and the inconsistent reporting to date regarding specifics of the co-design sessions [65].

Thus, the purpose of this research was to co-design a smartphone app prototype of an EFT intervention, namely, "Luminaut." The app aims to support individuals with their health-related behavior change goals via EFT by drawing on the perspectives of adults in the "prerisk" phase for chronic health conditions. The "prerisk" phase refers to the stage before risk factors for chronic conditions emerge whereby individuals are still relatively healthy but aiming to prevent the development of chronic health conditions. Specifically, this study used an iterative co-design process to (1) understand the optimal characteristics and components (eg, content, format, and delivery) of the *Luminaut* app based on the perspectives of potential end users, and (2) gather end users' feedback based on interacting with the *Luminaut* app prototype.

Methods

Overview

This study used patient and public involvement, defined as research designed and conducted *with* or *by* members of the public rather than *to*, *about*, or *for* them [66]. Specifically, we used a co-design approach based on the British Design Council's Double Diamond Design Process—a framework that structures the design process into 4 stages: Discover, Define, Develop, and Deliver [67]. Co-design was chosen for its participatory nature, engaging users and stakeholders throughout the process [68]. The Double Diamond framework uses an iterative, user-centered process and involves collaboration between stakeholders to revisit and refine design solutions based on emerging insights and continuous feedback. Gero and Milovanovic's [69] Situated Function-Behaviour-Structure was used as an analytical framework as it provides a dynamic model for understanding how design evolves as a result of collaborative interactions, feedback, and ongoing refinement through the various stages of co-design. Using this lens, feedback, and decision-making among participants including users, researchers, and designers can help actively shape the development of the design, ensuring that it remains responsive to user needs and emerging insights.

Ethical Considerations

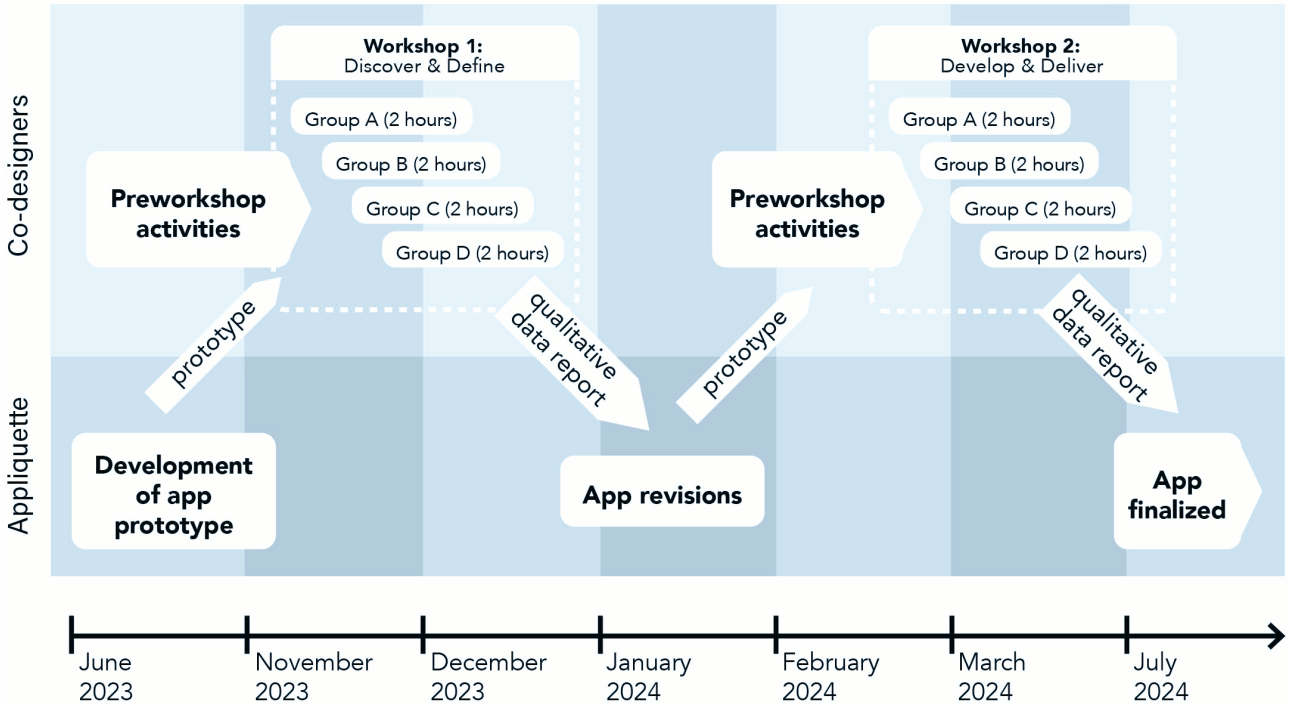
This study was approved by the Commonwealth Scientific and Industrial Research Organisation Human Research Ethics Committee (ID 2023_055_LR). All procedures were conducted in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Declaration of Helsinki (1975), as revised in 2000. We adhered to the GRIPP2-SF (Guidance for Reporting Involvement of Patients and Public Short Form) reporting checklist, which is used for reporting the involvement of people with lived experience in research [66]. To maintain participant privacy, the authors deidentified any personal information contained in the data and results so that individual participants cannot be identified.

Participants and Sample Size

Participants were adults aged 25-44 years. This age group was selected as individuals in this age group are considered to be in the "prerisk" phase for chronic health conditions [70] and are more likely to adopt and use health apps [71]. In line with co-design conventions, we aimed to recruit a minimum of 8 participants per co-design workshop, with no more than 20 - 25

XSL•FO
RenderX

participants in a single workshop and up to a maximum total sample size of 36. Sample size calculations for co-design research are focused on accessing the viewpoints of different stakeholder groups, the development of saturation of insights, and deep engagement regarding the research questions, rather than focusing on statistical significance [72,73]. In many generative co-design practices, the focus is on accessing tacit and latent knowledge and insights through exploratory practices, rather than on accessing explicit knowledge, behavioral data, or generalizable "facts" [74].



Co-Design Facilitator Team

The co-design project team comprised a research team including 2 behavioral scientists, a nutrition scientist, and a research dietitian who was also the study coordinator, along with a team of 3 design researchers with expertise in co-designing for health.

Study Design

An overview of the study design is illustrated in Figure 1. Briefly, a prototype of the Luminaut mobile app was developed by a third-party app developer (Appliquette Pty Ltd). Once a prototype of the app was developed, participants installed the app on their personal mobile devices and provided feedback via a face-to-face workshop ("workshop 1"). Revisions to the mobile app were then made and presented to participants in a second workshop ("workshop 2"). The app was revised a second and final time to reflect any additional feedback raised.

Figure 1. Schematic representation of the study design.

Development of the "Luminaut" Mobile App Prototype

Before commencing engagement with the co-design facilitators, the researchers worked directly with Appliquette to develop an app prototype as a starting point for the design challenge that translated the mechanics of the principles of Future Discounting into an app-based experience. This iterative prototyping approach is commonly used in user experience design and provided a shared starting point of (immediate) past experience for the workshop, rather than relying on having had experience with other analogous smartphone apps [75].

A schematic depiction of the app was developed using mood boards in a collaborative interface design tool, Figma, as a way for Appliquette to develop iterative prototypes and collect feedback from the researchers to satisfy the functional requirements of the app. Figma was used to cocreate and illustrate the page layout and order, content (eg, formatting and arrangement), functionality (eg, help and back buttons), images and animations, and different interface displays. The app was pilot-tested by a minimum of 2 researchers during all stages of development. The content of the app is outlined in Textbox 1. Of note, participants can be allocated to complete all or any combination of these app components but were asked to complete all components in this study.

XSL•FO
RenderX

Textbox 1. Luminaut app components and specific activities.

Health Goals

- Users selected a health domain (ie, physical activity or dietary behavior).
- Users created 3 health goals (related to the chosen health domain) that were achievable within 3 predetermined timeframes (3, 6, and 12 months).
- Users rated how achievable and important their goals were (1=very achievable or unimportant to 5=very achievable or important).
- Users who rated health goals as 3 or less were asked to regenerate a goal that was important and achievable.

Future Events

- Users described 3 future events that they have planned or anticipate could take place within 3 predetermined timeframes (3, 6, and 12 months).
- Each event had to be positive, vivid, and described using present tense, and must occur within a 24-hour timeframe.
- Users rated how enjoyable, important, exciting, and vivid each event is (1=very achievable or unimportant to 5=very achievable or important).

Episodic Cues

- Combine health goals with each positive future events to form cues delivered via daily in-built notifications (personalized).

Ecological Momentary Assessment

- Questions to capture momentary mood and emotions included
- Fatigue
- Sleepiness
- Alertness
- Energy

Procedure

Participants were recruited through paid advertisements on Facebook and Instagram (Meta). Interested individuals were directed to complete a lead generation form, which prompted them to enter their name and preferred email address. Those who expressed interest in participating were emailed a brief online questionnaire hosted in REDCap (Research Electronic Data Capture; Vanderbilt University, 2004), which included an electronic participant information sheet and consent form that outlined the study inclusion and exclusion criteria. Individuals were required to tick a checkbox to indicate electronic informed consent. Those who provided informed consent were directed to a set of questions to determine eligibility, dietary requirements, availability (ie, date and time), and preferred workshop location. Those who completed the initial questionnaire were assigned a unique identifier code, which was generated in REDCap. To be eligible to participate, individuals needed to be (1) aged between 25 and 44 years, (2) fluent in the English language, (3) have access to an internet-connected smartphone device (iOS or Android) that has the minimum required operating system (ie, iOS11 or Android 6), (4) willing and able to install a free prototype of the "Future Self 4 Health" smartphone app on their device, and (5) able to attend up to 2 face-to-face workshops held in a metropolitan area of Adelaide, South Australia. Individuals with a self-reported diagnosis of aphantasia, namely, the inability to imagine or visualize or create mental images, were not eligible to participate. Of note, the app was originally called "Future Self for Health" and was then later changed to *Luminaut* following feedback obtained during the co-design process (for more information, see Multimedia Appendix 1).

Those deemed eligible were provided a unique link to complete an online survey to collect demographic information (ie, age, gender, education level, fluent speaker of languages other than English, health conditions, postcode, and smartphone device) hosted in REDCap. Participants were then contacted by the research coordinator and sent a follow-up email containing preworkshop activities and specific details about the face-to-face workshops. Participants received an honorarium in the form of an e-gift card up to the value of Aus $100 (US $71.48) for each workshop that they attended.

Preworkshop Activities

The *Luminaut* prototype app was free for participants to download via the App Store (Apple) or Google Play Store (Android) using beta-testing links (ie, TestFlight). Prior to workshop 1, participants were emailed instructions about how to install and login to the app and information concerning their allocated workshop (ie, date, time, and venue), as well as an infographic to familiarize participants with the concept of future discounting. Participants received a link to download the app prototype and were asked to test its functionality and features over approximately a 1-week period.

Co-Design Workshops

A series of 8 workshops (4 iterations of workshop 1, and 4 iterations of workshop 2) were conducted between November 2023 and March 2024. Participation involved completing up to two, 2-hour face-to-face workshops. Co-design workshops were facilitated through Match Studio (a creative research laboratory at the University of South Australia). To increase participant diversity, a series of workshop times and locations were offered, with the aim to recruit a sample of individuals with different

XSL•FO
RenderX

levels of socioeconomic advantage. The locations chosen encompassed Local Government Areas (LGA) with both high and low rankings according to the Australian Index of Relative Socio-economic Advantage and Disadvantage (IRSAD) [76]. The two locations in South Australia were (1) the University of South Australia City West Campus, Adelaide (LGA IRSAD quintile 5); and (2) the Christie Downs Community House, Christies Downs (LGA IRSAD quintile 3) [76]. Two time slots were offered: daytime (10:30 AM to 12:30 PM) or evening (5:30 PM to 7:30 PM).

In response to participant preferences, most workshops (6/8, 75% comprising 4 daytime and 2 evening) were facilitated at the University of South Australia City West Campus as well as 2 daytime workshops at the Christie Downs Community House. The workshops used a combination of participant-led documentation and recording during the sessions. Where small group verbal sharing took place, these parts of the workshops were recorded using Dictaphones (Panasonic RR-US065, Olympus VN-731PC, and Sony R41174041), while facilitators also took field notes to aid in transcription and thematic analysis. Light refreshments were offered to participants throughout as a way of offering additional value to participants and providing an opportunity to invert power relationships between the facilitators (serving) and participants (receiving).

Workshops were informed by previous studies and iteratively by findings arising from each co-design session, in accordance with the Design Council's Double Diamond Design Process framework (ie, Discover, Define, Develop, and Deliver), which combines both divergent and convergent approaches [67]. The first workshop was designed to engage with the "Discover" and "Define" phases of the Double Diamond, using creative activities to help participants access and share tacit and latent, as well as explicit, knowledge [74]. Activities involved facilitated discussions and participant-led documentation (worksheets, low-fidelity prototypes, and card-sorting activities). A timeline of activities during workshop 1 is provided in Table 1, with a longer description of each workshop contained in Multimedia Appendix 2.

Table . Timeline of activities during workshop 1.

25	Activity 2: Where and when activity stories
10	Break
30	Activity 3: App inventory exercise
30	Activity 4: Specific app test feedback
5	Wrap up
	Close

Following the completion of each instance of this workshop, insights were synthesized to clarify the app's intended function, the behaviors it aimed to support, and to refine the design objectives. Across the workshop 1 series (ie, 4 workshops), small changes were made to the length of time spent on each of the activities to respond to the experiences and interests of the co-design participants. At the completion of the 4 instances of this workshop, the data were analyzed by AD and KL using inductive thematic analysis [77]. The analysis was then translated into an interim report that was shared with the researchers who reviewed the collated feedback in collaboration with AD and KL. The researchers devised a list of changes to be made to the app. Appliquette Pty Ltd addressed and implemented the changes, which were categorized as "high," "medium," and "low" priority, and released an updated version of the app to participants.

A few weeks prior to workshop 2, participants were given the opportunity to test the revised version of the app (over approximately a 1-week period) and were asked to provide feedback and reflections via an anonymous online survey, hosted via the Qualtrics survey platform (Qualtrics). This survey was designed to prompt open-ended reflection while also asking participants to compare what they had been testing with the original prototype. Participant contributions to this survey were analyzed through an inductive thematic analysis process and were used to shape the design and focus of workshop 2, which engaged the "Develop" and "Deliver" phases of the Double Diamond process. A timeline of workshop 2 is provided in Table 2.

XSL•FO

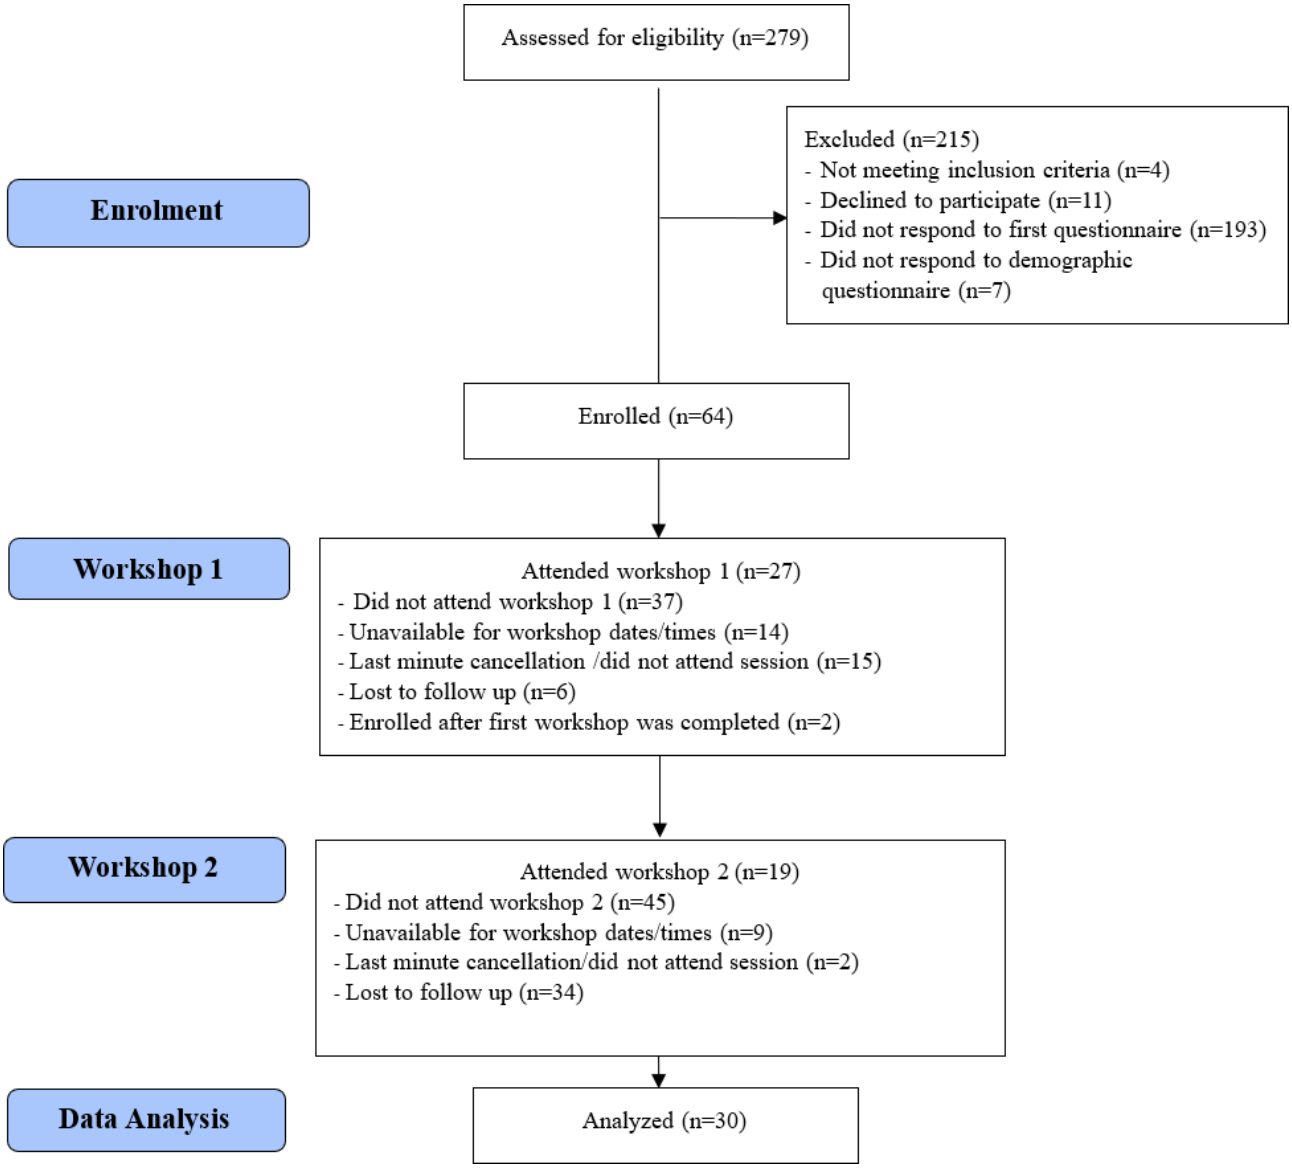
Thematic Analysis

Involvement in the co-design workshops allowed researchers to immerse themselves in the data. The reflexive thematic analysis framework established by Braun and Clarke [77] was used for inductive coding, namely, generating codes directly from the data rather than from preexisting categories. Following each workshop, all data, including participant-led documentation, researcher field notes, transcribed audio recordings, and survey responses, were reviewed to identify key themes and patterns and coded using NVivo (QSR International) and Microsoft software (Microsoft Inc, ie, Excel and Word).

Data from each of the 9 activities across the workshops (workshop 1 series=4 activities, workshop 2 series=5 activities) were reviewed independently by the co-design facilitators after each iteration of the workshop to ensure that the workshops were effectively contributing to the ongoing development process. The co-design facilitators made small changes, such as adjusting the time spent on different activities, to ensure that all intended explorations in the workshop were undertaken across the workshop series. Initial themes were also reviewed by the co-design facilitators to develop a rich understanding of the data following Braun and Clarke's [78] recent guidance on quality practice in reflexive thematic analysis at the end of the workshop series to develop recommendations and overarching themes.

Across the series of co-design workshops, the process of theme development involved multiple cycles of coding, categorizing, and revising. Themes were reassessed at each stage to ensure that they accurately captured the core patterns in the data, with codes merged, split, or redefined as necessary. This iterative approach enabled the identification of key themes that emerged as most relevant to the area of enquiry [77]. A final report was then generated by the co-design team for the nutrition and behavioral scientists (Multimedia Appendix 3). The report included high-level insights from the co-design process, a description of the workshop structure and activities, interim recommendations following workshop 1 series, data from the asynchronous feedback process, and data from both workshop series.



Results

Participant Recruitment

A total of 279 individuals expressed interest in participating in the study via the social media (Facebook and Instagram) advertisements. Of these, 71 individuals provided informed consent, completed the follow-up questionnaire, and met the study eligibility criteria, following which 64 (90%) individuals completed the demographic questionnaire and were enrolled into the study. Eligible participants were contacted by the research coordinator (MR) to confirm their availability to participate. A total of 30 (47%) participants attended at least 1 workshop, 16 (25%) participants completed both workshops, 11 (17%) participants completed the first workshop only, and 3 (5%) participants completed the second workshop only (Figure 2).

XSL•FO

Figure 2. Participant flow diagram.

Sample Characteristics

The characteristics of the participants who attended workshops are shown in Table 3. Participants were mostly women aged 25 - 44 years with a bachelor or postgraduate university degree, who owned an Apple smartphone device, had relatively high socioeconomic advantage in accordance with the Australian Bureau of Statistics Socio-Economic Indexes for Areas, Australia [76], and lived with no or 1 chronic health condition. The characteristics of all participants who were initially enrolled into the study are provided in Multimedia Appendix 4.

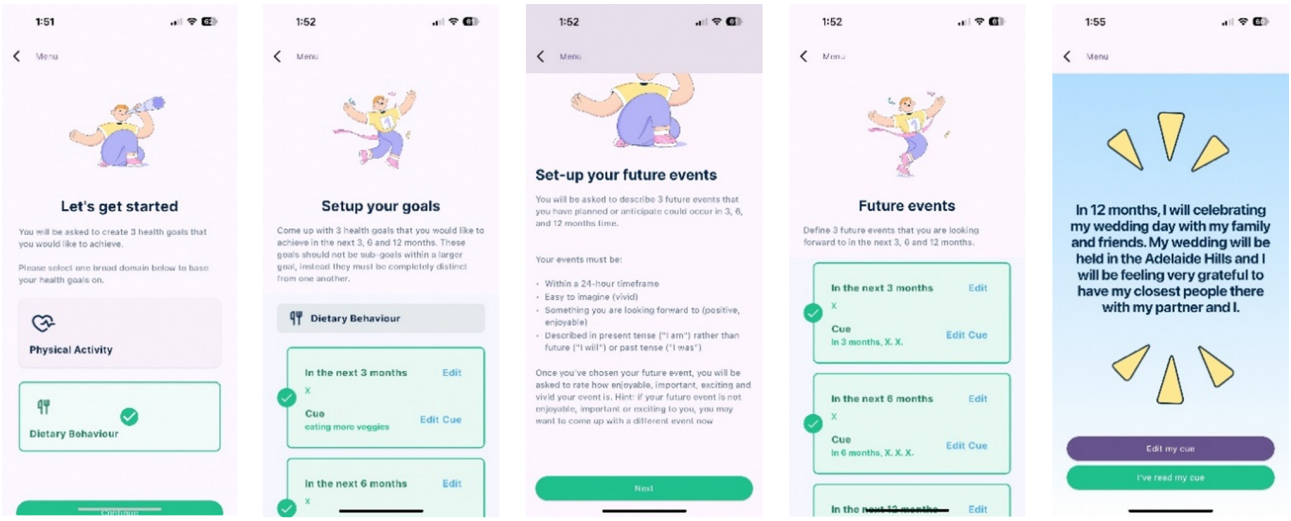
Specific App Feedback From Co-Design Engagement



At the end of the first workshop series, 26 suggestions for changes to the *Luminaut* app were identified from the data (Multimedia Appendix 3). These suggestions ranged from high-level conceptual suggestions (eg, shifting "language to be more positive rather than the negative framing of 'future discounting'") to specific feedback (eg, "lock or add friction to reentering quiz after completion to avoid looping"). The research team recommended implementing 16 of these suggestions within the app, which were categorized as high (n=8), medium (n=6), or low (n=2) priority. A high priority suggestion included adding in clearer instructions and screenshots that showed a preview of how to navigate the app, while a medium priority suggestion included using images to represent goals (icons or stock images) and a low priority suggestion included enabling push notifications that could be customizable based on personal preferences by asking participants to nominate suitable times of day practice visual imagery using the cues. Practical considerations including time and budget were the primary reasons for not implementing all user suggestions at this stage; however, these suggestions were noted for future possible versions of the app. An additional 4 suggestions were identified as needing further exploration and bespoke activities were developed to explore these ideas in the second series of workshops. These suggestions mostly included exploring an introduction narrative or ways to introduce the concept of "future discounting" quickly, as well as opportunities for various visual metaphors to be used as a structure for the app dashboard.

During the second workshop series, participants provided further feedback on the app design (see Figures 3A-3E for screenshots of the updated app prototype). Specifically, they provided

XSL•FO
RenderX

specific feedback on the experience of using the updated prototype, while also exploring the higher-level conceptual challenges identified during the first workshop series. This dual focus enabled the co-design process to explore ideas that could reasonably be integrated and explored in this project and were appropriate to the project stage, while also contributing to strategic opportunities for future research. Key feedback on the app included that there were "too many notifications" and exploring whether sentence starters or generative artificial intelligence could be integrated to help participants create realistic, yet aspirational health goals. Facilitators reflected that there was a tension between viewing the app as a goal setting and achievement app and understanding the principles of catalyzing subtle behavior shifts away from future discounting; in effect, a microexample of the challenge of future discounting itself.

Figure 3. . Design of the Episodic Future Thinking (EFT) Luminaut smartphone app. (A) The screen where participants select a health domain (physical activity or dietary behavior); (B) the instruction screen for setting up health goals for the 3 timepoints for the selected health domain; (C) the instruction screen for setting up the future events; (D) the home screen for the 3 timepoints for the future events; and (E) an example of an EFT cue delivered to participants daily to assist in practicing visual imagery.

A **B** **C** **D** **E**

A total of 8 narrative elements were identified for use within the app. The most common was variations of "make good choices now to enjoy the benefits later," which mirrored the introductory content presented to participants. However, a novel conception also emerged with "planting a seed and nurturing a plant" providing a metaphor that is positive in both the present and future framings. Preference for navigational metaphors also followed this biophilic concept with growth and trees identified as the most preferred way of arranging information. Metaphors that were identified as inappropriate tended to separate time into discrete moments rather than a continuum, including a portal to a future time, moving between islands, and jumping seasons.

Insights Into Future EFY Intervention Design

Overview

As well as delivering specific feedback that could inform the ongoing app development, the project also enabled the development of higher-level principles and learnings that can be widely applied in similar projects and systems using EFT interventions. Five overarching themes were identified, which were each grounded in the lived experiences of participants and integral to the design decisions made during the project. The five themes were (1) Perceived Value, Understanding, and Trust in Shaping Acceptance of the EFT Concept; (2) Factors Influencing Engagement: Triggers and Barriers; (3) The Role of Personalization in Enhancing User Experience; (4) Game Mechanics as Drivers of User Motivation; and (5) The Importance of Usability in Optimizing User Experience.

Perceived Value, Understanding, and Trust in Shaping Acceptance of the EFT Concept

Concept acceptance encompassed participants' understanding and trust in the underlying premise of the app. While many participants recognized the app's potential to facilitate behavior change, there was notable confusion regarding some aspects of the intervention, including its functionalities and intended outcomes. One participant remarked that, "[It needs] some explanation or context to help know what to do (e.g., infographic)" and another requested, "...guidance about how to set a goal and how to achieve it. 'Help me figure it out.'" This underscored the necessity for clearer communication about how the app would support users in their health journeys, particularly highlighting the importance of an introductory guide to convey this information effectively.

Trust also emerged as a crucial factor with participants indicating that the app's credibility and the reliability of its recommendations were essential for their ongoing use and for considering recommending it to others. The participants sought to use an app from a brand they could trust. They also sought evidence of scientific foundations and anecdotal evidence or direct experience of successful outcomes from using the app. One participant said, "I have to see the complete product, finished, use it for a bit and see that it is working for me." Others

XSL•FO
RenderX

remarked that they would need to see "scientific evidence" or have the app "recommended by a psychologist."

The concept of EFT is grounded in scientific evidence; however, communicating this effectively is challenging due to the complexity of the psychological underpinnings, a challenge that participants identified. This theme was explored iteratively throughout the co-design process, with potential solutions collaboratively developed during the co-design sessions to enhance clarity and understanding.

Factors Influencing Engagement: Triggers and Barriers

Participants identified various triggers that could influence their consideration of using the app, such as hearing about the illness of a friend or family member, health events, or personal milestones. These triggers could serve as motivators to engage with the app, prompting users to seek support for their health journeys. Examples include, "Family member diagnosed with illness, eg, diabetes," "Bad news from the GP," and "Change in location/moving."

Barriers were also identified that could hinder their engagement. These included competing priorities in daily life ("What are all the other things that I should be doing?"), time and effort required to use the app ("Effort, mental effort"), aversion to constraint ("You don't want to be the type of person who denies themselves"), difficulty navigating unfamiliar or complex tasks ("Inability to prioritise can be a big barrier, that overwhelm feeling"), technological illiteracy ("Some people don't even know how to install an app"), and financial cost ("Healthy food is expensive"). Understanding the interplay between triggers and barriers can help inform design decisions, ensuring that the app effectively supports users in overcoming obstacles while leveraging motivating factors to encourage sustained use.

The Role of Personalization in Enhancing User Experience

The theme of personalization emerged prominently, with participants emphasizing the significance of tailoring the app experience to individual needs and preferences. Many expressed a desire for customizable features, including editable goals, the ability to change notifications (time and frequency), and options to select avatars and images that reflect their personal preferences and circumstances. For example, one participant requested the "[o]ption to switch off [notifications]. [I'm] trying hard to reduce phone usage, for health." Participants indicated that a personalized approach could foster a deeper connection to the app, which may ultimately enhance motivation and adherence. This insight informed design decisions, resulting in the inclusion of flexible options.

Game Mechanics as Drivers of User Motivation

Overview

Participants showed enthusiasm for gamification elements within the app, believing that game-like features could enhance user engagement and make the experience more enjoyable. Suggestions included reward systems, challenges, social sharing capabilities, progress tracking, and streak tracking. Participants noted that incorporating these elements could transform engagement with the app into a fun and interactive experience, fostering community support and accountability, while offering rewards that reinforced positive behavior. Integration of gamified components designed to encourage sustained interaction and facilitate progress tracking is planned for future iterations of the app. The integration of these gamification elements is expected to create a more engaging and motivating user experience.

Reward Systems

Several participants suggested implementing a reward system, where users could earn rewards for completing tasks. For example, "[I] like goal setting aspects...and small rewards in-app for progressing." Suggested rewards included frequent flyer points, financial credit, vouchers, and in-app rewards (eg, badges). One participant mentioned that the app's use of positive language feels rewarding, remarking that, "Positive language is itself a reward. Maybe you don't need [other] rewards."

Challenges

Participants expressed interest in participating in challenges. One participant stated, "I like to enter competitions."

Social Sharing

The potential for social sharing features was also highlighted. Multiple participants contributed, with one remarking that, "Connecting with friends is a big one.[it's] encouraging and inspiring to see other people, including family and friends," and another commented, "I like that functionality, where you can give someone a virtual high five. Celebrate the fact that they reached the 100-day streak or whatever."

Progress Tracking

The ability to track progress through gamified elements was noted as a key feature, to record and present information for direct feedback and tracking over time, useful for monitoring progress toward personal goals. During the discussion, participants expressed their views: one noted, "[I like to] see information at a glance…[to] check if I'm improving," and another remarked, "Tracking...a way of showing in the app, this is where I started, and this is where I got to..."

Streak Tracking

The concept of tracking streaks was particularly popular among participants. One participant stated, "Streaks are motivating."

The Importance of Usability in Optimizing User Experience

Participants were prompted and encouraged to provide feedback on their lived experiences with the app. Bugs and glitches were identified and addressed throughout the process. Participants emphasized that an easy-to-navigate interface is essential for ensuring engagement and accessibility. Feedback underscored the need for simplicity and intuitiveness in app design, highlighting the importance of clear instructions, straightforward layouts, and visually appealing design elements. By prioritizing usability, there is an opportunity to create an engaging environment that fosters positive interactions with the app.

Discussion

Principal Findings

This study involved co-designing a digital health intervention, "Luminaut," which is aimed at disrupting future discounting via EFT in individuals at risk of developing chronic health issues. The co-design approach that was used generated app-specific feedback for technical improvements and led to high-level conceptual suggestions that helped shape the Luminaut intervention. This study revealed 5 high-level conceptual suggestions that were important to the participants when engaging with digital EFT interventions such as the Luminaut app. These themes included concept acceptance, triggers and barriers, personalization, gamification, and a user-friendly interface. Overall, the co-design approach was integral to shaping the Luminaut app and it also provides insights into EFT interventions more broadly regardless of delivery mode.

The first theme identified was that *concept acceptance* of future discounting may promote participants' understanding and trust in the underlying premise of the app. The co-design process provided valuable insights into how participants receive the concept of future discounting in the context of app creation and how they would like to interact with it. Specifically, the high-level conceptual suggestions related to this theme included the overarching challenge of engaging with the concept of future discounting. The concept of future discounting was perceived as being primarily negative in nature and it was suggested that more positive framing of the concept such as "future investing" be used when describing the intervention to participants, which should be considered when delivering EFT or other psychological interventions aimed at reducing future discounting. While it was relatively straightforward to include an explanation of the term "future discounting" into subsequent versions of the Luminaut app, it prompts further consideration of lay understandings of complex psychological phenomena. These contextual insights may elude formal assessments of efficacy, such as randomized controlled trials, which are necessarily more structured and less flexible; however, when combined, they may offer complementary insights at different stages of the research. Through the open, iterative, and creative process, participants shared their evolving understanding and active engagement with the concept, rather than simply providing feedback. By sharing their learning journey, participants revealed both the process of understanding and what they already know about the future discounting concept based on their prior experiences.

In addition, it was found that there are specific *triggers and barriers* that motivate or hinder individuals' engagement with the Luminaut app. Specifically, the participants identified that the recommendation of the app by a health care professional (eg, a psychologist) would boost trust, which expands on previous co-design research indicating that participants would be more willing to use an app if it was prescribed [79]. Such findings support the idea of using such apps as a way to empower individuals who are ready to take action toward health-related behavior change, which is consistent with the findings of previous co-design work in participants living with chronic health conditions [80].

The finding that participants valued *personalization* based on individual needs and preferences aligns with prior research indicating that profiling, tailoring, and autonomy are important when engaging individuals with digital health solutions for chronic disease prevention or management [79,81,82]. Taken together, such findings are a critical reminder that there is no "one-size-fits-all" approach when it comes to health care and that creating digital technologies that align with individual needs is a promising strategy for health behavior change [83]. Indeed, an advantage of the co-design process is its ability to identify diverse collectively agreed factors that may enhance engagement with such interventions to promote health behavior change.

In addition, elements of *gamification* including reward systems, challenges, social sharing, progress tracking, and streak tracking were also mentioned as features that could elicit a more enjoyable experience while using the app. The latter finding supports previous work showing that apps of gamified features in nongame settings, particularly in digital interventions for health and chronic conditions, are growing rapidly and may enhance the perceived experiences of users [84]. Future work is needed to determine whether the inclusion of such elements has benefits beyond boosting short-term engagement as indicated in recent systematic reviews [85].

Finally, a *user-friendly interface* was encouraged to ensure engagement and accessibility. The latter speaks to the idea of ensuring that digital interventions have high levels of usability, which may be enhanced via incorporating simple features (eg, a back button) and should be systematically evaluated such as via the System Usability Scale score [86].

Learnings From the Co-Design Process

One of the key learnings from the co-design process included the need to iteratively develop the workshop content based on participant feedback. Namely, the co-design process involved not only engaging with end users to co-design the product (ie, the Luminaut app) but the research process itself. For example, the co-design workshops involved exploring how the concept of future discounting could be communicated quickly and effectively, and the development of an overarching navigational metaphor for engaging with the future. A key piece of feedback from the first series of workshops was that the way the co-design facilitators explained the concept of future discounting made the whole project "make sense." Thus, in the second series of workshops, the facilitators constructed an activity using a storyboarding template to focus on how participants might explain the concept of future discounting to their friends.

In addition, our multidisciplinary approach provided both challenges and benefits, which is common when using such approaches [87]. For example, there were discipline-based differences regarding conceptualizations of bias in research whereby co-design practitioners consider health researchers a key stakeholder to include as participants in co-design workshops. In contrast, the nutrition and behavioral health scientists viewed researcher input as a potential source of bias in such settings, given their status as "experts" in their given

XSL•FO
RenderX

field. In this case, it was deemed useful to have one of the content experts (ie, researchers) present at each workshop as an observer and to answer any content-specific questions if they arose from participants.

Strengths and Limitations

This study had several strengths and limitations. While co-design studies often focus on involving end users in the conceptualization of research questions prior to any research taking place, this study was focused on exploring how access to support for overcoming future discounting behaviors might be scaled through digital technologies. The requirement of the research funding to develop a digital intervention served as a limitation; however, the advanced prototyping that was enabled by the imposition of this constraint enabled richer explorations of how technology mediated health interactions to take place. Indeed, other similar research aimed at developing digital health interventions has also used prototypes (ie, a website) as it provides stakeholders with a tangible artifact to engage with during the iterative testing process [88]. In this study, as the app design progressed, findings from the "Develop" and "Deliver" phases were used to refine earlier stages, ensuring that the design remained responsive to user needs and stakeholder input. This iterative process ensured that the design was continuously aligned with evolving insights. Nevertheless, it should be noted that this approach does necessitate the upfront allocation of time and money to support this iterative, stakeholder-engaged process, albeit the reward is a more sustainable and appropriate intervention in the medium to long term.

Although our sample was relatively large, which was a clear strength, the sample was subject to several limitations, such as comprising mostly female participants who spoke English fluently with high levels of education. Participants also had a relatively advantaged socioeconomic status, despite attempts to promote diversity through holding workshops in disadvantaged areas (eg, in the outer southern areas of Adelaide). Thus, the Luminaut app may be more tailored toward affluent women in terms of the look, feel, and technological familiarity. Of note, the lack of a representative sample in this study is consistent with previous work and remains an ongoing challenge in health co-design research [80]. Nevertheless, others have argued that as qualitative research relies on purposive sampling methods, there is less emphasis placed on achieving statistical generalizability than there would otherwise be when using quantitative methods [89].

Another limitation is that the 2 selected workshop locations may have excluded those individuals living in rural and remote areas and/or without readily available access to technology such as smartphone devices, which may have further contributed to the "digital health divide" based on an individual's social status [90]. Indeed, individuals with low socioeconomic status as well as older adults and ethnic minorities typically have lower digital literary and more difficulty accessing digital health interventions [91]. Such accessibility issues may be addressed in future research using non–digital health intervention solutions or via a digital and/or physical asynchronous co-design process. Specifically, the concept of "low-contact co-design" involving the use of technology to replicate the use of physical workshops conducted at different times and locations has been proposed to navigate the process of co-design when physical proximity is a challenge, which provides co-designers with new opportunities and possibilities for engaging with communities [92].

An additional strength of this study was the use of co-design methodology, which generates unique, insightful contributions and progresses unknowns. Nevertheless, such methods do not have the significance of larger-scale population research that will be derived from future clinical trials aimed at examining the efficacy of the app for improving health outcomes. Co-designing with a predetermined output (eg, a smartphone app–based intervention) is challenging as it constrains the process. However, we were subject to limitations of the funding for the current project and funding models more broadly, which require precise descriptions about the format and delivery of interventions in funding applications. While this approach allowed the research team to focus on exploring digital solutions, it may have limited the ability to critically evaluate whether an app was the ideal solution for delivering this intervention. Notwithstanding, a key component of EFT training involves sending reminders or prompts to participants to practice the mental imagery exercises, which is easily facilitated via techniques such as automated smartphone notifications. Since smartphone app development remains expensive, there is an ongoing tension between deep engagement with members of the community and conducting consumer market research or beta testing, the latter of which may be more economically efficient. Notwithstanding, consumer market research would not allow unique insights into EFT intervention development and the concept of future discounting more broadly.

Finally, the inclusion of both highly experienced facilitators with expertise in co-design [68] and content experts in nutrition and behavioral science within the project team is considered a strength and undoubtedly enhanced the research process. Indeed, the use of multi-disciplinary teams with different content expertise and methodological viewpoints is deemed critical for developing digital health solutions for complex problems [93].

Implications for Future Research and Health Policy or Practice

This study provides a blueprint for other researchers to determine the feasibility of using co-design practices in developing digital health behavior change mobile apps as well as EFT interventions more broadly. Furthermore, it would be useful to determine the extent to which co-designed apps enhance effectiveness in a more formal evaluative capacity. Nevertheless, the growing use of such practices speaks to the potential for creating sustainable and personalized digital preventive health programs to target a reduction in chronic conditions, a key priority area for Australian and global health strategies [94]. Finally, the insights gained from this project will help inform future large-scale clinical trials in prerisk or at-risk groups aimed at testing the feasibility, acceptability, and efficacy of the intervention alongside ongoing usability testing. Such trials could also serve the dual purpose of highlighting the cost-effectiveness of digital health interventions via an economic

XSL•FO
RenderX

evaluation [95], which is critical for reducing the gap between research and end user needs and increasing clinical research utility [96].

Importantly, this project represents the first phase of the co-design process. Specifically, co-design uses an iterative process whereby consumers and other key stakeholders are continuously involved in refinement and development of the intervention in response to ongoing feedback and changing needs. In addition, future co-design work could involve health professionals who may be involved in facilitating behavior change or self-management of chronic conditions in individuals. Indeed, the current finding that trust could be enhanced via recommendations from credible sources (eg, psychologists), which is essential for ongoing use, supports the idea of engaging health care professionals in the co-design process. Furthermore, previous research has identified that a lack of health professional recommendations is a major barrier to self-management app use primarily due to the preparedness and capacity of such professionals [97]. Thus, such engagement would likely facilitate a better understanding of health professionals' use of digital health apps in practice to support wide-scale implementation and community evaluation in the real world.

Finally, participants identified a range of suggested improvements that could be integrated into future iterations of the app. Some of these improvements involved using additional BCTs, namely, the active ingredients of interventions that are critical for changing behavior or the key mechanisms of action [21]. These included self-monitoring of behavior (ie, tracking against health goals) and providing information about health consequences if health goals were not achieved. Future research should aim to map these suggested improvements onto the taxonomy of BCTs based on relevant health behavior change theories and a theoretical framework known as the Theoretical Domains Framework [98,99], which was developed by behavioral scientists and implementation researchers. Such mapping could help inform which combination of BCTs to include in future versions of the app based on an evaluation of potential effectiveness drawn from the existing literature alongside the existing BCTs used. Specifically, EFT uses several techniques described in the behavior change taxonomy such as goal- and planning-related strategies as well as comparing future goals with existing behaviors [21].

Conclusions

This study used a co-design process to inform the development of the "Luminaut" app, a digital EFT intervention that could potentially improve and maintain health-promoting behaviors and disrupt the psychological phenomenon known as future discounting (ie, valuing smaller, immediate rewards over larger, delayed rewards). Such interventions may lead to an enhanced adoption of healthier lifestyle changes amongst Australian adults who are currently in the prerisk or at-risk phase for chronic conditions. Using co-design methods to refine the design of digital health interventions may improve the relevance, scalability, sustainability, and engagement for end users. Engagement with digital interventions is a priority to ensure long-lasting behavior change and enable healthy ageing of the Australian population. The current project was valuable in gaining consumer perspectives about what makes the "Luminaut" app a relevant and engaging tool to promote adherence to health-related behavior change interventions and, in turn, has the potential to reduce the risk and burden of chronic conditions.

Acknowledgments

The authors wish to thank David Cox for his input and advice during the early stages of the project, and Emily Brindal for her helpful advice on this project. The authors would also like to acknowledge Appliquette for developing the Luminaut smartphone app.

Funding

This work was supported by funding from the Commonwealth Scientific and Industrial Research Organisation Precision Health Future Science Platform.

Data Availability

The data that support the findings of this study are available from the corresponding author (NH) upon reasonable request and subject to relevant human research ethics approval.

Authors' Contributions

NH, CAH, MR, KL, IG, AD, and PGB facilitated or contributed to the co-design workshops. AD, KL, and MR conducted data analysis. NH, CAH, PGB, MR, AD, and KL contributed to writing the first draft of the manuscript. All authors have contributed to, and approved, the final version of the manuscript.

Conflicts of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest. Some of the authors (NH, CH, MAR, and PGB) were involved in the development of the app they have been evaluating.

Abstract

Background: Mental health problems are prevalent among young people aged 16 to 24 years. With the health care system prioritizing severe cases, most young people wait months before accessing professional support. One-to-one helplines offer alternative and accessible mental health services for young people with emotional support, psychoeducation, and signposting. Signposting empowers young people to access long-term support beyond a brief helpline session. However, young people often choose not to access the signposts. Despite its importance, there is a dearth of existing research examining signposting via digital mental health helplines for young people.

Objective: Using cross-sectional survey data from The Mix, a UK charity supporting young people aged 25 years or younger, this study conducted a mixed methods analysis of their multichannel (webchat, email, telephone, and web-based contact form) helpline survey between February 2020 and October 2023.

Methods: The analytic sample included 296 participants who collectively received 872 signposts (approximately 872/4500, 19% of signposts provided during the survey collection period), of which 822 with complete outcome data were included in the statistical models. Multinomial logistic regressions were conducted to examine whether young people's use and perceived usefulness of the signposts they received differed across modes of delivery and their demographic characteristics (gender, ethnicity, and age). Qualitative thematic analysis of 106 open-ended responses from 97 participants was also examined to illuminate why young people found signposting helpful and how it could be improved.

Results: In the overall model, which included all predictors, webchat users identifying as White, women, and aged 16 - 19 years were significantly more likely to use and find signposts helpful than to perceive them as unhelpful (odds ratios [OR] 0.28, 95% CI 0.17-0.46; *P*<.001), not intend to use them (OR 0.13, 95% CI 0.07-0.26; *P*<.001), or only plan to use them later (OR 0.29, 95% CI 0.18-0.46; *P*<.001). Thematic analysis of open-ended responses revealed that young people found the choice of signposts relevant and appreciated how signposting was integrated with emotional support. Young people also felt more hopeful after being signposted and gained both clarity and insight into the support available. However, they also noted challenges, such as feeling overwhelmed or encountering outdated signposts.

Conclusions: Given the increasing reliance on digital mental health services, ensuring that signposting remains accessible, relevant, and tailored to diverse user needs is essential. By optimizing signposting strategies, helplines can empower young people to seek appropriate long-term support, ultimately improving mental health outcomes.

Introduction

Mental Health Support for Young People

Mental health problems explain 13% of the global burden of disease for 10- to 19-year-olds and are experienced by 14% of adolescents [1]. In the United Kingdom, 22% of young people aged 8 to 25 years experience a probable mental health problem [2]. While young people experiencing severe conditions, like psychosis or eating disorders, were seen within 2 to 4 weeks of referral [3], half of those with mild-moderate mental health problems waited 5 to 18 weeks for support [4]. Due to this delay, young people perceive care to be inaccessible and unresponsive, and therefore, can be discouraged from seeking help and often rereferred with more severe conditions [5,6]. Many times, even when support is offered after long waits, young people are more likely to refuse it or drop out [7].

Digital mental health interventions such as one-to-one helplines, peer support, and self-help resources are alternative sources of mental health support for young people [8]. Available across multiple modes of delivery (eg, text, email, phone calls, and

XSL•FO
RenderX

webchat), one-to-one helplines offer brief, confidential support alongside signposting to specialist services [9,10]. Signposting encourages individuals to actively access specialist services, thus empowering them to build long-term support networks and develop healthy coping strategies beyond the helpline sessions [11]. However, many young people do not follow up on signposting [12]. Furthermore, there is a dearth of research examining young people's experiences of signposting via digital mental health helplines, especially across various modes of delivery and in relation to young people's demographic characteristics, information that is essential for improving the uptake and tailoring the usefulness of this service to different groups.

To help address this gap, this study examines signposting data from The Mix's helpline, the United Kingdom's leading digital mental health support platform for under-25s, to analyze differences in young people's signposting experiences according to the mode of delivery and young people's gender, ethnicity, and age. Using mixed methods, we combined quantitative findings with qualitative insights to inform recommendations to improve signposting via digital mental health helplines for young people.

Research Background

Signposting involves a practitioner sharing resources and encouraging individuals to actively access them [12]. It requires young people to acknowledge their need for support, identify which services to access, and feel confident that those services are helpful [13]. When young people seek support, many are unaware of the services available to them [14]. This lack of awareness can act as a barrier to accessing timely and relevant support. Even when young people are aware of the services available, only a fraction actively engage and access them. To unpack how signposting may support young people beyond the immediate helpline contact, we situate this study within complementary perspectives on help-seeking and engagement. Help-seeking models (eg, Andersen's behavioral model) conceptualize service use as shaped by (1) predisposing factors (eg, demographics and beliefs), (2) enabling factors (eg, access, knowledge of services, and perceived fit), and (3) perceived need. In this framing, signposting may function as a bridge between "in-the-moment" support and longer-term care by reducing informational barriers, increasing perceived options, and supporting readiness to act. In addition, frameworks for engagement in digital and brief interventions emphasize that uptake is more likely when support is experienced as relationally safe, autonomy-supportive, and tailored to the user's context (eg, clear rationale, collaborative choice, and practical next steps). Together, these perspectives support interpreting signposting outcomes as a function of both service design (eg, mode of delivery and the interactional context) and user context (eg, disclosure, identity safety, and perceived accessibility of resources). For instance, Mustafa et al [12] found that while 79% (26/33) of health students knew about the available mental health services, only 27% (9/33) accessed them, highlighting the critical role practitioners play in bridging the gap, not only by sharing information, but also by motivating young people to engage with support services. Poor signposting and repeated referrals [15] can also push young people between irrelevant services, reducing their confidence in getting support.

These frameworks directly informed this study. Andersen's model guided our focus on predisposing factors (gender, ethnicity, and age) and enabling factors (mode of delivery) as predictors of signposting outcomes, while engagement frameworks motivated our expectation that relational and interactional features of each mode would shape whether signposting felt relevant and actionable. Together, they justify a mixed methods approach—quantitative analysis to identify which user and service characteristics predict signposting outcomes, and qualitative analysis to illuminate the mechanisms that explain those patterns.

Research examining signposting has mainly focused on primary care and school settings. For example, previous qualitative studies have examined the barriers to signposting for primary care professionals in the United Kingdom, which included a lack of formal training, decreased motivation to signpost, and time constraints [16,17]. In terms of young people's mental health, Tegethoff and colleagues [18] found that using school mental health services for signposting significantly predicted the use of external mental health services, showing the importance of schools in raising awareness of available resources. However, there is a dearth of studies examining signposting for young people's mental health in the United Kingdom. In 1 notable exception, a qualitative study found that volunteers felt they lacked skills in person-centered signposting but benefited from the extensive signposting database [19]. This study, however, only focused on volunteers of a mental health helpline for young people delivered via email.

More research is needed to examine young people's signposting experiences for their mental health, especially across different modes of delivery. Helplines can be delivered asynchronously (eg, email and web-based contact form) or in real-time (eg, webchat and phone). Young people prefer to have control over how they access support, and offering a multichannel helpline can encourage help-seeking [20]. Helplines via email or contact form encourage young people to explain their situation without time constraints, which is particularly effective for those experiencing social anxiety [21]. Webchats empower users to share their concerns via text messages and have live conversations with helpline agents. Similarly, phone calls allow users to express themselves synchronously with their voice. Despite these differences in user preferences, there is little or no information on whether young people's use and their perceptions of signposts differ across modes of delivery. Such information would provide a better understanding of whether signposting is more or less well-received and used depending on how it is delivered.

There is also no current research examining whether young people's experiences of signposting differ across their demographic characteristics. Nevertheless, past studies have found differences in young people's use of helplines across demographic groups. Most helpline users tend to be White, women [22], and older adolescents [23], with men [24] less likely to access helplines. Due to the unavailability of culturally specific services [25], South Asian and Black Caribbean

XSL•FO
RenderX

adolescents are also less likely to seek help as they worry about confidentiality [22,26] and parent surveillance or disapproval [27]. It is increasingly important to examine diversity in young people's experiences with helplines, especially as gender and ethnic minorities [28] are not usually reported in helpline evaluations [23].

This Study

Using secondary cross-sectional survey data from The Mix regarding their multichannel helpline (ie, webchat, email, web-based contact form, and phone), quantitative analysis was conducted to examine whether young people's use and perceived usefulness of the signposts they received differed across modes of delivery and their demographic variables (gender, ethnicity, and age), reflecting the predisposing and enabling factors identified in help-seeking frameworks. Qualitative thematic analysis of open-ended responses was also examined to illuminate why young people found signposting helpful and how it could be improved.

Methods

Setting

The Mix's one-to-one, anonymous helpline provides emotional support and information via email, webchat, telephone, and web-based contact form. It is delivered by volunteers who have received a 25-hour training. Volunteers signpost young people based on The Mix's signposting database "The Red Book," which compiles national and local services for diverse problem areas. Following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist, we note this was a closed, postcontact web survey administered to recent users of The Mix's multichannel helpline (webchat, email, telephone, and web contact form) between February 2020 and October 2023.

Participants

From February 2020 to October 2023, The Mix emailed helpline users a survey link. Participation was voluntary. During this time, The Mix provided approximately 4500 signposts to users. Of the 807 participants over the age of 16 who responded to The Mix's survey, we excluded participants with missing signposting data (n=4), those who did not complete any demographic questions (n=58), those who were not signposted (n=387), and those who were signposted but did not report any outcomes (n=63), totaling 511 excluded participants. This resulted in an analytical sample of 296 participants who collectively received 872 signposts, representing approximately 19% of the signposts provided during the survey collection period. Of these, 49 participants only partially reported signposting outcomes, creating a sample of 822 signposts included in the statistical models. The characteristics of the analytical sample are presented in Table 1.

Fisher exact test revealed significant differences in mode of delivery (P<.001) between the analytical sample (n=296) and those who were not signposted (n=387), with the analytical sample showing a higher proportion of phone and contact form users, but a lower proportion of email and webchat users. Compared with those who were signposted but did not report any outcomes (n=63), the analytical sample (n=296) differed significantly according to mode of delivery (P<.001), gender (P<.001), ethnicity (P<.001), and age (P=.001). Specifically, the analytical sample had a higher proportion of users aged 16 - 18 and 19 - 21, users identifying as White, Asian, or Mixed ethnicity, and women or other genders.

Fisher tests also revealed no demographic differences between participants who provided qualitative responses and those who did not in the signposted group (mode of delivery: P=.98, gender: P=.98, ethnicity: P=.99, and age: P=.99).

Missing	49 (17)
Age (y)	
16 - 19	101 (34)
20 - 21	85 (29)
22 - 25	55 (19)
Older than 26	9 (3)
Prefer not to say	2 (1)
Missing	44 (15)
Ethnicity	
White	189 (64)
Asian	23 (8)
Black	10 (3)
Mixed	12 (4)
Other	1 (0.3)
Prefer not to say	7 (2)
Missing	54 (18)
Mode of delivery	
Webchat	127 (43)
Contact form	96 (32)
Email	54 (18)
Phone	19 (6)

Procedure

From February 2020 to October 2023, all helpline users aged 16 to older than 25 years who contacted the helpline were asked to complete their user survey via email. After clicking the survey link, participants read an information sheet explaining the research aims. Informed consent was then obtained online. Only survey responses from those aged 16 or above were included in this study in line with ethical guidelines for informed consent. Upon providing informed consent, participants completed the online survey on SmartSurvey (Appendix S1 in Multimedia Appendix 1).

This study analyzed only the demographic data and questions related to signposting. The survey platform, number of pages or items, use of randomization or skip or branching, presence of completeness checks, and whether answers could be reviewed or changed before submission were not specified.

Measures

Demographic Questions

Modes of delivery included webchat, contact form, email, and phone. Gender options included women, men, nonbinary, transgender, other, and prefer not to say. Consistent with the ethnic groups in the UK Census [29], ethnicity options included 19 ethnic groups. Since at least 10 observations per predictor group are required for multinomial logistic regressions to yield reliable findings [30], ethnicity was collapsed into 6 broad groups—White, Asian, Black, Mixed, Other, and prefer not to say. Age was collapsed into 16 - 19 years (further education and transition into adulthood), 20 - 21 years (higher education and graduation), 22 - 25 years (postgraduate education and employment), older than 26 years (caregivers or professionals), and prefer not to say.

XSL•FO
RenderX

Signposting Outcomes

For the young person's use and their perception of the usefulness of each signpost, as well as their overall signposting experience, the survey included multiple-choice and open-ended questions, outlined in Table 2. In line with CHERRIES, items comprised fixed-response options plus open-ended questions on experience and improvement.

Table . Survey questions on signposting outcomes.

Question types	Questions
Multiple-choice question on the outcome for each signpost	• Did you find the below organizations or resources recommended to you useful? • Yes (Used it and found it useful) • No (Used it and found it not useful) • I haven't used it but I'm planning to do so • I haven't used it and NOT planning to do so • Not relevant
Open-ended questions for each participant	• Please tell us how the service helped you. • How can we improve? • Please let us know if you have any other comments or feedback.

Data Analysis

Quantitative Analysis

As a closed survey, the view rate is not applicable. Participation and completion rates were not reported. Analyses used the analytic samples described below. Addressing each signpost as an independent item, item-wise analysis was carried out to explore whether demographic variables (categorical) predicted young people's use or perceived usefulness of the signposts (categorical). Using the *mblogit* function from the *mclogit* package in R (R Core Team) [31], multinomial logistic regressions were conducted with only the fixed effects of mode of delivery, gender, ethnicity, and age on signposting outcomes, alongside an overall model with fixed effects of all variables. "Yes" (useful) was the reference category. Although this outcome was a repeated measure depending on the number of signposts for each participant, the model could not converge after adding the random intercept of participants. Nonconvergence may reflect the complexity of the multinomial outcome and limited sample sizes in certain categories. As a result, we reported fixed-effects models treating each signpost outcome as an item-level observation. This decision prioritized model stability and interpretability given sparse cells, but may underestimate uncertainty because outcomes are clustered within participants; findings should therefore be interpreted as exploratory associations.

Qualitative Analysis

Inductive, critical realist thematic analysis [32] was conducted. Responses relevant to signposting from the open-ended questions were first shortlisted by filtering responses from participants who were signposted, then searching for keywords (eg, "link," "resource," "signpost," "organisation," and "website"), and reading the remaining responses to include relevant ones without the keywords (eg, "I decided to book an appointment with my GP to get help").

From these shortlisted responses, 18 initial codes were developed and later organized into 4 main themes using NVivo 14 (Lumivero) [33]. Themes emerged from responses reflecting similar signposting experiences or impacts, with smaller subthemes representing recurring concepts. A codebook with 4 themes and 12 subthemes was eventually created (Appendix S2 in Multimedia Appendix 1).

With varying length and depth of responses, some were coded to more than 1 subtheme. For intercoder reliability, 25 responses were independently coded. The percentage of agreement (ie, proportion of items assigned to the same codes by both researchers) was 76%, indicating substantial agreement between the coders even when responses were mapped to multiple codes [34].

To compare differences in the qualitative feedback across demographic groups, simple sentiment analysis was also conducted by contextually reading each response and annotating it as expressing either positive or negative sentiment. Positive responses were identified as those expressing satisfaction, perceived benefits, or motivation to engage with signposts (eg, "I found a really helpful support group"). Negative responses were categorized as those highlighting barriers, dissatisfaction, or challenges (eg, "the signposted resources didn't meet my needs"). Responses were contextually read and annotated accordingly. Coding of sentiment was conducted manually, with annotations guided by an agreed-upon framework to ensure consistency.

Ethical Considerations

Ethical approval was granted by the University College London Research Ethics Committee (ethics ID: 16583/003). Participants first viewed an online information sheet and then provided informed consent before answering any items. To protect participant privacy, all survey data were fully anonymized, and no personally identifiable information was collected or retained. As compensation for their time, participants were entered into a prize draw with the chance to win a £50 (US $66.64) Amazon voucher.

Results

Overview

Due to varied levels of data missingness for demographic variables, observations with missing data were removed before analyzing each predictor (ie, participants with missing data for ethnicity were only excluded from analyses on ethnicity).

Quantitative Analysis: Signposting Outcomes

As illustrated in the Appendix S3 in Multimedia Appendix 1, individual models were first conducted for the mode of delivery (n=822), gender (n=684), ethnicity (n=669), or age (n=697) before running an overall model with all predictors included (n=669). The individual models demonstrated patterns broadly consistent with the overall model, with some notable differences. The mode of delivery model highlighted that webchat was the most effective channel for signposting outcomes, with other platforms (contact form, email, and phone) associated with a lower likelihood of participants using and finding signposts helpful. The gender model showed that participants identifying as other genders or those who preferred not to disclose their gender were less likely to find signposts helpful, with a greater likelihood of reporting irrelevance or a delayed intention to use them. The ethnicity model revealed that individuals who preferred not to disclose their ethnicity were significantly more likely to perceive signposts as unhelpful or irrelevant, a trend more pronounced than in the overall model. The age model showed that older participants (20 - 25 y) were less likely to find signposts helpful, with these effects being slightly more potent in the individual model than when controlling for all predictors in the overall model. In the overall model, which included all predictors, webchat users identifying as White, women, and aged 16 - 19 years were significantly more likely to use and find signposts helpful than to perceive them as unhelpful (odds ratio [OR] 0.28, 95% CI 0.17-0.46, P<.001), not intend to use them (OR 0.13, 95% CI 0.07-0.26, P<.001), or only plan to use them later (OR 0.29, 95% CI 0.18-0.46, P<.001). These results demonstrate the importance of both the delivery mode and participant demographics in predicting the perceived effectiveness of signposting.

Of 669 signposts in the overall model, 360 (54%) were given via webchat, 480 (72%) were shared with participants who identified as women, 521 (78%) with White participants, and 350 (52%) with 16- to 19-year-olds. Thus, webchat, women, White, and 16- to 19-year-olds were the reference categories for the multinomial logistic regressions.

A multinomial logistic regression examined whether mode of delivery, gender, ethnicity, or age predicted signposting outcomes. A significant chi-square difference test (F_{64}=181.27, P<.001) indicated that our model significantly improved upon the null. The model explained 43% of the variance (Nagelkerke R^2) with a low Akaike Information Criterion (AIC=1934) and Bayesian Information Criterion (BIC=2240).

Shown in Table 3 as the intercept, webchat users identifying as White, women, and 16- to 19-year-olds were significantly more likely to use the signposts and find them useful than perceiving them as unhelpful (OR 0.28, 95% CI 0.17-0.46; P<.001), not intending to use them (OR 0.13, 95% CI 0.07-0.26; P<.001), or only planning to use them (OR 0.29, 95% CI 0.18-0.46; P<.001). This reference group, therefore, represented the most favorable signposting outcomes in the model.

Compared with webchat users, users accessing other platforms (contact form, email, and phone) were less likely to use and find the signposts helpful. Contact form users were more likely not to plan to use the signposts (OR 4.98, 95% CI 2.29-10.83; P<.001), only plan to use them later (OR 3.95, 95% CI 1.98-7.89; P<.001), or find them irrelevant (OR 2.90, 95% CI 1.60-5.25; P<.001). Email users were more likely to only plan to use the signposts (OR 2.77, 95% CI 1.50-5.13; P=.001). Phone users were even more likely to have used the signposts but find them unhelpful (OR 4.17, 95% CI 1.58-11.00; P=.004).

Compared with women, participants identifying as other genders or preferring not to say their gender were less likely to find signposting useful. Those identifying as other genders were more likely to plan to use signposts later (OR 8.46, 95% CI 2.13-33.66; P=.002) or find them irrelevant (OR 4.49, 95% CI 1.22-16.59; P=.02). Participants who preferred not to disclose their gender were more likely to have no intention to use the signposts (OR 3.82, 95% CI 1.19-12.26; P=.03).

Compared with White participants, those who preferred not to share their ethnicity were more likely to find the signposts unhelpful (OR 45.97, 95% CI 3.56-594.15; P=.003) or irrelevant (OR 16.95, 95% CI 1.50-191.26; P=.02). The wide CIs reflect the small sample size for this group and should be interpreted with caution.

Compared with 16- to 19-year-olds, 20- to 25-year-olds were less likely to find signposts helpful. 20- to 21-year-olds were more likely to only plan to use the signposts (OR 3.13, 95% CI 1.64-5.97; P=.001) or perceive them as irrelevant (OR 1.80, 95% CI 1.01-3.20; P=.045), while 22- to 25-year-olds were more likely to not plan to use them (OR 2.92, 95% CI 1.30-6.53; P=.009) or find them irrelevant (OR 1.80, 95% CI 1.05-3.08; P=.03). This suggests engagement with signposting decreases progressively across 20- to 25-year-olds.

[a]Note. Nagelkerke R^2=0.430. Extremely large odds ratios and wide CIs (eg, 0.00 to infinity) may result from zero or small sample sizes for comparisons. Nonbinary (n=8) and transgender (n=6) were collapsed due to small sample sizes. Other ethnicities (n=3) and those who preferred not to say their age (n=4) were not collapsed due to the distinct theoretical implications, but relevant findings should be interpreted with caution.

Qualitative Analysis

Of 358 participants who were signposted to at least 1 resource, 257 participants submitted 441 responses across 3 open-ended questions. Among these, 106 responses from 97 participants relevant to signposting (eg, “Sent me some links to places to help”) were analyzed. Among 106 responses, 76 (72%) indicated positive sentiment, while 30 (28%) were negative. Furthermore, 4 main themes were identified: “choice of signposts,” “signposting experience,” “responses to signposting,” and “effectiveness of signposting.” Table 4 presents the definitions, examples, and number of responses across themes. Note that each response could be coded to multiple subthemes.

XSL•FO
RenderX

Table . Definitions, examples, and number of responses across themes and subthemes.

Theme and subtheme	Response type and examples
Theme 1: choice of signposts	Comments specific to the signposts that influence young people's perception of whether signposting was effective
Relevance (n=8)	Whether the signposts were relevant to the young people's specific concerns • "provided some websites and organizations which would help me with my issue" • "Recommend me to an organization that can help me with my bank account issue"
Personalized (n=14)	Whether the signposts were specific to the young people's demographics (eg, geographical location, age, and support needs) • "clear and useful about what would be available to someone my age" • "Make note of the personal details I sent to you and tailor the help offered with those details"
Expectation (n=5)	Whether the signposts met young people's other expectations (eg, number, features, and specific requests) • "an app would be good with some resources"
Theme 2: signposting experience	Comments specific to how signposting was completed by helpline volunteers
Integration of emotional support with signposting (n=30)	How signposting was integrated with offering emotional support by the volunteers • "They understood what I was going through and gave me organizations to look at" • "…feel a bit demoralizing…better balance between providing some level of support and recommending services"
Elaboration on signposts (n=4)	Whether sufficient details of signposts were provided to young people • "…gave detailed explanations of when and how to use them" • "…explain more about what the websites are"
Preference for additional support (n=5)	Preference for receiving additional support such as direct referrals • "Employ some experts in the field of sexual assault…" • "contact the other agency with you"
Theme 3: responses to signposting	Immediate responses to signposting during or shortly after the chat
Hopefulness and direction (n=14)	Signposting inspiring hope and a sense of direction • "…gave me hope that things will improve" • "…pointing me in the right direction of where to go"
Rejection and overwhelm (n=7)	Signposting leading to feelings of rejection or overwhelm • "…felt like most comments…was a lead-in to recommend a specific service" • "I'm struggling to get through the list"
Theme 4: effectiveness of signposting	Effects of signposting on young people's well-being after the chat has ended
Insights into resources (n=53)	Enhanced knowledge of resources for young people • "…made me aware of some local resources that I didn't know was available"
Empowerment (n=13)	Enabling young people to learn more about their situation and seek support • "…managed to get some plan figured out for myself and scheduled appointments" • "feel a lot more confident in myself"
Access to signposts (n=10)	Ease for young people to access the signposts • "helplines provided to me were either no longer available or outdated" • "helped me to access the resources I needed"

XSL•FO
RenderX

Theme and subtheme	Response type and examples
Impacts on well-being (n=5)	Long-term mental health outcomes from signposting • "…helped not to kill myself" • "received counseling to get past…a time where I felt lost"

Theme 1: Choice of Signposts

Relevance

Participants appreciated the relevance of signposts to their concerns, while some critiqued their relevance. Participants valued the volunteers' effort in selecting the most pertinent signposts: "They also took the time to make sure they directed me to the most relevant resources." However, several participants highlighted that volunteers sometimes misunderstood their needs and shared less suitable signposts. For instance, "The websites that were recommended for me […] were to give me more information on my situation, rather than what I could do next to improve."

Personalized

Some participants recognized how signposts were tailored to their age, location, or support needs, whereas others found them too general. Participants liked it when volunteers inquired about their needs before signposting ("before recommending other services, I was asked how I'd like to contact people"). However, some felt that the volunteers failed to personalize the signposts despite their efforts to communicate their needs ("Make note of the personal details I sent to you and tailor the help offered").

Expectation

Responses mentioned specific requests, such as being signposted to apps ("an app would be good with some resources").

Theme 2: Signposting Experience

Integration of Emotional Support and Signposting

Participants felt heard alongside being signposted ("felt really listened to and actually heard"), while others expressed dissatisfaction with the signposting experience. Participants appreciated being "welcomed with compassion and understanding in very quick time frames" and the nonjudgmental space to share ("gave me the space to get things off my chest"). Yet, some responses suggested that the emotional support felt scripted ("might have been [an] automatic response") and "a lead-in to recommend a specific service." One participant noted the imbalance between emotional support and signposting: "Try not to solely rely on signposting loads of organisations, as it can feel a bit demoralising to just be moved onto someone else."

Elaboration on Signposts

Some responses valued detailed explanations of signposts, while others anticipated further information. Participants appreciated how the volunteers "gave detailed explanations of when and how to use [the signposts]," while others wanted volunteers to "[explain] what each thing could do, such as explaining what counselling is and what it would benefit."

Preference for Additional Support

Responses indicated a preference for additional support, such as in-house specialists ("Employ some experts in the field of sexual assault, rape"), more partnerships ("working with more [organizations]"), or direct referrals. One participant suggested that direct referrals may be more effective than signposting because young people may not be well-informed enough to access support: "Make the referral for [the person] because they may be confused and not do it, putting themselves at more of a risk."

Theme 3: Responses to Signposting

Hopefulness and Direction

Participants illustrated that signposting inspired hope and a sense of direction. Before using the helpline, participants were desperate for support ("I was really desperate for some help and you gave it to me"). Signposting then led them to feel more hopeful about the future ("given me some hope that improvement to my situation is possible") and seek help ("I hope at least one or more [of the signposts] will be helpful"). Additionally, some acknowledged how signposting guided them to appropriate services ("point me in the right directions to organizations and resources"), and they "don't feel stuck again."

Rejection and Overwhelm

Participants conveyed feelings of rejection or overwhelm. Several participants felt dismissed to other services and regretted seeking help: "I was just being referred to other services, so I am quite unhappy that my reaching out didn't pay off as I feel like I'm not gonna get helped." Another emphasized that the excessive number of signposts demotivated them from seeking support: "I was overwhelmed by the amount of other places to look for help that I'm struggling to get through the list."

Theme 4: Effectiveness of Signposting

Effective signposting empowers young people to learn about, trust, and take action to access support [13]. Subthemes were developed to reflect these aspects.

Insights Into Resources

Many participants discovered new local resources ("[…] made me aware of some local resources that I didn't know was available") or found suitable resources ("helped me to find the resources to get the help I need").

Empowerment

Participants demonstrated how signposting empowered them to express themselves and seek help. They found their situations more manageable ("Made me feel in control of my situation") and became confident to open up ("I had the courage to speak up to someone about how I felt"). Some took immediate action to access support: "With only contacting the helpline yesterday

XSL•FO
RenderX

I have already managed to get some plan figured out for myself and scheduled appointments."

Access to Signposts

Participants critiqued that signposts were inaccessible, although 3 accessed the suitable signposts ("helped me to access the resources I needed"). Furthermore, 6 participants were unable to use The Mix's counseling services due to unavailability: "I did want telephone counselling but the referral pathway was closed due to no space." One highlighted other signposts were outdated: "helplines provided to me were either no longer available or outdated."

Impacts on Well-Being

Participants shared that the signposts improved their well-being ("I still use the app that they suggested to me, and so far it's been helping"). Signposting helped participants navigate difficult times ("received counseling to get past […] a time where I felt lost") and was even lifesaving ("It helped found myself and the right people to go. It helped not to kill myself").

Connections With Quantitative Findings

A breakdown of the participants' demographics and the sentiment of their responses is presented in Table 5. Regarding the mode of delivery, email (n=12, 63%), telephone (n=4, 67%), and contact form (n=34, 68%) showed similar levels of positive sentiment, while webchat had the highest proportion of positive sentiment (n=26, 84%). Email helpline users mentioned that signposts were given too quickly *(*"Through email, take time to work through each issue, rather than quickly offering other organisations") while others reported otherwise *(*"With the email I can take my time and follow each link"). Contact form users had mixed sentiments, with some appreciating its asynchronous delivery ("helpful in visualising and stepping away from my issue") and others dissatisfied with feeling pushed away *(*"[…] actually help me rather than referring"). A few phone helpline users commented on the relevance of signposts ("Provide more relevant support services").

RenderX

Table . Demographics characteristics and sentiments of the open-ended responses (n=106).

Characteristics	Positive, n/N (%)	Negative, n/N (%)
Gender		
Women	38/55 (69)	17/55 (31)
Men	11/16 (69)	5/16 (31)
Nonbinary	2/2 (100)	0/2 (0)
Transgender	1/1 (100)	0/1 (0)
Other	3/3 (100)	0/3 (0)
Prefer not to say	2/4 (50)	2/4 (50)
Missing	19/25 (76)	6/25 (24)
Age (y)		
16 - 19	30/45 (67)	15/45 (33)
20 - 21	9/11 (82)	2/11 (18)
22 - 25	16/23 (70)	7/23 (30)
Older than 26	3/3 (100)	0/3 (0)
Prefer not to say	1/1 (100)	0/1 (0)
Missing	17/23 (74)	6/23 (26)
Ethnicity		
White	47/66 (66)	19/66 (66)
Asian	6/9 (67)	3/9 (33)
Black	0/2 (0)	2/2 (100)
Mixed	1/1 (100)	0/1 (0)
Other	0/0 (0)	0/0 (0)
Prefer not to say	2/2 (100)	0/2 (0)
Missing	20/26 (77)	6/26 (23)
Mode of delivery		
Contact form	34/50 (68)	16/50 (32)
Email	12/19 (63)	7/19 (37)
Phone	4/6 (67)	2/6 (33)
Webchat	26/31 (84)	5/31 (16)

Regarding gender and ethnicity, the same proportion of participants who identified as women (38/55, 69%) and men (11/16, 69%) reported positive sentiments, while 100% (6/6) of those identifying as nonbinary (n=2), transgender (n=1), or other genders (n=3) expressed positive sentiments. Of those who preferred not to say their gender (n=4), 2 (50%) expressed positive sentiment. White (n=47, 71%) and Asian (n=6, 67%) participants showed similar levels of positive sentiments, but there were 100% positive responses among those identifying as mixed ethnicity (n=1) or who preferred not to say (n=2). Black participants exclusively left negative responses (n=2, 100%), with one hoping for support from in-house experts in sexual assault and another commenting on access to The Mix's internal counseling services.

In terms of age, responses from 16- to 19-year-olds (n=30, 67%) and 22- to 25-year-olds (n=16, 70%) had a similar percentage of positive sentiments, compared with much higher proportions of 20- to 21-year-olds (n=9, 82%), older than 26-year-olds (n=3, 100%), and those who preferred not to say (n=1, 100%). Several responses are directly related to age. For example, a 22- to 25-year-old preferred more age-tailored signposts ("more information about […] different services that are available to young people"), while an older than 26-year-old parent appreciated the helpline ("My daughter is really struggling. Just knowing I contacted someone helped her").

Discussion

Overview

Our study revealed that participants generally perceived signposts as helpful or were at least motivated to access them after using the helpline, illustrating how signposting may empower young people to seek relevant support. Signposting outcomes varied across modes of delivery, with webchat showing the strongest association with positive outcomes, the

XSL•FO
RenderX

contact form yielding mixed results, and email or phone showing weaker associations. Similar outcomes were observed across gender, ethnicity, and age, although certain minority groups (eg, those preferring not to say their gender or ethnicity, 20- to 25-year-olds) were more likely to ignore or find signposts irrelevant.

Qualitative thematic analysis indicated that participants generally found the signposts relevant and personalized. They valued volunteers' efforts in listening actively and explaining the signposts, which appeared to inspire hope and motivate participants to access support. However, some felt bombarded with too many signposts, leading to feelings of rejection or overwhelm, potentially reducing their intention to use signposts. Those discouraged from accessing signposts often faced barriers such as outdated information, explaining why some participants may have used signposts but found them unhelpful.

Mode of Delivery

The mode of delivery was significantly associated with participants' perceptions of usefulness and their use of signposts, underlining their benefits and disadvantages for young people. Across the 4 modes, webchat was associated with the strongest positive outcomes, with participants perceiving signposts as relevant, trustworthy, and helpful. Real-time interactions with volunteers via webchats may facilitate collaborative therapeutic relationships by allowing young people to control the pace of disclosure, without the social pressure to respond instantly in phone calls. This may empower young people to share emotionally challenging experiences [35], such as suicidality, thus helping volunteers to identify the most suitable signposts. Although helpline contact is brief, relational processes, such as emotional containment, trust-building, and perceived autonomy, are central to whether signposting feels safe and usable. Our qualitative themes suggest that when young people feel heard and validated, signposting is more likely to be experienced as supportive rather than overwhelming. These relational processes are particularly important for young people at higher risk, such as those disclosing suicidality or experiencing a mental health crisis. Volunteers should be trained to prioritize risk assessment and immediate safety planning, ensuring that signposting or referrals to external services complement rather than replace immediate support.

The contact form showed weaker associations, with signposts often perceived as irrelevant. The contact form requires users to explain their situation and receive one-off support asynchronously. For this reason, the degree of personalization in signposts may be limited by the amount of information the users share [19], causing some to perceive the signposts as less tailored.

Similarly, email support was associated with less positive outcomes for young people, possibly due to its asynchronous nature, with participants not using the signposts but intending to. Limited information may affect volunteers' ability to select appropriate signposts, lowering their confidence to provide appropriate support via email [19]. Volunteers' reduced emotional connection to users who contact via email [19] may further encourage volunteers to focus on signposting rather than taking more time to understand their issues, which our findings suggest may lead to some user dissatisfaction with their signposts and email support, more generally.

Despite positive reception in the existing research [36], the phone helpline in our study mainly offered 1 signpost per user, which was often perceived as unhelpful. Potential power imbalances between volunteers and users may explain this finding. Telephone helplines enhance the authority of volunteers [35], possibly reducing young people's sense of control in the conversation, and they could agree to signposts that they may not find beneficial [20].

Integrating Findings Across Methods

Our qualitative themes help interpret why webchat was associated with more favorable signposting outcomes. Webchat had the highest proportion of positive sentiment (26/31, 84%), compared with 63% - 68% across other modes. Young people most often described signposting as helpful when it was embedded within an emotionally validating interaction (refer to Integration of Emotional Support With Signposting section under Theme 2) and when resources felt personally relevant rather than generic (refer to Personalized section under Theme 1). Webchat may support this because synchronous text-based conversation allows users to disclose at their own pace while also enabling volunteers to check understanding, collaboratively narrow options, and immediately clarify barriers to follow-through (eg, eligibility, waiting lists, and how to access), conditions that facilitate both personalization and emotional integration. Where these conditions were absent, young people described feelings of rejection or overwhelm (refer to Rejection and Overwhelm section under Theme 3), or found signposts insufficiently tailored to their demographics or circumstances (refer to Relevance section under Theme 1). This relational "fit" may be harder to achieve in asynchronous modes (email or contact form) where reduced back-and-forth can limit tailoring, and in phone-based interactions where perceived authority dynamics may reduce collaborative choice.

Gender

Signposting was generally associated with positive outcomes across genders, including women, men, nonbinary, and transgender young people. Those identifying as "other" tended to either plan to use the signposts or find them irrelevant, whereas those preferring not to disclose their gender were more likely not to use the signposts. Gender minorities, who may be hesitant to seek help from general services, could find signposting valuable for discovering lesbian, gay, bisexual, transgender, queer or questioning, and others (LGBTQ+) informed services [37], boosting their confidence in accessing support [13]. Nonetheless, as existing LGBTQ+ services may not meet the needs of all, some may find their signposts irrelevant. Participants who preferred not to share their gender might have received less relevant signposts, as volunteers had insufficient information to identify suitable services. Preferences not to disclose gender may reflect broader concerns about confidentiality and stigma, as well as uncertainty about whether the service is gender-affirming, rather than simply a lack of relevance of the signposts. While the open-ended responses seem to indicate that young people who identified as nonbinary, transgender, or other were extremely positive about The Mix's

XSL•FO
RenderX

signposting, the sample sizes for gender minorities were notably small (6 to 25 signposts, 6 to 17 participants), requiring further research to validate our findings. Nondisclosure of gender or ethnicity may reflect safety and trust considerations. Qualitative comments suggest that perceived cultural fit and confidentiality concerns shape willingness to engage with signposts.

Ethnicity

Signposting was generally associated with positive perceptions across ethnicities, although participants preferring not to say their ethnicity were more likely to find signposts unhelpful and irrelevant. For those who preferred not to disclose their ethnicity and found signposts unhelpful, volunteers may have lacked sufficient personalized information to customize their signposts. As with gender, nondisclosure of ethnicity may reflect that building trust with marginalized groups can take longer due to broader issues related to privacy, stigma, and cultural norms around help-seeking, alongside previous experiences of discrimination when seeking support, causing some to withhold their details [22,26]. In our qualitative analysis, Black participants critiqued the signposts; one mentioned limited access to counseling, and the other preferred receiving sexual assault support within The Mix rather than being signposted elsewhere, demonstrating that access to support remains a major barrier to help-seeking. Overall, the results suggest a need to regularly review and update the signposting database to provide more culturally specific and tailored services. Nonetheless, sample sizes for other ethnicities are remarkably small (3 signposts, 14 participants), so these findings should be interpreted cautiously. More broadly, nondisclosure can be understood as an equity signal. When services feel uncertain in cultural safety, young people may reduce identifiable data-sharing. Service design should therefore treat demographic "prefer not to say" responses not as missingness alone, but as potentially meaningful indicators of trust, perceived stigma, and safety.

Age

Signposting was generally helpful across age groups, yet 20- to 25-year-olds were more likely to find signposts irrelevant. 22- to 25-year-olds were more inclined not to use the signposts, while 20- to 21-year-olds would plan to use them. Our qualitative findings suggest that these results indicate that more age-tailored support is needed. For example, 20- to 21-year-olds could be signposted to student support and external services [38], while 22- to 25-year-olds may require more services focused on the transition from school to work, relationship advice, and parenting. Notably, advice-seeking users older than 25 years were often caregivers or professionals seeking advice for young people.

Limitations

There are several limitations to this study. First, since the participants were recruited by emailing helpline users the survey link, self-selection bias may have influenced our results [39]. Those having strong opinions about the helpline may have been more likely to share their feedback, hence skewing the data. Additionally, listwise deletion based on missing demographic data could have retained participants who were more comfortable or engaged with the service. Future studies should consider using stratified sampling to ensure that demographic groups of interest are sampled equally. Second, as we used survey data from a general UK-based helpline for young people, our analytic sample, 64% White (n=189) and 74% (n=221) identifying as men or women, was representative of the user demographic at The Mix, which is 82% (24,158/29,389) White and 97% (34,053/35,215) men or women. Due to the small percentages of ethnic and gender minorities, we collapsed categories for the quantitative analyses. Inflated ORs were still found, as not all minority groups have sufficient observations for each signposting outcome. Future research should focus on gender, ethnicity, and sexuality to enrich the existing findings, conducting focus groups or interviews for more in-depth qualitative analysis.

Furthermore, the outcomes measured in the survey may not be easily compared with outcomes used by other helplines, such as quantitative, self-report measures (eg, study by Law et al [40]). As both our study and other helplines tend to rely on retrospective self-report, recall bias may have affected the accuracy of participants' responses. To understand the different stages of signposting [13], additional research could split the question on signposting into 4 subquestions asking participants whether they found the signposts relevant, whether they planned to use them, whether they accessed the signposts, and whether the signposts were helpful if they used them.

Recommendations

These findings highlight the critical role of signposting in supporting young people's mental health, particularly through webchat, which emerged as the most effective mode of delivery. Given the increasing reliance on digital mental health services, ensuring that signposting remains accessible, relevant, and tailored to diverse user needs is essential. By optimizing signposting strategies, helplines can empower young people to seek appropriate long-term support, ultimately improving mental health outcomes.

Given the mixed findings of other communication channels (eg, email, contact form, and phone), enhancing volunteer training in these areas is recommended. Training should focus on balancing emotional support and signposting in asynchronous communication, as well as effectively navigating suitable signposts during phone-based interactions [13]. For webchat, volunteers should be trained to use brief collaborative checks (eg, confirming priorities, offering 2 - 3 best-fit options, and checking practical barriers such as eligibility, cost, and waitlists) so that signposting feels tailored and actionable rather than overwhelming. For email and contact-form interactions, templates that include a short, personalized rationale for each resource and clear "next-step" instructions (eg, who to contact and what to say) may improve perceived relevance and follow-through.

Additionally, periodic reviews of the signposting database are essential to ensure signposts are up to date and comprehensive. Detailed descriptions of available signposts (eg, referral requirements, waitlist lengths, and access pathways) can enhance the user experience and improve the perceived relevance of signposts [16]. Where feasible, services could also provide an

XSL•FO
RenderX

"actionable signpost pack," particularly suited to asynchronous modes, such as email and contact form (eg, 1 - 3 links plus a brief explanation of why each option fits, what to expect next, and how to access), to reduce cognitive load and increase the likelihood of uptake. Expanding the database to include additional services tailored to ethnic minorities and older youth (20- to 25-year-olds) is also critical, as these groups were identified as having unique needs that may not be adequately addressed by existing services [14]. To further support marginalized groups, services could train volunteers to introduce optional demographic questions as a tool for personalizing support rather than an administrative requirement, and to incorporate explicit affirmations of cultural safety and inclusivity at the start of interactions.

Finally, integrating feedback mechanisms into the signposting process can ensure continuous improvement and adaptability to the evolving needs of young people. As part of routine quality improvement, services could monitor signposting outcomes by mode of delivery and patterns of nondisclosure, treating increases in "not relevant" responses or high "prefer not to say" rates as potential signs to review training, cultural safety, and the signposting database. For webchat, real-time postsession feedback prompts may be the most feasible. For asynchronous modes, follow-up survey links could be embedded in email responses. Periodic evaluations of these mechanisms will allow helplines to refine their signposting strategies, ensuring they remain effective and user-centered. Strengthening these approaches will not only enhance engagement but also reinforce the role of helplines as a vital bridge between immediate support and long-term health care.

Acknowledgments

We are grateful to The Mix, especially Bohdana Dock, for their support throughout the study.

Abstract

Background: Despite their benefits, digital health tools often face adoption barriers because of the digital divide. Identifying the fundamental user skills required to effectively navigate these tools and the usability barriers is essential to addressing disparities in use.

Objective: This study aimed to identify the skill and usability barriers to using digital health tools.

Methods: This study included English-, Spanish-, or Cantonese-speaking patients, aged ≥50 years, who received care at an urban safety net health system in the United States. Participants completed a survey examining sociodemographic characteristics and digital health tool use and were observed and video recorded as they navigated four digital health care tasks: (1) launch a video visit, (2) visit a health website through a URL, (3) log in to the patient portal, and (4) sign up for a patient portal account. Participants who could not independently perform the tasks received additional support. Tasks were conducted in English, while instructions and additional assistance were provided in each participant's preferred language. Video recordings were thematically coded to identify the fundamental skills needed for effective digital tool use and usability barriers in the design of digital tools. We examined whether task independence was associated with participant demographics and thematic categories using Kruskal-Wallis, χ^2, and Fisher exact tests.

Results: In total, 74% (34/46), 52% (31/60), 71% (44/62), and 70% (43/61) of participants (N=64) independently completed digital tasks 1, 2, 3, and 4, respectively. Older age, minoritized races and ethnicities, non-English language preference, lower educational attainment, access to cellular data only or no internet access, and lack of a portal account were associated with a higher likelihood of requiring assistance or being unsuccessful at completing each task (P<.001, except for older age [P=.004]). The qualitative coding of video recordings identified 3, 4, and 6 categories of typing, navigation, and human-computer interaction (HCI) skills, respectively, as fundamental skills required to independently complete digital tasks. χ^2 and Fisher exact tests indicated significant associations between most typing, navigation, and HCI categories and independent task completion. We coded usability barriers as one of 6 learnability challenges or 3 operability challenges.

Conclusions: This study identified that independent use of digital health tools requires fundamental typing, navigation, or HCI skills as well as high usability of digital tools. The inclusion of 4 different digital tasks added specificity to the type of skills and usability considerations necessary to ensure accessibility of digital health tools to diverse older adults. This study underscores the need for vendors to cocreate digital health tools with historically excluded end users in mind. As health care systems expand

XSL•FO
RenderX

digital tool adoption, they must distinguish fundamental skill gaps from usability barriers, as each may require different intervention strategies.

Introduction

Electronic health records, patient portals, telemedicine, and eHealth (often referred to as digital health tools) have increased the opportunities for individuals to engage more directly in their own care. Access to these tools enables appointment scheduling, medication refills, and communication with health care providers, reducing some of the accessibility burdens of face-to-face interactions [1]. These tools have been linked to improved chronic disease outcomes [2-7]. However, there are documented differences in their use among marginalized populations who may face individual and systemic barriers that hinder adoption [8-11]. Previous research has demonstrated different rates of digital health tool use among individuals and groups from minoritized racial and ethnic backgrounds (including those who prefer languages other than English), age groups, and genders, as well as differences in use for those who report barriers to broadband internet, devices, or data (eg, due to cost) [2,8-14]. In particular, older adults, especially those with non-English language preferences or who identify as a racial or ethnic minority, experience large disparities in digital health tool adoption because of steep disparities in device, internet, or cellular data access [9,14,15]. For example, the Pew Research Center reported that, according to a 2025 survey, although 97% of adults younger than 50 years owned a smartphone, only 78% of those 65 years and older owned a smartphone [16]. The Pew Research Center also found that while 81% of White adults in the United States had home broadband, only 71% of Black adults and 68% of Hispanic adults had it. Similarly, Black (19%) and Hispanic (28%) participants were more likely to rely on their smartphones for internet access (which may be less stable than broadband) than White (13%) or English-speaking Asian (11%) participants [16]. This digital divide may be exacerbated in health care settings that rely on digital health tools in routine practice, which is becoming increasingly common [10,13,15,17]. Studies within the past 5 years show that nearly 90% of US health care systems offered telehealth services, especially nonprofit hospitals, which have adopted telemedicine at a higher rate than other health systems [18,19].

To address these barriers for marginalized populations, there is a need for pragmatic research rooted in identifying and understanding digital literacy skills and user needs [20-23]. There is a growing body of literature documenting the self-reported digital literacy skills needed to access digital tools, yet the fundamental user skills required to effectively navigate these tools have not been well defined [23-27]. Self-reported digital literacy skills refer to a user's perceived ability or confidence to perform general digital tasks and frequency of engagement, such as confidence in sending emails or frequency of using search engines. However, these metrics fail to delineate the fundamental knowledge and skills required to engage successfully with digital tools [25-27]. Fundamental knowledge and skills, in contrast, are the observable digital abilities required to navigate and interact with *any* digital device or system that must be present to successfully complete a digital task, such as being able to navigate a web browser, knowing how to open device apps, or recognizing clickable links [25-27]. Observational data are necessary to identify the fundamental knowledge and skills that impact self-reported digital literacy. To our knowledge, no studies have evaluated the fundamental digital knowledge and skills that individuals need to use digital health tools, particularly in marginalized communities disproportionately affected by the digital divide.

It is also important to identify usability barriers—which arise from poor product design—that prevent individuals from successfully interacting with digital tools and contribute to disparities in digital health tool uptake and use [17,22,28-30]. These usability challenges can impact both patients and clinicians. Clinical care team members may not be comfortable with workflows or tools for using eHealth or offering and supporting patients in using digital health tools [31]. Poorly designed interfaces, unclear navigation paths, and accessibility issues disproportionately impact individuals with limited digital literacy, disabilities, or language barriers [11,17,29,30,32]. These usability challenges, which often arise from limited patient participation in co-designing a digital health tool, can create unnecessary friction, discourage continued engagement, and deter patients from using digital health tools to engage in continuity of care [11,30,33]. Moreover, individuals from marginalized communities are less often represented in usability studies, limiting our understanding of the specific challenges they face when navigating these tools and hindering the development of equitable interventions to build the skills essential to improve the uptake of digital health tools [21,33]. Pragmatic human-centered research rooted in identifying the usability barriers for marginalized populations, using representative sampling within health care systems outside academic medical centers, may reveal key themes to improve user experience and mitigate disparities.

To address these gaps in the literature, we conducted a mixed methods study among multilingual older adults receiving care at an urban safety net health system. The aim of this study was to assess patient characteristics associated with successful completion of digital health tasks and to identify the skill and usability barriers that prevented successful completion. Using observational data of participants interacting with real-world digital health tools, we focused on the qualitative identification of skills and usability barriers mapped to existing frameworks. We then linked these qualitatively identified skills and barriers

XSL•FO
RenderX

to the observed completion rates of digital health tasks (such as completing the process of logging in to a patient portal) to pinpoint the fundamental skills necessary to complete each digital health task independently and the usability barriers that many individuals face when navigating these tasks. We also examined the task completion rates overall and by key sociodemographic characteristics to assess disparities in task completion success.

Methods

Study Setting

This study was conducted within the San Francisco Health Network (SFHN), San Francisco County's safety net health system encompassing 14 community-based primary care clinics. The SFHN serves a racially and ethnically diverse patient population of about 60,000, most of whom are enrolled in Medicaid or citywide insurance plans. The SFHN patient population is primarily non-White (80%); notably, 45% do not identify English as their primary language (35% prefer Spanish and >10% prefer Cantonese exclusively), and more than half report barriers to accessing and using digital health technology [34,35].

Recruitment and Participation

Individuals were eligible for participation in this study if they met the following inclusion criteria: (1) receiving primary care at an SFHN clinic; (2) being aged 50 years or older; (3) speaking English, Spanish, or Cantonese as their primary language; (4) and not having a cognitive or behavioral impairment that would preclude them from providing informed consent or completing the digital tasks. We focused on adults aged 50 years or older, given the prevalence of digital barriers within this population. We focused on these 3 languages, as these are the most spoken languages among patients at SFHN, where our study was conducted. Between April 2023 and June 2024, patients at SFHN who met these inclusion criteria were recruited by the study team over the phone after receiving prior approval from their primary care providers. Study team members recruited 101 eligible patients who subsequently completed a participant questionnaire and performed the digital tasks.

Ethical Considerations

The study was approved by the UCSF institutional review board (#22 - 36493). A subsample of 64 participants provided written consent to record their progress through each digital task for this study. Participants were advised of their right to stop taking part in the study at any time. Participant questionnaires, observation notes, and video recordings were deidentified using study identification numbers during data collection. All physical documents with data were stored in a locked cabinet in a secure location. All electronic data were stored on Research Electronic Data Capture (REDCap; version 13.4.10; Vanderbilt University) and on servers accessible only to the study team. Participants were compensated US $20 for completing the questionnaire and US $40 for completing up to 4 digital tasks while being observed.

Data Collection

The participant questionnaire, administered in the participant's preferred language, included items eliciting information on participant age, sex, race, ethnicity, preferred language, comfort speaking English, and educational attainment and questions about device preference, access to a device with video capability, type of internet access, and current enrollment in the SFHN patient portal. Questionnaires were administered in person or over the phone by study staff. All digital task observations were conducted and video recorded in person. See Multimedia Appendix 1 for questions from the participant questionnaire included in this analysis.

After the participants completed the questionnaire, they were asked to use their preferred digital device, if on hand, or to choose a device provided by the research team that they felt comfortable using (either an Android smartphone, an Apple iPad, a Microsoft Windows laptop, or an Apple MacBook) to complete the digital task assessment. Participants were filmed as they attempted four digital tasks that simulated the necessary skills and actions required to use digital health technology effectively: (1) launching a video visit, (2) going to a specific health website, (3) signing in to a patient portal emulator using a dummy account, and (4) signing up for a patient portal account via the emulator. These tasks were selected due to their importance for engaging with digital health tools. While digital health tools have become more inclusive in recent years and offer the ability to switch between English and Spanish (and sometimes other languages) on the platform itself, many elements of these digital tools (such as automated text messages or notifications and prompts) are often unavailable in languages besides English; therefore, to replicate that experience, the platforms that the participants navigated to complete each task were in English only. Further details about the steps involved in each task are detailed in Multimedia Appendix 2, and specific instructions for each task are available online [40].

Participants were asked to independently complete each task by following a set of written instructions in their preferred language; if they were unsuccessful after 2 attempts, research staff provided a standardized instructional handout or video, followed by tailored, language-concordant verbal assistance if necessary. After each step of assistance, participants were asked to try the task again; if they were unsuccessful again, the research staff proceeded to the next level of assistance. Participants were deemed unsuccessful if they were unable to complete the task after receiving tailored one-on-one assistance. The level of assistance provided was logged by the research team member conducting the assessment. For accuracy, a second team member reviewed video recordings and assigned their score. If the 2 scores differed, discrepancies were addressed via team discussion.

The participant questionnaire, written task instructions, and assistance from the research staff were administered in the participant's preferred language, as determined during recruitment. The questionnaire was either verbally administered by an interviewer proficient in the participant's preferred language or completed as a paper questionnaire translated into their preferred language. Additionally, the interviewers provided

XSL•FO
RenderX

translated instructions and, if needed, delivered verbal assistance.

Analysis

Qualitative Analysis

For the qualitative analysis, we used framework analysis—a matrix-based method that allows for systematic comparison of themes across cases while retaining case context—to identify both the fundamental skills required of users and the usability barriers that prevented successful use [36]. First, we watched a subsample of video observations to gain a comprehensive understanding of the participants' experiences and behaviors across the digital tasks. This initial stage helped to identify recurrent ideas, patterns, and areas of interest (typing skills, navigation skills, and human-computer interaction skills). We then developed a thematic framework to guide our analysis by generating a priori coding categories guided by the research questions ("what are the specific and foundational skills a user needs to successfully use digital health tools?" and "what are the usability barriers of these tools?") and the existing literature about digital literacy and usability [27,32,36-38]. We categorized qualitative codes according to the level of digital literacy they reflected and distinguished them as novice or advanced, where appropriate. This categorization was informed by the digital literacy framework of van Deursen et al [27] and modified to appropriately reflect the skills pertinent to using digital health tools rather than the internet in general. This framework differentiates operational, formal, informational, and strategic digital skills, which capture the range of competencies needed to use digital tools effectively [27]. We primarily focused on operational and formal skills, such as device handling, typing, and navigating digital interfaces, which were most relevant to the tasks in our study. Novice-level skills included novice keyboard skills and novice device skills, which were observed as operational inability or skill gaps when performing a task. Advanced-level skills included advanced typing and advanced device skills—skills that encompassed strategic problem-solving abilities, such as troubleshooting errors and intuitive device understanding. We also mapped the predetermined coding categories of learnability (the capability of digital health tools to enable the user to learn their application) and operability (the capability of digital health tools to enable the user to operate and control them) to challenges associated with completing digital tasks due to usability issues [38]. We also used an inductive coding approach to allow codes to emerge from the data to limit a priori bias. Inductive and deductive coding ensured that both anticipated and novel insights were captured.

Next, we compiled and organized the codes in a structured matrix format, which enabled us to summarize and compare the nature and context of responses, while preserving the richness of the video observations. Each row represented an individual participant, and each column presented the themes associated with a specific task (Figure S1 in Multimedia Appendix 2). As a calibration step, 3 independent coders watched a sample of the videos and created a templated summary for each task in the matrix tool. This was used to assess the template and confirm that the domains were intuitive; identify any missing or incorrectly labeled domains; clarify any issues; and ensure consistency in content, style, and organization across coders. During this process, actions that supported or deviated from these predicted codes led to additional codes, iteratively expanding upon and updating the codebook to include relevant concepts (see Multimedia Appendix 3). After finalizing the codebook and template, to assess coding consistency, 3 members of the research team independently coded 25% of the recordings. After ensuring >85% agreement, the 3 members independently coded the remaining recordings.

Quantitative Analysis

For the quantitative component, survey responses were first exported from REDCap for preliminary descriptive summaries, focusing on the variables age, sex, race and ethnicity, preferred language, educational attainment, access to a device with video capability, source of internet access, and enrollment in the SFHN patient portal. These sociodemographic characteristics comprised the covariates for analysis.

Our primary quantitative outcome variable was task completion, which assessed whether a participant independently performed the task only with simple written instructions, performed the task after receiving standard assistance (ie, detailed handouts and video tutorials), performed the task after receiving tailored assistance (ie, verbal instructions and one-on-one help), or was unsuccessful. For analyses, we dichotomized this outcome, categorized as performing a task independently versus requiring any support (standard or tailored) or being unsuccessful (examples of these materials are available online) [39]. This cut point was chosen, as it represents the key distinctions between a user demonstrating fundamental skills and those requiring further assistance or training. Because of technical issues (eg, malfunctioning cameras or recording failures) and participants occasionally declining tasks that they found too difficult, the number of video recordings varied slightly across tasks, as individuals without recordings were treated as missing data and removed from the analysis for that task.

We conducted global tests of association to evaluate relationships between participant sociodemographic characteristics and task completion across all 4 tasks. Kruskal-Wallis tests were used to test the association between age—modeled as a continuous variable—and task completion. χ^2 tests of independence were used for categorical sociodemographic variables, and Fisher exact tests were used when the expected cell counts were <5. These tests evaluated whether task completion status differed by sociodemographic characteristic when considering all tasks jointly, rather than within a single task. R software (version 4.3.3; R Foundation for Statistical Computing) was used to conduct all analyses.

Comparison of Qualitative Findings and Quantitative Data

To assess the relationship between identified themes and task completion, qualitative and quantitative analyses were conducted in parallel using a convergent triangulation design in which the datasets were integrated prior to the combined analysis [40-42]. Key qualitative themes were grouped into higher-order categories to facilitate interpretation. This involved identifying

XSL•FO
RenderX

conceptual connections between codes and organizing them into thematic categories. These thematic categories were then converted into categorical variables and incorporated into the quantitative dataset. Triangulating the 2 types of data supported the identification of foundational skills necessary to use digital health tools successfully (and, conversely, the skill gaps that required interventional support). We used χ^2 tests of independence and Fisher exact tests to determine the significance of associations between each identified skill or skill gap and the task completion outcome. Fisher exact tests were used when the expected cell counts were <5.

Results

Participant Characteristics

In total, 64 participants, comprising 40 men and 24 women, provided consent for the video recording of their digital task completion efforts. The language spoken by most participants (n=42, 65.6%) was English, followed by Cantonese (n=14, 21.9%) and Spanish (n=8, 12.5%). The mean age was 61.9 (SD 7.4; range 51.0 - 83.4) years. Notably, 79.7% (51/64) of the participants identified as non-White, and 53.1% (34/64) of the participants had an educational attainment of a high school degree or less. Most participants (55/64, 85.9%) strongly preferred using their smartphone, with some preferring a desktop or laptop computer (12/64, 18.8%) or tablet (9/64, 14.1%), and only 1.6% (1/64) preferred using a simple cell phone. Moreover, 90.6% (58/64) of the participants owned a device with video capability. Of the 64 participants, 60.9% (n=39) had both Wi-Fi and unlimited data on their smartphones, whereas 23.4% (n=15) used Wi-Fi only and 10.9% (n=7) had unlimited data only. Lastly, 65.6% (42/64) of the participants were enrolled in the patient portal at SFHN. Participant characteristics are displayed in Table 1.

Task Completion

Task completion rates per task are displayed in Table 2. As shown in Table 2, 46 to 62 participants were filmed while completing the 4 digital tasks. Independence in task completion was the highest for task 1 (34/46, 74%) and lowest for task 2 (31/60, 52%).

Global tests of independence were used to evaluate associations between participant characteristics and task completion across all 4 tasks. Age, race and ethnicity, preferred language,

XSL•FO
RenderX

educational attainment, access to a device with video capability, source of internet access, and enrollment in the patient portal were significantly associated with task completion. Participants who were older were more likely to require assistance or be unsuccessful across tasks (P=.004). Participants who were White were significantly more likely to complete each task independently than participants of other races and ethnicities (P<.001). Similarly, preferred language was associated with task completion, with those who preferred Spanish or Cantonese more likely to require assistance or be unsuccessful than those who preferred English (P<.001). Participants with a high school education or less were also more likely to struggle to complete the tasks independently and had higher rates of being unsuccessful or requiring assistance (P<.001). Access was also significantly associated with task completion, with those who had access to a device with video capability and Wi-Fi more likely to complete tasks independently than those without video capability (P=.05) or who relied on data to access the internet (P<.001). Individuals already enrolled in the patient portal tended to be more successful and had a higher likelihood of completing each task independently than those who were not enrolled in the patient portal or were unsure (P<.001).

Video Observations

Thematic Coding

The following findings were based on 91% agreement between the 3 coders for the first 15 participants and independent coding of the remaining videos. Thematic findings were grouped into factors, mapped to the overall dimensions of fundamental skills and usability barriers, and reorganized for interpretation. To ease analysis, we decided to separate the codes representing usability barriers from those representing fundamental skills, with several codes representing skills and usability barriers. Figure 1 shows an overview of themes generated during the observational coding process, with subcategories within each key theme, and separated by fundamental skills and usability barriers.

Figure 1. Qualitative thematic maps for fundamental skills and usability barriers.

Fundamental Skills

Video observations revealed that participants exhibited a range of digital skills from novice to advanced. The coding matrix categorized participant behaviors into key themes, including typing skills, navigation skills, and human-computer interaction. Typing skills referred to a participant's ability to navigate the keyboard (particularly capitalizing letters and finding special keys) and demonstration of inefficient typing ("hunting" and searching for letters) or advanced typing skills (proficiency with typing, capitalization, and special keys). Navigation skills comprised inefficient navigation (eg, extraneous scrolling or tapping on the device), novice device skills (eg, unfamiliarity with device layout or apps), advanced navigation and device skills (often indicated by minimal scrolling), and continuous progress of the task. Human-computer interaction (HCI) encompassed codes that demonstrated the way participants engaged or did not engage with their devices to complete the tasks, ranging from how they responded to prompts; whether they were unsure how to proceed, requested assistance, or ineffectively interacted with pop-ups or prompts; to having

XSL•FO
RenderX

trouble with specific elements of the tasks (eg, novice URL skills, trouble finding or using a web browser, or novice password skills).

A significant proportion of participants exhibited novice-level digital skills, particularly in typing and navigation. Many participants relied on inefficient typing techniques, such as hunt-and-peck typing and relying on using one finger or a stylus to locate and enter subsequent characters. The inability to appropriately capitalize letters or locate and select special characters created significant barriers to completing the tasks independently. Similarly, many participants demonstrated navigation inefficiencies. Participants exhibited trouble navigating their device with extraneous and repeated tapping or scrolling, confusion locating specific apps or phone settings, or difficulty using a touchscreen or trackpad. In contrast, participants who demonstrated success at navigating the tasks independently almost exclusively displayed advanced navigation skills and the ability to progress through the tasks continuously without breaks in performance flow.

Many individuals also struggled with more complex HCI actions beyond simply navigating their device or using the keyboard. Common observations included participants not understanding how to proceed through the task because they struggled with fundamental concepts such as recognizing common digital icons (eg, settings icon, “close window” button, home icon, or back/forward arrows) or clicking the “next” button, having trouble finding or navigating to a web browser (or conceptually understanding what it is), ineffectively interacting with task pop-ups or prompts (eg, ignoring a pop-up/prompt or choosing the wrong link), and difficulty using the web browser (eg, not knowing how to select the web browser icon to open a new window or how to proceed once the web browser was open). Individuals also demonstrated novice URL and password skills, as they struggled with accurate text entry to successfully type in a URL for a website or enter the provided password. Difficulty performing complex tasks despite receiving instructions was a common reason why participants asked for assistance, often demonstrated even before they attempted the task or after several unsuccessful attempts to complete an action.

Table 3 presents the association between typing, navigation, and HCI codes and task performance. Most notably, across tasks, keyboard skills, navigation skills, and HCI skills showed a significant association between the factor and the ability to complete each task independently. Individuals who demonstrated unfamiliarity with navigating the keyboard, particularly with how to capitalize letters or find special characters, always required assistance or were unsuccessful at completing the digital tasks (P<.001 in all cases). Inefficient navigation with extraneous scrolling or tapping of their device was strongly associated with needing assistance or unsuccessfully completing the task, particularly in task 1 (P=.001), task 2 (P<.001), and task 4 (P=.006), which required more complex device navigation to complete the task. Novice device skills, demonstrated by lack of familiarity with one’s device, whether it be the layout, finding and using apps, or navigating the trackpad, were significantly associated with requiring assistance or unsuccessfully completing the task across tasks (task 1, P<.001; task 2, P<.001; task 3, P=.004; task 4, P=.002). Typing skills (both inefficient typing and advanced typing skills) were not significantly associated with digital task completion (exact P values given in Table 3). However, we did not assess speed to completion.

The complexity of the digital tasks required several fundamental human-computer interaction skills, beyond navigating one’s device, to complete each task. Displaying confusion or hesitation with how to proceed during a task was a significant barrier for individuals during each task, ranging from not being sure how to proceed to confusion about how to navigate barriers that arise or where to put information (tasks 1, 2, and 4, P<.001; task 3, P=.02). Individuals also often asked for assistance when stuck on a task, demonstrating the complexity of progressing through a task as a barrier to independently completing a task (P<.001 in all cases). In task 2, the ability to find and use a web browser appropriately and the ability to type in a URL correctly were also significantly associated with being unsuccessful or requiring assistance to complete the task (P<.001 for both). In tasks 3 and 4, having trouble with creating a username or password (eg, not sure how to create one) was associated with needing assistance or unsuccessfully completing the task (task 3, P=.004; task 4, P=.006).

[b]Indicates Fisher exact test; χ^2 tests of independence used in all other instances. $P \leq .05$ was considered significant.

Usability Barriers

Video observations also revealed that task completion was hindered by several usability barriers. The key usability barriers across all the tasks were related to learnability and operability. Tables 4 and 5 summarize the learnability and operability issues for each task. In task 1, joining a video visit from a text message and unfamiliarity with system-generated notifications led to hesitation or errors in navigating the log-in prompt (characterized by the codes “confusion/hesitation regarding text messages” and “unsure how to proceed”), illustrating learnability barriers to joining video visits, despite the instructions in the text. In addition, individuals often did not select the video link, instead opting to choose an alternative method, such as replying to the text (despite it being a no-reply message) or attempting to join the video visit unsuccessfully. Additionally, once the participant successfully selected the link in the text message, additional pop-ups and links necessary to join the video call confused the participant, resulting in those pop-ups and links being ignored or ineffectively addressed. The operability limitation of this task was that the system did not provide clear enough cues for individuals to correctly select the link to join the video visit; therefore, individuals often did not know which link to select and instead selected the wrong link, either delaying their ability to join a video visit or preventing it altogether.

XSL•FO
RenderX

Table . Examples of learnability usability barriers by task.

Task	Thematic code	Example	Illustrative quote
1: sign in to a video visit	• Confusion or hesitation regarding text messages • Unsure how to proceed • Not knowing which link to select	• Clicking on a video call link from a text message requires a level of understanding (to click the link) that users might not have • Results in hesitating to click the link, ignoring the text, or replying to a no-reply text • Individual ignores necessary prompts for joining a video call or selects other incorrect links	• "Ok so I have to copy that link and put it on my phone?" • "So, I open it, I guess?" • "Ok but what does…main menu? What does that look like?"
2: go to a specific website	• Mistake search bar for URL bar • How to do manual credential entry • Unsure how to proceed • Not knowing which link to select	• Individual types the URL into the search bar instead of the URL bar • Individual is not sure how to proceed once they type the URL in • Individual does not select the appropriate link or button; instead, they select elsewhere	• "I don't know how to get to a website." • "If I put it up here, it doesn't come down here." [in reference to search bar] • "Now I'm stuck."
3: sign in to the patient portal	• How to do manual credential entry • Unsure how to proceed	• Individual does not display the basic level of knowledge for password or username duplication (copying the given password/username into account) • Individual stops after typing in password, without clicking enter to continue	• "Oh, it says Patient, I'm the patient!" [in response to the username being "Patient123" after entering only "123"]
4: sign up for a patient portal account	• How to create a password • Unsure how to proceed	• Individual does not display the basic level of knowledge necessary to create a password • Individual does not know how to proceed once they type in a password or username	• "Did it accept? Did it accept, or not?" • "I don't know what you mean by that." [in response to being instructed to capitalize a letter] • "Is that the password? Nothing? I have to create? Invent something?"

XSL•FO
RenderX

Table . Examples of operability usability barriers by task.

Task	Thematic code	Example	Illustrative quote
1: sign in to a video visit	• Selecting wrong link	• Individual clicks on a wrong link to join the video call	—[a]
2: go to a specific website	• Generic error notification leads to repeated errors	• Complexity and length of the URL results in errors difficult to discern and correct	• [Participant mistakenly typed a forward slash instead of a backslash]
3: sign in to the patient portal	• Sign-in process difficult to remember or master • Generic error notification leads to repeated errors	• “Login failed” notification does not indicate the error, resulting in difficulty correcting username or password errors	• "Even if I signed in now, after I walk out the door I won't know how to do it again." • "Those are the little things that make a difference." [when noticing that "s" in the password “AppleSauce” needs capitlizing]
4: sign up for a patient portal account	• Activation code disrupts sign-up process • Generic error notification leads to repeated errors	• Activation code causes confusion and leads to error making • “Login failed” notification does not indicate the error, resulting in difficulty correcting username or password errors	• “I don’t know [where the activation code is].” • “Where do I put [the activation code], right here?” • "I'm confused.” [when unable to quickly identify error]

[a]Not applicable.

Task 2 was the most difficult for participants, with learnability and operability barriers affecting the ability to complete the task of signing in to the patient portal on a web interface. Many participants displayed misinterpretation of browser suggestions and confusion regarding where to type in the URL (coded as “mistake search bar for URL bar”) and the extent to which the URL needs to be complete (categorized as “how to do manual credential entry;” many stopped before typing in the complete URL or mistakenly used autofill to create a false URL), illustrating the learnability barriers associated with this task. In addition, individuals were often unsure how to proceed, sometimes selecting irrelevant links or failing to recognize the correct link to continue to the patient portal website. Typing in a URL with multiple characters and capitalizations also proved to be a user burden, as many individuals made small mistakes that led to repeated failures, without indications of where the error was, illustrating the operability barrier in URL design. These mistakes included typos in the URL or using autofill to automatically complete the URL, despite the autofill not matching the provided URL.

Participants struggled with the password aspects of tasks 3 and 4, further exposing learnability and operability barriers. They often misunderstood the login prompts, illustrating conceptual clarity issues in password duplication or creation for digital tools (categorized as “how to do manual credential entry” and “how to create a password”). The knowledge required to understand and replicate the complexity required for password creation is too steep, resulting in learnability barriers for many users who do not possess the basic level of knowledge necessary to navigate username and password duplication or creation. Additionally, in task 4, once individuals created a password, they often did not know what to do next to proceed, illustrating the learnability issues of progressing successfully through the steps required to sign in or sign up for a patient portal account.

The operability limitation of these tasks was notifications that did not adequately notify the participant of their error, leading to repeated errors (categorized as “generic error notification leads to repeated errors” and “‘login failed’ notification leads to repeated errors”). For example, the activation codes were confusing and led to errors among participants without proper indication. When prompted that an activation code was needed, many did not know what it was, where to find it, or what to do with it. If they mistyped the activation code but not the username or password, they would receive only a “login failed” notification that did not properly indicate where the error occurred.

Discussion

Principal Results

Our study identified the fundamental skills necessary to be able to effectively navigate digital health tasks, found significant disparities in those skills among participants, and established usability issues associated with navigating digital health tools.

Although nearly universal access to digital devices has resulted in increased device ownership and personal use, only 53.1% (34/64) of participants were able to complete more than half of the tasks independently. Notably, 15.6% (10/64) were unable to complete any tasks independently, indicating a discrepancy between device ownership and ability to navigate these devices effectively, particularly for digital tasks related to health care. These data are supported by prior work assessing disparities in digital health tool use [9,11,43].

We expected that typing skills, navigation skills, and HCI skills would be associated with the ability to complete the digital tasks independently, but it was found that only a subset of these

XSL•FO
RenderX

factors were associated with task completion, which may be limited by our sample size.

Challenges in Task Completion

Nearly half of the participants were able to complete each task independently, with 56.3% (36/64) able to complete tasks 1, 3, and 4 independently. The task of typing in a URL in task 2 posed unique barriers and resulted in more participants requiring assistance or being unsuccessful. This is potentially explained by the fact that typing in a complete URL is increasingly uncommon in digital health contexts, where users typically rely on search engines (eg, searching "SFHN MyChart patient portal" in the search bar), use autocomplete based on browsing history, or access the portal through an app. This is further supported by the fact that many participants struggled to recognize the URL bar or conceptually understand what was being asked of them during task 2. Despite this, many informational handouts about the patient portal continue to direct users to type in a specific URL to access the patient portal. These materials should consider providing alternative instructions that align with common user behavior, such as using search terms or app-based access.

Disparities in Task Completion

We anticipated that there would be disparities in task completion based on age, sex, race and ethnicity, preferred language, education, access to a device with video capability, source of internet access, and patient portal enrollment. Older age, minoritized races and ethnicities, preferred languages other than English, low educational attainment, possession of a device without video capability, data as the source of internet access, and not being enrolled in the patient portal contributed significantly to gaps in digital skills. These sociodemographic characteristics were significantly associated with requiring assistance or being unsuccessful, particularly for tasks that involved multiple steps or complex engagement with digital interfaces. This suggests that individuals from these groups may be disproportionately less likely to have the skills required to feel confident and able to complete each task independently. Moreover, tasks 3 and 4 were more complex, involving reading comprehension and following multiple prompts to enter pertinent text or create a unique password. These elements (such as log-in prompts and password creation details) were in English only, which posed obvious barriers to individuals who preferred non-English languages.

Although this study is not sufficiently powered to examine the intersectional vulnerabilities of participants who experience multiple, overlapping socioeconomic disadvantages—factors that may confound their ability to complete digital tasks independently—there remains a critical need for future research to adopt an inclusive approach to participant recruitment and analysis in usability studies. Specifically, examining how compounded forms of marginalization (eg, low income, limited education, language barriers, and age-related factors) shape digital engagement is essential for uncovering the full extent of challenges faced by individuals most at risk of digital exclusion. Such efforts are key to informing the design of equitable digital health tools and implementation strategies that promote broader and more effective adoption across diverse populations [17,21,22,33,44].

Challenges in Digital Proficiency

These results illustrate that the basic foundational skills necessary for successful navigation and use of digital health tools include competency with one's device, such as knowing basic keyboard navigation and how to find appropriate apps or change settings, being able to navigate complex processes such as interacting with pop-ups and successfully navigating web browsers, and being able to proceed after each step. Without these basic foundational skills, an individual's ability to successfully use and navigate digital health tools decreases significantly. Strategies for improving digital skills to ensure that individuals have the necessary foundational skills include implementing digital competency screening tools and providing digital skills workshops and trainings that emphasize hands-on practice with common tasks such as manual text entry, device and keyboard navigation, managing settings, and interacting with complex pop-ups or prompts. Prior work from our team has demonstrated that the brief, 9-item Skills Measurement and Readiness Training for Digital Health (SMART Digital Health) Scale is reliable for measuring skills for digital health-related tasks and activities and predicting the level of support an individual may need [23].

In addition, prior studies have found that providing support such as technical support or digital education alleviates some of the digital proficiency challenges faced by many and promotes the use of digital health tools, particularly among those who face greater barriers to digital use [45-47]. In addition to providing detailed assistance and training to address the complex barriers faced by those with limited digital literacy, ongoing or repeated support may be necessary, as one-time training or technical help may not be sufficient to overcome persistent technical challenges [47].

Usability Barriers May Impact Digital Task Success

The findings highlight the critical role of learnability and operability challenges across a range of digital health tasks commonly required for digital patient engagement. Participants encountered distinct barriers during each task, verbalizing frustration and making repeated assistance requests. Many of the difficulties were often tied to misunderstandings about how to initiate or complete a task, suggesting that digital inclusion efforts should simplify interfaces, provide clear prompts, and reduce extraneous steps to mitigate the usability issues faced by many participants.

Learnability issues can lead to a range of negative user experiences, including hesitation and confusion, a greater need for assistance and additional support to complete each task, and low user confidence. Each task required a level of understanding that users might not have to complete the task, resulting in a system that does not equally support users of all backgrounds to adapt and use the system. In addition, there were operability barriers across each task. Particularly, difficulties such as clicking the wrong link, making errors without descriptive or specific notifications, or being confused about how to proceed during a task result in a system that does not provide users with

XSL•FO
RenderX

the necessary functionalities to allow users of all backgrounds to adapt and use the system. Efforts to improve the clarity of digital task prompts and processes, ranging from simplifying the URL to log in to the patient portal to clarifying how to successfully join a video visit from a text (or link) or how to engage with certain prompts, will enhance system learnability and operability and allow users to better engage with the system and remember how to use the system going forward.

These findings are consistent with prior research identifying digital navigation and account access as common friction points for users with limited digital literacy [9,11]. However, our human-centered design (HCD) approach to this study adds nuance by documenting how these challenges manifest in real time and vary by task complexity. Previous literature often examines digital competence in aggregate, but our task-specific analysis reveals that even users with some experience may struggle with unfamiliar or multistep processes, particularly when there are long task completion times or when confusing interfaces or prompts lead to repeated errors [48,49]. As adoption of digital health tools continues to increase, there are opportunities to use HCD approaches to identify usability barriers and align digital health tool design with user needs to ensure a more equitable distribution of digital health tool benefits [32]. This is particularly important, as there are numerous examples in which digital tools exacerbate inequities. HCD approaches can help uncover previously unknown health equity issues and drive efforts to address those inequities more acutely experienced by marginalized populations that are often not considered priorities in research [28-30,32,33].

Vendors Need to Prioritize Co-Design to Address Usability Barriers

The findings from this study underscore the pressing need for digital health vendors to take a more active role in addressing usability barriers and skill gaps through cocreation. While health systems increasingly rely on digital platforms to facilitate patient engagement, results demonstrate that usability challenges and complex design, often resulting from a failure to cocreate with users, are common friction points that inhibit successful digital health tool use. These barriers are not merely technical inconveniences; they are structural barriers that prevent users from accessing care and support. Prior studies have similarly identified usability challenges—such as manually entering data, following procedures to retrieve data (such as appointment details), and understanding medical terminology—as key barriers that prevent equitable use of patient portals among diverse populations [49,50].

To address usability challenges, vendors must adopt HCD principles and co-design strategies that engage diverse users throughout the design process to ensure that digital interfaces are intuitive, accessible, and responsive to users' varying levels of digital proficiency. This includes incorporating plain language, reducing unnecessary steps, improving language functionalities for non-English speakers, and reducing privacy and security complexities that act as a barrier to users with low digital literacy [50]. Vendors must not assume a baseline level of digital literacy and should instead actively test for, design against, and consult patients about learnability, operability, and task complexity barriers in these digital health tools. By treating usability and accessibility as core priorities rather than downstream implementation concerns, vendors can play a pivotal role in promoting digital equity and closing gaps in health care access. For example, strict security needs for usernames and passwords (including activation codes and other 2-factor authentication) are not "user-friendly," and while they make sense from a security perspective, they are advanced skills that many users do not understand or have experience with. Issues with complex password creation, entering an activation code, and other 2-factor authentication methods are demonstrated tension points for users from marginalized backgrounds who may have little experience in engaging with strict and complex privacy protocols. Vendors must include patient voices when weighing privacy concerns against usability to ensure that access and usability decisions do not further inequities [28,50].

In the meantime, without more usable products, health care systems need to be prepared to support patients in accessing and using existing digital health tools. As prior studies have shown, explicit identification of a "digital navigator" to support patients in using digital health tools facilitates equitable access and use of digital health tools [51,52]. Unfortunately, this technical assistance often falls to clinical care team members who are not trained to provide this type of support; as a result, patients do not receive adequate support, particularly in safety net systems [52,53]. Increasing support for digital navigator training and incorporating them as members of the clinical care team will be crucial to help overcome gaps in foundational skills and usability barriers.

Limitations

We note several limitations of our study. We recruited participants from a large urban safety net health system that serves a diverse population, but our stratified samples based on core sociodemographic characteristics are small, limiting our ability to evaluate disparities in fundamental skills by sociodemographic characteristics. Additionally, the Hawthorne effect may have resulted in participants changing their behavior while completing the digital tasks because they were being observed. While the chosen tasks are essential in accessing and using digital health technology, they may not be representative of specific usability barriers that individuals face within the patient portal app itself (such as scheduling an appointment) or may be considered by some as antiquated processes (such as using a URL to access the patient portal). We used a patient portal emulator for this study, which was a web browser–based process; this may not reflect the same usability barriers that would exist for the use of a smartphone app. However, the fundamental skill challenges that were present for many patients would impact the use of a mobile app. Moreover, despite advances in digital health tool accessibility (translation to multiple languages and apps available on most devices), there are still limitations to the ability of digital health tools to be inclusive, resulting in issues that are not strictly due to lack of skills but are also influenced by language barriers or other sociodemographic barriers. However, our results will still provide further direction for future digital inclusion studies.

XSL•FO
RenderX

Implications for Future Research

Future studies should more deeply examine usability issues of digital health tools, evaluating the tools themselves and not just tasks that are related to these tools. Future studies should also explore longitudinal improvements in digital skills following structured training interventions. Evidence has shown that provision of multimodal and audiovisual digital training is supported by patients and has been associated with improved use [45,46]. This evidence suggests that training among populations with marginalized identities can be beneficial, yet evidence is needed to assess training implications on digital skills. Additionally, assessing the impact of different instructional approaches—such as interactive tutorials versus guided assistance—could yield insights into optimizing digital literacy education.

Furthermore, there are benefits of improving digital literacy broadly, not only specific to digital health tools and digital health engagement. This study demonstrated that there are disparities in foundational skills that are not specific to digital health tools; therefore, designing collaborations with libraries or continuing education classes could serve as implementation strategies that can help mitigate the effects of these skill disparities and reduce digital exclusion.

Conclusion

By integrating the results of the fundamental skills necessary to use digital health tools and usability barriers to using these tools, this study highlights critical gaps in digital literacy, particularly in device navigation and progressing through complex tasks. This study underscores the importance of usability-driven improvements to reduce digital barriers. By addressing these challenges through targeted interventions, digital accessibility may be enhanced, empowering users to navigate digital environments more effectively. Future work should explore user-tailored interventions aimed at providing individuals with the core fundamental skills necessary to use digital health tools, iterative usability testing to improve the usability of these tools, and personalized support mechanisms to support individuals as they navigate these tools. By systematically identifying and addressing these usability challenges, researchers and developers can create more inclusive digital health solutions that promote equitable health care access and improve patient outcomes across all populations.

Abstract

Background: Although fitness apps could promote healthier lifestyles, evidence on the effectiveness of app-based interventions remains inconsistent. Previous studies have used affordance theory to identify the factors that generate exercise-related value for users. However, many fitness app affordance studies have examined multiple fitness apps collectively, assuming similar design intentions across platforms. Moreover, most have relied on predefined affordances rather than investigating emergent or novel ones that may reveal unique user–fitness app interactions.

Objective: This study aimed to identify the common affordances actualized by Fitbit users and uncover novel affordances that emerge from their interactions with this specific app, thereby extending the understanding of how affordances contribute to user engagement and health outcomes.

Methods: We used a 2-stage mixed methods design. First, a cross-sectional web-based survey was conducted with 442 US-based Fitbit users engaging in regular exercise. The participants selected affordances from a list identified in prior literature and could report additional affordances in open-text responses. To corroborate and extend the survey findings, 15,000 user reviews were collected from the Google Play Store, of which 2674 (17.8%) comments were automatically categorized into affordance themes and 1182 (7.9%) were manually validated as relevant. Reviews were thematically classified into affordance categories via a generative pretrained transformer–based approach guided by survey-identified affordances.

Results: The survey revealed that the most frequently actualized affordances were updating (351 participants and 749 review mentions; total=1100) and reminding (319 participants and 143 mentions; total=462), underscoring Fitbit's role in tracking progress and sustaining routines. Competing (99 participants and 88 mentions; total=187) and rewards (133 participants and 32 mentions; total=165) highlighted gamification, whereas comparing (151 participants and 8 mentions; total=159) and guidance (118 participants and 25 mentions; total=143) reflected benchmarking and instructional support. Other affordances such as searching (135 participants and 2 mentions; total=137), encouraging (75 participants and 19 mentions; total=94), and watching others (68 participants and 3 mentions; total=71) were less common, whereas recognizing (58 participants and 0 mentions; total=58) and self-presentation (47 participants and 1 mention; total=50) were the least common. The novel affordances included encouraging others (14 participants and 1 mention; total=15), accountability (3 participants and 9 mentions; total=12), and self-comparison (3 participants and 5 mentions; total=8).

Conclusions: Most Fitbit users actualized updating and reminding affordances, whereas a limited number of users actualized the other affordances. Moreover, few Fitbit users actualized novel affordances that reflect self-regulation, an extension of social connection, and personal meaning. This study emphasizes that Fitbit should focus on core tracking and reminding for most users while providing optional features that foster guidance, community, accountability, and personal relevance. Designing features that facilitate the actualization of common and novel affordances may improve app effectiveness and, ultimately, the health benefits of fitness technologies.

KEYWORDS

fitness apps; exercisers; affordance; affordance actualization; exercise behaviors

Introduction

Mobile fitness apps have emerged as widely adopted digital tools intended to support individuals in pursuing healthier lifestyles [1]. Through their interactive and data-driven nature, fitness apps encourage consistent exercise, potentially enhancing both physical fitness and cognitive health while contributing to the prevention of chronic illnesses [2-4].

Although these apps hold potential for improving exercise behaviors, evidence on the effectiveness of app-based interventions remains inconsistent [5]. Several studies report minimal to no observable improvements in exercise following app-based interventions [6,7], whereas others demonstrate meaningful gains in exercise engagement and outcomes among adults [8,9]. These mixed findings indicate that the effectiveness of fitness app interventions in promoting exercise is not yet definitively established, highlighting the need to better understand the pathways through which these apps contribute to exercise improvement.

To clarify these inconsistencies, recent research has shifted from solely examining intervention health-related outcomes to investigating the factors that generate exercise-related value for users [4,10-12]. Some of these studies interpret fitness app use through the lens of technology affordance actualization, emphasizing what the app enables users to do rather than the app feature list. For example, while some fitness apps offer group-based exercise features, certain users may actualize them as sources of exercise guidance, whereas others may use them primarily for comparing themselves to other participants. This view recognizes that users may use apps in ways that either follow or depart from the purposes intended by the designers [13,14]. Thus, studying the apps' affordances can help explain the core benefits of using apps from the users' perspective despite their design differences because affordances are driven by users' goals and how users interact with the app to achieve these goals.

Prior fitness app research has identified several affordances that users actualize while interacting with app features, such as self-monitoring, exercise guidance, competition, and social comparison [10,11,15-17]. However, many of these studies have analyzed multiple fitness apps collectively, with the assumption of shared design purposes across platforms. While such breadth may provide useful generalizations for some studies' purposes, it risks overlooking meaningful differences rooted in users' interaction with specific fitness apps that differ in design, even among apps with similar functions. For example, although Fitbit (Google LLC) and MyFitnessPal (MyFitnessPal, Inc) offer similar features (eg, activity tracking), we cannot assume that they are identical or that their users behave in the same way. What each app measures, how it tracks those measurements, and how the data are presented to users can differ substantially.

Furthermore, most prior fitness app research has focused on applying the literature-uncovered affordances rather than exploring new ones [15,16,18-20]. This approach may limit opportunities to discover new affordances, particularly given that affordance theory suggests that users actualize possibilities based on their diverse goals, needs, and intentions [13,14,21]. While applying literature-identified affordances can deepen our understanding of how these affordances contribute to exercise improvement, exploring new affordances can broaden research possibilities and provide developers with clearer insights into what their apps are used for.

This study aims to address these limitations by investigating both common (fitness app literature–predefined) affordances focusing their actualization on one fitness app (Fitbit) and novel (not yet uncovered) affordances actualized by users of the app. Specifically, we aimed to answer the following research questions: (1) which of the fitness app literature affordances are Fitbit app users actualizing? (2) What are the novel affordances actualized through users' interactions with Fitbit?

This study used a 2-stage methodology to uncover the actualized affordances of the Fitbit app. First, a survey was conducted to identify both common and novel affordances experienced by users. On the basis of the survey findings, user reviews from the Google Play Store were analyzed and thematically classified via a generative pretrained transformer (GPT)–based approach guided by the affordances identified in the survey.

Methods

Study Design

This study used a cross-sectional web-based survey, and its design and findings were reported in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines [22]. The survey investigated the common and novel affordances actualized through user interaction with a widely used fitness app, Fitbit. To complement the survey, user reviews from the Google Play Store were analyzed. The affordances identified in the survey, both common and novel, were used as thematic categories to classify review comments through a GPT-based approach. By triangulating survey data with a large corpus of user reviews, we sought to establish robust evidence of the affordances actualized by Fitbit users.

Measures

Survey

To uncover the common affordances actualized by Fitbit users, participants were provided with a list of established fitness app affordances, as shown in Table 1, and asked to select all that applied to their use of the app. Each affordance was accompanied by a short definition adapted from prior studies [11,17]. The participants could select one or multiple affordances that Fitbit enabled during their use.

XSL•FO
RenderX

Table 1. Survey items used to uncover the actualization of common fitness app affordances in the context of Fitbit.

Affordance	Definition
What did you use Fitbit for? Choose all that apply.	
Comparing	To compare my exercise performance with others
Guidance	To get guidance how to perform my exercise
Self-presentation	To present myself as a physically active person
Rewards	To receive rewards for my exercise
Recognizing	To get recognition from others for my exercise
Encouraging	To have other people encourage my exercise
Competing	To compete with others
Watching others	To keep an eye on others' ways of doing exercise
Reminding	To remind me to do an exercise activity
Updating	To update me with the status of my exercise progress
Searching	To search for exercise information

To capture novel affordances, the survey included an "other" option that allowed participants to write in additional action possibilities not included in the predefined list. These written responses were analyzed to determine whether they represented true affordances, that is, goal-directed action possibilities emerging from user-technology interaction rather than simple descriptions of Fitbit features. In doing so, we applied the 3 affordance identification principles described by Alshawmar et al [23], which are grounded in established affordance theory [13,21,24]. First, affordances must reflect a user-perceived action possibility. If a response did not contain a user goal or intended action, it was treated as a feature rather than an affordance. Second, affordances must be described in terms of *why* the user engages with the technology, not *what* the technology provides. For example, the ability to share achievements is a feature; "receiving encouragement from others" is an affordance because it reflects a purpose or goal behind using that feature. Third, multiple features may enable the same affordance. Therefore, responses were grouped at the level of user goal rather than specific app components.

All written responses were independently reviewed by 2 coders trained in affordance theory. Coding disagreements were discussed and resolved through consensus. Interrater agreement before reconciliation was 0.92, indicating high reliability. Responses that reflected affordances already included in the predefined list were classified as common and removed from this step. The remaining responses were examined for thematic similarity, which resulted in the identification of 3 novel affordances. Each novel affordance was then defined based on prior literature to ensure conceptual clarity. For example, written responses such as "to hold myself accountable" were classified as the novel affordance accountability, consistent with the definition of accountability by Dhiman et al [25] as the need to justify one's actions to oneself.

In addition, demographic information and use data (eg, age, gender, duration and frequency of use, and premium subscription) were collected to provide context for interpreting users' affordance actualization patterns.

User Review Data

To support the survey findings of common and novel affordances, we analyzed Fitbit app users' review comments. User reviews were collected from the Google Play Store via an automated web scraping tool [26]. Approximately 380,000 reviews were initially gathered spanning multiple app versions and time ranges. After preprocessing and filtering, we removed duplicates, non–English-language content, very short reviews with fewer than 6 words, and reviews retained from the past 3 years that contained the word "to" as a simple heuristic for goal-directed app use (eg, "to track progress" and "to stay updated"). Standard text-cleaning steps such as lower casing and punctuation removal were applied to prepare the data for analysis. This data preprocessing resulted in a final sample of 15,000 reviews.

For thematic classification, we developed a model based on 14 predefined affordance-based themes identified from prior literature and the survey findings. Each review was analyzed using GPT-4.1 mini (OpenAI) via an instruction-based, zero-shot, label-constrained prompt designed for thematic classification (refer to Multimedia Appendix 1 for more details about the prompt).

The prompt introduced the model to the predefined affordance categories, each clearly defined and exemplified (eg, "Comparing; comparing performance with others" and "Guidance; receiving instructions on how to exercise"). The GPT was instructed to select exactly 1 theme per review when applicable or to generate a single-word new (nonaffordance) theme if the review did not fit any predefined category. The large language model's temperature was set to 0.3 to minimize variability and ensure stable classifications across reviews [27,28].

This resulted in a dataset consisting of 12,378 reviews categorized as "nonaffordance" and 2622 reviews assigned to the predefined affordance themes.

This design encouraged the model to apply conceptual reasoning rather than keyword matching, aligning the classification with

XSL•FO
RenderX

the theoretical framework of affordance actualization (refer to the example classifications in Multimedia Appendix 2).

To ensure classification accuracy, human validation of the GPT-based thematic assignments was conducted. After the GPT classified the full dataset, a stratified random sample of 300 reviews was drawn. One author manually coded the validation sample, applying the same thematic definitions provided to the language model. To assess agreement, the author-coded labels were then compared to the GPT-generated labels. Of the 300 double-coded reviews, 255 (85%) received identical theme assignments.

Finally, the 2622 Fitbit review comments categorized into the 14 affordances were reviewed by 1 author. This resulted in 1182 comments being retained for relevance.

Participants and Recruitment Procedures

Before launching the main study, we carried out a pilot survey between June 1, 2022, and July 5, 2022. The participants were recruited through a university Sona Systems participant pool and via social media platforms (Facebook [Meta Platforms Inc] and Reddit [Reddit Inc]). In total, 403 individuals responded. After incomplete submissions, responses that failed validation checks, and cases showing inattentive patterns (such as straight-lining or unusually short completion times) were excluded, 81 usable responses remained. These participants were aged 18 to 52 years, with 318 (78.9%) participants being aged ≥25 years. Insights from this pilot, including feedback on the chosen affordances and the comments written in the "other" category, provided evidence supporting the adequacy of the survey instrument.

For the main study, we determined the required sample size via the formula by Gaskin [29]. Because social media recruitment produces a high rate of invalid responses, we opted to use Prolific (Prolific Academic Ltd), a crowdsourcing platform recognized for providing higher-quality data [30]. A prescreening survey was first distributed to 1300 participants, of whom 622 (47.8%) current adult US-based Fitbit users who engaged in exercise were identified. Of these 622 users, 506 (81.4%) completed the main survey. After applying quality control measures, including attention checks, of the 622 users, 442 (71.1%) valid responses were retained for analysis.

Ethical Considerations

Both the pilot and main studies received approval from the institutional review board (IRB-22-0351) of the Worcester Polytechnic Institute and were conducted in accordance with ethical guidelines for human subject research. The participants provided informed consent electronically at the beginning of each survey, where they were informed about the study's purpose, the voluntary nature of participation, and their right to withdraw at any time. The consent form also noted that the data would be stored securely and accessible only by the research team. All the responses were collected anonymously.

For the pilot study, student participants recruited through the university's local participant pool received 0.5 course credit as an incentive, whereas participants recruited through social media received an opportunity to enter a raffle for 1 of 10 US $10 prizes as an incentive. The distribution of incentives was managed by one of the authors. For the main study, all recruitment and distribution of incentives were managed by Prolific. The participants recruited for the prescreening survey received a flat rate of US $0.18 as an incentive. Among these participants, those who were eligible to take part in the actual study (current Fitbit users who engaged in exercise) received a flat rate of US $6 as an additional incentive.

Results

Descriptive Statistics

The main study sample demographics are shown in Table 2.

All participants were current Fitbit users with varying use patterns, as shown in Table 3.

Common Fitbit Actualized Affordances

Common affordances discovered in the fitness app literature, as presented with definitions in Table 4, were actualized by the participants in this study via Fitbit. However, as per the arguments in this study, users' actualizations may vary from one fitness app to another. When Fitbit was used, as shown in Table 5, the most frequently actualized affordances among users were updating (n=351, 79.4%; 351 participants and 749 review mentions; total=1100) and reminding (n=319, 72.2%; 319 participants and 143 review mentions; total=462). These findings indicate that users rely primarily on Fitbit to maintain awareness of their activity status and receive prompts that help sustain exercise routines. Other affordances also demonstrated meaningful engagement: competing (99, 22.4%; 99 participants and 88 review mentions; total=187) and rewards (n=133, 30.1%; 133 participants and 32 review mentions; total=165) highlight the motivational role of competition and incentives, whereas comparing (n=151, 34.16%; 151 participants and 8 review mentions; total=159) and guidance (n=118, 26.7%; 118

XSL•FO
RenderX

participants and 25 review mentions; total=143) emphasize the app's instructional and benchmarking functions.

Additional affordances were less prevalent but still notable: searching (n=135, 30.5%; 135 participants and 2 review mentions; total=137), encouraging (n=75, 16.9%; 75 participants and 19 review mentions; total=94), and watching others (n=68, 15.4%; 68 participants and 3 review mentions; total=71). Finally, recognizing (n=58, 13.1%; 58 participants and 1 review mention; total=59) and self-presentation (n=47, 10.6%; 47 participants and 4 review mentions; total=51) were the least actualized, reflecting more specialized uses such as acknowledgment and image projection. Overall, the results show that Fitbit affordances extend beyond core tracking functions to include social, motivational, and comparative features, although these were less consistently used across the user base.

Table 4. Definitions of common affordances based on the fitness app literature.

Common affordance	Definition
Comparing	Allows users to evaluate their performance relative to that of others [11,17,31]
Guidance	Offers structured instructions or exercise recommendations that help users perform activities effectively [17,31]
Self-presentation	Allows users to publicly share achievements or statuses, facilitating impression management and self-image [17]
Rewards	Provides recognition in the form of badges, points, or virtual incentives, reinforcing desired behaviors [11,17]
Recognizing	Facilitates acknowledgment or praise from others for achievements, enhancing validation and social reinforcement [11]
Encouraging	Permits users to receive motivational messages from others, facilitating social support [11]
Competing	Enables users to engage in challenges or contests, fostering motivation through social rivalry [11]
Watching others	Allows users to observe others' activities or progress [17]
Reminding	Provides timely prompts or reminders for workouts and goals, supporting consistency and habit formation [11]
Updating	Enables continuous self-tracking and progress awareness [11]
Searching	Provides tools to look up workouts, information, or content, enabling discovery and information retrieval [11]

Table 5. Common affordance actualizations uncovered through the online survey and supported by Fitbit app reviews.

Affordance	Actualization via survey (N=442), n (%)	Actualization via Fitbit reviews—relevant comments (n=2648 Fitbit review comments in total), n/N (%)	Total actualizations (survey+reviews)
Updating	351 (79.4)	749/1124 (66.6)	1100
Reminding	319 (72.2)	143/245 (58.4)	462
Competing	99 (22.4)	88/129 (68.2)	187
Rewards	133 (30.1)	32/55 (58.2)	165
Comparing	151 (34.2)	8/27 (29.6)	159
Guidance	118 (26.7)	25/143 (17.5)	143
Searching	135 (30.5)	2/18 (11.1)	137
Encouraging	75 (17)	19/475 (4)	94
Watching others	68 (15.4)	3/3 (100)	71
Recognizing	58 (13.1)	0/1 (0)	58
Self-presentation	47 (10.6)	1/25 (4)	51

Novel Actualized Affordances

The participants also selected an option in the survey to write down different affordances that they had actualized via Fitbit. This resulted in 158 written responses (affordances). Some of the affordances written were similar to those listed in the survey but were written by participants with more use specifications. For example, while one of the choices for using Fitbit in the survey was "to update me with the status of my exercise," some participants selected "others" to write "to see my progress for the day." We excluded responses related to common affordances (n=129, 81.6%) and were left with 29 responses for further analysis.

We analyzed these 29 responses based on the 3 affordance principles we followed [23]. This resulted in the identification of 3 novel affordances, as defined in Table 6 and shown with user comments and quotes from the survey in Table 7. For example, as a purpose of using Fitbit, some participants wrote "to hold myself accountable." This finding indicated that, using Fitbit, users built a sense of accountability toward exercising. In other words, Fitbit affords users the feeling of being

XSL•FO
RenderX

accountable as a motivation to accomplish their regular exercise. These 3 affordances were used as themes to be uncovered within users' comments on Fitbit.

As shown in Table 8, novel affordances included encouraging others (n=14, 3.2%; 14 participants and 1 review mention), accountability (n=3, 0.7%; 3 participants and 9 review mentions), and self-comparison (n=3, 0.7%; 3 participants and 5 review mentions).

Table 6. Definitions of novel affordances.

Affordance	Definition
Accountability	A sense of accountability for pursuing their exercise using various features such as today's activity, cheer, and friends
Self-comparing	Assessing oneself against specific criteria or standards to gain insights into one's strengths, weaknesses, areas for improvement, and overall effectiveness
Encouraging others (the opposite of receiving encouragement)	Offering support, motivation, or positive feedback to someone to boost their confidence, inspire action, or reinforce desirable behavior

Table 7. Participant and user quotes reflecting the novel affordances.

Affordance	Actualization via survey (N=442)	Actualization via Fitbit reviews (n=2648 Fitbit review comments)
Accountability	• "To hold myself accountable" • "To hold each other accountable" • "To hold myself accountable to good exercise"	• "Very easy way to check my progress and hold myself accountable to my fitness goals." • "Let us me know to move, check my blood sugar & monitors my progress. Makes me accountable!"
Self-comparing	• "To compare myself with my past performance" • "I like to see my overall trend for the week" • "Love to compare what I do week to week"	• "My favorite app! I have 10 years of step data and can look back to see how various activities have increased my steps over the years. All the data is still there through several Fitbit trackers and 3 phones." • "Do not realize how much walking I'm doing. However, it great to see I'm no longer a couch potato."
Encouraging others	• "To encourage my friends when competing" • "To encourage others' exercise" • "To give other people motivation"	• "Love the Fitbit app and all it has to offer helps me stay on track and encourage others to challenges."

Table 8. Novel affordance actualizations uncovered through the online survey and supported via Fitbit app reviews.

Affordance	Actualization via survey (N=442), n (%)	Actualization via Fitbit reviews—relevant comments (n=2648 Fitbit review comments), n/N (%)	Total actualizations (survey+reviews)
Accountability	3 (0.7)	9/112 (8)	12
Self-comparing	3 (0.7)	5/81 (6.2)	8
Encouraging others	14 (3.2)	1/1 (100)	15

Discussion

Principal Findings

Although prior studies have identified several frequently actualized affordances in fitness apps, much of this work examines multiple platforms collectively and relies largely on affordances already established in the literature. This broad approach obscures meaningful app-specific differences and constrains the discovery of novel affordances that may emerge from users' diverse goals and interaction patterns. As a result, existing research provides an incomplete account of how fitness apps generate value in real use contexts.

This study explored how Fitbit users actualized both common and novel affordances for the sake of deeper understanding of fitness app true value. The study integrated insights from survey responses and app store reviews and used established guidelines to uncover the affordances. The findings reaffirm that certain affordances, particularly updating and reminding, are central to users' engagement. These affordances align closely with prior research emphasizing self-monitoring and feedback mechanisms as key drivers of continued use in fitness app contexts [32-35]. By enabling users to track their current activity and receive prompts to sustain routines, Fitbit fulfills core behavioral support functions that encourage habit formation and long-term adherence [10,11,15-17].

While updating and reminding dominated the value that users derived from Fitbit, other affordances played meaningful roles in shaping some of the users' engagement. Competing and rewards, for instance, highlighted the motivational force of gamification, consistent with previous work demonstrating the

XSL•FO
RenderX

appeal of competitive challenges and incentive-based reinforcement in fitness technologies [36]. Similarly, comparisons and guidance emphasize the importance of reference points and instructional support, showing that users draw value not only from tracking but also from situating their performance against that of others and learning how to optimize their efforts [37]. These findings resonate with affordance actualization theory, which stresses that technologies are appropriated in ways that reflect both design intent and users' personal goals.

Although less frequent, affordances such as encouraging, watching others, recognizing, and self-presentation revealed meaningful but more specialized social and motivational dimensions of use. Encouragement and recognition, in particular, pointed to the social support embedded in fitness apps even if these affordances are not commonly actualized. Self-presentation emerged as the least actualized affordance, suggesting that most Fitbit users may not use the app primarily for impression management. These findings indicate that not all the possible affordances will be actualized by all fitness apps users. As this study showed, some affordances were barely actualized by users. These findings may contrast with those of prior work that documents high user reliance on socially oriented fitness app affordances, including competition and peer encouragement [10,18], suggesting that affordance actualization mechanisms are not uniform across fitness technologies. This could be due to their type of users or the way in which these fitness apps are designed. Consequently, the study findings suggest that affordance actualization should be examined at the level of the individual technology as even similar technologies (eg, fitness apps) demonstrate distinct actualization patterns shaped by their design configurations and user populations.

Most fitness app studies have applied common affordances [15,16,18-20], but this study revealed several novel affordances contributing to the niche literature [10,11,17,31]. The *emergent* affordances were accountability, self-comparison, and encouraging others. These affordances represent additional ways in which a subset of users interact with Fitbit. For example, accountability reflects users' desire to justify actions to themselves, aligning with broader theories of self-regulation [25]. Previous studies have discovered that comparing oneself to others is an affordance of fitness apps [11,17]. Self-comparison extends the comparison literature by shifting the frame of reference from others to one's past self, highlighting reflective, longitudinal self-evaluation [38]. These affordances illustrate the nuanced ways in which users may reinterpret features to satisfy individualized goals.

It is important to interpret the novel affordances with caution. These emergent themes were reported by a small subset of participants and, therefore, should not be considered dominant affordances of the Fitbit app. Rather, they represent preliminary evidence of user-technology relations that extend beyond commonly applied, predefined affordance taxonomies. Although low in frequency, such responses are theoretically meaningful, as affordance actualization theory acknowledges that users may perceive and enact unintended or highly individualized action possibilities depending on personal goals and situational contexts [13,21]. These emergent patterns, while not widespread, highlight opportunities for future research to validate and elaborate on these affordances using larger samples and person-centered analytical approaches.

From a design perspective, the identification of these novel affordances suggests actionable avenues for developers to support users who seek stronger behavioral reinforcement and self-referential goal alignment. For example, to better enable the accountability affordance, fitness platforms could implement a commitment contract module (eg, structured pledges such as "I commit to..." with self-defined consequences) and provide an accountability dashboard that transparently tracks completed vs missed exercise sessions. To facilitate the self-comparison affordance, apps may incorporate temporal self-evaluation features such as "Past me vs now" comparison cards, digital snapshot summaries, and personal improvement challenges that benchmark current performance against a user's historical averages (eg, past–7-, 30-, or 365-day activity baselines). Finally, to support the affordance of encouraging others, platforms can introduce encouragement-based interactive elements, including peer cheer buttons, shareable motivation templates, and encouragement badges or kudos that users can award to friends or groups to reinforce social support behaviors.

Taken together, these design examples demonstrate how specific features can be engineered to strengthen the perception and actualization of emerging affordances, particularly for users who rely on digital tools not just for tracking activity but also for sustaining routines, reflecting on personal progress, and motivating others. This reinforces the importance of examining affordances within the context of a single technology ecosystem and tailoring future affordance research to behavioral patterns, motivational drivers, and downstream outcomes that reflect real user goals rather than only surface-level feature descriptions.

Limitations and Future Research

The first limitation of this study relates to the sample composition and self-report nature of the data. Although the dataset included a robust number of respondents (N=442), the sample consists exclusively of current US-based Fitbit users, limiting generalizability to broader global populations or non-Fitbit fitness app users. Most participants were White (358/442, 80.9%), employed (371/442, 83.9%), and aged 25 to 44 years (283/442, 64%), which may underrepresent the perspectives of older adults, unemployed individuals, or ethnically diverse groups, segments that may perceive or actualize affordances differently. Additionally, while 74% (327/442) reported more than 12 months of app use and 43.9% (194/442) used Fitbit daily, exercise behavior regularity was not directly measured beyond self-identification, meaning that the group-based causal inferences about exercise consistency or app-enabled intervention needs remain interpretive rather than behavioral. Finally, only 41% (181/442) used a Fitbit wearable device, and 62% (274/442) tracked walking activities, suggesting that affordance experiences may reflect tracking-light or single-activity use patterns, potentially overlooking affordances that emerge in more intensive, multiactivity, or device-dependent exercise contexts. Therefore, future studies should replicate the model with diverse, international, and

XSL•FO
RenderX

behavior-verified samples and explore predictors and outcomes of affordance actualization to deepen explanatory insights.

The second limitation is that review comments were analyzed primarily to corroborate the survey findings rather than identify additional affordances. Future research could extend this approach by systematically examining other Fitbit affordances within user reviews, thereby offering a more comprehensive understanding of the range of affordances that a technology such as Fitbit offers to users.

The third limitation is that, although demographic and use characteristics were collected, several variables exhibited substantial distributional imbalance (eg, duration of use and exercise type), limiting the feasibility of fine-grained subgroup analyses. Future research with more balanced and behavior-verified samples is needed to examine the heterogeneity of Fitbit affordance actualizations in greater depth.

Conclusions

This study shows that Fitbit users actualize a range of common and novel affordances, highlighting how individuals engage with fitness technology in diverse and app-specific ways. By identifying common actualized and emerging affordances, the findings reinforce the importance of examining affordance actualization within a single technological context. Overall, this study advances understanding of how fitness apps create value for users and offers direction for designing features that better support sustained engagement and healthier behavior.

Abstract

Background: Providing tailored information is an essential part of health care. However, physicians often lack time for detailed education during the consultation. An additional, tailored digital health information service (DHIS) could help physicians meet their patients' information needs regardless of time and place and extend physician-patient communication to the digital realm.

Objective: This study aimed to examine physicians' intentions to provide a DHIS to their patients and identify facilitating factors and barriers, guided by the extended unified theory of acceptance and use of technology.

Methods: A cross-sectional online survey with German physicians from various specialties was conducted in March 2022. The sample (N=364) ranged in age from 33 to 75 years (mean 53.92, SD 8.12), and the majority were male participants (31.9% [n=116] female participants). A blockwise multiple linear regression analysis was conducted to identify facilitating factors and barriers of physicians' intentions to provide a DHIS.

Results: Overall, 54.1% (n=197) of the surveyed physicians were (rather) willing to provide a tailored DHIS, 23.9% (n=87) were undecided, and 22% (n=80) were (rather) not willing to provide such a service to their patients. The overall model of a blockwise multiple linear regression analysis explained 56.8% of the variance of physicians' intentions. Perceived usefulness for job performance and patient outcomes as well as personal innovativeness was positively associated with physicians' intentions to provide a DHIS to their patients. Ease of use, social influence, facilitating conditions, price value, and habit were not associated with their intentions.

Conclusions: The perspective of the majority of surveyed physicians suggests that a tailored DHIS seems to be a promising way to provide additional health information and thus enhance face-to-face physician-patient communication. Efforts supporting the implementation of DHIS should address job performance and patient outcomes in particular. Further, physicians with a more positive attitude could serve as multipliers to increase the adoption of DHIS.

digital health information; information provision; physician-patient communication; health technology acceptance; UTAUT2; extended unified theory of acceptance and use of technology

Introduction

Digital Provision of Health Information

Since patients have a right to informed medical decision-making [1], and providing tailored information is an essential part of health care [2], physicians are required to meet their patients' needs for adequate, high-quality information [3]. However, physicians often lack the time to provide their patients with detailed information during the consultation [4,5]. Further, an increasing amount of false or misleading information, particularly prevalent during the COVID-19 pandemic [6], poses a challenge in providing accurate health care. These barriers emphasize the need to rethink physician-patient communication in general and consider new ways of providing high-quality health information to patients.

The digital age, characterized by advances in information and communication technology [7,8], offers new opportunities for information provision that could help to supplement the traditional relationship between health professionals and their patients [9]. For example, face-to-face physician-patient communication could be extended to the digital provision of health information, enabling physicians to meet their patients'

XSL•FO
RenderX

needs for high-quality information regardless of time and place. Such a digital health information service (DHIS) is also in line with global objectives of strengthening health care and improving patient education through the implementation of digital health technologies [10,11]. It can be understood as a web-based platform through which physicians can provide their patients with information tailored to their individual disease or health situation (eg, on symptoms, medical examinations, treatment options, prevention, and early detection measures) in addition to the explanations given during the consultation. Thus, patients receive tailored, high-quality information from their most trusted source of health information [12,13] that can be accessed via a computer or mobile phone, enabling them to autonomously build an adequate knowledge base for informed decision-making.

A basic requirement for realizing the potential of a DHIS in overcoming barriers to information provision and complementing routine health care is physicians' acceptance of such a service [14,15]. Existing studies on digital health interventions revealed mixed results regarding physicians' willingness to engage with digital services. On the one hand, physicians in Germany perceived great opportunities from health apps with regard to prevention, reminder, and lifestyle support features [16] and showed high use of internet-related technologies for patient support [17]. On the other hand, prior studies showed a moderate acceptance of mobile apps for disease management [18] and a rather low acceptance of eHealth interventions in inpatient routine care [19].

Based on the heterogeneous state of research, this study aimed to examine physicians' intentions to provide a DHIS to their patients as well as identify facilitating factors and barriers. The study was guided by the extended unified theory of acceptance and use of technology (UTAUT2) [20], which is a widely accepted theory for understanding physicians' adoption of digital health interventions [21,22] and informing eHealth implementation [23].

Theoretical Background

Postulates of the UTAUT2

The UTAUT2 [20], which we used as a guiding framework to examine physicians' intentions to provide a DHIS, is a common technology acceptance model that was originally developed to explain consumers' acceptance and use of innovative technologies. It can be understood as an integrative model as it unifies elements of 8 theoretically proven models from different fields of research, such as information systems research (eg, Technology Acceptance Model), sociology (eg, Innovation Diffusion Theory), and psychology (eg, theory of planned behavior). UTAUT2 is an extension of the unified theory of acceptance and use of technology (UTAUT) [24], which postulates performance expectancy, effort expectancy, social influence, and facilitating conditions as key determinants of usage intentions. UTAUT2 additionally considers hedonic motivation, price value, and habit as predictors of the intention to use a specific technology.

Previous research has shown that UTAUT and UTAUT2 are also effective in various health contexts, explaining patients' and health care providers' acceptance of health-related technologies such as teleconsultation technology [25-27], electronic health records [28-32], mobile health apps [18,33-37], or eHealth interventions [19,38].

Modeling Predictors of Physicians' Intentions to Provide a DHIS Using UTAUT2

Overview

Based on the UTAUT2 and extant research in the health context, performance expectancy, effort expectancy, social influence, facilitating conditions, price value, and habit were integrated into our research model. Hedonic motivation is conceptualized within UTAUT2 as the pleasure or enjoyment derived from technology use and has primarily been applied in consumer-oriented and leisure-related contexts [20]. In contrast, physicians' use of digital health technologies occurs within professional roles and clinical responsibilities. Consistent with prior health care-related applications of UTAUT2, we therefore excluded hedonic motivation [27,31,33]. In addition, personal innovativeness was added as an important factor to explain physicians' intentions to provide a DHIS to their patients.

Performance Expectancy

In the health context, performance expectancy [20,24] is defined as the degree to which a physician expects that using a specific digital technology provides personal benefits in the daily work life, for example saving time during office hours or improving patient communication [22]. It thus describes the perceived usefulness of the DHIS for improving physicians' job performance. Previous research has shown that performance expectancy is a key predictor of healthcare providers' intention to use digital, health-related technologies [18,19,28]. However, digital health services for tailored information provision not only aim to improve job performance but also to promote patient-centered care [10]. In line with research showing that physicians perceive digital health services' potential to support patients' health promotion and prevention [16,17], performance expectancy might also refer to the physicians' perceived usefulness for improving patient outcomes, for example, meeting information needs, supporting decision-making, and improving health and well-being. According to the theoretical assumptions and state of research outlined, we derived the first hypothesis:

H1:Perceived usefulness for job performance (H1a) and perceived usefulness for improving patient outcomes (H1b) will be positively related to physicians' intention to provide a DHIS.

Effort Expectancy

Effort expectancy [20,24] refers to the perceived ease of use associated with using a specific technology which is a well-supported facilitator of a higher intention to use a digital, health-related technology [25,28,29,37]. In the context under study, effort expectancy refers to the extent to which a physician expects to be able to use a DHIS with low effort [22]. We derived the following hypothesis:

H2: Perceived ease of use will be positively related to physicians' intention to provide a DHIS.

XSL•FO
RenderX

Social Influence

Social influence [20,24] covers subjective norms as a known driver of a variety of social and health behaviors such as using digital, health-related services [19,28,39]. Applied to our study, these codes of conduct can be defined as the extent to which a health care provider perceives that important reference groups think that he or she should use a particular technology [22]. In the medical setting, relevant reference groups could be patients as well as colleagues [19]. Accordingly, the perception that patients think one should provide a tailored DHIS for them and that colleagues think one should provide digital information to one's patients may be related to the intention to provide such a service. Thus, we assumed the following:

H3: Subjective norms related to patients (H3a) and colleagues (H3b) will be positively related to physicians' intention to provide a DHIS.

Facilitating Conditions

Facilitating conditions [20,24] refer to the available external support and resources for using digital technology. For example, the practices' or hospitals' technical infrastructure and knowledge necessary to support its implementation could influence physicians' intentions to provide a DHIS [20,22,24]. In line with former research that found a higher degree of facilitating conditions to be positively related to higher usage intentions among health care providers [25,28,29,39], we derived the following hypothesis:

H4: Facilitating conditions will be positively related to physicians' intention to provide a DHIS.

Price Value

Price value [20] refers to the monetary costs associated with using digital technology and positively affects intentions to use digital, health-related technologies in general [26,32,40]. Thus, we assumed the following:

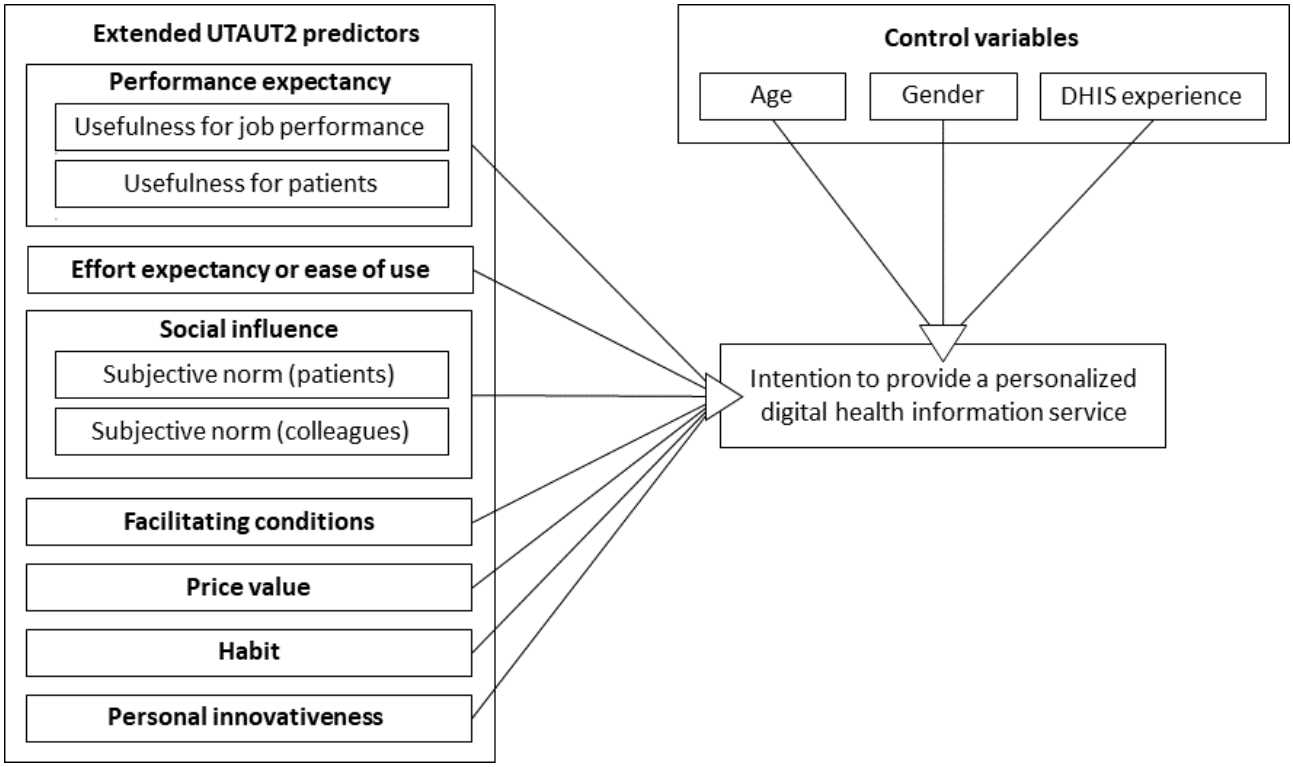
H5: Price value will be positively related to physicians' intention to provide a DHIS.

Habit

Habit [20] describes the extent to which the use of digital technology is perceived as an automatic process based on prior experiences which is associated with higher usage intentions [37]. It refers to physicians' perceptions that they have already developed a routine or habit of using digital technologies such as a DHIS in their daily work lives. Therefore, we postulated the following hypothesis:

H6: Habit will be positively related to physicians' intention to provide a DHIS.

Personal Innovativeness



Although personal innovativeness is not included in the UTAUT2 model, first studies support that integrating it into UTAUT2 to explain patients' and health care providers' acceptance of digital, health-related technologies provides additional explanatory power [26,33,34,37,41]. Thus, it can be considered as a further important construct that requires more attention in health service acceptance and implementation research [40]. Innovativeness is a personal trait that refers to the "extent to which an individual is innovative by his or her perception of new idea or technology" [26], leading these individuals to be more likely to try innovations. In the current context, it can be postulated that physicians with higher personal innovativeness may be more willing to provide a tailored DHIS for their patients, leading to the following hypothesis:

H7: Personal innovativeness will be positively related to physicians' intention to provide a DHIS.

An overview of the proposed research model is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Research model. DHIS: digital health information service; UTAUT2: extended unified theory of acceptance and use of technology.

Methods

To test our hypotheses, we conducted a cross-sectional online survey in March 2022 with physicians from various specialties (eg, general medicine, cardiology, dermatology, and gynecology). The physicians were recruited and invited to use different strategies. At first, physicians and medical associations were contacted and asked to forward the invitation to the survey. In addition, the call was published in professional journals for physicians. A commercial online access panel was used in the second step.

Measures

Intention to Provide a DHIS

To measure physicians' intentions to provide a tailored DHIS to their patients, they first received an introduction describing the service as a digital, web-based platform through which tailored health information (eg, on the basics of a disease, symptoms, risks, or treatment options) can be provided in addition to the explanations given during the consultation and accessed by patients at home via a computer or smartphone (S1 in Multimedia Appendix 1). This description was based on the features of an existing DHIS. Subsequently, they were asked whether they had provided a comparable service to their patients in the past and to rate their intentions to (continue to) provide such a service using the 3 original UTAUT2 items adapted to the current context [20] (Table S2 in Multimedia Appendix 1). The 3 items were measured on a 5-point Likert-type scale (1=*strongly disagree* to 5=*strongly agree*). The scale showed excellent internal consistency and was summarized into a mean index (α=.94, mean 3.45 [*SD* 1.17]).

Performance Expectancy: Perceived Usefulness for Job Performance and Patients

The measurement of perceived usefulness of the DHIS for job performance and improving patient outcomes was adapted from the original UTAUT2 items [20] (Table S2 in Multimedia Appendix 1). Both constructs were measured with 5 items on a 5-point Likert-type scale (1=strongly disagree to 5=strongly agree). The scales showed excellent internal consistency and were summarized into mean indices (usefulness for job performance: α=.90, mean 3.49 [SD 0.94]; usefulness for patients: α=.91, mean 3.68 [SD 0.83]).

Effort Expectancy: Perceived Ease of Use

Perceived ease of use was also measured with a modified version of the UTAUT2 items [20], using 3 items on 5-point Likert-type scales (1=strongly disagree to 5=strongly agree) (Table S2 in Multimedia Appendix 1). The mean index was calculated due to the good internal consistency (α=.86, mean 3.21 [SD 1.02]).

Social Influence: Subjective Norms

Subjective norms related to patients and colleagues were each measured with 3 items adapted from Venkatesh et al [20] and Park and Smith [42] (Table S2 in Multimedia Appendix 1). The participants assessed their responses on 5-point Likert-type scales, ranging from 1=strongly disagree to 5=strongly agree. Both scales showed acceptable internal consistencies and were transformed into mean indices (subjective norm patients: α=.76, mean 2.94 [SD 0.84]; subjective norm colleagues: α=.79, mean 2.81 [SD 0.82]).

Facilitating Conditions

Facilitating conditions were measured with the original UTAUT2 items [20] (Table S2 in Multimedia Appendix 1). The 4-item measure was rated on a 5-point Likert-type scale

XSL•FO
RenderX

(1=strongly disagree to 5=strongly agree). A mean index of high reliability was calculated (α=.74, mean 3.50 [SD 0.90]).

Price Value

Price value was measured with 3 items about physicians' requirements for the costs and incentives that might be associated with providing a digital service [20,40] (Table S2 in Multimedia Appendix 1). Participants rated their agreement that a DHIS should be free to physicians and patients on a 5-point Likert-type scale ranging from 1=strongly disagree to 5=strongly agree. However, as the scale showed poor internal consistency (α=.47), no mean index could be computed. Therefore, 1 single item that most accurately represented costs for the physician was selected for the analysis (mean 4.28 [SD 0.92]). We note that this item reflects physicians' perception of whether the service should be free rather than the traditional UTAUT2 definition of price value, which captures the trade-off between perceived benefits and costs of using a technology.

Habit

The habit of using digital technologies was measured using the original 3-item UTAUT2 measure [20] (Table S2 in Multimedia Appendix 1) and was evaluated on a 5-point Likert-type scale (1=strongly disagree to 5=strongly agree). The scale showed good internal consistency and was summarized into a mean index (α=.81, mean 3.78 [SD 0.95]).

Personal Innovativeness

Personal innovativeness was measured with 3 items that were adapted from Baudier et al [27] (Table S2 in Multimedia Appendix 1). Participants rated their responses on a 5-point Likert-type scale, ranging from 1=strongly disagree to 5=strongly agree. The scale was compressed into a mean index (α=.84, mean 3.30 [SD 1.03]).

Control Variables: Age, Gender, and DHIS Experience

Age, gender, and DHIS experience were used as control variables as these constructs are also assumed to affect technology usage intentions [20]. To measure physicians' experience with a tailored DHIS, they were asked if they had provided a comparable service to their patients in the past (no/yes; 15.4% (56/364) with DHIS experience).

Data Analysis

To identify facilitating factors and barriers of physicians' intentions to provide a tailored DHIS in line with hypotheses 1 to 7, we conducted a blockwise multiple linear regression analysis. The first block considered the control variables age, gender, and DHIS experience. In the second block, the theoretically derived factors were included.

Ethical Considerations

The study received ethical approval from the Central Ethics Committee at Leibniz University Hannover (review number: EV LUH 19/2021). All participants were informed about the content of the survey prior to their participation and provided informed consent. No personally identifiable information was collected. Participants recruited through the commercial online access panel received financial compensation from the market research company in accordance with its standard remuneration rates. There were no further compensations. All methods were performed in accordance with the Declaration of Helsinki. The study was reported in accordance with the American Psychological Association Journal Article Reporting Standards for quantitative research.

Results

The sample (N=364) ranged in age from 33 to 75 years (mean 53.92, SD 8.12) and the majority were male participants (31.9% [n=116] female participants). Overall, 97% (n=353) worked in a physician's practice and 3% (n=11) worked in a hospital or other medical facility in Germany. The majority participated via the commercial online access panel (n=329).

Overall, 54.1% (n=197) of the surveyed physicians were (rather) willing to provide a tailored DHIS, 23.9% (n=87) were undecided, and 22% (n=80) were (rather) not willing to provide such a service to their patients. The overall model of the blockwise multiple linear regression analysis explained 56.8% of the variance of the intention to provide patients with a tailored DHIS. The amount of explained variance of the theoretically derived predictors usefulness for job performance, usefulness for patients, ease of use, subjective norms, facilitating conditions, price value, habit, and personal innovativeness was 42.1%. The results are displayed in Table 1.

[a]The table shows model 2 of the blockwise multiple linear regression analysis, identifying physicians' intentions of providing a tailored digital health information service to their patients. The overall model was significant ($F_{12,350}$=40.70, P<.001) and explained 56.8% of variance. All variance inflation factors <5.

[b]DHIS: digital health information service.

[c]P≤.001.

[d]UTAUT2: extended unified theory of acceptance and use of technology.

[e]P ≤.01

As assumed in H1, perceived usefulness for job performance (β=.29; P<.001) and perceived usefulness for patient outcomes (β=.20; P=.002) were positively related to physicians' intentions to provide a DHIS. Physicians who expect a tailored DHIS to be useful in their daily work life (eg, for saving time during office hours, improving patient communication) and for improving patient outcomes (eg, decision-making, empowerment, improving health) tend to be more willing to provide such a service to their patients. Thus, our results supported H1a and H1b.

H2 focused on perceived ease of using a DHIS, which we postulated to be positively related to physicians' intentions to provide such a service. However, ease of use (β=.07; P=.20) showed no significant association with providing intentions. Based on these findings, H2 had to be rejected.

Considering social influence, we postulated that subjective norms related to patients (H3a) and colleagues (H3b) as physicians' relevant reference groups are positively related to physicians' intentions to provide a DHIS. Contrary to our assumptions, both patient-related (β=.03; P=.53) and colleague-related subjective norms (β=−.01; P=.88) were not associated with physicians' intentions. Accordingly, H3a and H3b had to be rejected.

In H4, we assumed that facilitating conditions are positively related to physicians' intentions to provide their patients with tailored health information via a digital service. However, there was no relation between facilitating condition (β=−.01; P=.77) and physicians' providing intentions. Thus, H4 had to be rejected.

XSL•FO
RenderX

H5 concerned the monetary costs that are associated with the provision of a DHIS, which we assumed to be positively related to physicians' intentions to provide such a service. However, price value (β=.03; *P*=.46) did not serve as a facilitating factor of physicians' intentions. Therefore, H5 had to be rejected.

H6 focused on the habit of technology use being positively related to physicians' intentions. Our results indicated that habit (β=.05; *P*=.33) is not associated with physicians' intentions to provide a DHIS to their patients. Accordingly, H6 was rejected.

In H7, we postulated that physicians' personal innovativeness is related to higher intentions to provide a DHIS. Indeed, personal innovativeness (β=.25; *P*<.001) was related to the intention to provide such a service, indicating that a more positive attitude toward digital innovation tends to be a facilitating factor. Thus, H7 was supported.

Discussion

Principal Findings

The current study examined physicians' intentions to provide a tailored DHIS for their patients. Our findings revealed that the physicians surveyed showed moderate intentions, with the majority (n=197, 54.1%) being rather willing to provide such a service. Guided by the theoretical framework of the UTAUT2, we identified factors that are associated with their intentions. Perceived usefulness for job performance, perceived usefulness for patients, and personal innovativeness were positively associated with their intentions to provide a DHIS, while perceived ease of use, social influence, facilitating conditions, price value, and habit were not significantly associated with their intentions.

Theoretical Implications for a Model of Physicians' Intentions to Provide a DHIS

The analysis revealed that the tested model, based on the UTAUT2, accounted for 56.8% of the variance. Nevertheless, the effectiveness of this framework in explaining physicians' intentions to provide a DHIS is questionable, as only 3 out of the 9 integrated factors contributed significantly to variance explanation. Physicians' perceived usefulness for job performance and perceived usefulness for patients were most strongly associated with their intentions to provide a DHIS, which is in line with prior research on health professionals' intentions to use health-related technology in general [18,19,28].

Furthermore, the inclusion of personal innovativeness within the UTAUT2 framework demonstrated a positive association with physicians' intentions to provide a DHIS. This finding strengthens the suggestion to integrate the personal innovativeness construct into models explaining physicians' intentions to engage with digital services. Such an implication is also supported in prior studies on both patients' [33,34] and physicians' [37] acceptance of digital health technologies. As an interim conclusion, it can therefore be stated that performance expectancy, separated for job performance and patient outcomes, and personal innovativeness could serve as basic factors for a robust model.

The majority of theoretically derived factors were not associated with physicians' intentions to provide a tailored DHIS. First, perceived ease of use did not prove to be relevant, indicating that in the specific context of a tailored DHIS, its implementation might be worth any effort, as digital health information is a "common good" [10] that should be accessible to everyone [11]. In this regard, Zhai et al [39] point out that physicians usually have a high workload and therefore might not mind spending more time on familiarization with a new service that could diminish their workload. In addition, the fact that perceived ease of use is not a key determinant of physicians' intentions could be related to the sample of the online access panel, which may be more digitally savvy and therefore perceive fewer difficulties in the context of handling DHIS. The potential value of integrating perceived ease of use into a model for explaining physicians' intentions to provide a DHIS should thus be explored with a less digitally savvy sample.

Second, social influence—the perception that patients or colleagues think one should provide a DHIS—was irrelevant to the physicians' intentions. However, the mean scores of these variables were mediocre, indicating that norms regarding the provision of a DHIS might not be established and thus be less influential. Indeed, digital health services are not yet widely used in Germany [43]. In this regard, our study found that only 15.4% (n=56) of respondents had already provided a comparable service to their patients. The inclusion of social influence as a potential determinant of physicians' intention to provide a DHIS could therefore be fruitful at a later stage, when the relevant norms are more established in Germany.

In addition, facilitating conditions were not related to physicians' intentions to provide a DHIS. This finding suggests that having the necessary infrastructure such as technical resources and support might not be relevant until the actual implementation of such a service, which is in line with the first version of the UTAUT framework [24]. Moreover, physicians may already have a good infrastructure in this respect. For example, a DHIS only requires computer and internet access, which is available in the majority of German practices and hospitals. In addition, the presumably digitally savvy participants of an online access panel may also have the technical know-how to use a DHIS. Therefore, it may be worthwhile to investigate the significance of facilitating conditions within a less digitally savvy sample, while also considering the digital infrastructure of the respective medical facilities.

Furthermore, price value, as measured in this study, was not related to physicians' intentions to provide a DHIS. The item used reflected physicians' preference for the service to be free of charge, rather than the traditional UTAUT2 definition of price value, which captures the trade-off between perceived benefits and costs. While many physicians indicated that the service should be free of charge, this does not allow us to conclude the influence of actual costs on their intention to provide a DHIS. Previous studies often did not include price value when examining usage intentions of health-related technologies, as it may be less relevant in professional health care contexts [27,31,33,38]. This highlights the need for context-specific adaptations when specifying models to explain physicians' intentions to use digital health technologies.

XSL•FO
RenderX

Habit was also not related to physicians' intentions to provide a DHIS. Thus, familiarity with digital technologies in general is not relevant in the context of a DHIS. This result could be attributed to our measurement. As DHIS are not yet widely used in Germany [43], we asked about physicians' habits regarding digital technologies in general and not about the perceived routine of using a DHIS in particular. Thus, integrating habit in handling a DHIS as a determinant of physicians' intentions to provide such a service appears less meaningful until DHIS are more established in Germany.

Limitations and Resulting Tasks for Future Research

Our study is not without limitations. First, as we conducted a cross-sectional survey, it is not possible to draw causal conclusions. Second, our study is not representative of all physicians in Germany. Since we focused on physicians working in practices and did not stratify by their expertise, physicians in hospitals and other medical institutions as well as certain specialties are underrepresented in this study. Hence, a potential bias may exist, given that a DHIS may be considered more beneficial for certain disciplines. In addition, the majority of the surveyed physicians were participants in an online access panel and are possibly more digitally savvy, which does not necessarily reflect the perspective of most physicians in Germany.

Third, the physicians assessed their intentions to provide a DHIS solely based on a textual description of its features, which introduced the service in general terms and presented it as easy to use. They did not have the opportunity to try it out with their patients, and item-level responses may reflect assumptions based on the vignette rather than experience with a system. As a result, intentions reported in this study may not fully correspond to the actual provision of a DHIS. Although this approach is common in survey-based technology acceptance research, it may limit the validity of our findings. Future research should test a DHIS in practice, focusing on specific specialties to improve the quality of usage prediction by evaluating the actual use in a particular context (eg, cardiology) rather than intentions in general. Experimental or longitudinal designs could be used to allow for causal inferences and to explore the effectiveness of such a service on patient outcomes and physicians' job performance.

A fourth limitation concerns the theoretical framework applied in this study. Although UTAUT2 has been widely used in health care research, it is a consumer-oriented acceptance model that may not fully capture the professional and organizational context of physicians as users of digital health technologies. We partly addressed this limitation by adapting the model to the study context, for example, by excluding hedonic motivation. Nevertheless, future research should consider extending acceptance models to more explicitly reflect physicians' professional roles and decision-making contexts. Although hedonic motivation was excluded based on theoretical and contextual considerations, future studies could empirically examine its relevance in professional health care settings to determine whether enjoyment contributes to physicians' acceptance of DHIS.

Practical Implications

There are several practical implications that can be derived from our findings. First, when promoting a DHIS to physicians, the personal value for improving their daily work life, patient communication, and patient outcomes should be addressed. In detail, it should be explained that a DHIS can save time during the medical consultation and has great potential to support patients' decision-making by providing important, tailored health information. Second, physicians with a positive attitude toward digital innovation may support dissemination by sharing experiences and demonstrating use cases at medical congresses or other professional events, thereby increasing awareness of DHIS options. In addition, a digital information service and its potential could be presented in national medical journals, which could contribute to the establishment of social norms. Another sustainable approach to promote the provision of digital health information is the implementation of eHealth in professional education. At last, in the sense of empowerment and patient-centered care, patients could be encouraged to claim their right to be adequately informed and to directly ask their physicians for digital health information. Furthermore, the effects of providing a tailored DHIS on patient outcomes need to be examined in more detail to provide comprehensive evidence.

Conclusions

In conclusion, the perspective of the majority of surveyed physicians suggests that a tailored DHIS seems to be a promising way to provide additional health information and thus enhance face-to-face physician-patient communication. The key determinants of physicians' intentions to provide such a service—perceived usefulness for improving job performance and patient outcomes as well as physicians' personal innovativeness—underscore the importance of addressing these aspects when supporting its implementation. Future research should aim to identify additional determinants to further advance the development of a more comprehensive model and focus efforts to establish DHIS in Germany.

Acknowledgments

Parts of this work have been presented at the 73rd conference of the International Communication Association 2023 in Toronto, Canada.

Funding

This work was financially supported by the Volkswagen Foundation (grant number: 98975). The funding body did not contribute to the design of the study, the collection, analysis, and interpretation of data, or the writing of the manuscript.

Abstract

Background: Near miss events can reveal system problems before patients are harmed, but current reviews are inconsistent and often rely on simple counts that are distorted by patient volume and reporting culture. Consequently, leaders cannot tell whether a rise in reports means that safety is getting worse or that staff are reporting more, and current systems are not strong enough to clearly separate real safety risks from random variation.

Objective: This study developed a 3-level near miss framework (NM³), a conceptual framework that converts descriptive near miss data into decision-grade intelligence through a structured, evidence-based process, including baseline measurement and advanced interpretation and governance.

Methods: NM³ was developed to provide decision-grade analytics for acute inpatient hospital settings. The framework was designed as a maturity model, progressing from baseline measurement to advanced interpretation. It integrates standardized definitions, rate calculations, statistical process control, severity weighting, and learning metrics.

Results: Level 1 establishes an organizational baseline through near miss rates per 1000 patient-days and near miss–to-harm ratios monitored with control charts. Level 2 introduces domain-specific denominators and unit-level charts to detect local variation. Level 3 applies severity weighting to generate a Near Miss Index; incorporates learning yields at 90 and 180 days; and triangulates near miss trends with harm events, exposure, reporting volume, and culture measures. A synthetic example demonstrates how the framework converts raw reports into stable rates, weighted indices, and learning metrics.

Conclusions: NM³ provides a structured pathway for organizations to strengthen near miss analytics. By progressing through maturity levels, leaders can improve the interpretation of safety signals, prioritize high-consequence risks, and integrate near miss reporting into governance.

Introduction

Background

Near miss events, which reveal systemic hazards before harm occurs, are fundamental to proactive safety governance. Global health policies now emphasize their systematic analysis, a principle operationalized in frameworks such as the National Health Service England's Patient Safety Incident Response Framework [1-3]. Consequently, leaders must treat near miss data as a crucial leading indicator of systemic safety rather than as a secondary metric [1].

Effective safety oversight requires analyzing trends rather than isolated event counts. Best practices advocate interpreting safety indicators (eg, rates of near misses, medication errors, patient falls, or infection events) alongside workforce culture and patient experience metrics to discern meaningful signals from statistical noise, thereby strengthening governance [4,5]. However, translating this into practice is fraught with methodological challenges. Voluntary reporting systems suffer from significant underascertainment due to reporting culture, workload, and fear [6,7]. These barriers disproportionately suppress near miss submissions compared to harm incidents, distorting data and undermining valid comparisons [8-10].

Analytical choices add further uncertainty. Raw event counts are confounded by patient volume and reporting behavior, while meaningful rates require domain-aligned denominators [4]. Furthermore, overdispersion is common in health care data, meaning that conventional statistical process control (SPC) charts can produce false signals if used without adjustment [11]. Although corrective methods such as the Laney p' chart exist [12], they have not been embedded within a structured near miss analytic framework that links SPC to event classification, severity weighting, and organizational learning—a gap this study addresses.

XSL•FO
RenderX

Objectives

These challenges create a critical interpretive dilemma for leaders: does a rise in reported near misses signify deteriorating safety or an improving reporting culture? Without standardized terminology, risk-adjusted denominators, and dispersion-robust control charts, leaders risk misinterpreting these vital data, misallocating resources, and failing to address systemic vulnerabilities [1,4,13,14].

From a human factors perspective, this interpretive dilemma reflects a classic problem of decision-making under uncertainty within complex sociotechnical systems [15]. Leaders must derive meaning from incomplete, socially mediated, and variably coded safety signals. In the absence of structured analytic support, interpretation depends on informal sensemaking [16] and locally constructed mental models [17], increasing the risk of inconsistent prioritization and resource allocation.

Therefore, the objective of this study was to develop a conceptual framework that provides a structured, evidence-based methodology for near miss analysis. To achieve this, we designed a 3-level maturity model that integrates standardized terminology, SPC, severity weighting, and novel learning metrics. This structured approach aims to provide organizational leaders with reliable, decision-grade intelligence to guide and sustain safety improvement initiatives. The 3-level near miss framework (NM^3) does not treat reporting frequency as a safety outcome; rather, it provides a structured analytic pathway that transforms near miss data into interpretable, learning-oriented intelligence for governance and improvement.

Methods

Design and Approach

This study reports the development of a conceptual framework for analyzing near miss safety events, following the integrative methodology by Jabareen [18]. This method proceeds through a series of iterative phases: mapping selected data sources, reading and categorizing the data, identifying and naming concepts, deconstructing and categorizing those concepts, integrating them into a coherent framework, and validating the result through an iterative process of rethinking and synthesis. The approach constructs interrelated concepts by synthesizing theory and evidence rather than through empirical data collection. The aim was to create a structured, 3-level model for near miss analytics that offers decision-grade intelligence to support organizational safety governance. The process was exclusively analytic and integrative and did not involve human participants.

Evidence and Theoretical Sources

The framework integrates principles from peer-reviewed research and authoritative institutional guidance. To align with established international standards, its foundational definitions were derived from the World Health Organization (WHO) International Classification for Patient Safety (ICPS) and Agency for Healthcare Research and Quality (AHRQ) Common Formats for Event Reporting–Hospital (version 2.0) [19,20]. The analytical components were informed by literature on the application of SPC in health care, including tutorials on chart construction and reviews of its effectiveness [20-22]. Methods for weighting event severity were adapted from the Institute for Healthcare Improvement (IHI) Severity Assessment Code (SAC) Matrix. This tool is widely used in root cause analysis [23]. To account for known limitations in reporting data, the design was informed by recent systematic reviews that identify common barriers to near miss reporting [6,8]. Conclusively, to ensure contemporary policy relevance, the framework incorporates strategic priorities for safety measurement from key governance documents issued by the WHO and National Health Service England [1,3,19]. Only peer-reviewed publications and official institutional reports were used in the synthesis.

Framework Construction

Overview

The framework was constructed as a staged maturity model with 3 progressive levels, each representing greater analytic depth for interpreting near miss data. Construction followed a sequence of definitional alignment, operational specification, and integration into maturity levels. International taxonomies provided the definitional base, operational rules were derived from methodological literature on SPC and risk assessment, and maturity staging was informed by organizational safety models that emphasize progressive capacity building [18,19,24]. The 3 levels are summarized in Table 1, which presents their scope, core components, and associated formulas. These definitions and operational rules are further detailed and operationalized in Table 2 to ensure direct alignment between theoretical sources and the applied framework design. Together, these tables codify the design specifications of the framework and ensure reproducibility in application.

XSL•FO
RenderX

Table . Summary of the 3 levels of the decision-grade near miss framework[a].

Level	Scope and purpose	Core components	Formulas and calculations
Level 1—essential minimum (organization-wide baseline)	Establish consistent, decision-usable metrics across the whole hospital system	• Standardizes definitions (World Health Organization or Agency for Healthcare Research and Quality taxonomy: near miss, no-harm incident, unsafe condition, and incident) • Records if the event reached the patient • Captures detection mode (human, alarm, patient, and chance) • Collects system-wide numerators (counts) • Uses a single denominator: patient-days or admissions • Applies SPC[b] (u-chart) for rates	• Near miss rate=(near misses÷patient-days)×1000 • Reported near miss–to-harm ratio=reported near misses÷reported harm events • SPC=u-chart (Laney U' if overdispersed)

Level 2—targeted stratification (high-risk or high-volume areas)	Enables hot spot detection in specific clinical units or processes	• Applies domain-specific denominators
		  • ICU[c] or wards: per 1000 patient-days
		  • Pharmacy: per 10,000 doses
		  • Laboratory: per 1000 specimens
		  • Transfusion: per 1000 units
		  • Procedures: per 1000 surgeries or diagnostic studies
		• Generates unit-level SPC charts (interpreted trend over time rather than as league tables)
		• Identifies clusters and recurrent themes
			• Domain near miss rate=(near misses÷domain exposures)×constant
			• Examples
			  • ICU: (near misses÷ICU patient-days)×1000.
			  • Pharmacy: (near misses÷doses dispensed)×10,000
			• Unit-level SPC: separate u-charts by ward or domain

Level 3—advanced decision-grade analytics (mature organizations)	Prioritizes risks by consequence and integrates cultural context for leadership decision-making	• Applies IHI SAC[d] scoring
		• Creates a severity-weighted NMI[e]
		• Tracks corrective action yield
		  • Percentage implemented by 90 days
		  • Percentage sustained at 180 days
		• Triangulates with harm events, reporting volumes, exposure, and safety culture survey results
			• Severity-weighted NMI=Σ(IHI SAC scoring×event count)
			• Learning yield (90 days)=actions implemented÷near misses
			• Learning yield (180 days)=actions sustained÷actions implemented
			• Triangulation=interpretation of NMI, rates, harm events, and culture indicators together

[a]This table presents the staged maturity model used to interpret near miss data. Level 1 (essential minimum) provides an organization-wide baseline using standardized taxonomy, patient-day denominators, near miss rates, near miss–to-harm ratios, and statistical process control with Laney U' adjustment when overdispersion occurs. Level 2 (targeted stratification) adds diagnostic resolution with domain-specific denominators such as intensive care unit patient-days, medication doses, laboratory specimens, transfusion units, or procedures and generates unit-level u-charts interpreted longitudinally. Level 3 (advanced decision-grade analytics) introduces Institute for Healthcare Improvement Severity Assessment Code scoring; a Near Miss Index; learning yield metrics at 90 and 180 days; and triangulation with harm rates, exposure, reporting volume, and safety culture survey data.

[b]SPC: statistical process control.

[c]ICU: intensive care unit.

[d]IHI SAC: Institute for Healthcare Improvement Severity Assessment Code.

[e]NMI: Near Miss Index.

Table . Data elements and operational definitions used across the 3 levels of the near miss framework[a].

Data element	Operational definition	Allowed values or codes	Levels used	Source	Notes or pitfalls
Event type	Classification of an incident according to the World Health Organization or the Agency for Healthcare Research and Quality taxonomy	Near miss, no-harm incident, and harmful incident	L1, L2, and L3	[20,25]	Risk of misclassification if definitions are unclear
Reached patient	An indicator of whether the event reached the patient	Yes or no	L1, L2, and L3	[25]	Must be clearly distinguished from "no-harm incident"
Detection mode	How the event was detected	Human, alarm, patient, and chance	L1, L2, and L3	[25]	Requires training for consistent classification
Unit or domain	Location or process domain in which the event occurred	Intensive care unit, operating room, emergency department, pharmacy, laboratory, and transfusion	L2 and L3	Adapted from quality indicator conventions	Essential for stratification
Denominator type	Exposure measure aligned to the domain	Patient-days, doses, specimens, units, and procedures	L1 and L2	[21,26]	Denominator accuracy depends on data systems
Near miss rate	Standardized rate of near misses	(Near misses÷denominator)×scaling constant	L1 and L2	[21,26]	Must aggregate if denominators are too small
Near miss–to-harm ratio	Ratio of near misses to harmful incidents	Integer ratio	L1	[18,19,24]	Requires reliable coding of harm incidents
Severity score	Potential consequences if the event had not been intercepted	Minor, moderate, major, and catastrophic	L3	[23]	Interrater agreement is needed
Near Miss Index	Aggregate severity-weighted index of near misses	Σ(Institute for Healthcare Improvement Severity Assessment Code×event count)	L3	[23]	Sensitive to scoring reliability
Learning yield (90 days)	Proportion of near misses with actions implemented within 90 days	Action implemented÷near misses	L3	[27]	Requires reliable action tracking
Learning yield (180 days)	Proportion of implemented actions sustained at 180 days	Actions sustained÷actions implemented	L3	[28]	Measurement of sustainability is often weak
Triangulation indicators	Complementary safety indicators for context	Harm rates, reporting volume, and culture scores	L3	[29,30]	Must avoid simplistic correlations

[a]This table defines the data elements required for consistent measurement and interpretation of near miss events. It includes classifications, denominators, severity scoring, and learning metrics, with allowed values, levels of use, sources, and potential pitfalls. L1 (level 1: essential minimum) refers to organization-wide baseline measurement of near misses using standardized taxonomy, patient-day denominators, rates, and statistical process control (SPC) monitoring. L2 (level 2: targeted stratification) applies domain-specific denominators (eg, intensive care unit, pharmacy, laboratory, transfusion, and procedures) and unit-level SPC charts for hot spot detection. L3 (level 3: advanced decision-grade analytics) incorporates severity scoring; the Near Miss Index; learning yields at 90 and 180 days; and triangulation with harm, exposure, reporting volume, and culture indicators.

Level 1: Essential Minimum

The first level establishes a standardized foundation for organization-wide surveillance of near miss events. At this stage, events are classified using the WHO ICPS and the AHRQ's Common Formats, which define the categories of near miss, no-harm incident, and harmful incident [20,25]. Each event is recorded with an indication of whether it reached the patient and with specification of the detection mode, classified as human intervention, automated alarm, patient self-report, or chance discovery. These data elements are defined in Table 2, which provides the operational specifications required at all 3 levels.

For rate construction, the denominator is hospital patient-days, consistent with conventions used for monitoring hospital-acquired conditions such as falls and infections [26].

XSL•FO
RenderX

The calculations specified for this level, summarized in Table 1, are the near miss rate, defined as the number of near misses per 1000 patient-days, and the reported near miss–to-harm ratio, defined as the number of reported near misses divided by the number of reported harmful incidents. Temporal analysis is performed using u-charts, which accommodate variable denominators, and the Laney U' modification is applied when overdispersion is identified, ensuring stable control limits and valid interpretation of signals [21,26,31].

Level 2: Targeted Stratification

The second level adds analytic depth by applying stratification to high-risk or high-volume domains in which the opportunity for near misses is greatest. The framework specifies denominators that align with domain-specific exposures (Table 1): for intensive care, near misses per 1000 intensive care unit patient-days; in pharmacy services, near misses per 10,000 medication doses; in laboratory settings, near misses per 1000 specimens; in transfusion services, near misses per 1000 blood units; and in procedural areas, near misses per 1000 surgeries or diagnostic studies. These denominators are drawn from existing quality indicator conventions and are further defined in Table 2 to ensure consistent application across settings. Organizations must ensure these definitions are applied with high fidelity, as variations in how they are operationalized can compromise consistency and comparability. For example, a "procedure" or a "dispensed dose" can introduce measurement error.

Each domain generates unit-level u-charts that are interpreted longitudinally within the unit rather than across units, reflecting best practice in the application of SPC for quality improvement [21,26]. Where denominators fall below stability thresholds, data are aggregated to quarterly intervals to reduce small-number instability, which is a recognized limitation in attribute charting for health care data [26]. Aggregation applies primarily to low-volume domains such as transfusion or pharmacy services; higher-volume domains (eg, intensive care units or surgical units) maintain monthly analysis to preserve sensitivity to special-cause variation.

Level 3: Advanced Decision-Grade Analytics

Level 3 introduces prioritization and learning metrics. Severity weighting was adapted from the IHI SAC Matrix [23]. Each near miss is scored on a 4-point ordinal scale representing the worst reasonable outcome if not intercepted: minor, moderate, major, or catastrophic. The Near Miss Index (NMI) is calculated by summing severity scores across events in a reporting period. To capture the organizational response, specific learning metrics were defined. However, systematic reviews indicate that only a minority of reported incidents lead to implemented systemic changes, highlighting a critical gap between reporting and learning [27].

Learning yield (90 days) measures the proportion of near misses that generate an implemented corrective action within 90 days of reporting. This time frame is critical for ensuring timeliness; health care literature shows that prolonged delays between incident reporting and visible intervention can erode frontline staff engagement and undermine trust in the safety system [32].

Learning yield (180 days) assesses the proportion of those initial actions that are sustained at the 180-day mark. This follow-up period is a standard in implementation science used to differentiate a temporary, reactive solution from a change that has been successfully embedded into routine clinical practice. Evidence of sustainment should be determined through objective methods such as process audits or analysis of postimplementation performance data [28]. The 90- and 180-day intervals are operational thresholds specified by this framework to operationalize responsiveness and sustainment. Therefore, these metrics align with quality improvement literature by providing quantitative indicators of a functional learning system, measuring both its immediate responsiveness (action closure) and its ability to create lasting change (sustainment) [33]. Importantly, learning yield is a process metric that quantifies the timeliness and persistence of organizational response; it does not measure whether the implemented actions were effective at reducing harm. Demonstrating intervention effectiveness would require outcome-level studies with appropriate controls, which lies beyond the scope of a reporting-based analytic framework. Therefore, learning yield should be interpreted as evidence of a functioning learning loop rather than proof of harm reduction.

Finally, triangulation was embedded to contextualize near miss data. Framework design requires that near miss signals be interpreted alongside harmful incident rates, exposure denominators, reporting volumes, and scores from validated safety culture instruments such as the Safety Attitudes Questionnaire [29] and the Hospital Survey on Patient Safety Culture [30]. Triangulation addresses the limitation of voluntary reporting systems, in which fluctuations may reflect cultural variation more than underlying risk [8].

Ethical Considerations

This study did not involve human participants or patient-level data. All information was derived from peer-reviewed literature and publicly available institutional reports. Therefore, institutional review board approval was not required. Organizations implementing the framework with operational data should obtain local quality improvement or institutional review board determinations as appropriate.

Results

The outcome of this study is a 3-level framework for decision-grade analysis of near miss data. The framework integrates taxonomy, operational definitions, SPC, and severity weighting.

Framework Artifact

The framework begins with the capture of events through 3 complementary input channels: voluntary incident reporting systems, daily safety huddles, and targeted audits. In daily huddles, frontline staff verbally flag safety concerns and near miss events; a designated recorder enters qualifying events into the incident reporting system using the same WHO and AHRQ classification fields, ensuring a single integrated dataset. Audit-identified events, such as medication discrepancies found during pharmacy reconciliation, are likewise entered through

XSL•FO
RenderX

the reporting system. Therefore, all inputs are coded using the WHO and AHRQ classifications to ensure consistency of terms. Data elements include event type, a patient-reached flag, detection mode, and unit or domain. The information is processed through successive levels. The first level produces organization-wide rates and ratios with SPC monitoring. The second level produces domain-specific rates using aligned denominators and unit-level charts. The third level weights events by severity, computes an NMI, and links reporting to corrective actions and culture data. The flow from inputs to outputs, with feedback to learning systems, is depicted in Figure 1.

XSL•FO
RenderX

Figure 1. Framework architecture for decision-grade near miss analytics. Inputs from incident reporting systems, daily safety huddles, and targeted audits are standardized using World Health Organization (WHO) and Agency for Healthcare Research and Quality (AHRQ) definitions of near miss, no-harm incident, and harmful incident, together with event descriptors such as detection mode and whether the patient was reached. Data then progresses through 3 maturity levels. Level 1 (essential minimum) produces hospital-wide near miss rates per 1000 patient-days and near miss–to-harm ratios, monitored with u-charts (control charts for attributes) adjusted using the Laney U' adjustment method when overdispersion is present. Level 2 (targeted stratification) applies domain-specific denominators (intensive care unit [ICU] patient-days, medication doses, laboratory specimens, transfusion units, and procedures) and generates unit-level u-charts that are interpreted longitudinally. Level 3 (advanced analytics) weights near misses by potential severity using the Institute for Healthcare Improvement Severity Assessment Code (IHI SAC) scale and calculates a Near Miss Index (NMI=Σ[severity score×event count]). Near miss data are triangulated with harm rates, exposure measures, reporting volumes, and safety culture survey scores and are linked to organizational learning yields at 90 and 180 days (action implementation and sustainment). Outputs include an organizational dashboard, unit-level trend cards, and quarterly prioritization briefs.

XSL•FO
RenderX

Interpretation Matrix

The framework also serves as a structured aid for leadership interpretation. Patterns in near miss reporting require context. In some instances, near misses increase while harm decreases. This suggests stronger interception and more open reporting. In other cases, near misses increase while total reports remain flat. This indicates better detection in selected domains. A third pattern is when both near misses and overall reports increase. This is more complex and may reflect cultural shifts and emerging system strain. A fourth scenario arises when both near misses and harm decrease simultaneously, which may signal declining reporting engagement rather than genuine safety improvement. A fifth scenario, in which near miss and harm rates remain stable with no SPC signals, may indicate system equilibrium but still warrants periodic review to guard against complacency. Each of these patterns is linked to diagnostic checks such as denominators, SPC variation, harm rates, and culture scores. The matrix is presented in Table 3. It structures trends into observed patterns, diagnostic considerations, and leadership implications.

Table . Interpretation matrix for leadership decision-making[a].

Observed trend	Diagnostic checks	Possible interpretation	Leadership action
Increasing near misses while harm decreases or remains flat	Stability of denominators and SPC[b] signals	Interception and reporting culture have improved	Reinforce effective defenses and promote open reporting
Increasing near misses while overall reporting remains stable	Clustering in specific domains and detection processes in those areas	Detection has improved in selected domains	Investigate process precursors and address system vulnerabilities
Both near misses and overall reports increase	Harm rates, exposure changes, system vulnerabilities, and SPC variation	Reporting culture is improving, but system stress may be rising	Review high-consequence clusters using the Near Miss Index, apply corrective actions, and monitor sustainment
Both near misses and harm decrease	Culture survey trends, reporting volume, and staff engagement data	Reporting fatigue or disengagement rather than true safety improvement	Conduct targeted culture assessment, reinforce nonpunitive reporting, and verify harm data completeness
Both near misses and harm remain flat (no SPC signals)	Denominator stability, process changes, and culture survey trends	The system is at equilibrium, or surveillance sensitivity has plateaued	Conduct periodic review of detection processes and consider proactive audits to test reporting sensitivity

[a]This matrix presents 5 common patterns in near miss reporting and links each pattern to diagnostic checks, possible interpretations, and recommended leadership actions. The aim is to provide consistent decision guidance and reduce the risk of misinterpreting reporting variation as changes in underlying risk.

[b]SPC: statistical process control.

Application and Governance Outputs

A synthetic example was constructed to demonstrate the framework's application, using parameters detailed in Multimedia Appendix 1 [19,23,27,28,31]. In a hypothetical quarter, 50 reported harmful incidents and 10 reported near misses were modeled across 50,000 patient-days. This yields a reported harm rate of 1.0 per 1000 patient-days and a near miss rate of 0.2 per 1000 patient-days. The resulting reported near miss-to-harm ratio is 0.2:1, reflecting the common underreporting of near misses. Severity was then assigned using a weighted scale (minor=1, moderate=2, major=3, and catastrophic=5). The 10 near misses were distributed as 5 minor, 3 moderate, 1 major, and 1 catastrophic, which computes a severity-weighted NMI of 19. Organizational response was modeled over time: at 90 days, 3 corrective actions were implemented for a learning yield of 30% (3/10); at 180 days, 2 of those actions were sustained for a sustainment rate of approximately 67% (2/3). This example illustrates how the NM³ framework converts raw and even sparse reported data into standardized rates, a risk-prioritized index, and actionable governance metrics. The detailed rationale for each parameter is provided in Multimedia Appendix 1.

The framework produces outputs that can be integrated into governance processes. The first level produces a monthly organizational dashboard with standardized rates and SPC signals. The second level provides unit-level reports with stratified denominators and longitudinal trends. The third level delivers a quarterly report with weighted indices, learning yields, and triangulated indicators. Together, these outputs move near miss reporting from descriptive tallies to decision-grade intelligence that supports prioritization and oversight.

Discussion

Principal Findings

This study developed a 3-level framework to strengthen the analysis of near miss data. The framework integrates taxonomy, rate calculation, SPC, severity weighting, and learning metrics. It addresses the current challenge that near miss reporting often produces data but not reliable interpretation. By combining definitional clarity with analytic structure, it converts descriptive data into decision-grade intelligence.

The contribution of this work lies in its ability to unify 3 methodological strands. The first is a standardized classification of events, which ensures that data reflect common definitions rather than local interpretation. The second is the application

XSL•FO
RenderX

of SPC, which provides stable detection of variation over time and guards against overdispersion. The third is the use of severity weighting and learning metrics, which elevate high-consequence signals and link reporting to organizational action. Together, these strands close the gap between reporting and governance.

The NM³ framework can be understood as a decision support architecture within a health care sociotechnical system [15,34,35]. By standardizing how safety events are classified, stabilized over time, weighted by potential consequence, and interpreted in relation to exposure and culture metrics, the framework reduces cognitive ambiguity in governance decision-making. Rather than leaving interpretation to informal heuristics, NM³ provides a shared analytic structure that supports consistent situational awareness across organizational levels [36]. In this way, near miss analytics shift from a descriptive reporting exercise to a structured component of human-centered safety governance [37].

Comparison With Prior Work

Existing approaches often remain descriptive. Most incident reporting systems provide tallies and categorical breakdowns but do not resolve the dilemma of what rising or falling near miss counts mean. The WHO ICPS established a definitional foundation [25], but it does not specify analytic processes. The structure-process-outcome model by Donabedian [38] underpins quality measurement broadly, but it does not address the specific problem of near miss interpretation. More recent frameworks, such as the Value Transformation Framework in primary care [39], focus on organizational change at the system level rather than the metrics of event reporting. Therefore, this study adds a new lens that sits between operational reporting and strategic governance.

The framework also supports practical adoption. Levels are designed as a maturity pathway. Organizations at baseline can implement level 1 by adopting a taxonomy and calculating standardized rates with simple u-charts. More advanced organizations can progress to level 2, where stratification by domain exposes hot spots without generating cross-unit competition. The most mature can reach level 3, where severity weighting, NMIs, and learning yields allow prioritization of risk and assessment of system responsiveness. In this way, the framework adapts to capacity rather than demanding wholesale transformation at once. In terms of scale, level 1 analytics can be applied by any hospital with a functioning incident reporting system. For level 2 stratification, sufficient denominator volume is needed to produce stable u-charts at the unit level; where monthly event counts are very low, such as in small community hospitals, a quarterly aggregation, as specified in the framework, preserves analytic validity. Level 3 severity weighting and learning yields are most informative when the organization reports at least several dozen near misses per quarter, providing enough events for meaningful index calculation and trend detection.

For governance, the framework strengthens the link between frontline reporting and board oversight. Dashboards at level 1 provide stable high-level indicators. Stratified reports at level 2 support managers who need to identify domain-specific risks. The advanced analytics of level 3 help leaders focus on high-consequence clusters and track whether actions are sustained. This aligns with international calls for safety metrics that are not only valid but actionable.

Future work must test and refine the framework. Empirical studies should evaluate its feasibility in practice, assess the reliability of severity scoring, and compare outputs across institutions. Research should also explore how digital systems can automate rate calculation, control chart production, and NMI computation. Benchmarking across hospitals and international contexts will determine generalizability and adaptation needs. Such validation will establish whether the framework produces consistent intelligence and supports decisions that improve safety outcomes. Furthermore, research should explore the integration of qualitative data from near miss narratives with the quantitative outputs of the NM³ framework to provide richer contextual understanding.

Limitations

This framework has important limitations. It depends on voluntary reporting systems that are known to undercount events substantially; estimates suggest that voluntary systems capture as few as 5% to 10% of patient safety incidents, with near misses particularly underrepresented [7,9]. Reporting behavior is shaped by culture, workload, and fear, and these influences may distort numerators. Denominator data also present challenges. Accurate counts of patient-days, doses, or procedures are not always available or consistent across systems. Errors in denominators can lead to misleading rates.

Event classification introduces uncertainty at level 1: even with standardized WHO and AHRQ definitions, assigning the correct event type depends on individual reviewer judgment, and variability in interpretation may introduce classification error. At level 3, severity scoring presents a similar challenge; the IHI SAC score provides structure, but interrater reliability was not tested here. Training, calibration exercises, and periodic agreement checks are recommended for both event classification and severity scoring. Learning yield metrics depend on robust action tracking, which is not consistently available in many organizations.

Finally, this study is conceptual. The framework was derived from literature and policy rather than empirical testing. Its generalizability across different health care contexts remains uncertain until validation is undertaken. Pilot applications will be necessary to confirm feasibility, reliability, and value in governance. Implementation also presupposes dedicated human resources and analytic expertise. This may not be available, particularly for level 2 stratification and level 3 severity weighting in resource-constrained settings, and organizations should assess workforce readiness before progression beyond level 1.

Implications

This framework has direct implications for health care organizations, quality leaders, and researchers. For organizations, the staged design lowers the barrier to adoption by allowing hospitals to begin with standardized baseline measurement and progress to more advanced analytics as

XSL•FO
RenderX

institutional capacity grows, rather than requiring wholesale transformation at the outset.

For leadership, NM³ converts descriptive reporting into actionable intelligence that supports evidence-based governance. The tiered outputs provide a common language for safety oversight and enable boards to distinguish changes in reporting culture from genuine shifts in underlying risk, aligning with international calls for actionable patient safety metrics.

For researchers, NM³ provides a reproducible conceptual model that can be operationalized and validated across diverse health care contexts. Adoption in varied settings will help establish its role in patient safety improvement and determine the conditions under which the framework yields the greatest analytic value.

Conclusions

This study developed a 3-level framework for decision-grade interpretation of near miss data within acute hospital systems. The framework integrates taxonomy, SPC, severity weighting, and organizational learning metrics. It addresses the ambiguity that has long limited the use of near miss reports in governance.

By structuring analysis into progressive levels, the framework functions as a cognitive and organizational scaffold for interpreting safety signals in complex sociotechnical environments. It enables leaders to distinguish culture shifts from genuine changes in risk and to prioritize high-consequence signals. Adoption has the potential to strengthen human-centered safety governance and support proactive risk mitigation.

Abstract

Background: Digital health platforms can expand access to HIV care, but among men who have sex with men (MSM) and transgender people living with HIV and AIDS in Nigeria, adoption is shaped by structural stigma, criminalization, and fear of disclosure as much as by system functionality. Teleconsultation and medication-delivery platforms offer alternative pathways to care, but their acceptance within marginalized populations cannot be assumed and requires empirical investigation.

Objective: This study aimed to examine the factors influencing behavioral intention (BI) to adopt TechAids, a confidentiality-oriented digital health platform designed to support HIV consultation and service access among MSM and transgender individuals in Nigeria, using an extended Unified Theory of Acceptance and Use of Technology (UTAUT) framework.

Methods: A cross-sectional survey was conducted in Lagos, Nigeria, through HIV service delivery and outreach settings facilitated by partnering nongovernmental organizations, supplemented by online LGBTQ+ (lesbian, gay, bisexual, transgender, queer, and other sexual and gender minorities) networks. The study used nonprobability convenience sampling with prespecified eligibility criteria. Data collection was conducted from January 2025 to May 2025. The sample comprised 141 platform users and 27 health care providers (N=168). An extended UTAUT model incorporated performance expectancy (PE), effort expectancy (EE), social influence (SI), facilitating conditions (FC), trust, and perceived stigma (PS). Data were analyzed using correlation analysis and ordinary least squares (OLS) regression. Age and educational attainment were examined as potential moderating variables. Qualitative feedback was also collected to contextualize quantitative findings.

Results: FC emerged as the strongest predictor of BI to use the platform (β=.813; $P<.001$), explaining a substantial proportion of variance in adoption intention ($R^2=0.652$). Age demonstrated a modest but statistically significant positive effect on BI (β=.105; $P=.03$). Contrary to theoretical expectations, PE, EE, SI, trust, and PS did not significantly predict intention to adopt the platform. Qualitative feedback highlighted practical infrastructure-related concerns, including reliable internet access, offline functionality, and availability of technical support, as more salient than psychological or feature-based considerations.

Conclusions: In resource-constrained, highly stigmatized contexts, enabling infrastructure and practical support may outweigh cognitive, social, and attitudinal determinants of technology acceptance. Successful digital health interventions for marginalized populations therefore require privacy-conscious, user-centered design alongside sustained investment in the infrastructure that supports real-world use.

Introduction

Despite decades of progress in HIV treatment, sub-Saharan Africa continues to shoulder a disproportionate burden of infection and mortality [1]. Within this region, men who have sex with men (MSM) and transgender people are particularly vulnerable due to intersecting clinical, social, and legal factors. They experience higher HIV prevalence, reduced access to prevention and treatment services, and heightened exposure to stigma, discrimination, and violence.

Digitalization is reshaping how health services are designed and delivered, including the expansion of remote consultation, mobile health (mHealth) apps, and digitally mediated access to medicines and counseling. In HIV care, digital pathways can be particularly valuable where individuals face practical barriers (distance, time, and cost) and social barriers (fear of disclosure, stigma, and discrimination). These barriers are often intensified for MSM and transgender people in contexts where sexual and gender minorities experience marginalization, safety concerns, and reduced willingness to engage with clinic-based services. Although digital interventions promise improved continuity of care and confidentiality, adoption is not automatic; it depends on perceived value, usability, social context, enabling conditions, and trust in how sensitive information is handled [2-4]. A systematic review and meta-analysis of counseling support for HIV self-testing among MSM similarly underscores the centrality of structured counseling and linkage-to-care pathways within digital HIV interventions, reinforcing the case for embedding counseling and education functions, not only consultation scheduling, within platforms such as TechAids, developed by EO (lead author) [5].

Digital health technologies, including mHealth apps, teleconsultations, and online medication delivery, have been proposed as a way to extend care beyond physical clinic walls and offer discreet, flexible access to services. Evidence suggests that mHealth interventions can improve adherence to treatment and support self-management in chronic conditions [6], and that digital platforms can increase access to care in underserved populations [7]. However, acceptance of such tools depends on a complex interplay of perceived usefulness, usability, trust, privacy, and the structural conditions that enable or constrain use [8,9]. A recent randomized controlled trial of a chatbot-delivered HIV self-testing support intervention among MSM found it to be noninferior to human-delivered real-time support in increasing self-testing uptake and linkage to counseling, illustrating that digitally mediated, low-cost support models can match human-delivered care for key populations in other global settings [10].

The Unified Theory of Acceptance and Use of Technology (UTAUT), developed by Venkatesh et al [2], provides a well-established framework for understanding why individuals adopt or reject information systems. UTAUT has been widely applied across health care contexts, from electronic health record adoption by clinicians [11] to patient portal usage [12] and mHealth applications [13]. However, standard UTAUT constructs may inadequately capture the psychological and social complexities of HIV care, particularly for criminalized populations. HIV-related stigma, both anticipated and enacted, profoundly shapes health care-seeking behavior [14]. For MSM and transgender individuals, this stigma operates multiplicatively, intersecting with sexual orientation and gender identity stigma to create what researchers term “layered” or “syndemic” stigma [15,16].

Similarly, trust in health technologies becomes paramount when sharing sensitive information about HIV status, sexual behavior, and gender identity could expose individuals to discrimination or legal jeopardy [17,18]. McKnight et al [19] conceptualized trust in technology as comprising beliefs about reliability, functionality, and helpfulness, alongside faith in the provider’s benevolence and integrity. In stigmatized health domains, these dimensions acquire heightened salience; users must trust not only that systems will function reliably, but that data will be protected and that no harm will result from engagement.

This study examined BI to adopt TechAids, a digital platform developed specifically for discreet HIV service access in Nigeria. TechAids provides teleconsultation scheduling, medication delivery coordination, appointment reminders, and educational resources through a mobile app. The platform emphasizes privacy through end-to-end encryption, anonymous registration options, and discreet packaging for medication delivery. We extended the UTAUT framework by incorporating trust and Perceived Stigma (PS) as additional predictors, recognizing that standard technology acceptance models may inadequately represent the lived realities of marginalized populations navigating highly stigmatized health conditions.

Our research addressed three primary questions:

1. Which factors most strongly predict intention to adopt TechAids among MSM and transgender individuals living with HIV in Nigeria?
2. Do trust and PS play significant roles beyond standard UTAUT constructs in predicting adoption intention?
3. Do demographic characteristics, specifically age and education, moderate the relationships between UTAUT constructs and BI, suggesting the need for differentiated implementation strategies across user segments?

Methods

Theoretical Framework and Hypotheses

We built our conceptual model on UTAUT’s foundation while extending it to address the unique considerations of digital health platforms serving stigmatized populations. The UTAUT establishes a comprehensive framework that helps understand how users accept or reject technology solutions and how this shapes their behavioral patterns. In this work, we used the original UTAUT baseline model from Venkatesh et al [2]. This is taken up and elaborated in the context of a stigma-aware digital health context.

Performance expectancy (PE) represents the degree to which individuals believe that using TechAids will help them manage their HIV care more effectively [2]. In this context, PE encompasses beliefs about whether the platform will improve access to medications, simplify appointment scheduling, enhance

XSL•FO
RenderX

communication with health care providers, and ultimately contribute to better health outcomes. Prior research in HIV mHealth suggests that perceived utility for medication adherence and symptom monitoring strongly predicts app usage [18].

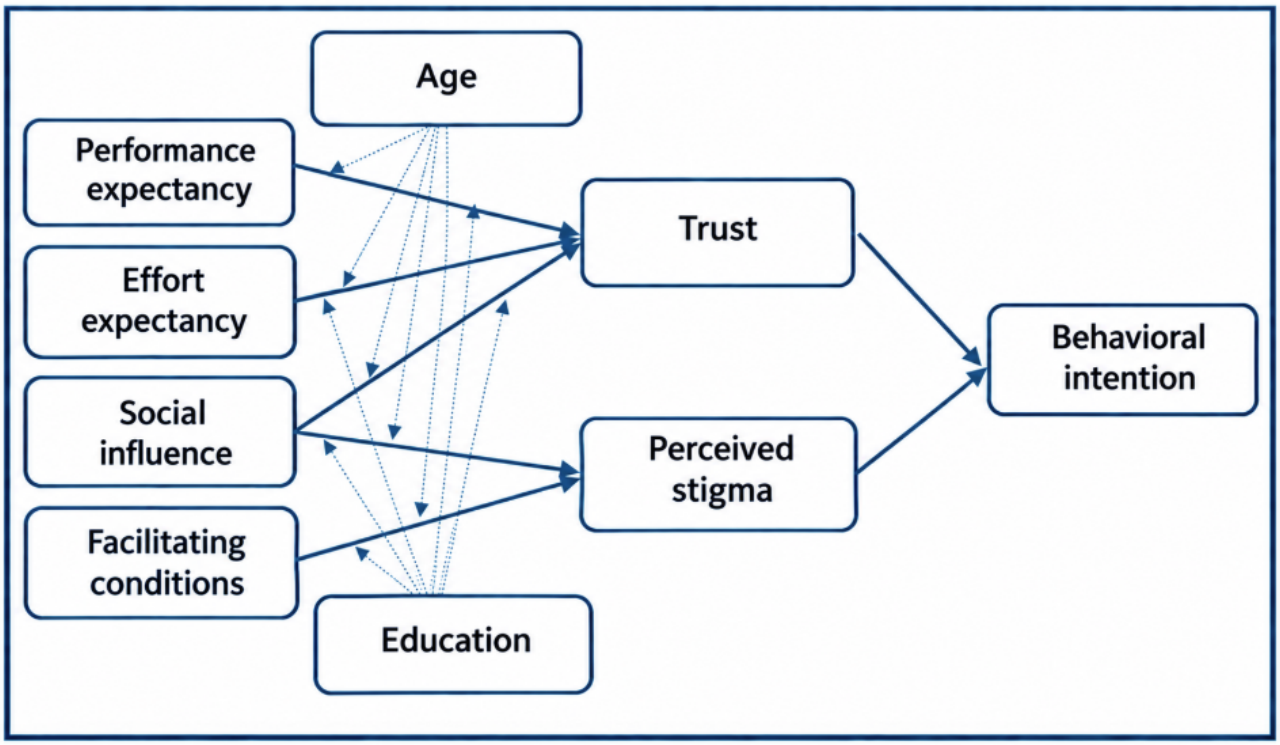
Effort expectancy (EE) captures perceived ease of use—the extent to which potential users anticipate that interacting with TechAids will be free from difficulty [2]. For populations with varying levels of digital literacy, interface simplicity and intuitive navigation become critical adoption factors [20]. Given that many MSM and transgender individuals in Nigeria access smartphones but may have limited experience with health applications, EE could substantially influence adoption intentions.

Social influence (SI) reflects the degree to which important others' opinions affect technology adoption decisions [2]. Within tight-knit MSM and transgender communities, peer recommendations and community advocate endorsements may carry particular weight [21]. However, social influence operates ambivalently in stigmatized contexts, while peer support may encourage adoption, concerns about community gossip or inadvertent disclosure might inhibit it [17].

Facilitating conditions (FC) encompasses perceptions of available resources and infrastructure support for platform use [2]. This construct includes access to smartphones and reliable internet connectivity, compatibility with existing devices, availability of technical assistance, and adequacy of bandwidth for app functionality. In sub-Saharan African contexts, where internet penetration remains uneven and data costs consume significant portions of household budgets, FC frequently emerge as critical determinants of mHealth adoption [22].

Trust represents confidence that TechAids will reliably protect sensitive information and operate in users' best interests [19]. We conceptualized trust as comprising 3 dimensions: confidence in the platform's technical security (data encryption and secure storage), faith in the organization's benevolence (commitment to user welfare), and belief in institutional integrity (honest representation of capabilities and limitations). For platforms handling HIV-related data, trust becomes foundational; users must believe their information will not be compromised, sold, or disclosed to authorities [17].

Perceived stigma (PS) captures individuals' concerns about potential discrimination, judgment, or social consequences resulting from platform use. We measured both anticipated stigma (expectations of being devalued if HIV status becomes known) and internalized stigma (negative self-perceptions related to HIV). While TechAids explicitly addresses stigma through confidentiality features, PS might still deter adoption if users worry about visible app icons, delivery package identification, or data breaches.



We also examined age and education as potential moderators, recognizing that technology adoption patterns often vary across demographic groups [2]. Younger individuals typically demonstrate greater digital fluency, while education level may influence both technical competence and health care information processing.

Education and counseling are also core, rather than peripheral components of HIV care, and this is reflected directly in TechAids' design: alongside teleconsultation and medication delivery, the platform provides educational resources intended to support adherence counseling and risk-reduction communication. We therefore situate PE and FC in this study not only as technology-acceptance constructs but also as proxies for whether the platform's behavioral and counseling functions are perceived as effective and accessible. This framing is consistent with the evidence that structured counseling support substantially improves linkage to care following HIV self-testing among MSM [5], reinforcing the theoretical rationale for treating educational and counseling content as integral to, rather than separate from, the technology-acceptance constructs examined here.

Figure 1 illustrates the hypothesized relationships among constructs.

XSL•FO
RenderX

Figure 1. Extended UTAUT model for TechAids adoption. Source: adapted from Venkatesh et al [2]. UTAUT: Unified Theory of Acceptance and Use of Technology.

Research Hypotheses

Research hypotheses serve as a cornerstone of empirical research. They provide a focused framework for data collection and analysis and are essential for confirming or refuting theoretical assumptions. Sekaran and Bougie [23] define a research hypothesis as a logically conjectured relationship between 2 or more variables expressed in the form of a testable statement. Developing research hypotheses through UTAUT enables examination of the theoretical connections between different constructs. They establish the direction for data collection and analysis while enabling researchers to validate or adjust the UTAUT model through empirical evidence in various contexts. Based on the specific context of TechAids, Multimedia Appendix 1 summarizes the hypotheses.

Study Design and Setting

This study adopted an explanatory mixed methods design combining quantitative survey data assessing UTAUT constructs with qualitative open-ended responses about platform preferences and concerns. The quantitative component tested an extended UTAUT model using ordinary least squares (OLS) models while the qualitative component used thematic analysis of open-ended responses to triangulate statistical findings and provide contextual interpretation. The UTAUT model created by [2] was used in the study to identify the variables influencing MSM and transgender individuals' acceptance and use of the TechAids app. According to the literature, the UTAUT model, which is used in various communities and research fields, can benefit from varying scale items and sizes. Items were organized into 7 latent constructs aligned with an extended UTAUT framework: PE, EE, SI, FC, trust, PS, and BI, alongside age and education. Constructs were operationalized using multiitem scales adapted from prior technology acceptance and e-health research. All items were rated on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). Explanation was made to discuss the use of the scale to ensure a clear understanding of the items by the researchers before completing the survey.

The TechAids Platform

TechAids is a mobile-optimized digital platform developed through participatory design workshops with Nigerian MSM and transgender communities [24]. The platform offers 4 core functions: (1) teleconsultation scheduling with trained HIV health worker clinicians, (2) confidential medication delivery coordination with discreet packaging, (3) automated appointment and medication reminders, (4) educational resources about HIV treatment and wellness. Security features include end-to-end encryption for all communications and automatic session timeouts. For this study, we developed a functional prototype incorporating these features to allow participants hands-on exploration before completing surveys.

Participants and Recruitment

We used nonprobability convenience sampling in recruiting participants who were accessible through HIV clinics and community service settings facilitated by The Initiative for Equal Rights (TIERs) and the Happiest Ones Health Support & Rights Initiative (HOHSRI), together with online LGBTQ+ (lesbian, gay, bisexual, transgender, queer, and other sexual and gender minorities) networks in Lagos, Nigeria. Eligibility criteria for the user group included (1) age 18 years or older, (2) self-identification as MSM, transgender, or gender diverse, (3) confirmed HIV-positive status or high engagement in HIV prevention services, (4) ownership of or regular access to a

XSL•FO
RenderX

smartphone, and (5) ability to provide informed consent. Recruitment materials emphasized voluntary participation, assured confidentiality, and clarified that declining to participate would not affect access to any health services. Nongovernmental organizations (NGOs) serve as gatekeepers for the recruitment of participants to build trust and minimize coercion concerns.

Criteria (2) and (3) were applied disjunctively ie, participants qualified by self-identifying as MSM, transgender, or gender diverse, or by having confirmed HIV-positive status or high engagement in HIV prevention services. This explains why, as reported in Multimedia Appendix 2, most participants identified as heterosexual and HIV-negative. Health care providers were recruited separately through the same NGOs and were eligible if they currently delivered HIV-related services to MSM or transgender clients. Providers and users were analyzed within a single regression model because both were prospective adopters of the same platform and UTAUT items were worded to apply across both roles. Recruitment proceeded via NGO and clinic staff introductions during routine service contact or outreach events, supplemented by online LGBTQ+ network recruitment. Recruitment source was not recorded, precluding a breakdown by channel. This was noted as a limitation of recruitment tracking.

Data collection and survey instrument: Participants interacted with the TechAids functional prototype and then completed a structured questionnaire comprising 28 Likert-scale items covering PE, EE, SI, FC, trust, PS, and BI. The measurement items are presented in Multimedia Appendix 3. The questionnaire also included 3 open-ended questions: (1) What are the things you like about a mobile app for consultation and medication delivery? (2) What are the things you dislike about using a mobile app for consultation and medication delivery? and (3) What do you think would make TechAids App more useful for people living with HIV and AIDS? A cross-sectional survey was conducted from January 2025 to May 2025.

Ethical Considerations

The Bournemouth University Research Ethics Committee approved this study (Ethics ID 51057). Given the sensitivity of research involving criminalized populations and HIV status, we implemented enhanced confidentiality protections. All data were stored on password-protected servers without personal identifiers and transferred via secure protocols.

Informed consent was obtained from all participants prior to enrollment; consent procedures explained the study's purpose, the voluntary nature of participation, the right to withdraw at any time without affecting access to health services, and the confidentiality protections in place, and were delivered verbally or in writing according to participant preference and literacy. To mitigate risk associated with participation in a criminalized legal context, study staff member (EOO) avoided collecting or recording any information that could independently identify a participant's sexual orientation, gender identity, or HIV status outside the secure survey instrument; prototype testing sessions were conducted in private spaces arranged by partnering NGOs to minimize visibility to others; and participants were not required to disclose sensitive identity or status items, consistent with the "prefer not to say" response option used throughout the survey. Data linking participant identities to survey responses were not retained beyond the minimum required for recruitment logistics, and all analytic data were fully deidentified prior to analysis.

Data Analysis

A priori power analysis using G*Power 3.1 (developed by Franz Faul) [25] was used to determine the minimum sample size. We conducted analyses using Statistical Package for the Social Sciences (SPSS) version 28 (IBM Corp.) [26].

Estimation Approach

OLS regression was used to estimate the relationships between the independent variables and BI to use the digital health platform. The operationalization of each theoretical variable was based on a composite index which consisted in averaging the responses for their corresponding Likert-scale indicators from validated measurement scales. This procedure allowed the constructs to be treated as continuous observed values that are suitable for regression analysis. The reliabilities of the scales were evaluated by Cronbach α during model estimation to examine internal consistency between the components [27]. Descriptive statistics and a Pearson correlation analysis were carried out to examine distributions of variables and preliminary associations.

Treating averaged multiitem Likert composites as approximately continuous for OLS estimation is a widely used convention in technology-acceptance survey research, including prior UTAUT studies in similar low-resource settings [28], and is generally considered acceptable when each composite is derived from four or more reliable indicators, as is the case for all constructs here (Multimedia Appendix 3). BI, like the other UTAUT constructs, reflects an underlying latent variable rather than a strictly interval-level measure, and that ordinal regression or structural equation modeling (SEM) would provide a valuable robustness check on the OLS findings reported below, particularly given the unusually strong association observed between FC and BI. This is a methodological limitation and direction for future analysis.

Composite reliability (CR) = (∑λi)2(∑λi)2+∑(1−λi2)where (lambda) is the standardized factor loading.

Average variance extracted (AVE) = ∑λi2n, where n is the number of indicators per construct

Predictive accuracy was evaluated through the coefficient of determination (R^2), which represents the proportion of variance in BI explained by the predictor variables. The OLS regression equation was estimated using standardized coefficients to facilitate comparison of effect sizes across predictors.

RBI2=1−∑(BIobs−BIpred)2∑(BIobs−BI−obs)2

A priori power analysis conducted using G*Power (effect size f^2=0.15, significance level α=.05, statistical power=0.80, and 8 predictors) indicated a minimum required sample size of 109. The final sample size of 168 therefore exceeded this threshold, confirming adequate statistical power for detecting medium-sized effects.

XSL•FO
RenderX

Measurement of Reliability and Validity of UTAUT Constructs

Reliability analysis was conducted to assess the internal consistency of the items for each latent factor of the UTAUT model before going into the model testing. Cronbach α was applied to ensure that the scale used for rating (Likert scale) is reliable. Multimedia Appendix 3 shows the Cronbach α scores achieved for each factor. An acceptable minimum threshold for Cronbach α is suggested to be 0.7 according to [29,30].

Relationships Among Constructs

Correlation Analysis

The study used correlation analysis to evaluate the strength and direction of the linear relationship between 2 variables. Correlation analysis helps to determine which factors are most strongly associated with users' willingness to adopt and use health technologies. A positive correlation indicates that as 1 variable increases (ie, perceived usefulness), the other (ie, intention to use the app) also increases. The coefficient (ρ) value ranges from −1 to +1. Quantitative analysis techniques like correlation are essential for testing the relationships among these constructs. The Pearson correlation coefficient is used to examine the strength and direction of linear relationships between UTAUT constructs ie,

$$\rho XY = \sum(Xi - \bar{X})\sum(Yi - \bar{Y}) \sum(Xi - \bar{X})2 \sum(Yi - \bar{Y})2$$

where X_i= scores on construct X (eg, PE); Y_i= scores on construct Y (eg, BI); $\bar{X}$ and $\bar{Y}$ are means of X and Y respectively.

Regression Analysis

OLS regression was used to help determine which constructs significantly impact BI to use the technology. It provides insights into which factors are most influential to enhance technology adoption. Regression analysis predicts the value of a dependent variable (eg, BI) based on independent variables (eg, PE, EE, SI, FC, trust, and PS). We estimated a set of standardized OLS regression models that map directly onto the extended UTAUT structure.

The baseline regression model is specified as follows:

$$BI = \beta 0 + \beta 1 PEi + \beta 2 EEi + \beta 3 SIi + \beta 4 FCi + \beta 5 TRi + \beta 6 PSi + \beta 7 Agei + \beta 8 Edui + \varepsilon i$$

Each construct is a latent variable represented by a set of observed indicators. For example,

$$PEi = \lambda PE1 XPE1,i + \lambda PE2 XPE2,i + \lambda PE3 XPE3,i + \lambda PE4 XPE4,i + \delta PE,i$$

$$EEi = \lambda EE1 XEE1,i + \lambda EE2 XEE2,i + \lambda EE3 XEE3,i + \lambda EE4 XEE4,i + \delta EE,i$$

$$SIi = \lambda SI1 XSI1,i + \lambda SI2 XSI2,i + \lambda SI3 XSI3,i + \lambda SI4 XSI4,i + \delta SI,i$$

$$FCi = \lambda FC1 XFC1,i + \lambda FC2 XFC2,i + \lambda FC3 XFC3,i + \lambda FC4 XFC4,i + \delta FC,i$$

$$TRi = \lambda TR1 XTR1,i + \lambda TR2 XTR2,i + \lambda TR3 XTR3,i + \lambda TR4 XTR4,i + \delta TR,i$$

$$PSi = \lambda PS1 XPS1,i + \lambda PS2 XPS2,i + \lambda PS3 XPS3,i + \lambda PS4 XPS4,i + \delta PS,i$$

$$Agei = \lambda Age1 XAge1,i + \lambda Age2 XAge2,i + \lambda Age3 XAge3,i + \lambda Age4 XAge4,i + \delta PS,i$$

$$Edui = \lambda PS1 XPS1,i + \lambda PS2 XPS2,i + \lambda PS3 XPS3,i + \lambda PS4 XPS4,i + \delta PS,i$$

where λPEi, λEEi, λSIi, λFCi, λTRi, λPSi, are factor loadings, XPEi, XEEi, XSIi, XFCi, XTRi, XPSi, are measured items, and δPE, δEE, δSI, δFC, δTR, δPS represent measurement errors.

Moderation Analysis

To test moderation hypotheses H7 and H8, interaction terms were created between each UTAUT construct and both demographic moderators (age and education). Both moderators were mean-centered before creating product terms to reduce multicollinearity. Eight separate regression models were then estimated, each including the full set of main effects plus one interaction term, consistent with the estimation approach described above.

Categorization of Qualitative Data

Open-ended responses to the 3 qualitative survey questions (Table 1) were analyzed using an inductive, data-driven thematic-categorization approach, following the reflexive thematic analysis approach described by Braun and Clarke [31]. Analysis proceeded in 4 steps: (1) the lead author (EOO) read all open-ended responses in full to gain familiarity with the data; (2) initial descriptive labels were generated inductively from the responses, question by question, rather than applied from a preexisting framework; (3) labels were iteratively grouped and refined into a smaller set of categories per question as additional responses were reviewed with earlier responses rechecked against revised category definitions; and (4) the resulting categories were tabulated against illustrative response counts (Table 1). Coding was conducted by a single coder, EOO (the lead author); no second coder independently coded the data, and consequently, no formal interrater reliability statistic (eg, Cohen kappa) was calculated and no coding discrepancies required resolution through discussion or arbitration. The categorization should therefore be read as a descriptive thematic summary intended to contextualize the quantitative findings, rather than as output from an independently verified, consensus-based qualitative analysis. Independent double-coding, with formal interrater reliability assessment, is identified as a priority for future mixed methods work with this dataset. This is revisited in the Limitations section.

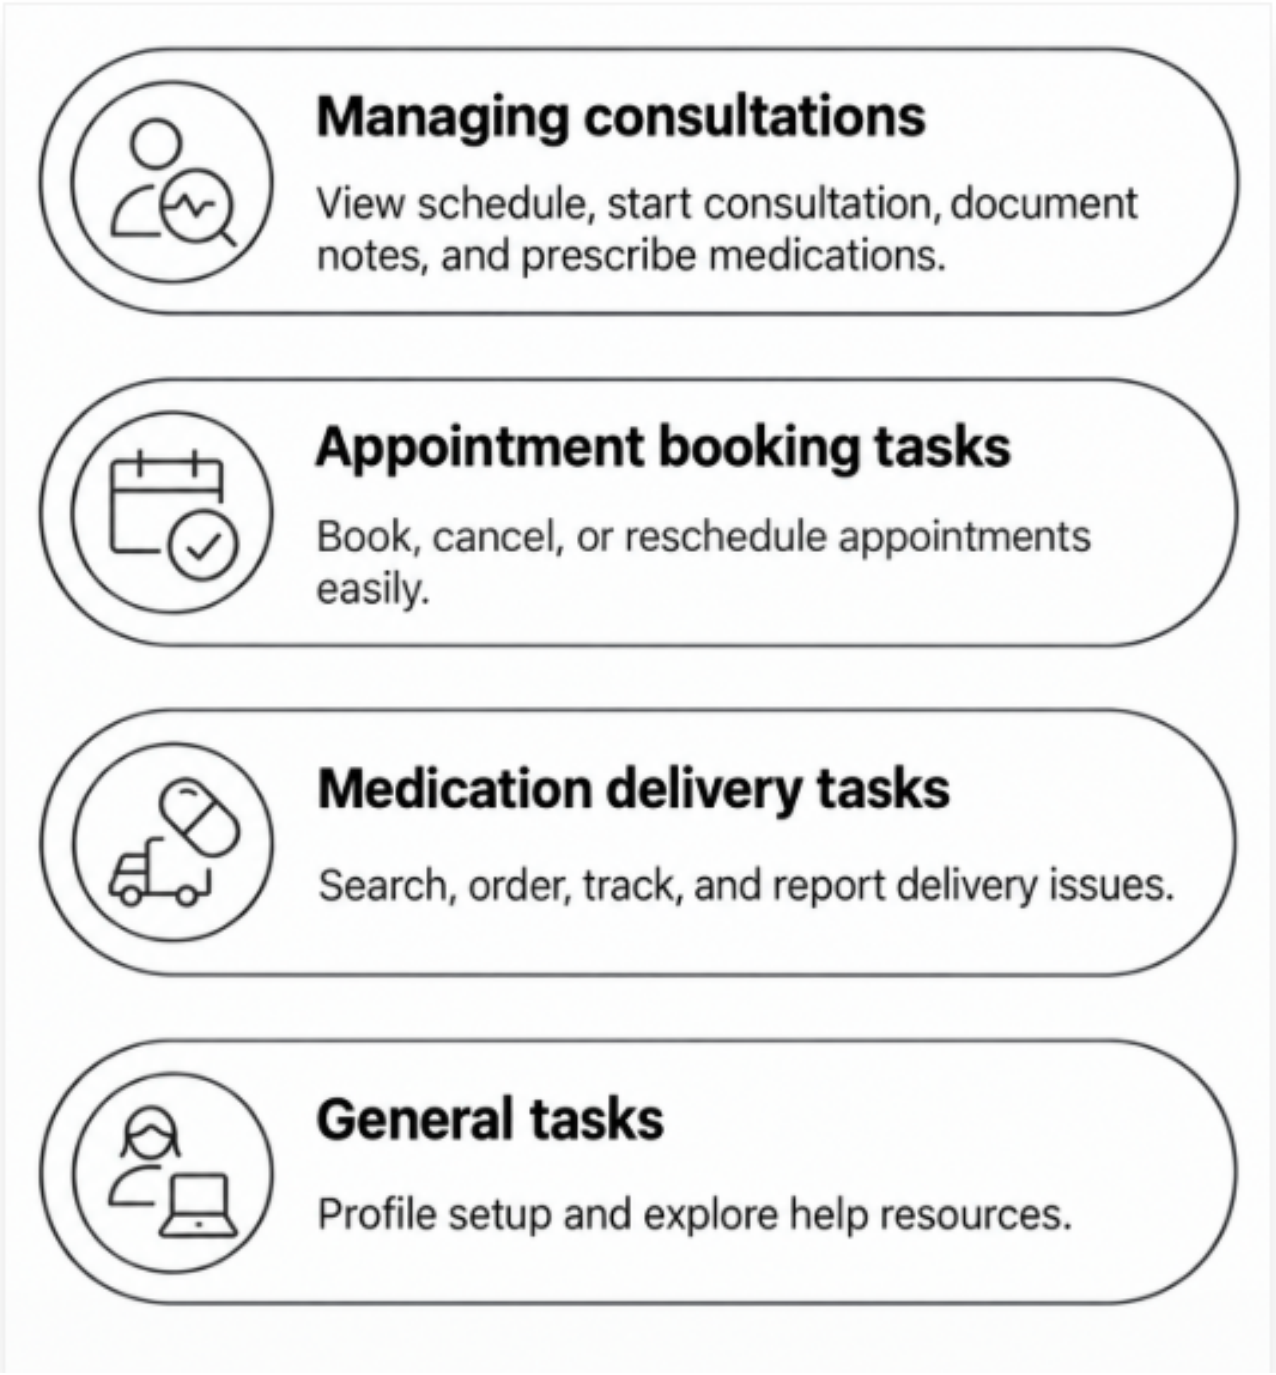
Table . Qualitative feedback from the survey.



Serial number	Survey questions	Categorization of the survey responses
1.	What are the things you like about a mobile app for consultation and medication delivery?	• Access and convenience. • Personalization and control. • Privacy and security. • Medication management and delivery. • Communication and support. • Health information and education.
2.	What are the things you dislike about using a mobile app for consultation and medication delivery?	• User experience. • Technical performance and app stability. • Access to specialists and services. • Internet dependence and connectivity.
3.	What do you think would make TechAids app more useful for people living with HIV or AIDS?	• Access to educational content • Access to health care providers • End-to-end encryption • Free and fast internet • Offline functionality • Quick helpline access • Regular app update • Smart reminder

Research Participants

The study population of this research consists of 168 respondents who participated in the completion of a survey which consisted of 2 stakeholders ie, health care providers and patients. The respondents that did not complete the survey questions were expunged from the sample. On average, completion of the survey took approximately 32 minutes, which could contribute to the reason some respondents did not complete the survey. The survey focuses on evaluating the willingness to adopt the use of digital health care technologies among MSM and transgender individuals living with HIV/AIDS. The relatively small sample size in this study reflects practical constraints associated with conducting research in underserved communities [32]. The research participants were given some tasks to perform on the TechAids app's prototype. The tasks completed are highlighted in Figure 2 below.

Figure 2. Prototype design tasks.

Results

Overview

Two sets of results from the UTAUT-based survey were presented in this section. First, quantitative analysis, and especially descriptive and inferential analyses, were used to explore key factors influencing the use and acceptance of technology. Second, the qualitative data were analyzed using a categorization of ideas approach, highlighting themes and patterns in participants' perceptions and experiences. Both qualitative and quantitative methods offer a comprehensive understanding of technology adoption in HIV/AIDS care among MSM and transgender people living with HIV/AIDS.

Participant Characteristics

Multimedia Appendix 2 summarizes demographic characteristics. The final sample comprised 141 platform users (patients) and 27 health care providers (n=168). User participants averaged 31.2 (SD 4.7, range 21 - 40) years. Nearly half (n=69, 48.9%) fell in the 31 - to 40-year age bracket, while 51.1% (n=72) were aged 21 - 30 years. Educational attainment was relatively high: 34% (48/141) held master's degrees, 30.5% (43/141) bachelor's degrees, and 35.5% (50/141) diplomas or equivalent technical qualifications.

Gender identity patterns reflected the sensitivity of these questions in the Nigerian context. Among users, 31.2% (44/141) identified as male, 36.2% (51/141) as female, and 32.6%

XSL•FO
RenderX

(46/141) preferred not to disclose. Only 2 participants (2/141, 1.4%) explicitly identified as transgender, though an additional 46.8% (66/141) preferred not to answer this question, suggesting possible transgender identity among nondisclosers. Nearly half (69/141, 48.9%) declined to state sexual orientation, while 49.6% (70/141) identified as heterosexual and 1.4% (2/141) as gay or lesbian. These patterns likely reflect justified caution given Nigeria's criminalization of same-sex relationships.

Regarding HIV status, 54.6% (77/141) of users indicated HIV-negative status (likely reflecting engagement in prevention services), while 45.4% (64/141) declined to disclose, a pattern consistent with pervasive HIV stigma. Health care provider participants (n=27) averaged slightly older (19/27, 70.4% aged 31‐40 years) and showed similar reluctance to disclose personal information on sensitive items.

Reliability Analysis

Consistency of the constructs of the model was measured using Cronbach α. Internal consistency was assessed for each multiitem construct, targeting α≥0.70. Construct validity was evaluated using exploratory factor-analytic logic, together with the interconstruct correlation matrix among the 7 construct means. Factor analysis was used to investigate underlying relationships (called factors) among a set of observed variables. It helps reduce a large number of variables into fewer unobserved variables (factors) that explain the patterns in the data. This was used to generate the factor loadings for the predictors.

All constructs demonstrated acceptable to excellent internal consistency (Multimedia Appendix 3). Cronbach α values ranged from 0.701 (BI) to 0.887 (trust), well exceeding the 0.70 threshold [27]. Trust showed the highest reliability, suggesting that items measuring confidence, security, and confidentiality concerns cohered strongly. Item-total correlations within each construct ranged from 0.52 to 0.84, indicating that individual items contributed meaningfully to their respective scales. Factor loadings from exploratory factor analysis ranged from 0.668 to 0.903, confirming that items loaded strongly on their intended constructs. CR and AVE computed from single-factor loadings extracted per construct via principal axis factoring are reported alongside Cronbach α in Multimedia Appendix 3. All 7 constructs exceeded the conventional CR threshold of 0.70 (range: 0.707 to 0.889). AVE exceeded the conventional 0.50 threshold for 5 of the 7 constructs (SI=0.509, FC=0.561, trust=0.669, PS=0.572), while PE (AVE=0.429), EE (AVE=0.457), and BI (AVE=0.382) fell modestly below this threshold, indicating that convergent validity for these 3 constructs, while supported by adequate CR and Cronbach α was not fully confirmed by AVE alone. This was reported transparently as a measurement limitation in the Limitation and Future Research section rather than treating CR or alpha as sufficient on their own. A Fornell-Larcker discriminant-validity check, comparing the square root of each construct's AVE against its correlations with all other constructs (Table 2), confirmed discriminant validity for all construct pairs except FC and BI: the FC-BI correlation (r=0.802) exceeded both constructs' √AVE (0.749 and 0.618, respectively), indicating a discriminant-validity concern between these 2 constructs specifically. This finding statistically corroborates, rather than merely conceptually motivates, the caution urged elsewhere in this study regarding the magnitude of the FC–BI association and is consistent with the possibility of conceptual or item-level overlap between these 2 constructs that should be addressed through item refinement in future research. A full confirmatory factor analysis was not conducted, given sample size constraints relative to the number of constructs and items; this is noted as a limitation.

Correlation Analysis

Hypotheses were tested using correlation coefficient. This was used to find the linear relationship between 2 constructs. Table 2 shows the correlation coefficients between multiple variables. Each cell in the matrix reflects the strength and direction of the linear relationship between 2 variables using a value between −1 and +1.

Table 2 presents zero-order correlations among all study variables. FC showed a remarkably strong positive correlation with BI (r=0.802; P<.001), a magnitude rarely observed in technology acceptance research. This relationship was notably stronger than correlations between other UTAUT constructs and intention: PE (r=−0.071; P=.37), EE (r=0.038; P=.63), and SI (r=0.025; P=.75) showed negligible associations with intention. Trust correlated negatively with intention (r=−0.078; P=.32), while PS showed essentially zero correlation (r=0.003; P=.97).

Age demonstrated weak positive correlations with BI (r=0.048; P=.54) and PS (r=0.087; P=.26). Education showed small negative correlations with most constructs, but none reached statistical significance. The intercorrelations among UTAUT predictors were generally weak, with 1 notable exception: EE and PS correlated at r=0.203 (P=.008), suggesting that individuals who anticipated greater stigma also perceived the platform as more difficult to use.

Regression Analysis

The relationship between the independent variables X (ie, PE, EE, SI, FC, TR, PS, age, and education) and the dependent variable Y (BI) are shown in Table 3. Each coefficient quantifies how much the dependent variable is expected to increase or decrease when the corresponding independent variable increases by one unit, assuming all other variables are held constant.

Table 3 presents regression results predicting BI. The overall model explained substantial variance: R^2=0.652, $F_{8, 159}$=37.25; P<.001, indicating that our extended UTAUT model accounted for approximately 65% of variation in adoption intentions. This model was estimated on the combined sample of platform users and health care providers (n=168), as justified in Participants and Recruitment section. As a sensitivity check, we reestimated the model restricted to the (n=141) platform users only. The pattern of results closely replicated the combined-sample findings: FC remained the dominant predictor and, if anything, showed a slightly larger standardized effect in the user-only model (β=.856, t_{132}=19.37; P<.001) than in the combined sample (β=.813), and age remained a significant, modestly sized positive predictor (β=.133; P=.003 in the user-only model vs β=.105; P=.03 in the combined sample). PE, EE, SI, trust, PS, and education remained nonsignificant in both models, and the user-only model explained more variance overall (R^2=0.746 vs R^2=0.652 for the combined sample). The significance pattern across all 8 predictors was therefore identical between the combined and user-only samples (Table 4), indicating that including health care providers in the primary analysis did not materially distort the substantive conclusions of this study.

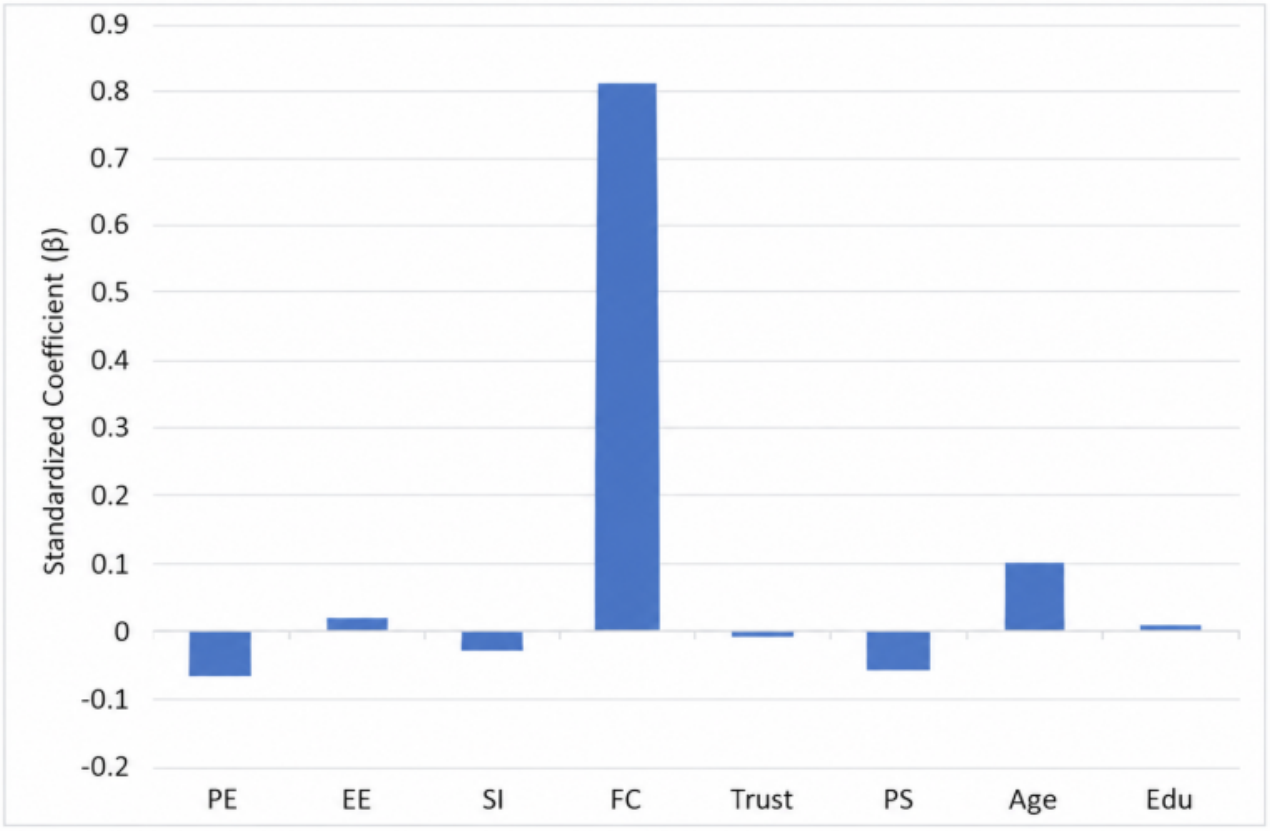
[a]PE: performance expectancy.

[b]EE: effort expectancy.

[c]SI: social influence.

[d]FC: facilitating conditions.



[e]PS: perceived stigma.

In the regression analysis, FC emerged as the overwhelmingly dominant predictor (β=.813; SE=.041; t_{159}=17.47; *P*<.001) (Figure 3). The standardized coefficient magnitude indicates that a one-standard-deviation increase in perceived FC corresponded to a .720 standard deviation increase in intention to adopt TechAids—an exceptionally large effect. Age showed a small but statistically significant positive effect (β=.105, SE=.006, t_{159}=2.253; *P*=.03), suggesting that older participants within our age range expressed slightly greater adoption intention.

Contrary to our hypotheses, PE (β=−.071; *P*=.13), EE (β=.023; *P*=.63), SI (β=−.030; *P*=.53), trust (β=−.008; *P*=.87), and PS (β=−.055; *P*=.25) did not significantly predict BI. Education also showed no effect (β=.005; *P*=.91).

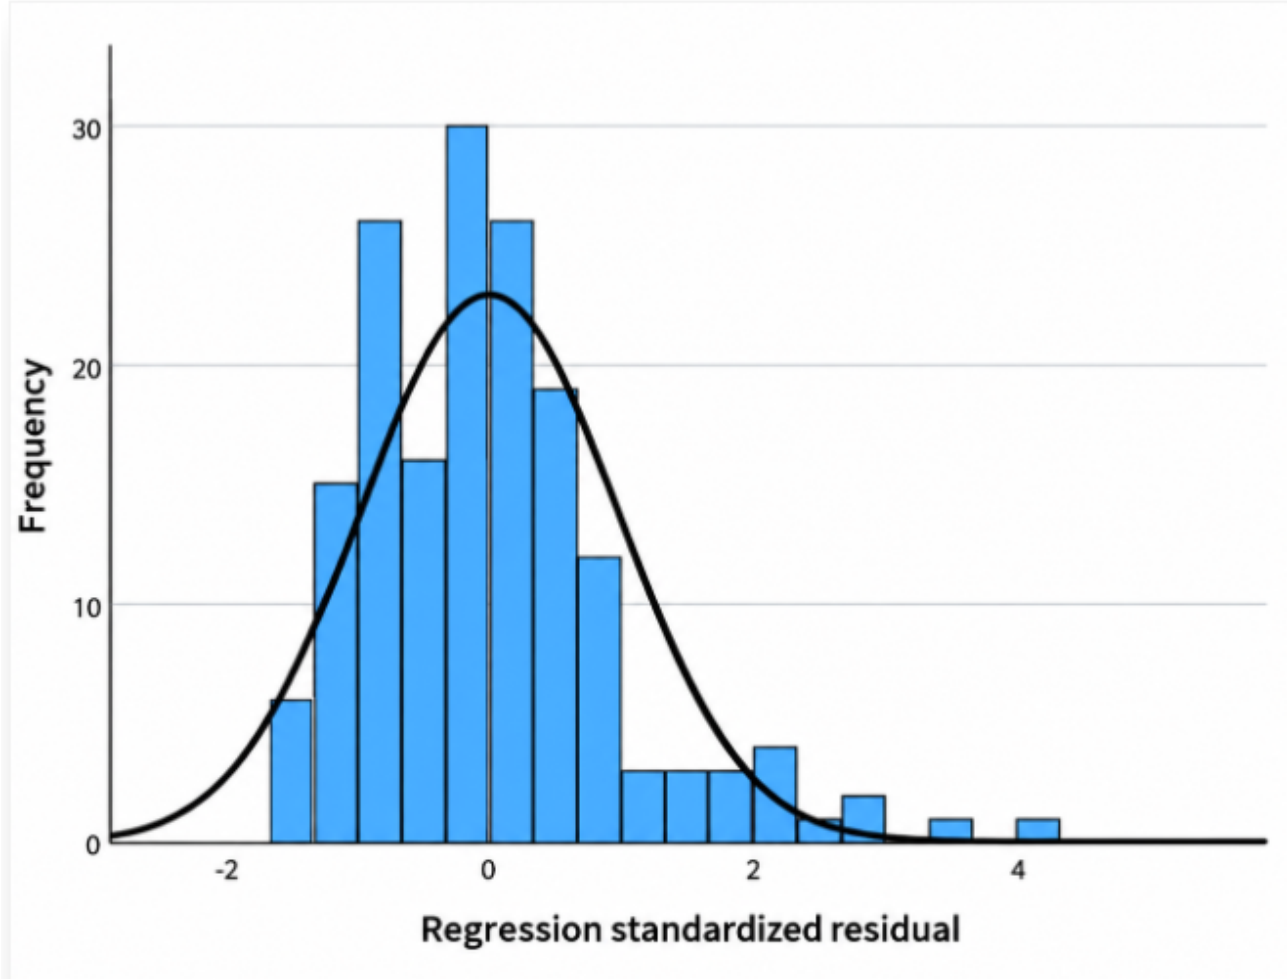
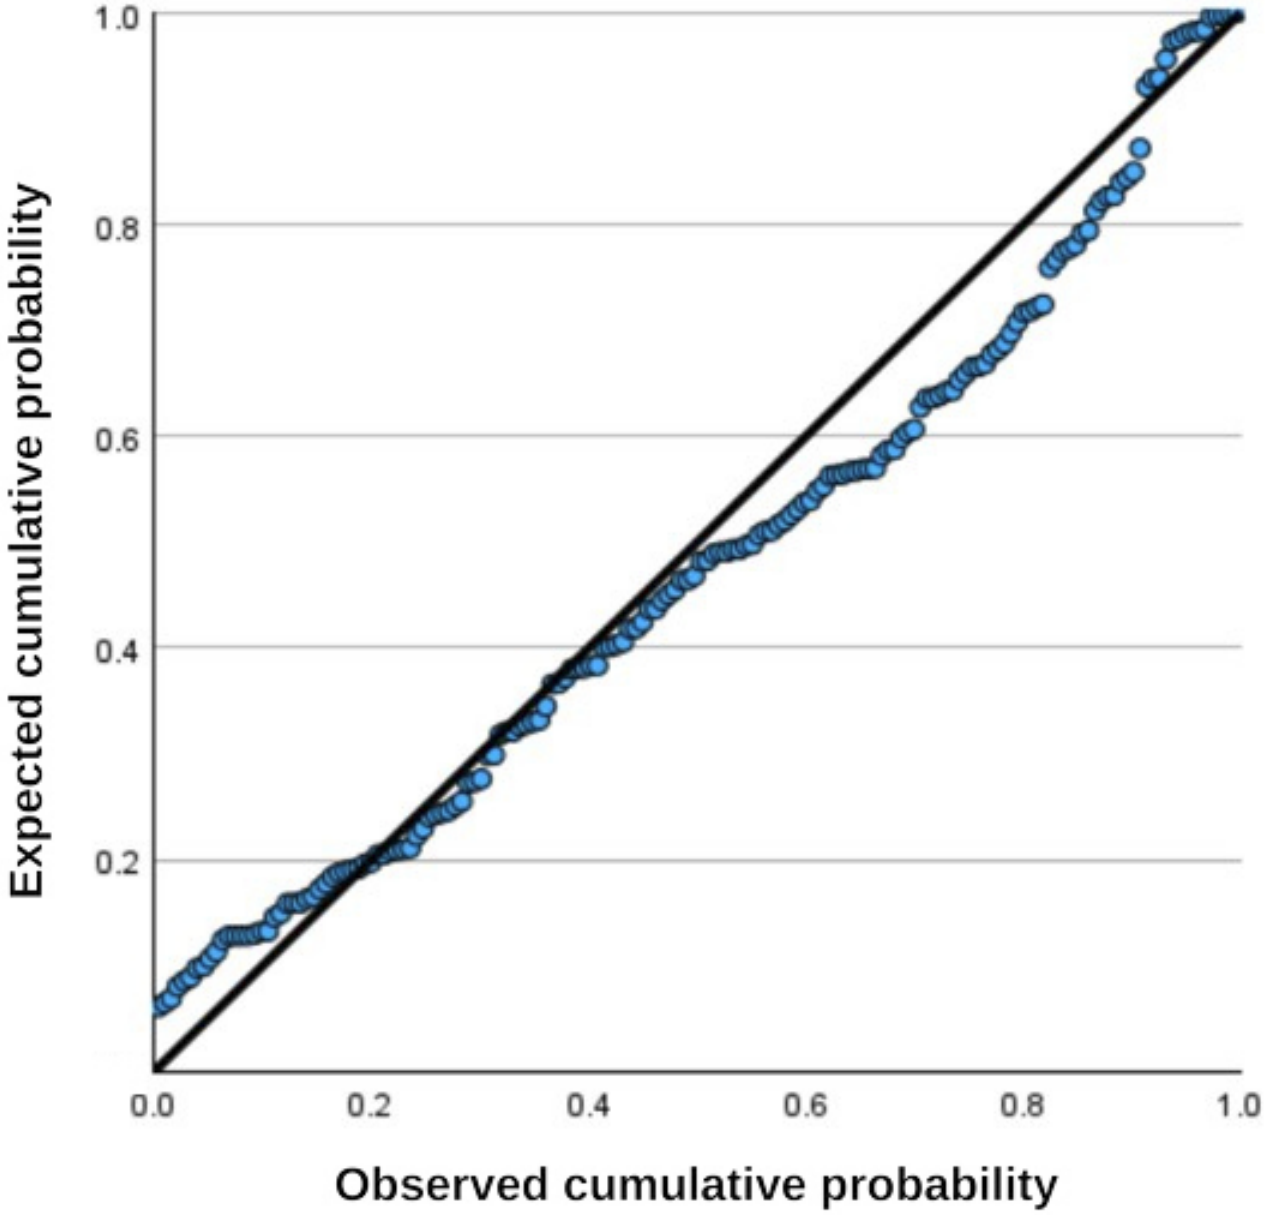
Figure 3. Standardized beta (β) of UTAUT constructs predicting intention to use the TechAids App. EE: effort expectancy; FC: facilitating conditions; PE: performance expectancy; PS: perceived stigma; SI: social influence; UTAUT: Unified Theory of Acceptance and Use of Technology.



We examined variance inflation factors (VIFs) to assess multicollinearity, which indicated no cause for concern. FC showed VIF=1.02, well below conventional thresholds of 5, indicating that its strong effect was not attributable to collinearity with other predictors. All other VIF values ranged from 1.022 to 1.065 (Table 3), suggesting minimal shared variance among predictors (independent variables). Tolerance values, the reciprocal of VIF, confirmed this pattern (range 0.939 - 0.980) with all values well above the conventional concern threshold of 0.10. The Durbin-Watson statistic was 1.782, within the conventionally acceptable range of 1.5 to 2.5, indicating no evidence of autocorrelation among residuals. Case-level influence diagnostics likewise raised no concerns: the Cook distance ranged from approximately 0 to 0.140 (mean 0.006, SD 0.014) with no case exceeding the threshold of 1.0 conventionally used to flag seriously influential observations; 8 cases (4.8%) exceeded the more conservative screening threshold of 4 /n, a proportion consistent with chance variation at this sample size. Leverage (hat) values ranged up to 0.192 (mean 0.054, SD=0.026), with 8 cases (4.8%) exceeding the 2(k+1)/n screening threshold; critically, no case was flagged by both the Cook distance and leverage simultaneously, indicating that no single observation was both high-leverage and disproportionately influential on the fitted model. Together, these diagnostics indicate that the regression results are not attributable to a small number of unduly influential cases.

Residual diagnostics revealed no substantial violations of OLS assumptions. Residuals appeared approximately normally distributed, as indicated by inspection of the standardized residual histogram (Figure 4), and residuals-versus-fitted plots showed no systematic patterns suggestive of heteroscedasticity (Figure 5). While the low VIF for FC (1.020) rules out collinearity with other predictors as an explanation for its dominant effect, it does not, on its own, rule out conceptual overlap between the FC and BI item sets, or common-method variance arising from collecting all constructs via a single self-report instrument at a single timepoint. A comparison of item wording (Multimedia Appendix 3) shows the 2 construct sets to be conceptually distinct. FC items ask about resources, knowledge, compatibility, and support, while BI items ask about future usage, recommendation, and reliance, but we cannot rule out common-method bias as a contributor to the magnitude of the observed association given the single-source, single-timepoint design. We formally examined this possibility using Harman's single-factor test, entering all 28 items across the 7 constructs into an unrotated principal component analysis. Seven components had eigenvalues greater than 1.0, consistent with the intended 7-construct structure, and the first, largest unrotated factor accounted for only 16.0% of total variance, well below the 50% threshold conventionally used to flag a common-method-variance concern. This result indicates that common-method bias is unlikely to be a major contributor to the magnitude of the FC -BI association; the Fornell-Larcker discriminant-validity violation between these 2 constructs reported in the Reliability Analysis section, rather than common-method variance, is therefore the more likely explanation for the strength of this association.



XSL•FO
RenderX

Figure 5. Normal probability-probability plot of regression standardized residual.

Moderation Analysis

Using the 8 interaction models described in the Methods section, results indicated no significant moderation. All interaction coefficients had *P*-values exceeding 0.10. For example, the Age × FC interaction yielded β=−.002 (SE=.009, *P*=.83) (Table 5), suggesting that FC's strong positive effect on BI operates equivalently across younger and older participants. Similar nonsignificant patterns emerged for all other interactions. H7 and H8 were therefore not supported: neither age nor education moderated the relationship between any UTAUT construct and BI. This is distinct from the significant main effect of age on BI reported in the Regression Analysis section (β=.105; *P*=.03); that finding indicates older participants reported somewhat higher intention overall, not that age altered the strength of any UTAUT relationship, and the 2 findings should not be conflated.

Qualitative Findings

Table 1 presents the key themes identified from the qualitative feedback, categorized using the approach described in the Categorization of Qualitative Data subsection of the Methods section. Open-ended responses were collected for 3 survey questions (Table 1). Of the total sample (n=168), 168 participants responded to Question 1 (things liked about mHealth apps); 162 participants responded to Question 2 (things disliked about mHealth apps); and 157 participants responded to Question 3 (what would make TechAids more useful for people living with HIV and AIDS). Not all participants provided feedback to every open-ended question.

Several aspects the users appreciate about using mobile apps for consultation and medication delivery were highlighted. The users value the ability to reach health care providers anytime in terms of accessibility and convenience. It will afford them the opportunity to manage care from their preferred location. Features like reminders for appointments and medication intake are highly appreciated through personalization and control on the app. Users feel secure through strong end-to-end privacy and security measures put in place. Timely alerts and easy access to prescriptions help users adhere to their medication intake and stay on track with their treatment. Users are empowered to better understand and manage their health condition through access to reliable health information and education on the app. Communication and support roles leave users feeling supported and informed, especially in managing their ongoing care needs (Figure 6).

XSL•FO
RenderX

Figure 6. Users' perceived benefits of a mobile app-based platform for consultation and medication delivery

Four key areas of dissatisfaction were identified by users of mobile apps for consultation and medication delivery. User experience during face-to-face consultation is always limited to the allotted time so as to give other opportunities to be attended to. This will only allow limited interaction time and a lack of personal connection with health care providers, leaving users feeling unheard and unsatisfied. Users submitted that poor technical performance and app instability, including frequent crashes, freezing, lagging, and delayed responses disrupt smooth usage and undermine trust in the app. Another major issue pointed out is access to specialists and services, as users often face long waiting times and difficulty finding relevant HIV and AIDS expertise. Dependence on internet connectivity was identified as a significant barrier, as the system will record failure in the use of the app without internet connectivity. The users in low-network or rural areas will find it difficult to receive timely care and support.

The survey findings suggest 8 key areas of improvement to make the mobile app more useful for MSM and transgender individuals living with HIV/AIDS in Nigeria. Users want offline functionality and free internet, which will allow them to use essential features without data or network glitches. Privacy and data security are essential as users expect their sensitive information to be well secured and protected. There is a strong demand for quick helpline support and access to health care providers at any point in time, most especially during emergencies. They also need health education and engagement through regularly updated app content and smart reminders (Figure 7).

Discussion

Principal Findings

This study applied an extended UTAUT model to understand acceptance and intended use of TechAids among MSM and transgender individuals in Nigeria. Using construct-level data and a detailed regression specification, we produced a robust mathematical model of BI and visualized the relative importance of different predictors. The results converge on a clear message that FC is the dominant driver of intention to adopt TechAids. When respondents perceive that they have the necessary resources, infrastructure, and support, they are highly likely to intend to use the platform; when these conditions are absent or fragile, even strong beliefs about usefulness and ease of use do not translate into intention. The nonsignificance of PE, EE, and SI contrasts with much of the prior UTAUT and mHealth literature, warrants more critical interpretation than setting alone can provide. Three contextual explanations, not mutually exclusive, are worth distinguishing. First, infrastructural dominance may be statistically suppressing the explanatory contribution of other predictors: with FC explaining the large majority of variance in intention (r=0.802 with BI), the remaining variance available for PE, EE, and SI to predict may simply be too small to detect with this sample size, even if these constructs retain genuine, smaller, theoretical importance. Second, measurement-related explanations are plausible: high nondisclosure rates on sensitive items may have restricted variability not only in trust and PS but, indirectly, in the broader pattern of responses, attenuating observed associations. Third, sample-characteristic explanations are relevant given that the analytic sample combined platform users and health care providers with potentially different bases for evaluating usefulness, ease of use, and social influence. This was addressed directly in the Regression Analysis section via a user-only sensitivity check. We do not interpret these findings as evidence that PE, EE, and SI are unimportant in principle, but rather that, in this resource-constrained and highly stigmatized setting, their influence may be empirically overshadowed by more immediate infrastructural and measurement constraints.

The prominence of FC is consistent with findings from other developing-country contexts where access to devices, connectivity, and support is uneven [28]. In such settings, abstract beliefs about usefulness can be easily overridden by concrete constraints: intermittent data, shared phones, unreliable electricity, or lack of technical help. Our FC items capture perceptions of device availability, internet access, compatibility, and support, all of which proved critical for respondents considering a digital HIV app. From an implementation perspective, this means that digital health tools cannot be divorced from their infrastructural environment. The small but significant effect of age suggests that older respondents within the 21 - 40 year range are modestly more inclined to adopt TechAids. Older participants may have longer histories of engagement with HIV care and may view digital tools as a pragmatic way to manage frequent appointments and medication refills. This finding echoes broader work on technology adoption in households, where life cycle and accumulated responsibilities often shape perceived benefits [33].

Trust and PS did not emerge as significant predictors of BI in the regression model, but this should not be taken to mean that they are unimportant. Qualitative work and broader HIV

XSL•FO
RenderX

literature emphasize that trust and stigma are central to health-seeking behavior among MSM and transgender communities [34,35]. Qualitatively, users explicitly valued "Privacy & Security" as a feature they liked about consultation and medication-delivery apps, and identified "End-to-end encryption" as a top recommendation for making TechAids more useful (Table 1), both directly relevant to trust and PS. These concerns surfaced spontaneously and prominently in open-ended responses, while the corresponding quantitative constructs were not significant predictors of intention, suggesting this is a measurement and variance issue rather than evidence that trust and stigma are genuinely unimportant to this population. Several factors plausibly explain the gap: high rates of nondisclosure on sensitive identity and HIV-status items (Participant Characteristics) likely restricted the variability available to detect trust and PS effects in the regression model; and because recruitment proceeded through trusted NGO gatekeepers under assured confidentiality conditions (Participants and Recruitment section), participants who agreed to take part may represent a subgroup with comparatively higher baseline trust and lower perceived risk than the broader key population, further compressing variance on these constructs.

For designers, implementers, and policymakers working on digital health for key populations in low-resource settings, the findings point to several priorities:

1. Invest in FC, not just app design: device support, zero, or low-rated data packages, offline functionality, and local helpdesks or digital navigators should be treated as core components of the intervention, not optional extras.
2. Design for infrastructural fragility: features such as low-bandwidth modes, delayed synchronization, SMS fallbacks, and robust error-handling can ensure continuity of care even when connectivity is intermittent.
3. Interpret the age effect cautiously: age showed a small but significant positive main effect on BI, and older participants in our sample expressed modestly higher adoption intention overall. However, moderation analysis found no evidence that age altered the strength of any UTAUT relationship. The data therefore do not support differentiated, age-targeted UTAUT-based messaging strategies, and any age-related design choices should be informed by further targeted research rather than this finding alone.

Limitation and Future Research

Beyond methodological considerations already discussed, several substantive limitations warrant acknowledgment. Our study examined a single country context (Nigeria) which may not be generalizable to other developing or developed contexts where infrastructural, cultural, or policy conditions differ. Small sample size (N=168) is another limitation of this study which may restrict the statistical power of the analysis and the ability to detect subtle relationships among the UTAUT constructs. Future research could extend this work by collecting larger, multisite samples to strengthen the robustness and combining longitudinal usage data from the deployed TechAids platform with survey measures. The cross-sectional design precludes causal inference, and BI may not reflect sustained real-world use. Analytically, OLS regression of composite Likert constructs should be supplemented by SEM or ordinal regression. AVE fell below the 0.50 threshold for 3 constructs, leaving convergent validity unconfirmed, and a discriminant-validity concern exists between FC and BI. Full Confirmatory Factor Analysis was precluded by sample size. Although Harman's test found no pervasive common-method bias, single-instrument, single-timepoint measurement cannot fully rule it out; temporally separated measurement of key constructs is recommended.

Combining platform users (n=141) and providers (n=27) in 1 model limits subgroup comparisons; a larger provider sample is needed for stratified analysis. High nondisclosure rates on gender, sexual orientation, and HIV status (33% - 49%) constrain confidence in sample representativeness. Qualitative coding by a single author (EOO) without interrater reliability checks limits robustness. Selection bias through NGO and clinic gatekeepers likely underrepresents the most marginalized individuals, while social desirability bias may affect sensitive disclosures. Finally, use of a prototype rather than the live platform may not capture real-world barriers or sustained engagement challenges.

Conclusion

This study examined factors predicting intention to adopt TechAids, a digital HIV care platform, among MSM and transgender individuals in Nigeria. Using an extended UTAUT framework, we found that FC, perceptions of internet access, device compatibility, technical knowledge, and support availability emerged as the overwhelmingly dominant predictor of adoption intentions, explaining approximately 65% of variance. Traditional UTAUT constructs (PE, EE, SI) and our theoretical extensions (trust, PS) showed no significant effects, though qualitative data suggested these factors remain conceptually important.

These findings challenge assumptions underlying much digital health discourse. Technology acceptance discussions frequently emphasize cognitive factors, usefulness, ease of use, features, treating infrastructure as merely enabling background conditions. Our results suggest that in resource-constrained settings, this hierarchy inverts: infrastructure becomes foreground, overwhelming cognitive considerations. Well-designed platforms with privacy-enhancing features may generate enthusiasm among potential users, but this enthusiasm translates into adoption only when individuals possess reliable connectivity, adequate devices, and confidence they can access technical support when needed. These findings describe a strong cross-sectional association between perceived FC and BI to adopt TechAids, not a demonstrated causal effect of infrastructure on actual platform use or downstream health outcomes. FC being strongly associated with intention does not, on its own, prove that infrastructure alone determines whether people go on to use the platform or experience improved HIV care outcomes; verifying that pathway requires the longitudinal and real-world usage data called for in Limitation and Future Research section.

For digital health implementers, these findings carry clear implications: infrastructure support must be treated as core intervention components, not optional supplements. Zero-rated

XSL•FO
RenderX

data plans, offline functionality, low-bandwidth optimization, device loan programs, and community-based technical support infrastructure should be budgeted alongside platform development. Without these enabling foundations, even the most thoughtfully designed platforms will fail to achieve meaningful adoption and sustained engagement.

Acknowledgments

We extend deep gratitude to the men who have sex with men (MSM) and transgender individuals who participated in this research, sharing their time and insights despite risks associated with disclosure in Nigeria's criminalized context. We thank the nongovernmental organizations (NGOs) that facilitated recruitment while protecting participant safety: The Initiative for Equal Rights (TIERs); and Happiest Ones Health Support & Rights Initiative (HOHSRI). We used the generative AI tools (ChatGPT and Anthropic-Claude) for language refinement, grammar editing, and visual generation of figures and diagrams. All AI-assisted outputs were critically reviewed.

Funding

The authors declared no financial support was received for this work.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to the sensitive nature of data involving HIV status and criminalized populations. Deidentified data may be available from the corresponding author upon reasonable request and with appropriate ethical approval.

Abstract

Background: The ready-made garments (RMG) industry is a crucial component of Bangladesh's economy, using over 4 million workers from low-income backgrounds who often neglect their health care needs. Historically, this sector has faced criticism for labor exploitation, unsafe working conditions, and rights violations, as highlighted by tragic accidents resulting in loss of life. Compliant factories may uphold higher labor standards, but many noncompliant factories expose workers to poor conditions, increasing health risks. The COVID-19 pandemic intensified vulnerabilities, leading to widespread factory closures and job losses, increased health risks, and left millions of workers without wages. Although the government attempted to provide some relief, it fell short in offering job security, social protection, health services, and emergency assistance. Limited access to technology due to digital literacy gaps further hinders these workers, who primarily use basic mobile phones for communication rather than accessing health or emergency services. Thus, there is a pressing need to develop a sustainable system that capitalizes on their existing technological familiarity.

Objective: Our goal was to gain a deep understanding of RMG workers' experiences, focusing on their work environments, technological interactions related to health care management, and the impacts of COVID-19 on their circumstances. This understanding aims to inform the design of a technology-based framework that is both sustainable and contextual.

Methods: In phase 1, we conducted in-person interviews with 55 RMG workers, comprising 32 female and 23 male participants from urban and suburban areas of Dhaka and Gazipur, before the pandemic. Participants were aged between 18 and 40 years. In phase 2, we reconnect with 12 phase 1 participants during the pandemic and also consulted 3 stakeholders from RMG factories via phone. Each interview, conducted in Bengali, was recorded with consent, totaling 846 minutes of discussion that were translated and transcribed. Thematic analysis was used to analyze the results.

Results: Insights gathered revealed variations in working conditions, personal experiences, perceptions of health care, lifestyle choices, and technology use tied to factory compliance. Workers at compliant factories had better health care support and used technology more effectively than those in noncompliant settings. The pandemic drastically altered the landscape for all workers, heightening health and safety concerns and shortages of emergency assistance. The RMG sector faces significant challenges, highlighting the urgent need for targeted emergency relief and health services.

Conclusions: This research examined the challenges and technology use among RMG workers during the pandemic, with a focus on health care perspectives. Based on our findings, we proposed a technology-based framework called VOICE (Virtual Outlet for Integrated Community Engagement) that connects workers with service providers through a simplified interface. This aims to assist marginalized communities during emergencies and enhance their overall well-being.

Introduction

Background

The ready-made garment (RMG) industry is a crucial sector of Bangladesh's economy, contributing over 10% to the national gross domestic product and 84% of total export earnings [1-3]. The sector employs over 4 million workers, with nearly 90% being female workers from low-income and rural backgrounds [4,5]. This aligns with Lewis's economic growth model, characterized by an unlimited labor supply driven by low labor costs [4,6]. As of 2018, the entry-level wages for workers were US $62.42 [7-10]. The government of Bangladesh raised monthly wages by about 51% that year, setting the minimum wage at $94.22 [10]. In 2023, the entry-level wage was adjusted to BDT 12,500 ($102) per month with a 9% annual increment [11], which still reflects low pay. Though this sector is economically significant, it has also been criticized for labor exploitation, unsafe working conditions, and violations of workers' rights [12-15]. Such incidents have sparked greater awareness of workers' rights, mandating that all RMG factories comply with internationally recognized standards [14,16-19]. In Bangladesh, RMG factories are divided into compliant and noncompliant factories. While some facilities follow international labor standards and provide workers with better rights and living conditions (compliant factories) [20], many (noncompliant factories) expose workers, especially female, to verbal and physical abuse, lack of sanitation, long working hours, excessive workloads, and health risks [20-24]. Such a situation impacts the health of workers, especially female workers. Accordingly, health care awareness among RMG workers remains low [25], and access to formal health services is limited due to economic constraints, stigma, and limited health information [24,26].

The health-wealth gradient in labor markets demonstrates that workforce participation sometimes depends on workers' capacity to accept positions, which is shaped by population health and social safety nets [27]. The COVID-19 pandemic intensified the vulnerabilities of this workforce. Global supply chain disruptions and order cancellations (approximately USD $2.8 billion worth of orders were withdrawn) by Western brands led to the closure of thousands of factories [28,29], leaving over a million workers temporarily unemployed without wages or severance pay [30]. While the government of Bangladesh attempted relief packages (approximately US $13,549 million), there were no safeguarding policies to ensure job and health security or social protection [31]. In addition, living in densely populated settlements, RMG workers faced heightened health risks, food insecurity, inadequate emergency aid, and emotional distress during the pandemic [32,33].

The pandemic has, in addition, underscored the growing role of technology in emergency response. In both developed and developing contexts, crisis response technologies, such as crowdsourcing platforms, helplines, and mobile health services, have improved access to timely support [34-36]. In Bangladesh, services such as 999 (general emergency) and 333 (COVID-19), as well as telehealth platforms such as Tonic (Telenor Health and Grameenphone) and Doctime (Doctime Limited), became available [37-39]. Recent work on AI-based risk assessment tools highlights critical considerations for deploying conversational health technologies in real-world settings, including the need for evidence of grounding and safety-focused evaluation [40]. However, these solutions often remain inaccessible to low-income populations due to limited digital literacy, lack of trust, and gendered disparities in technology use [41,42]. Workers in informal economies, including RMG workers, typically use basic mobile phones primarily without internet connectivity for communication rather than accessing health or emergency services [43,44].

Given this context, there was a critical need to understand how RMG workers interact with technology, manage health needs, and cope with crises in order to design meaningful, accessible digital interventions. Yet, no such research has explored the living realities of this particular industrial low-income group in developing countries, especially during global crises such as COVID-19.

To address this gap, we examined the daily experiences of RMG workers before and during the pandemic on the basis of compliant and noncompliant factories, with a focus on health perceptions and technology use. Specifically, we investigated:

- Research question 1: How do RMG workers manage their daily lives, health care needs, and technology use in their existing work environment?
- Research question 2: How did the COVID-19 pandemic affect their daily lives, health, and access to support?

Aims and Approach

This research aimed to investigate key research questions and develop technology-based design implications that can provide emergency support for ready-made garment workers and other low-income groups during times of crisis. The goal is to create a platform that amplifies their voices. However, many existing technology services are underused due to usability barriers and a lack of contextual relevance. To address this issue, we propose a technology-based framework called VOICE (Virtual Outlet for Integrated Community Engagement). This framework leverages service interface platforms to offer emergency support while ensuring that the voices of low-income communities are heard. In this paper, we report the results of in-depth interviews conducted with RMG workers in Bangladesh.

Methods

Overview

We conducted qualitative interviews in 2 phases: before the COVID-19 pandemic (phase 1) and during the pandemic (phase 2) in Bangladesh, specifically between January and April 2020.

Phase 1 occurred from January to February 2020, before the COVID-19 lockdown in Bangladesh that started at the end of March 2020 (by that time, China halted the shipping of raw materials, accessories, machinery, and spare parts; it affected the apparel and textile industries [29]). During this phase, we interviewed 55 RMG workers (32 female and 23 male workers) across 6 focus group discussions (FGDs) to gain insights into their lives and daily experiences.

XSL•FO
RenderX

In phase 2, we conducted one-on-one follow-up phone interviews with 12 RMG workers (9 female and 3 male workers) from phase 1 during the first week of April 2020, after the COVID-19 lockdown was imposed in Bangladesh. Additionally, we interviewed 3 stakeholders (including merchandisers, managers, and factory owners) connected to the financial policies of the RMG sector.

Phase 1 Method

Participant Recruitment Technique

We recruited participants from 3 areas in the Dhaka division: Mirpur, Ashulia, and Gazipur, as shown in Tables 1 and 2. Key informants (KIs), such as landlords and house managers who are well-known and trusted within the local community, assisted us in recruiting workers.

Table . Dimensions of research and details of the participants.

Phase 1: study before the COVID-19 pandemic (January 20 to February 20)						
FGD[a] groups	Participants count, n	Sex	Age range (years)	Area	Factories workers are engaged, n	Working experiences (years)
Group 1	11	Female	22 - 38	Mirpur, Dhaka, Urban	9	3 - 10
Group 2	7	Male	25 - 40	Mirpur, Dhaka, Urban	7	3 - 10
Group 3	12	Female	20 - 30	Ashulia, Dhaka, Suburban	3	3 - 5
Group 4	8	Male	18 - 30	Ashulia, Dhaka, Suburban	7	3 - 10
Group 5	9	Female	18 - 40	Gazipur Circle, Gazipur, Suburban	7	3 - 5
Group 6	8	Male	18 - 40	Gazipur Circle, Gazipur, Suburban	7	3 - 15

[a]FGD: focus group discussion.

Table . Details of the participants.

Phase 2: study during the COVID-19 pandemic (first week of April 20)						
One to one interview	Participants count, n	Sex	Age range (years)	Area	Factories workers or stakeholders are engaged, n	Working experiences (years)
RMG[a] workers	12	Male and Female	18 - 35	Mirpur, Ashulia, and Gazipur Circle, Dhaka	10	3 - 10
Factory owner	1	Female	18 - 35	Dhaka	1	8
Assistant manager (compliance)	1	Male	18 - 35	Dhaka	1	8
Merchandiser	1	Male	18 - 35	Dhaka	1	5

[a]RMG: ready-made garment.

These workers frequently communicate with KIs regarding rent-related matters. The KIs managed RMG workers in various roles, such as helpers and operators, from both compliant and noncompliant factories. The participants were related but not family, such as friends and colleagues. We ensured that male and female workers were recruited separately in each area for their comfort. The participants' age range was 18 to 40 (mean 27.37, SD 5.65) years, and they represented 40 different RMG factories, as indicated in Table 1. Among them, 31% (17/55) worked in compliant factories, while 69% (38/55) were employed in noncompliant factories. The participants were eager to share their experiences, reflecting Bangladesh's collectivist societal structure [45]. FGDs allow participants to express their beliefs, experiences, perceptions, and attitudes [46]. Each discussion format involved an interactive exchange between participants and the research team in a group setting [46,47].

Workers typically work 6 days a week and spend their weekends, particularly Fridays, attending to necessary tasks at home and outside. To accommodate their schedules, we preferred to form large focus groups of up to 12 workers at a time within the same community. This format also encouraged participants to have their voices heard [48].

Study Design and Procedure

The study aimed to gain a brief understanding of the personal lives, social aspects, relationships, and everyday workplace experiences of RMG workers. We divided the interviews into 2 segments that highlight these workers' positive and negative

XSL•FO
RenderX

insights. First, we examined the daily work systems, including workload, health issues, work environment, relationships with coworkers, and interactions with supervisors. Second, we explored the workers' personal lives, focusing on financial stability, family dynamics, friendships, sources of entertainment, technology use, social relationships, and their responsibilities regarding children.

Before each discussion, we engaged with the participants to arrange the discussion venue, prioritizing their comfort [49], and an evaluator for the qualitative study. We aimed to create an interactive zone through informal discussions. We explained the research objectives, methods, ethics, and incentives at the beginning of each discussion. We ensured participants provided consent and addressed their concerns about the topics. Once consent was granted, the lead researcher (RJR) guided the discussions, while other team members assisted with follow-up questions and took notes. The study was semistructured and conducted in Bengali, with nontechnical questions for the participants. Each FGD lasted, on average, 120 (mean 121, SD 2.19) minutes. We audio-recorded each discussion with the participants' consent.

Analysis

The interviews were conducted in Bengali, which required transcription and translation of all the interviews. A total of 726 minutes of audio was translated and transcribed into English. Being fluent in both English and Bengali, we carefully transcribed and translated the audio directly into English (forward translation). We revised the translated transcription to ensure data validity and manually analyzed it. We read and reread all the transcriptions multiple times to become thoroughly familiar with the data. We started the analysis process after completing the first FGD because the collected contents and the analysis mutually apprised each other [50]. We used thematic analysis, starting with an open-inductive coding procedure that also includes both inductive and deductive processes [51,52]. After the first phase of open coding, we generated a codebook that the authors (RJR and NA) collectively revised to group similar codes into second-order codes. The first author (RJR) reviewed all the themes multiple times, and the authors (RJR and NA) generated the themes collaboratively. Theme 1 addressed the challenges RMG workers face in noncompliant factories, significantly affecting their well-being. In contrast, theme 2 emphasized the opportunities for RMG workers in compliant factories, positively impacting their quality of life.

Ethical Considerations

The institutional review board approved the research (application: IRB-No.0501). Participants had the right to skip any questions or withdraw from the discussions at any point without losing their incentives. All recordings, notes, and data collected are securely stored in a private drive, with access granted only to the researchers. For participating in the FGDs, we offered snacks and daily grocery items worth BDT 500 (US $4 as of Sep 1, 2026) to each participant as incentives. Each KI received the same snacks, daily grocery items, and BDT 1000 (US $8 as of Sep 1, 2026) for their additional fieldwork.

Phase 2 Method

Participant Recruitment Technique and Study Design

We could reach 12 individual RMG workers (9 female and 3 male workers) from the participants of phase 1 for one-on-one phone interviews (Table 1), having collected their phone numbers during that study. The significant reduction from 55 participants in phase 1 to 12 in phase 2 reflects the extraordinary circumstances during the initial COVID-19 lockdown in Bangladesh, when participants could be reached only by phone due to a complete shutdown. This represents a subset that may not fully capture the diversity of experiences across all factory types and locations. However, they did represent 10 different factories and the same 3 geographic areas, providing some breadth.

This follow-up investigation aimed to understand the impact of the COVID-19 pandemic on these workers, including how they receive immediate support and the health and safety situations in their localities. Additionally, we formally requested that factory authorities assist us in contacting potential stakeholders in the RMG sector. Through this process, we recruited 3 participants: a factory manager, a merchandiser, and a factory owner, all from different garment factories. This allowed us to gain insight into the overall state of the RMG sectors and the future challenges workers face, buyers' perspectives, and the role of authorities in relation to COVID-19.

Study Procedure and Analysis

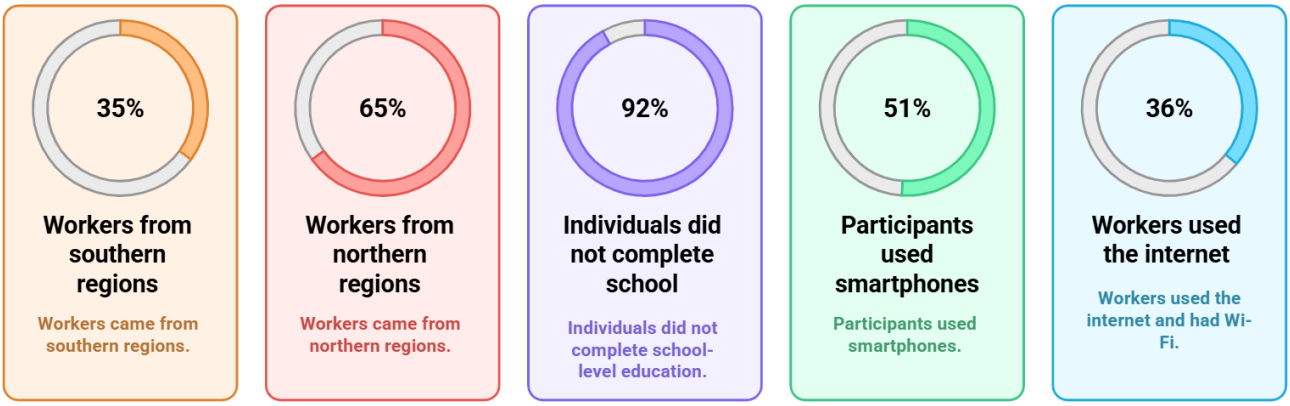
We conducted audio phone conversations with the workers, each call lasting around 10 minutes. In total, we had 120 minutes of conversation (mean 10.1, SD 1.40 minutes). The 3 conversations with stakeholders were approximately 30 minutes each, resulting in 90 minutes of discussion (mean 30, SD 2 minutes). We did not record any phone calls and took real-time notes during the conversations. All discussions were conducted in their native Bengali language, and the lead researchers moderated the data collection.

We used the same content analysis method as previously discussed. Through inductive open coding, we generated first-order codes, grouped similar codes into second-order codes, and ultimately developed the final theme 3, which addressed how the COVID-19 pandemic made the RMG workers' lives difficult.

Ethical Considerations

This study was conducted under the same institutional review board guidelines. We ensured the anonymity of all participants and securely stored the notes in a locked drive. No incentives were provided for participation in the phone conversations; we verbally thanked each participant after our calls.

Results



Overview

The holistic demography is shown in Figure 1. These participating workers came from the southern (19/55, 35%) and northern (36/55, 65%) regions of Bangladesh, both of which are low-income areas. Due to economic constraints, 92% (51/55)

XSL•FO
RenderX

of these individuals did not complete their school-level education. Despite their limited education, many secured early employment in RMG factories, as these facilities often prioritize hiring younger, physically fit workers to boost productivity. It was interesting since, in Bangladesh, male workers generally earn more than female workers in households [53]; however, female workers contribute significantly to family earnings, particularly in the RMG sector.

Figure 1. Participants' profile.

Additionally, 51% (28/55) of participants used smartphones, with higher use among male participants, though many were unaware of how to use them. About 36% (20/55) of workers used the internet and had Wi-Fi support at home, mostly from compliant factories. Their internet use was primarily limited to online calling apps (eg, IMO; PageBites, Inc) for communication with distant relatives and coworkers. A few male workers had social media but were inactive, while others rarely watched YouTube.

In the context of wages, at the time of phase 1 data collection (January-February 2020), the minimum wage for RMG workers was BDT 8000 (approximately US $65 as of August 17, 2026). However, a significant portion of workers, particularly in noncompliant factories, earn below the minimum wage. By the time of phase 2 (April 2020), the COVID-19 pandemic had led to widespread factory closures, leaving many workers without any wages or severance pay, compounding their existing financial vulnerability.

Theme 1: Sounds of Distress From Noncompliant Factory Workers

The working environment for employees in noncompliant factories greatly affects their well-being and lifestyles. Participants noted that noncompliant RMG factories often neglect workers' rights and health, resulting in these workers facing the harshest conditions (eg, limiting water intake or the ability to visit the toilet to increase productivity). Many female workers in noncompliant factories experience abuse. They reported that senior officers, such as line chiefs, floor managers, and supervisors, often exert pressure and punish primarily female employees. Additionally, these workers frequently do not receive their rightful salaries and remain silent about these injustices. Fearful of losing their jobs, female workers are reluctant to confront authority regarding abuse, making their situation even more challenging. Despite these hardships, they continue working due to their obligations, which impact their well-being all over. One female worker from a noncompliant factory expressed her emotional and mental state as follows:

> *Some line chiefs treat us very poorly. Supervisors are mean. I frequently feel like crying–we can't even wipe our eyes. If we cry, they will punish us by standing in front of the chamber for hours. They say this is not a place for crying; this is a workplace.* [Female worker, Ashulia, group 3]

Male participants shared that factory authorities often prefer hiring female workers over male workers because female workers tend to be quieter and less likely to protest against irregularities and misbehavior. Many female participants agreed, mentioning that there have been fewer protests in factories due to the high number of female employees, which has led to increased injustices impacting passively their well-being. A male worker from a noncompliant factory described the biased recruitment process, stating that young, attractive, and healthy workers are favored, particularly female workers. He said:

> *RMG authorities do not prefer elderly people or men. Overweight will not get a job. It's all about being young and slim. They prefer female because they are less likely to protest against mistreatment. They can pay female less.* [Male worker, Mirpur, group 2]

Because of such conditions, workers get sick and also often neglect their health and personal care to focus on their job responsibilities. They believe that their roles require them to remain healthy, but typically they do not receive adequate health care support from their factories. Additionally, authorities overlook workers' health care needs and treatment costs. Many workers reported that they often do not have proper restroom breaks due to excessive pressure, which limits their water intake throughout the day. Consequently, many are concerned about potential job loss that may arise from significant health issues. One female participant highlighted how their workload adversely affects their health:

> *We start working in the morning and continue without breaks, only pausing for lunch, then sitting again until we finish. We don't drink water or go to the restroom. Drinking water makes us feel pressured to use the washroom, which hampers production. Taking*

XSL•FO
RenderX

> *bathroom breaks is not prohibited, but we avoid them saving time.* [Female worker, Ashulia, group 3]

In addition, these workers often restrict the use of phones in the workplace. They have shared that they secretly use their phones on staircases or near restrooms to make calls during work hours. Otherwise, they will be punished. Furthermore, many do not have internet access to their home phones, as they cannot bear the additional costs of the internet for low pay. Additionally, due to heavy workload, they cannot manage time to use the phone, resulting in they cannot explore entertainment and any support options through phone. Therefore, this theme shows that noncompliant factory environments and lack of support decrease workers' quality of life.

Theme 2: Workers in Compliant Factories Lead Better Quality of Life

Participants from compliant factories unanimously highlighted the importance of timely salary payments and fair overtime compensation. Female workers reported significantly better job experiences, positively impacting their lives.

They also receive support from the factories regarding any workers' issues. One female worker expressed her feelings about increased income and teamwork at compliant facilities:

> *We do not feel overwhelmed by our workload. If someone is under too much pressure, management assigns additional workers to help. Sometimes, they implement a double process to meet targets. During shipment, we may work overtime until a maximum of 7 PM, and they compensate us properly for that. All the workers cooperate during shipment, and we are okay with it.* [Female worker, Gazipur, group 5]

Participants mentioned that compliant factories provide personal health facilities. Workers can take breaks whenever needed and access plenty of drinking water during their shifts. One female participant shared that there are medical staff at the factories, which many workers rely on due to the free services provided:

> *There is a medical team inside the factory. If someone feels ill, they prescribe medication, sometimes even provide medicines. They can be granted emergency leave or transported to a hospital by ambulance, with the company covering the expenses. Their salary will not be deducted; we depend on this support.* [Female worker, Gazipur, group 5]

Compliant factories also do not impose strict restrictions on communication, providing dedicated mobile phones on the factory floors for emergency calls, which the workers feel is good, as it helps to reduce the cost of regular personal communication. One female worker explained:

> *We do not use our personal mobile phones in the garments, but we are not bothered because several phones are available on every floor. We can use those for communication. If someone needs to reach us, they can call on those phones. We can talk even under heavy work pressure and frequently access them without any cost.* [Female worker, Gazipur, group 5]

Workers with internet access at home are typically employed in compliant factories. They usually share internet costs and live in relatively better areas than workers in noncompliant factories. This support often extends beyond shared costs, primarily provided by the house owner. Some believed that internet-based technology provided better resources for their children at home. They encourage their children to use mobile phones and the internet for educational purposes. One participant shared that he bought a computer for her daughter to use it:

> *She reads the Bengali newspaper online (on laptop). I encourage her to watch animations and tutorials on YouTube. I want to make my daughter a computer engineer.* [Male worker, Ashulia, group 4]

Therefore, the theme highlighted that compliant factory workers received significantly better support at the workplace, which encouraged them to lead a quality life.

Theme 3: COVID-19 Pandemic Makes Workers' Lives Difficult and Threatening

The COVID-19 pandemic has negatively impacted all factory workers, regardless of their compliance status. We found workers faced significant health care risks during the pandemic, as COVID-19 was highly contagious. Many workers lived in congested areas, often sharing a single floor with 6 to 8 families [54,55]. As a result, they struggled to maintain social distance, as their families shared kitchens and washrooms. Participants noted that they could not prevent their children from playing together in the evenings. This situation was consistent across all study areas. Compliant factory workers typically relied on medical support from their factories, but this support was halted due to the pandemic, raising concerns for their well-being. A female worker expressed her worries about social distancing:

> *We can't maintain social distancing because our area is very congested. If you want to do it personally, I think you can't. We have a shared kitchen. If anyone is infected here, the situation will be dangerous. We do not have health care support or food from anywhere.* [Female worker, Mirpur, Dhaka]

Participants reported that their factories closed suddenly, often without prior notice, and many did not receive their salaries. This lack of communication left them struggling to survive in the following days. They expressed the need to be financially prepared due to the uncertainty brought about by the pandemic, particularly concerning their ability to pay monthly house rent, grocery bills, and utility costs. Most of them found it difficult to save money due to low incomes, with many workers indicating that they had no savings to cover their monthly expenses. Some participants noted that they did not receive emergency relief from the private or government sectors since relief efforts often focused on the extremely poor. Other participants echoed a similar sentiment. This lack of adequate support was voiced by a male worker, who said:

> *We do not get any salary in advance. We received no relief from anywhere, not even from our garments. The situation is the same for everyone. Our living areas are not slum areas, so government and private relief efforts focus on slum areas. The government*

XSL•FO
RenderX

> *announces salaries for workers. That might be another reason we are not receiving emergency relief. We are on an unpredictable journey. We just need food and treatment now, nothing else. We only need rice, red lentils, and oil, and that's it.* [Male worker, Mirpur, Dhaka]

Accordingly, the stakeholders in this study expressed concerns about the RMG sector, which has historically faced significant losses. During the study period, they noted that the Bangladesh government announced a US $592 million incentive package to support RMG factories and their workers [31]. This support is provided to 4000 registered RMG factories by the Bangladesh Garment Manufacturers and Exporters Association, all of which are either compliant or partially compliant with regulations. However, stakeholders were worried that the thousands of unregistered and noncompliant factories and their workers would not receive any incentive support. The factories lost ongoing contracts, which added financial pressure due to their reliance on imported goods from China during the early days of the COVID-19 outbreak. One support authority representative shared his thoughts on the challenges faced by RMG workers:

> *The pandemic leads to food crises. People need food, treatment, not clothing. Our foreign income will decline, and we must support 4 million workers. This is extremely difficult.* [Merchandiser, an RMG group]

Another representative highlighted the plight of RMG workers. Approximately 4 million workers are employed in both compliant and noncompliant factories, and their wages are directly tied to the factories' income. Workers and individuals connected to the RMG industry will experience difficulties if these factories cannot sustain their operations. A management representative reinforced this sentiment:

> *The entire garment sector is at risk. Even if some factories collapse, millions of families will be affected; only Allah (God) knows what will happen!* [Assistant manager, a textile factory in Bangladesh]

Discussion

Principal Findings

We interviewed RMG workers and stakeholders from the RMG industry in Bangladesh. The interviews provided insights into the working environment, work experiences, perceptions of health care, lifestyle, and technology use, which varied depending on the type of RMG factory. This variation significantly impacted the well-being of the workers. Specifically, workers from compliant factories received essential health care support and demonstrated more effective use of technology than those in noncompliant factories. The disparities between compliant and noncompliant factory workers in our study mirror the regional disparities observed in labor market analyses [27]. As the pandemic spread globally, the circumstances for all workers changed, irrespective of their factory type. This shift profoundly affected their daily lives, raised health and safety concerns, and created a lack of emergency support.

The RMG industry faced numerous challenges, highlighting the urgent need for focused emergency relief and health care solutions for this community. Although the RMG industry has since begun to recover from the pandemic impacts, our findings reveal the community's vulnerabilities during emergencies. Based on these insights, we proposed a technology-based framework design, VOICE, to improve the lifestyle and well-being of this community, which struggles with limited exposure to technology. This initiative could also benefit other low-income communities in the future.

Requirement of Contextualized and Accessible Technology Intervention

The participants expressed that they work hard in a noncompliant work environment, but overall neglect their health issues. Although several earlier studies have highlighted the challenges faced by RMG workers. For instance, one study examined the workplace challenges faced by RMG workers in both export processing zone and nonexport processing zone factories [56,57]. While their findings were similar to those observed in noncompliant factories (theme 1), the studies did not address the conditions in compliant factories (addressed by theme 2), which is a crucial point to note, because compliant factory workers are facilitated with better support at the workplace. We cannot change the work environments of noncompliant factories, which depend on high-level stakeholders, and the National Tripartite Plan of Action on Fire Safety and Structural Integrity is constantly working to improve them [13,15,58]. We mostly consider their health problems, as previous studies found similar findings [21-24,59], but this worsened during the pandemic. They also needed emergency relief to survive. Another study analyzed the numerical impact of the COVID-19 pandemic on RMG workers [55] but did not empirically examine the situation (addressed by theme 3). Our research differs from existing research, focusing on supporting the health and emergency response of RMG workers through technological implications.

During the COVID-19 pandemic, workers lacked emergency aid, including health care support, financial assistance, and food. National policymakers prioritized monetary factors over workers' safety and health. As a result, RMG factories remained open [60], leading to confusion over the payment of outstanding employee salaries and prompting large numbers of workers to return to their factories [61]. Thousands of RMG workers walked toward factories as public transport was unavailable due to lockdown measures [60]. This situation highlighted a gap in information dissemination and created confusion about where to seek help. The prolonged COVID-19 crisis led to the spread of the Delta variant, resulting in further factory closures [62] and the need for emergency support. Later, the Omicron variant also affected RMG factories [63]. The disparities experienced during this crisis called for urgent attention. The continuous struggle of the workers, who held on to hope for a better future, was evident in their dreams. Maintaining social distance [64] was frustrating for many, as they relied on daily earnings. Some relocated to villages to manage their expenses, disregarding the risks of COVID-19 [32,33,65]. Engaging participants enabled researchers to explore ways to help communities seek assistance and support from one another. The intuitive systems designed

XSL•FO
RenderX

for Western countries require redesigning and reforming to better suit the conditions of poverty-stricken, densely populated regions like Bangladesh [66]. The challenges participants face present design opportunities to incorporate the voices of low-income and marginalized communities.

RMG workers in Bangladesh frequently struggled to access online health care services [38,67,68] due to limited access to and knowledge of technology. Toyama [69] discussed that technology integration could address existing societal problems; however, low-resource communities often require unique, simple, and effective systems that accommodate limited technology options. Connecting them with available technology poses challenges. Thus, a contextualized design approach can support users with restricted technological capabilities. That is why understanding their technological familiarity through this research was important.

Information from various contact points is widely available on social media but remains inaccessible to many communities. For instance, the recent flooding in southern Bangladesh demonstrated that obtaining information from victims was challenging, and many victims were excluded from emergency relief [70]. A point-of-contact–based service could function similarly to Facebook's service in terms of location and crisis response during emergencies [34]. One notable example is Ushahidi, a crisis-mapping organization in Kenya, Afghanistan, Haiti, and Mexico that gathers data from social media networks [35,71]. In Bangladesh, OpenStreetMap has delivered emergency support to remote regions during natural disasters [36]. In Pakistan, experts have suggested that coordination platforms could be effective tools for facilitating communication among donors and volunteers during emergency relief [72].

During the COVID-19 crisis, nongovernmental organizations and foundations in Bangladesh collaborated on a single online platform to offer nationwide support [73]. For instance, to address food and medicine shortages among low-income and marginalized communities, Building Resources Across Communities developed a map pinpointing slum areas in Bangladesh, helping donors assist at specific locations [74]. Existing emergency response systems often require internet access and advanced technology, whereas a more feasible service could leverage mobile networks across Bangladesh, enabling communities to reach out via a toll-free number. Toll-free services have been implemented multiple times in Bangladesh [37,38,67,68,73], but these efforts have not yet converged to create a platform for donors and volunteers during emergencies [72]. Our understanding of RMG workers showed that they possess mobile phones but limited skills. Therefore, the technology design should consider a simple mechanism that requires minimal new skill learning.

Design Implication as VOICE: Merging Service Interface and Service Providers

Overview

We propose a technology-based framework design named "VOICE," focusing on consolidating existing support systems into a single minimalist platform, working as a community to assist low-income and digitally low-literate groups, particularly in emergency support and health care, using their existing technology access and knowledge. While advanced AI-based health assessment tools show promise, their deployment in low-resource settings requires careful attention to evidence of grounding and safety evaluation to prevent harm from unverifiable outputs [40]. Our VOICE framework avoids these complexities by providing a simple and human-mediated interface. Table 3 shows how the empirical findings guide the design considerations for VOICE. Then, in the VOICE framework design illustrated in Figure 2, a service interface will collaborate with service providers to offer user-requested services to communities and individuals, and the communication model will be virtual.

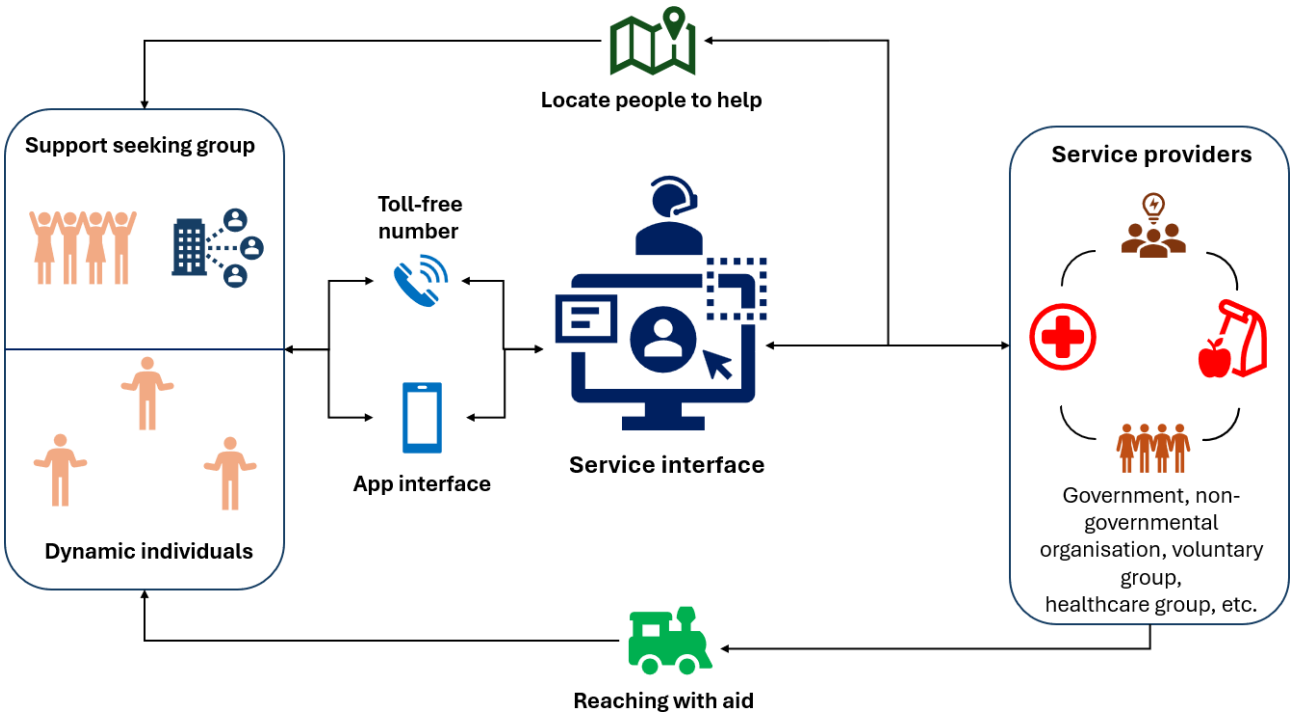


Table . Bridging empirical insights to the VOICE[a] framework design.

Empirical finding	Design implication	VOICE feature
Workers have limited digital literacy and use basic phones (theme 1)	System must function without smartphone or internet dependency	Toll-free number as primary access point
Workers lack access to health care during emergencies (themes 2 and 3)	Need for integrated health support regardless of factory type	Health care provider integration module
Workers face sudden factory closures without communication (theme 3)	Need for emergency alert systems accessible to all	Broadcast notification capability
Workers live in congested areas with shared facilities (theme 3)	Support systems must account for community-level needs	Location-based relief coordination
Workers lack knowledge of available services (themes 1 - 3)	Single, consolidated platform needed	Unified service interface aggregating existing providers
Workers experience financial constraints (theme 1)	Service must be free to access	Toll-free number with no call charges
Workers change locations or phone numbers frequently (themes 2 and 3)	System must accommodate mobile populations	Dynamic user database with flexible contact updates

[a]VOICE: Virtual Outlet for Integrated Community Engagement.

XSL•FO
RenderX

Figure 2. VOICE framework for supporting low-income groups. NGO: nongovernmental organization; VOICE: Virtual Outlet for Integrated Community Engagement.

Service Interface

The service interface will act as a platform that provides all users with a toll-free number, enabling multiple ways to access these services in their native language. This will facilitate interactions between service providers and individuals or groups seeking support. This will allow individuals to request assistance with emergency aid, health care, and related matters. For instance, if someone requests emergency assistance, the service interface can create a location-based database, as has been done in South America to map the supply chain of the offshore wind industry and send the main goods when demand is high [75]. This database can identify nearby individuals who may also need help, enabling efficient distribution of emergency relief. Similarly, if a group seeks health care assistance, the service interface can connect them remotely with a health care platform. At this point, the service interface can initiate the Relief Centre model suggested by Ozen and Krishnamurthy [76] to expand the services, which will include points of distribution, physical capacity such as volunteers, potential inventories to points of distribution, and a triage queue to check victim information before item distribution.

Even outside of crises, service providers can help individuals access the regular health care system at a marginal cost by using the databases available through the service interface. Though it is discussed that emergency medical services development in low-income countries involves understanding the unique needs of diverse communities, requires broad stakeholder involvement to maintain volunteer networks, and can be achieved through low-cost, bottom-up strategies [8], these needs need to be incorporated into the service interface and service providers. The community's mobility is essential, as workers often change locations, contact points, and phone numbers over time. Therefore, community contact points must be flexible and able to adapt to real-time needs, given the dynamic nature of these populations. Stakeholders, such as telecommunications companies, can support and facilitate the service interface model.

Service Providers

We examine the existing service providers in Bangladesh that use various interfaces inspired by best practices. For example, mapping tools are designed to connect donors with needy communities [74]. Some nongovernmental organizations and volunteer organizations contacted low-income individuals to offer assistance [73]. The Bangladeshi government sold rice at BDT 10 per kilogram to support low-income families [77]. There are also health care platforms [38,67,68] that support individuals seeking help. However, many of these services currently use a top-down approach, in which providers conduct community needs assessments. In this proposed technology-based design, we suggest that service providers and interfaces collaborate on a single platform, thereby enhancing the effectiveness of the services offered. This VOICE framework design and its possibilities could ensure that the voices of low-income communities are heard, with implications for future developments.

Addressing Digital Literacy Barriers in VOICE Design

Our findings revealed that while 51% (28/55) of participants had smartphones (themes 1 and 2), actual use was limited to basic calling apps (eg, IMO), with few accessing health services online. This digital literacy gap informed 4 core design principles in VOICE:

- No internet dependency: Workers do not need internet connectivity or data plans. The system operates through standard cellular networks in the country.

XSL•FO
RenderX

- No cost to access: Users do not incur call charges, eliminating financial barriers. This was critical, given workers' economic constraints (theme 1).
- Language accessibility: All interactions can be performed in their native language using simple, nontechnical vocabulary.
- Human backup: Live operators can be available 24/7 for users who cannot navigate automated systems, recognizing that some workers may need human assistance.

By focusing on these aspects, VOICE aims to make support accessible even to users who have never used digital services before.

Limitations and Way Forward

We have acknowledged our limitations for this research. First, we interviewed 55 RMG workers before the COVID-19 pandemic, but we could reach only 12 during the pandemic. This reduction reflects the unprecedented disruption caused by Bangladesh's national lockdown in April 2020, including transportation suspension, worker displacement, and communication barriers. This limited participation limits us from gaining insight into all the unique challenges the pandemic poses. The findings from phase 2 are presented as exploratory insights rather than statistically representative data. Similar to qualitative research, the focus is on depth and theoretical saturation rather than sample size. The data from phase 2 provided a rich and contextual understanding of the immediate impact of the pandemic on a specific group of workers. In addition, such limitations can potentially be mitigated in future emergencies through the following recruiting strategies by Kim et al [78], who recruited rural participants during the COVID-19 pandemic via local pharmacist referrals and community outreach, which helped facilitate communication and build trust and rapport between participants and researchers.

Second, during FGDs, not all participants were equally responsive because we had to arrange large groups, leading a few to remain silent. According to Simmel's [79] theory of group size, large groups result in weaker member involvement and participation. At this point, we noted nonverbal cues (eg, expressions) and brief comments from quieter participants, which were included in the analysis. Silent participants' perspectives were also partly captured through the similarities in experiences expressed by more vocal participants and the consistency of themes across groups. In future research, it is necessary to arrange small focus groups to obtain rich data, primarily from female participants [80]. In addition, social, religious, and aristocratic sectors are relevant for small interviews [79].

Third, following this study, it took approximately 3 years to achieve regular support; however, the necessary support systems during the emergency were not implemented. In future research, we can involve such RMG communities in design sessions, such as co-design or participatory design workshops, where users can cocreate or ideate the design recommendations, highlighting the practical real-world challenges and making the system inclusive [81,82].

Conclusions

This research explored the workplace environment, daily lives, challenges, personal perspectives on health care, and the use of technology by RMG workers, as well as the crisis they faced during the pandemic. We found that many of them neglect their health care needs and require more support from various sources. The complexity of issues arising from the COVID-19 pandemic is significant. The workers expressed significant concerns about job security, food availability, and health care, highlighting the gaps in support that are often overlooked by authorities and themselves. The workers' distress was echoed by the stakeholders. In response, we have proposed a technology-based conceptual framework, VOICE, that suggests workers could connect with service providers through a simple point-of-contact interface, such as a toll-free number. This setup would enable service providers to reach marginalized communities during emergencies or in regular situations, providing the support needed to improve their lives and well-being.

Acknowledgments

The authors thank all their participants for their cooperation and support. The authors extend their special thanks to Dr Kimia-tuz-Zaman from North Dakota State University, and Gazi Fokhrul Islam and Anik Saha for their contributions during this study's design and interview phases. During the preparation of this manuscript, the authors used Grammarly for the purpose of language editing and improving readability. The authors reviewed and edited the suggested text changes and take full responsibility for the final version of the manuscript.

Funding

This study was financially supported by BRAC University, Bangladesh, and logistically supported by the Design Inclusion and Access Lab at North South University.

Data Availability

The datasets generated during the study are not publicly available due to participants' confidentiality restrictions but are available from the corresponding author on reasonable academic request, subject to institutional review board approval.

Abstract

Background: AI is increasingly prevalent within health care; however, its implementation within the hospital setting may come with its own limitations, given the high-pressure and sensitive environment. Barriers and facilitators to the implementation of AI within hospitals have been largely explored quantitatively, and there is a scarcity of qualitative research on the implementation of AI tools to improve air quality.

Objective: This study aims to qualitatively explore, through a normalization process theory (NPT) lens, the anticipated barriers and facilitators to the successful implementation of an AI tool to guide the placement of mitigation strategies to reduce airborne transmission of infections within the hospital setting. Specifically, we sought to (1) understand the day-to-day work of key hospital staff involved in reducing airborne transmission of infections, (2) identify potential barriers to the implementation of an AI tool to guide the placement of mitigation strategies in the hospital setting, and (3) recognize necessary conditions for the successful implementation of the AI tool within the hospital setting.

Methods: We conducted ethnographic observations (n=4) and semistructured interviews (n=18) with hospital staff following preliminary one-on-one meetings and group discussions involving patients, members of the public, national leaders in ventilation working within academic and industry environments, and hospital staff (n=70). Data were collected between October 2025 and May 2026 in the United Kingdom. Interview transcripts, field notes, and summaries from preliminary wider engagement work activities were analyzed in NVivo (Lumivero; version 12) following codebook thematic analysis to facilitate confirmatory triangulation. Findings were organized according to the core constructs of NPT.

Results: Hospital staff understanding of the AI tool and their preparedness to invest time in its implementation varied across those consulted. The anticipated work required by hospital staff to successfully implement the AI tool and its recommended mitigation strategies was identified as a significant challenge for its scalability. Differences in the ways of working among trusts and the competition for limited resources (collective action), and issues associated with hospitals' physical estate (coherence) were seen as particularly problematic. The need for local champions (cognitive participation) was raised as a facilitator, as well as expert validation and the assessment of the AI tool's effectiveness (reflexive monitoring).

Conclusions: This preimplementation study suggests that the successful implementation of an AI tool to improve air quality in the hospital setting depends not only on the effectiveness demonstrated by the AI tool but also on the way trial outcomes are conveyed to hospital staff. Hospital staff anticipate an initial resistance to the AI tool's implementation. Further, the impact of the AI tool and suggested mitigation strategies in workflows, costs, and staff and patient outcomes may be decisive.

Introduction

AI is increasing its prevalence within health care and its adoption is supported by UK health policy, such as the National Health Service (NHS) 10-year plan and the creation of AI working groups to steer the use of AI and speed up its use within the NHS [1,2]. While AI's predominant use has been in medical imaging [3], it has the potential to contribute to other areas, facilitating clinical decision-making, early diagnosis [4], and hospital documentation [5]. This aligns with the NHS ambition to shift "from analogue to digital," prioritizing digital tools, including AI-driven solutions, to promote continuous monitoring and the shift "from sickness to prevention." These shifts are intended to improve population health and the sustainability of health care [2].

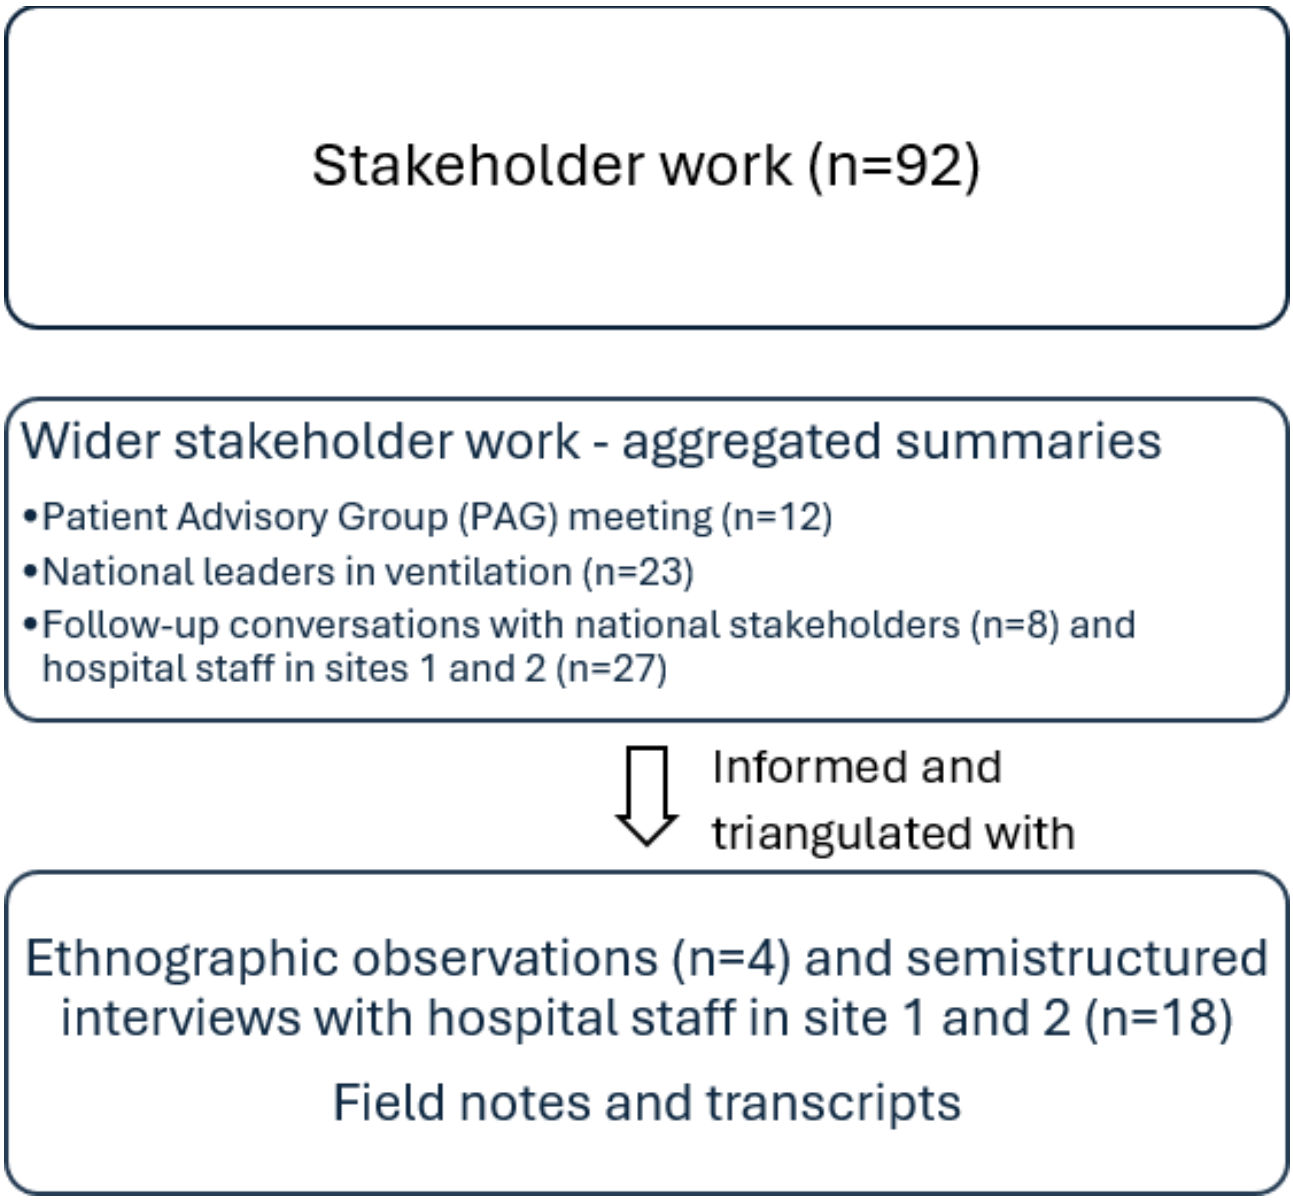
AI-enabled tools have already shown potential in predicting hospital-acquired infections with high accuracy [6]. Early detection and intervention of airborne disease transmission can protect frontline workers and facilitate hospitals working at full capacity by reducing staff sickness. Our wider research team is developing and implementing an AI tool—the Artificial Intelligence Air Safety Tool (AISaT; University College London). AISaT will process data about the characteristics of a hospital room, such as its dimensions and the position of people in the room, to then produce recommendations on where best to position mitigation strategies within that room to reduce airborne infection transmission. Examples of mitigation strategies could include devices such as high-efficiency particulate air (HEPA) filters [7], or equipment such as screens, curtains [8], windows, or doors.

Despite the promise of AI in infection prevention and the potential of qualitative research to help facilitate implementation [9], few studies have focused on qualitatively exploring barriers and facilitators to implementation of AI within hospital settings [10,11]. This is known to be challenging [12], and identified barriers include the lack of trust, issues with generalizability, privacy and maintenance plans, or the previous lack of AI implementation guidelines [13], which have only been recently addressed [14]. When qualitative methods have been used, studies have mostly focused on AI looking to improve patient care directly (eg, by speeding diagnosis) [11,15].

The aim of this study was to explore, through a normalization process theory (NPT) lens [16,17], the anticipated barriers and facilitators to the successful implementation of AISaT, a tool that seeks to protect both staff and patients. This theory was chosen to map the anticipated requirements for the integration of AISaT into daily practice and facilitate trial delivery. By focusing on stakeholder experiences, including those of clinical, technical, and leadership teams, this work seeks to inform strategies that align with the NHS's preventative care vision and support the normalization of such innovations in routine hospital practice.

The study sought to answer the question: how do relevant stakeholders perceive the implementation of an AI tool to guide the placement of mitigation strategies to reduce airborne transmission of infections within the hospital setting? Our objectives were to (1) understand the day-to-day work of key hospital staff involved in reducing airborne transmission of infections, (2) identify potential barriers to the implementation of an AI tool to guide the placement of mitigation strategies in the hospital setting, and (3) recognize necessary conditions for the successful implementation of the AI tool.

Methods



Design

Wider stakeholder engagement activities, drawing on findings from 2 systematic reviews in this area [18,19], were conducted. These comprised (1) an in-person patient advisory group (PAG) meeting, (2) an online workshop with national leaders, (3) follow-up conversations with national leaders, and (4) hospital staff based at 2 hospitals who would be involved in the subsequent clinical trial (trial registration number: ISRCTN12421486). Summaries containing data gathered from the informal conversations (wider stakeholder work) informed recruitment and topic guide development for formal data collection, while contributing to the joint analysis.

Drawing on insights from this wider stakeholder engagement, we conducted formal data collection (ethnographic observations and semistructured interviews) between October 15, 2025, and May 7, 2026, at a large teaching hospital in Greater London and a smaller teaching hospital in an urban town. The focus of this research was on the roles and responsibilities of hospital staff working to keep hospitals free from airborne disease transmission. Data collected at this stage were triangulated with aggregated summaries from the wider stakeholder engagement activities (informal conversations with hospital staff, national leaders in ventilation, and members of the public) as reflected in Figure 1.

XSL•FO
RenderX

Figure 1. Summary of types of data collected.

Wider stakeholder engagement, and particularly informal interviews, compensated for relatively less formal semistructured interviews. Ethnographic observations complemented what was being said during semistructured interviews by allowing us to understand staff's day-to-day work in ventilation. Formal semistructured interviews included questions raised in informal conversations and expanded on current practices, acceptability, and feasibility aspects. Data obtained formally and informally aligned well.

All data were collected before trialing of the AISaT system, so both informal discussions and formal data collection were based on a hypothetical future implementation of AISaT rather than on its actual use or implementation. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used to support the presentation of methods and results [20] (Checklist 1).

For context, AISaT will require the user to introduce details on room geometry, airflow (including the nature of air conditioning if present), occupancy, and mitigations used (air filter, screens, fans, and so on). AISaT then uses computational fluid dynamics (CFD)–based simulations to generate 2D and 3D representations of the entire room, with a color chart showing ranked recommendations (from highest to lowest) based on the likelihood of chosen mitigations to reduce the number of respiratory particles. AISaT may only need to be used once in rooms where occupancy remains similar over time (eg, consulting rooms), while in areas where occupancy changes, it may need to be rerun accordingly. The ultimate decision to place the mitigation strategies where AISaT recommends lies with the human operating the device, who will be provided with alternatives and will need to avoid hazardous placements.

Wider Stakeholder Engagement

The PAG was involved throughout the study. The PAG was consulted on the relevance and priority of clean air within hospitals, and their initial reactions to HEPA filters and to AISaT. Members of the group were recruited through advertisement on the National Institute for Health and Care Research (NIHR) People in Research website, charity

XSL•FO
RenderX

connections, and established patient networks. The interaction with patients was led by SM, guided by Simon Watt and FS.

National leaders were invited to the online workshop and follow-up conversations were drawn from academic, industry, and health care sectors, through connections with members of the trial team and through online searches, because of their contributions to the field of ventilation. The workshop shared the project aims, sought first reactions about the trial, and helped to identify further national leaders in the field and key hospital job roles to target in ethnographic observations and interviews. It lasted 60 minutes to maximize participation by people working in the health service in high-pressure roles. The online workshop was led by YB-M and SM, with support from FS, ZK, and SEC.

The online workshop was supplemented by follow-up conversations, which allowed stakeholders to share more detail in relation to their views. Follow-up conversations were also conducted with people who could not join the workshop, and those who were identified through snowball sampling (n=8 [YB-M: n= 7; SM: n= 1]). After collecting information during the workshop about relevant hospital roles to engage with, the research team scheduled follow-up conversations with professionals in these roles (n=27 [YB-M: n= 25; SM: n= 2]). These informal conversations clarified the contribution of different job roles in keeping the hospital free from airborne disease transmission. A draft summary of barriers and enablers identified through the PAG, national leaders' workshop, and preliminary contacts in hospitals is provided in Multimedia Appendix 1, which is the focus of a separate publication reporting on the development of an implementation strategy for rollout. Further description of the data collection process followed for wider stakeholder engagement is provided in Multimedia Appendix 2.

Ethnographic Observations and Semistructured Interviews

Hospital staff were recruited following a combination of purposive and snowball sampling techniques. Participants in diverse roles (eg, infection prevention and control [IPC], estates, and clinical) were invited to capture the views of all those likely to be involved in the implementation of Air Safety. Potential participants were approached up to 3 times by email. We completed ethnographic observations in the work environment and online semistructured interviews following a predefined internal study protocol. Researchers had no prior relationship with participants. Participants had read a participant information sheet and knew the aims of the study. The researcher introduced themselves and their role in the study and explained the aims of the semistructured interview or ethnographic observation.

Ethnographic observations were used to understand hospital staff's day-to-day involvement in keeping the hospital air free from infection while complementing and facilitating understanding of the content of interviews. Ethnographic observations were unstructured, but a minimal data collection template was used (Multimedia Appendix 3). These were conducted by female researchers trained in ethnographic research methods and with previous experience in ethnography (FS and YB-M). Hospital staff at both site 1 and site 2 (the two trial sites) were invited to participate in ethnographic observations; however, volunteers were only found for site 1. A total of 8 hours of ethnographic observation were conducted at site 1 with the 4 research participants who volunteered to be shadowed. Field notes were taken in situ and transcribed electronically as soon as possible after the ethnographic observation. Interactions with nonparticipants were not included in field notes.

Each semistructured interview was guided by an interview schedule (Multimedia Appendix 4) which had been pilot-tested in preliminary conversations with stakeholders. Two researchers with expertise in qualitative methods (YB-M and SEC) and a background in psychology and molecular medicine conducted the interviews (YB-M: n=9; SEC: n=9). The interviews were conducted iteratively, building on previous insights.

Semistructured interviews lasted on average 33.9 (SD 6.61) minutes (ranging from 25 to 49 minutes; median 33.09, IQR 28.7-38.1 minutes). All interviews were audio- or video-recorded on Microsoft Teams with automatic transcription. The researchers (YB-M and SEC) cross-checked transcripts for accuracy and pseudonymized the data. Given hospital staff's limited availability, interviews were not returned to participants to check their content, but during the interview, summarization and clarification were used instead.

Semistructured interviews concluded when thematic sufficiency had been reached, considering input both from semistructured interviews and previous informal conversations with hospital staff from the same hospitals. No interviews were repeated. Participants did not provide feedback on the findings.

Analysis

Ethnographic observations and semistructured interview transcripts were analyzed using codebook thematic analysis [21], which sits between coding reliability and reflexive approaches of thematic analysis [22], in NVivo (Lumivero; version 12) [23]. YB-M coded 2 interviews and developed a preliminary coding framework inductively that was presented and discussed with FS. The rest of the ethnographic observations and semistructured interviews, and the wider stakeholder engagement work, were coded by YB-M applying this framework. Coding was conducted iteratively, and new codes and refinements were incorporated and discussed with the team while analyzing the remaining data. Subthemes were organized according to the core constructs of NPT [16,17,24]. We selected NPT to understand how the use of AISaT would need to be embedded in the day-to-day routines within the hospital, rather than focusing on a list of elements that could influence its successful implementation. However, we have used the Consolidated Framework for Implementation Research (CFIR) in a separate publication to develop the implementation strategy for rollout and the Non-Adoption, Abandonment, Scale-Up, Spread, and Sustainability (NASSS) framework to understand how AI implementation was affected by different factors in previous research [19].

We completed the following steps: (1) familiarization with the data started during data collection and continued through successive readings of the transcripts and field notes; (2) generating initial codes involved inductive coding of the data;

XSL•FO
RenderX

(3) refining the codebook led to the organization of codes into units of meaning, still quite attached to the data and similar to what would have been topic summaries; and (4) the NPT constructs were then brought into the analysis and initial codes were reexamined, searching for more interpretive content relevant for each of the constructs.

Different data sources were analyzed together, adding depth to the analysis. Summaries of data from all informal conversations, PAG meetings, conversations, and workshops with national leaders were aggregated with an indication of the respondents supporting it. Feedback from wider stakeholder engagement was initially analyzed separately, leading to the generation of summaries and informing recruitment and topic guide development for ethnographic observations and semistructured interviews. For instance, informal conversations with stakeholders suggested different hospital staff needed to be involved in deciding on the use of AISaT. Ethnographic observations suggested that those staff would be part of committees that would review and decide whether changes or the introduction of AISaT would go ahead. Subsequent semistructured interviews tried to unpack who would be leading the implementation and cascading those decisions at the local level. The aim of this study was not to quantify responses; instead, we have indicated within the findings section the agreement or disagreement between data sources, or the origin of the data supporting the different themes.

Rigor

The workshop with national leaders was recorded to facilitate accurate note-taking by researchers (YB-M and SM) and support credibility. Likewise, semistructured interviews were recorded and transcribed to capture hospital staff's accounts accurately. Field notes were taken during each follow-up conversation with national leaders and informal conversations with hospital staff. Field notes were then summarized via a Rapid Research Evaluation and Appraisal Lab (RREAL) data collection sheet [25] that reflected areas of agreement and disagreement, as well as areas requiring further data collection. Informal conversations were not audio-recorded as they were exploratory and aimed to understand the level of involvement of different professionals and their initial reactions. Once relevant staff had been identified through informal conversations and the study had received ethical approval, semistructured interviews were conducted with further staff in relevant roles to avoid participant burden, enrich data collection, and facilitate confirmatory triangulation. This approach, together with the ethnographic observations, allowed a more diverse and prolonged engagement of the researcher with hospital staff in relevant roles. The resulting sample size of the interviews was smaller but more relevant than those involved in informal conversations. To reinforce dependability, we kept a record of every interaction with stakeholders in a spreadsheet, field notes were made during informal conversations and ethnographic observations, and interview transcripts were checked and stored together to facilitate an audit trail. An entry was added to a reflexive diary after every interaction with the stakeholders, regular discussions were held with the rest of the research team, and quotes from interviews are provided throughout the findings to ease confirmability. Finally, while the aim of this study was not to produce generalizable findings but to inform the development of AISaT and the next stages of the trial, we described in detail the types of data collected and the setting, so other researchers can gauge the contextual similarities.

The implementation research team consists of experts in digital health, implementation science, medical sociology, and qualitative research. Researchers involved in data collection and analysis were not involved in AISaT's development other than by providing our insights to members of the wider team, including engineers working on the development of AISaT. Hence, our knowledge of AISaT was limited to the information shared with participants and discussed during interviews.

Ethical Considerations

The Air Safety Trial was approved by the Health Research Authority and Health and Care Research Wales Ethics Committee (ref 25/EM/0156). All participants involved in ethnographic observations and semistructured interviews provided informed written consent.

Results

Stakeholder Characteristics

We involved 12 public contributors (through the PAG) living around the Greater London area. All have a long-term condition and experience of care in multiple hospitals. Contributors were aged between 20 and 80 years, included 8 women and 4 men, self-identifying as Black, African, Caribbean, or Black British (n=4); Asian or Asian British (n=4); and White (n=4).

A total of 58 stakeholders were involved in conversations around the project and its potential implementation: 23 were involved in a workshop with national leaders (including senior NHS staff and policymakers, industry experts, and academics), and 8 national leaders took part in follow-up conversations, such as the 27 hospital staff who were identified either using online searches or purposive sampling within the 2 clinical trial hospitals.

Ethnographic observations were conducted with 4 hospital staff and semistructured interviews with 18 staff members, including 11 male and 11 female staff from Black, African, Caribbean or Black British (n=2), Asian or Asian British (n=8), and White (n=12) ethnic backgrounds. Staff interviewed had not been observed. Of 56 hospital staff members initially approached for observation and interviews at site 1, 5 declined to participate (feeling other colleagues were better placed to respond [n=1], having no time [n=4]). A further 22 did not respond to our contact, and with another 7, communication was lost after having expressed initial interest.

The job roles of those observed or interviewed were clinical (n=11), IPC (n=3), estates (n=6), and roles within the management of the hospital (n=2). Among those interviewed who shared job-related details, they had been in post for an average of 10.4 (SD 7.32) years (min=1; max=26), and most ranked the importance of ventilation within their roles as high (min 1 – max 10): 1 or 2 (n=1), 4 (n=1), 8 (n=3), and 10 (n=4).

Hospital staff interviewed or involved in follow-up conversations as part of the wider stakeholder work described

XSL•FO
RenderX

several tasks undertaken as part of their role to reduce airborne disease transmission (summarized in Table 1). Their main role was isolating or managing patients with known airborne-transmitted infections, placing them in appropriate spaces (according to their risk level), or advising others on how to do this.

All stakeholders and participants provided their views on the hypothetical implementation of AISaT rather than during or after interacting with it. This work informed further development of AISaT prior to its testing and rollout.

Table . Hospital staff's reported roles in keeping the hospital free from airborne disease transmission.

Category	Specific tasks
Room usage and air changes	• Assessing room-use changes • Checking that required air changes per hour are being achieved within rooms
Ward and patients' oversight	• Management and placement of patients with known airborne-transmitted infections (including isolation prioritization) • Conducting ward audits • Daily review of side-room usage • Ensuring adequate testing of patients
Staff supervision	• Ensuring staff are aware of infections and alerting IPC[a] when needed • Ensuring compliance with IPC training and practices • Ensuring staff have adequate protection and providing related advice
Ventilation system management	• Ensuring the ventilation system is functioning adequately • Following Health Building Notes and Health Technical Memoranda
Liaison with other teams	• Continuous liaison with estates regarding ventilation issues • Attending multidisciplinary quarterly ventilation meetings within the trust

[a]IPC: infection prevention and control.

Main Findings

Findings are organized according to the 4 constructs of NPT: coherence, cognitive participation, collective action, and reflexive monitoring (Table 2).

XSL•FO
RenderX

Table . Summary table.

NPT[a] construct	Focus	Subthemes	Key insights	Expected enablers	Anticipated risks and barriers
Coherence	Understanding how the intervention could work in the hospital environment	• Current practices to mitigate airborne disease transmission • Shared goals • Anticipated barriers and facilitators to adoption of AISaT[b] • Anticipated requirements for AISaT's implementation	• Understanding of value varies • Organizational staff are optimistic, while clinical and IPC[c] staff are more skeptical or cautious	• Use in outpatient areas • User-friendly interface • Inclusion in national guidelines • Senior leadership buy-in	• Conflicts with fixed ventilation systems • Old NHS[d] building infrastructure • PPE[e] and handwashing seen as higher priority • Focus on aerosol particle dispersion versus air changes
Cognitive participation	Developing interest in the implementation and enhancing its relevance	• Decision-making and ownership of AISaT • Content and design of AISaT • Timing of AISaT's implementation	• Engagement depends on multidisciplinary buy-in and having designated "champions" to lead	• Multidisciplinary decision-making • Local champions to cascade information • Potential (though risky) mandated use	• Lack of staff agency or ownership • Staff burnout and workload • Financial constraints • Not seen as a top priority in comparison with patient care
Collective action	Planning for the implementation and rollout	• Identification of resources • Generalizability and sustainability	• Implementation is anticipated to be hampered by technical fragmentation and the cost of maintaining mitigation strategies	• External contractors to manage tool (reduces staff workload) • Integration with EHRs[f]	• Costs of potential implementation and maintenance of mitigation strategies • Restricted data access • Expected fragmented AI tool use within trusts • Lack of universal EHR systems
Reflexive monitoring	Planning for the evaluation and refinement	• Providing key metrics and assurances • Futureproofing AISaT	• Success is expected to be facilitated by long-term evidence and expert validation of effectiveness	• Expert validation • Strong evidence from clinical trials	• Lack of a clear plan for future refinement support • Uncertainty regarding postproject sustainability

Coherence (How Do Stakeholders Understand AISaT and Its Recommended Mitigation Strategies?)

Current Practices to Mitigate Airborne Disease Transmission

The most common mitigation strategy used is the building management system (or air handling units) that represents the centralized ventilation system of the building. Our ethnographic observations captured how different units provide clean air and extract used air from hospital areas. Typically, the placement of ventilation outlets is decided by architects, and any changes to these require an authorizing engineer's sign-off.

> *HEPA filters available [within ventilation outlets] all have been allocated at design stage. It could be possible to uninstall as needed, things can change, and more things can be added. The authorising*

XSL•FO
RenderX

> *engineer (AE) for ventilation would need to agree and sign off.* [Ethnographic observations, informal conversation, estates, HS104]

However, some interviewees raised concerns where portable HEPA filters have been trialed within the trust, mainly related to space constraints where they can obstruct staff's work or pose a hazard to patients.

> *if they [agitated patients] move the locker or they're able to reach that and push it, it poses quite a danger of the actual physical unit being dropped and damaged, but also it then causing harm to somebody if it falls on them.* [Semistructured interview, clinical, HS102]

Further concerns included the impact of a device, such as a portable HEPA filter, increasing room temperature and noise; competing for limited sockets; lacking evidence proving their effectiveness; taking significant time to clean the air; requiring maintenance plans and a large number of devices in wards; and their associated costs. Despite these reservations, staff who had HEPA devices within their work environment agreed they would be happy to have HEPA devices affixed to walls.

Other mitigation strategies reported included: prioritizing isolation of potentially infectious individuals, faster patient testing, improving hand hygiene, reducing the number of visitors when necessary, using personal protective equipment (PPE), constructing further isolation single or side rooms in new buildings, allowing longer cleaning times after conducting procedures with patients with certain infections, and using curtains or transparent partitioning screens. An interviewee flagged that some of this equipment is hardly being used after the COVID-19 pandemic due to limited storage and risk of falls for patients though. Also discussed in the interviews was that some spaces contain or have tested air filtration machines (such as HEPA mobile devices); however, this is not a generalized approach across the hospital.

> *As far as I know there are some units like I think dental units that have filtration machines. But it's not something that we would routinely put in all...areas such depends... on the risk assessment of what sort of procedure they're going to undertake in the room, the size of the room, obviously. What's the current air change? What's the supply and extract...within the room. So yeah, we have some mitigations like filtration machines, but they're not widely used...* [Semistructured interview, IPC, HS110]

The NHS estate is generally old and comes with its own limitations (eg, lack of ceiling space, limited ability for new infrastructure projects, and limited electrical supply and clinical space).

> *...when we build new buildings (...) there's always more and more required from an engineering point of view. (...) you end up with a situation that (...) there's just no space. (...) a good idea is to look at the ceiling heights and make sure that you've got more space. The problem is, the more space you have and the higher the building, the more expensive it is...* [Semistructured interview, management, HS101]

Natural ventilation was not generally recommended but does seem to be the only option in some older buildings. Despite this, some staff in the older buildings had to work with sealed windows due to nearby building works.

Overall, mitigation strategies were welcomed as a way of protecting staff and patients, and staff were happy with current strategies in place but did share that they would appreciate further isolating rooms and "20 air changes that would be great. (...) that was the envy that I held for other areas. But in terms of [wanting further] technology, not really" (semistructured interview, clinical, HS103).

Hospital staff also reflected on the high costs of enhancing ventilation, the limited impact of mitigation strategies on air changes, and the limited number of isolation rooms. Due to financial constraints and the need for space, sometimes hospital areas have been repurposed without following the required procedures, resulting in tension between teams.

> *...they'll just change the use of a room, but obviously there's a process to go through to do that, to make sure it's safe, but not everybody understands that, and to be honest, they think (...) it's a bit of a fuss, and they know it's going to cost them money (...) And if they don't have any money, but yet they desperately need to do something in a space because it's the only space they've got, they're just going to go ahead and do it.* [Semistructured interview, management, HS101]

Shared Goals

Hospital staff interviewed reported that the aims of AISaT were a good fit with the trust's overall goals of keeping staff and patients safe. Individuals involved in the wider engagement work raised that hospitals are perceived as risky spaces where people can catch infections, so they need to be protected, prioritizing the most vulnerable. Staff interviewed also described that the AI tool could be a source of reassurance to demonstrate the effectiveness of existing practices and support faster decision-making.

> *I think it would give everyone reassurance. Certainly, in terms of pandemic or significant heightened risk, it would be helpful, not really for the confidence of the staff, but also the safety of the staff. And it would overcome the challenge we have in not being able to change the footprint of the healthcare facility.* [Semistructured interview, clinical, HS103]

Interviewees were positive about the potential impact of AISaT on their work, as it would make their environment safer, if it did not take a lot of their time to input the data into AISaT. A couple of staff raised that AISaT could guide hospital staff but also architects and engineers to keep the hospital air clean and optimize staff capacity and space use.

> *If we had a tool like that (...) every time that you had a new space (...) you could run the whole of the design through the AI software, and it would identify where you may (...) add in things at the base build level (...)*

XSL•FO
RenderX

> *I can't see a problem with using models to help to help give you the optimum design for a room. It's a good idea.* [Semistructured interview, management, HS101]

Anticipated Barriers and Facilitators to Adoption of AISaT

Hospital staff observed and interviewed, and wider stakeholders, pointed out that new buildings still have ventilation issues, but that it may be easier to implement AISaT in these settings as they are more likely to have standardized room measurements to comply with the latest regulations. Hospital staff also raised that AISaT would be particularly valued in areas where ventilation cannot be improved systemically across the site (eg, old buildings).

> *...in an ideal world, we would have something like a built-in air conditioning system or something that was systemic across the building. But being such an old building and I think the electrical grid is the reason why we couldn't have anything more systemic built-in. So, we're having to rely on things like windows and maintaining good infection control with our isolation in our side rooms...* [Semistructured interview, clinical, HS102]

Concerns related to staff resistance were raised as:

> *it is quite tricky in a Trust to get them [staff] to accept changes like this and to get them to think it's worthwhile because they can't. They don't necessarily see the value of it.* [Semistructured interview, management, HS101]

Not seeing a clear benefit from AISaT and its recommended mitigation strategies or not experiencing an immediate benefit were anticipated to be the main barriers to staff engagement. Additional anticipated barriers included the lack of awareness and knowledge around ventilation and the impact that the positioning of mitigation strategies can have; limited digital understanding and guidance; lack of preventative mindset; and limited trust or confidence in AI in general. In contrast, some hospital staff felt the pandemic had raised staff's awareness of ventilation, and they were now actively requiring ventilation improvements within the trust. Trust in AI was also described as a potential facilitator for the adoption of AISaT, as staff reported AI is becoming more present in daily lives and at work. Hospital staff's workload could be a source of staff resistance; however, if the AI could reduce workload, it could be seen also as a facilitator.

Some hospital staff interviewed and involved in wider engagement work referred to inpatient areas or wards as areas where the potential implementation would not be a priority given the number of people working within those areas, with the associated movement, the lack of space, connectivity issues within hospitals, and the number of beds which would require several HEPA devices. Wider stakeholder engagement work involving hospital staff encouraged the use of mitigation strategies already existing within the wards, and that AISaT should consider the space available and size of any new suggested strategies. The potential implementation of AISaT in outpatient areas, isolation rooms, labs, or neonatal spaces was more acceptable.

> *...you have 6 - 7 patients in there and then some patients, they bring quite a lot of their stuff...they put a lot of things in their cupboard and we have only a small one (...) they need to consider... space (...) It's another tool [HEPA device] that they don't see any results from it. It's just there physically. (...) they're still getting sick. They're still getting infection (...) I don't think anything would eradicate that. They don't see any success to it. They're just thinking, you know, it's another thing that's occupying the space of the patient, that it's unnecessary. It's another tool that...they have to make sure it's on (...) let's be honest, it's not a priority for us to do that. It's not our job...to do that (...) it shouldn't be us who needs to check it.* [Semistructured interview, clinical, HS108]

Besides some clinicians not feeling that dealing with AISaT and the associated mitigation strategies would be part of their role, an interviewee was struggling to think in what area of the hospital the AI tool could be of use:

> *...[AISaT] it's an interesting tool... in certain areas like theaters or operating rooms I don't think they would be useful because if the air changes... will have to depend on the... centralized ventilation system, because...they're essentially critical departments...With the AI tool, I'm not sure where we can use them.* [Semistructured interview, IPC, HS110]

Stakeholders mentioned that PPE may be seen as a cheaper alternative to the mitigation strategies AISaT may offer. This was in contrast with several staff members mentioning the inconvenience of working with PPE: "It's not amazing, to be honest, if you can imagine doing quite a difficult procedure over a pronounced amount of time wearing masks and PPE is not amazing." (semistructured interview, clinical, HS112), particularly in buildings with poorly balanced temperatures.

Hospital staff did not perceive the need for further mitigation strategies in their workplace, and some failed to see the point of AISaT. However, highlighting AISaT advantages, such as staff and patient benefit and cost reductions, may be needed to make AISaT attractive to hospital staff (see the "Reflexive Monitoring" section).

> *People's time is the crux. (...) you can usually win hearts and minds from people if they can really see a benefit to a bit of effort that they might have to put in during implementation. But if they can see that this is going to reduce my staff sickness is going to mean I've got less patients getting cross infected on the wards. And I'm going to have my beds all open and not closed due to infection. I think they're massive pluses.* [Semistructured interview, management, HS111]

XSL•FO
RenderX

Anticipated Requirements for AISaT's Implementation

Hospital staff and wider stakeholders suggested using a series of strategies that could facilitate implementation and a future rollout of AISaT. The most frequently discussed strategy was gaining buy-in from senior staff (eg, the chief executive, IPC director, and authorizing engineers), board members, and champions on the ground.

> *Your best bet is to go to the director of infection control and prevention. If he was interested and if he thought it was an advantage, I would say that would be a good place to start. (...) If you could get [Chief Executive] interested, obviously that would be the best person (...) if he was interested and thought it was a good idea and it was protecting his patients.* [Semistructured interview, management, HS101]

Clear communication was recommended, with staff and patients, about what is needed from users and about AISaT complementing human decision-making. Also raised was the need to transparently report how AISaT is better than a human, how the AI works, and clarity on its benefits as well as its limitations.

Wider stakeholder work suggested that gaining support from recognized bodies would also be required, through appearance in guidelines such as NICE (National Institute for Health and Care Excellence); dissemination at national meetings (National Clinical Engineering, Ventilation Teams Meetings); and having the support of medical organizations.

Providing training on AISaT to hospital staff who would use it or work around it could facilitate its uptake and build trust in the AI tool. Ensuring all staff are involved in training could be positive, to promote inclusivity and facilitate the acceptability of AISaT. Stakeholders thought training should include ventilation, the relevance of positioning the mitigation strategies, and AISaT itself. However, one interviewee doubted the need for training as they envisaged the implementation of AISaT as a one-off interaction with an external contractor. Another participant cautioned that colleagues may not react well to training on ventilation when they are faced with poor ventilation levels, high temperatures, and are unable to open (sealed) windows or use fans due to electrical supply limitations and scarcity of sockets.

> *I think it [training] would be beneficial, but I think the response would be...interesting. (...) we've had such challenges every summer...where it's been very hot on the ward and we've had to use fans and...We're trying to as best as we can to isolate these patients who've got airborne infections to then talk about ventilation and the joys of ventilation. I think that may not be received as well.* [Semistructured interview, clinical, HS102]

Hospital staff were generally cautious and expressed concerns about the need for appropriate validation and assurances that the AI would be providing safe recommendations. This caution was not necessarily negative, as "proper use of it could really help ease our workflow (...) having it do the recommendations for you and then you just check it makes it convenient" (semistructured interview, IPC, HS113). However, some interviewees stated they could not comment on the acceptability and potential to implement AISaT without having seen it, and knowing in detail how it had been trained, or having a summary of its impact when used within the hospital environment.

Cognitive Participation (How Will Staff Engage With AISaT and Its Recommended Mitigation Strategies?)

Decision-Making and Ownership of AISaT

It was agreed that early staff engagement would be required, not only to gather their views to develop AISaT but to facilitate the decision-making process of who should take ownership of the AI tool. Like current practice, the development of a multidisciplinary working group would ensure the decision-making was not "down to a person" but to a multidisciplinary team to determine whether AISaT should be used, and the details on when and how.

First funding would need to be sought. Then, the contractor (HS104 and their team) would gather evidence and information about AISaT. Then they would present the idea to the Committee. If the Committee agrees, then they would need to ensure buy-in from IPC. Discussions between estates, medical, and IPC teams would need to happen to explore what effect this is going to have (eg, having to close an area to assess the impact of adding new HEPA filters or placing them where AISaT suggests) and would provide suggestions as to how this effect could be managed. Nine out of 10 times medical teams and IPC will say no; the area cannot be closed, and there will need to be negotiations until there is agreement between all parties. This may mean that the implementation does not occur soon, as pointed out during ethnographic observations.

A few interviewees suggested a similar process of group decision-making when choosing among the recommended mitigation strategies suggested by AISaT.

> *...the decision will not ultimately be from one person. It's always a multidisciplinary thing.You'll have to present the options to the end users, to other experts to see what is really the best option in practise.* [Semistructured interview, IPC, HS110]

> *Say it's showing that we need HEPA filters... 100% estates, finance, infection control would all want to be involved in that. And it wouldn't be...just down to the ward manager to say, yeah, we're going to buy four HEPA filters for this ward.* [Semistructured interview, clinical, HS203]

Another interviewee suggested that the implementation of AISaT should come as an imposition from IPC rather than an exercise requiring hospital staff's engagement and acceptance.

> *I think for this realistically it wouldn't so much be staff engagement and encouragement, it would be imposed. So, if it's supported, it would be supported on one ground or another, be a patient safety or financial and they would be imposed.* [Semistructured interview, clinical, HS103]

On this line, another interviewee wondered whether the strategies shared by AISaT would be recommendations

XSL•FO
RenderX

(something staff could choose to follow or not) or actual policy they would need to follow. If the latter, current policies in this area come from the trust and from IPC, so any AISaT recommendations should be aligned with those existing policies.

Despite most interviewees being in favor of a multidisciplinary effort involving IPC, clinical, estates, and operations for AISaT's implementation, none of them suggested themselves or their team would be involved in leading the implementation of a tool such as AISaT. Only one IPC staff member agreed when prompted by the researcher that IPC may be best positioned to lead on AISaT's implementation.

> *Well, it could fall under IPC... 'cause sometimes with estates, if we let them lead on it...some trusts outsource them. So, I do get the point of IPC trying to lead on this... I would agree, it's part of the things that we check and that we try to enforce as a team to ensure that the ventilation throughout the hospital is good. So yeah, I think we can take a lead on it.* [Semistructured interview, IPC, HS113]

Most hospital staff involved in interviews and wider stakeholder work placed ownership on IPC: "infection control [IPC] (...) can oversee the project because (...) when it comes to infection, they need to be involved in that" (semistructured interview, clinical, HS109), given their cross-trust presence. Contrasting this, an IPC staff member insisted this would be a role for the estates team, who have expertise in ventilation and lead critical ventilation meetings.

> *I think it should be a multidisciplinary approach on the initial stages until we all have a full understanding of...how it works in practise. But I think ultimately it will have to be estates leading on it. Obviously with our...expert input from ...clinical areas, IPC, ventilation engineers...Anything ventilation related would fall under estates responsibility.* [Semistructured interview, IPC, HS110]

> *I think the IPC would probably come to someone in estates and we would accompany them to that space, and if there's a measurement issue, we could figure that out... But they [IPC] would decide where is the best place to put any device that might impact have a clinical impact on patients or staff.* [Semistructured interview, estates, HS116]

There were mixed opinions among hospital staff involved in interviews and wider stakeholder work who felt that, as long as staffing costs were funded, then the inputting of data into AISaT could fall under estates, engineers, or IPC.

There was more agreement in the cascading down of decisions where estates and facilities teams would be the ones in charge of cleaning, maintaining, and replacing the recommended devices or equipment to mitigate airborne transmission of infections. Interviewees further raised that if the HEPA filters are considered nonmedical devices, then installation could come from estates.

Content and Design of AISaT

There was a difference in opinions on how AISaT should be designed to facilitate its uptake. Some hospital staff thought a ranking of potential mitigation strategies that are the best at preventing airborne transmission of infection should be provided. They felt that, regardless of the lack of availability within the trust, staff having a comprehensive list may help the trust push to purchase these items, especially in preparation for a future pandemic. Others suggested a ranked list should only contain mitigation strategies available within the trust as it may create anxiety among staff if they do not have access to the best rated options, or they may get "overwhelmed" (HS113) by a list of endless options.

Interviewees shared some technical factors that may help with the implementation of AISaT; this included ease of use, integrating AISaT within NHS systems (or whitelisting websites or the AI tool); compatibility with diverse devices such as computers and iPads; facilitation of automatic data entry through LiDAR software to capture room dimensions, or importing patients' data from electronic health records. Further suggestions on AISaT's functionality included its ability to perform a risk assessment for the use of physical separation equipment and an air filter (eg, HEPA device) with a prediction model to alert staff of outbreak risks. Also suggested was demonstrating through AISaT the variable cost of a mitigation strategy, which could help to choose from what is available in the market. The ethnographic work suggested it would be helpful if AISaT could keep a record of HEPA filter performance and dates of installation, and other stakeholders suggested AISaT could include reminders to staff to attend PPE fit testing. It was suggested that AISaT should account for movement and that it should consider the fact that staff may be contagious. This is particularly relevant in wards with more vulnerable patients who are usually seen by a range of staff. Two clinical hospital staff members also reflected on the need to involve clinical experts to tailor the AI tool to the needs of different areas with different ventilation needs.

> *...you need people or clinical staff that understand their local areas so you can tailor it for the area that you're using it in because each procedure each diagnosis, medical diagnosis, etcetera has a different outcome for every different area* [Semistructured interview, clinical, HS112]

Timing of AISaT Implementation

Among interviewees, many agreed that implementation of AISaT was not a priority now, but it would become a priority in future pandemics and, hence, highlighted the relevance of this research. However, about one-third of those interviewed felt AISaT is currently relevant for the prevention of infection.

> *I'd hope that you could use it every day, because I'd hope it would really help us to prevent cross infection, prevent outbreaks...So I think... for prevention, be proactively using it... I'm sure it's useful...in a pandemic or an outbreak as well. But...I'd want to use it before you got to that point. I'm completely*

XSL•FO
RenderX

with...try to prevent it and control it. [Semistructured interview, management, HS111]

Collective Action (How Will Staff Work to Implement AISaT and Its Recommended Mitigation Strategies?)

Identification of Resources

Often, hospital staff were unclear about who would fund the potential implementation and rollout of AISaT and its recommendations. When hospital staff had suggestions, they mentioned:

> *...maybe NHSE can provide a sponsorship if we're looking into a bigger perspective of the whole UK.* [Semistructured interview, clinical, HS109]

However, there were also suggestions that "executives would agree to fund from a central pot because it's not one area (semistructured interview, management, HS111)" or that Integrated Care Boards (ICBs) should be able to provide funding or suggestions of possible funding. The need to develop a business plan to cost staff and time required for the implementation of AISaT and its recommendations was mooted.

Likewise, hospital staff interviewed and involved in wider stakeholder work raised concerns about the costs to maintain the mitigation strategies (eg, HEPA filters), as well as the impact of maintenance on staff's workload and capacity. They also referred to the high costs of making changes to ventilation systems and that any changes must meet the latest guidelines or Health Technical Memoranda (HTMs). Conversations reflected the items' costs (eg, AISaT and implementing its recommendations), the associated staff costs (eg, data entry into the AI tool, delivering on maintenance plans, and so on), and concerns as to whether the trust would be willing to invest in AISaT and its recommended mitigation strategies even if the trial proved its effectiveness.

> *I think with the amount of (...) maintenance involved like routine cleaning, routine maintenance, reporting of equipment that's faulty, it's already a bit of a challenge just on day-to-day with clinical items that patients use(...) It can be quite challenging on a large [busy] ward (...) and a substantial service to then add another item in there that isn't immediately impacting the day-to-day tasks or benefiting the patients in that immediately visible way. It can be a barrier.* [Semistructured interview, clinical, HS102]

As previously mentioned, an interviewee envisaged AISaT being used by an external contractor, as the rooms of interest would usually maintain their size and characteristics, and so the need to enter data into AISaT and to choose a recommended mitigation strategy was perceived as a one-off action. However, the one-off use was shared by most interviewed: "you probably only use it once, and that's probably it (semistructured interview, clinical, HS202)," who would only use it again if there was a change in the placement of objects in the room. Such implementation was seen as advantageous as it would not impact staff's capacity or require further training. In successive interviews, further hospital staff members agreed this could be a feasible option to facilitate implementation without negatively impacting staff's workload.

> *...Like a contractor. (...) Yeah, like I said... it's just another thing to think of and we already have a load of things...you know, pressured. So you...don't want to commit to something that you can't really [do].* [Semistructured interview, clinical, HS108]

Generalizability and Sustainability

Hospital staff interviewed raised that communication among staff could become a barrier to the implementation of AISaT when different members of staff work on similar issues but from different teams, such as the NHS and contractors working together. Also raised was fragmentation in how different trusts incorporate new devices, and a lack of guidelines on how to integrate new digital developments into hospitals, which would take a long time to develop. Unsurprisingly, the acquisition of funding for AISaT's implementation may also be different across trusts.

Access restrictions were also identified as barriers by hospital staff involved in wider stakeholder work regarding data on room characteristics (eg, size, height, objects in the room, and ventilation characteristics) and floor maps. Difficulties may also arise when attempting to import data, as floor maps are often in PDF format instead of in electronic formats that could be easily exported. Different hospital buildings, even within the same trust, also have different levels of data available within their records. This would, therefore, require manual data entry, which would require costing staff time.

The ethnographic work suggested that the potential implementation of AISaT and its recommended mitigation strategies would need approval from multidisciplinary committees. The implementation timing would need to be agreed, as it is not uncommon for projects to be approved but face delays in green lights for actual implementation. Within the approval process, the different management systems in different buildings (eg, privately funded or NHS-maintained) would need to be factored in, as there are differences in these processes even for buildings within the same trust. In privately funded buildings, for instance, there is the need to factor in the landlord's position regarding the implementation of AISaT and its mitigation strategies.

> *Don't forget that this building is not owned by the NHS. It's rented. They [Landlords] would need to be in agreement with it, so you'd have to bring them in if potentially you were thinking about that [installation of mitigation strategies].* [Semistructured interview, clinical, HS112]

Reflexive Monitoring (How Will People Assess the Success of AISaT and Its Recommended Mitigation Strategies?)

Providing Key Metrics and Assurances

Hospital staff interviewed referred to the need to prove the effectiveness of AISaT, addressing the 3 NHS priorities: costs, effectiveness, and implementation practicalities. Key metrics should include those of interest for IPC, such as the extent

XSL•FO
RenderX

AISaT reduces infections; whether it has an impact on staff, patients, or both; whether it leads to bed-day savings or fewer closed beds, fewer appointment cancelations (in outpatients); and reduction of outbreaks. But also the extent to which it is effective, such as the impact on air changes per hour; its energy and financial savings (eg, reduction of costs to ventilate an area). It would need to produce benefits on safety grounds but also need to lead to financial benefits.

> *...they're pushing for sustainability and they're pushing for capacity, bed capacity, patients flow and reduction of infections as such. And it would help the hospital if it's done properly, that they have seen all the areas of concerns before they actually invest into something. Because...we've seen some projects that had been invested, they've spent quite a lot of money, but it hasn't been pushed through...before the commitment to be set out there, they really need to make sure that this is... worth it to the benefit of the hospital, the patients and the staff.* [Semistructured interview, clinical, HS108]

Beyond the health economics assessment, hospital staff also anticipated the need for expert validation to explore to what extent AISaT's recommendations are aligned with gold standards, and evaluate differences between human and AISaT, to explain why AISaT is better.

> *As long as we're happy that it's...tested and validated and that there's always the double check until we've got confidence that it does actually predict. I think there's got to be that validation process continually (...) sort of accuracy tolerances built in. (...) Because it's there's a lot at stake if it takes us to the wrong decision or the wrong action.* [Semistructured interview, management, HS111]

Participants also suggested the need for live monitoring of the quality of the air in parallel to the implementation of AISaT and its recommended mitigation strategies.

> *If introducing HEPA, there would need to be a live measurement of pressure, as this will tell them when the filter is filled and needs changing.* [Ethnographic observations, notes from informal conversation, estates, HS106 and HS107]

Future-Proofing AISaT

Interviews with hospital staff and conversations with those involved in wider stakeholder engagement referred to the need to develop AISaT to be able to adapt to different technologies (eg, PC, phones, tablets, and advancements in these devices), settings (eg, different hospitals and room characteristics), and policy, as these are likely to evolve with time. When considering preparedness for the future, an individual involved in the wider stakeholder engagement work raised the need to confirm who would be responsible for refining and providing technical support to hospitals following the research trial or development phase of AISaT, showing concerns about the ongoing feasibility and ownership of AISaT.

Discussion

Principal Findings

This paper explores key stakeholders' anticipated barriers and facilitators to the implementation of AISaT to improve its acceptability at the implementation stage [11]. Our findings, organized around NPT, suggest that while AISaT and its recommended mitigation strategies are generally positively received, their wide implementation may be hindered by its associated maintenance and staff costs; the lack of perceived need and immediately observable benefits; and organizational differences within trusts and hospital buildings.

Coherence (How Do Staff Understand AISaT and Its Recommended Mitigation Strategies?)

Coherence was variable across hospital staff. While hospital staff in organizational roles anticipated AISaT's usefulness in their daily work, hospital staff in clinical and IPC roles were more divided on the value of the AISaT tool, with some reluctant to share their views on AISaT's potential prior to reviewing results from a clinical trial. This may reflect staff not seeing the clinical need required to facilitate AISaT's implementation [26]. The main risks anticipated to AISaT's implementation were that existing strategies used within hospitals, such as fixed ventilation systems, are hard to change and may be different from the strategies AISaT may recommend, which are likely to involve portable HEPA filters. Additional anticipated risks to AISaT's implementation were the potential challenges associated with HEPA devices and the lack of standardized rooms in old NHS buildings. A number of additional potential challenges have also been identified, such as PPE being seen as a more economical alternative; that handwashing and isolation rooms are being prioritized in current guidelines [27]; and that hospital staff felt improving air changes should be prioritized, whereas AISaT's current prioritization is focused on diminishing aerosol concentrations. The main expected enablers identified related to the implementation of AISaT in outpatient areas; ensuring the AISaT interface is easy to use and responsive to staff's needs; buy-in from senior staff; and its dissemination through national guidelines. In line with findings from previous research, there is a need to communicate that using AISaT does not remove human involvement from the decision-making process [11,15]. AISaT may be more likely to enhance its coherence in the hospital environment by tailoring its implementation approach to the ways of functioning of different hospitals, while providing staff with proof of the effectiveness of the tool in a way that is relevant for the metrics used within the NHS (eg, justifying cost savings and benefits for staff and patients).

Cognitive Participation (How Will Staff Engage With AISaT and Mitigation Strategies?)

Cognitive participation is anticipated to depend on multidisciplinary decision-making on the implementation of AISaT and its recommendations and having champions to cascade decisions down and encourage implementation on the ground. Anticipated barriers to implementation could be overcome by imposing the use of AISaT rather than relying on

XSL•FO
RenderX

staff's engagement. Imposition, however, would come with the inherent risk of losing the feeling of shared ownership, which would add to a lack of agency among staff, becoming a potential implementation challenge [28]. The potential implementation of AISaT was often not perceived as a priority, in a climate where staff feel overloaded, there are increasing financial constraints, and direct patient care is the most pressing matter. Such a lack of agency, particularly among those in clinical and estates roles, while raising the need to involve multidisciplinary teams may reflect the ways of working within the NHS as well as the nature of the AISaT tool falling in a confluence of responsibilities among different roles.

Collective Action (How Will Staff Work to Implement AISaT and Recommended Mitigation Strategies?)

Collective action is anticipated to be impacted by costs associated with the implementation and maintenance of AISaT and its recommended mitigation strategies; the fragmented implementation of AI tools and devices within trusts; restrictions in accessing data; and variations in approval processes within trusts and buildings. While it was suggested that AISaT could be best integrated within a comprehensive electronic health record, this comes with an added layer of difficulty since electronic health record systems are not universally used across UK hospitals, which would require further adaptations to different systems used. This is a known generalizability issue previously identified in the literature [29,30]. An expected enabler identified was the external implementation of AISaT (eg, by a contractor), which would reduce its impact on staff workload.

Reflexive Monitoring (How Will People Assess the Success of AISaT and Mitigation Strategies?)

Reflexive monitoring is anticipated to derive from expert validation and evidence on effectiveness and impact prior to the implementation of AISaT. However, previous research has also pointed out that such evaluation should continue after implementation [31]. An anticipated risk identified is the need for future refinement support that is unclear after the end of this project.

Comparison With Prior Work

Our findings are consistent with those of a recent systematic review where AI implementation within hospitals was found to be influenced by understanding and trust in AI, quantification of the benefits of the AI, external validation to facilitate generalization, costs of implementing the AI, training staff and maintaining the AI, and the availability of policies to fund and regulate AI solutions [19]. However, our findings also point toward other critical elements, such as specific environmental characteristics where the AI and mitigation strategies will be implemented (eg, old buildings with busy and crowded wards, with scarce space and overloaded hospital staff), together with the priority given to AISaT and its mitigation strategies within the existing ways of working and measures already available. These findings also align well with a recent criticism of the NHS 10-year plan that AI implementation cannot sort out the whole structural issues within the NHS such as the constrained budgets [32]. Likewise, our findings are aligned with the need to transparently report on how the AI was trained as well as the benefits associated with its use, providing relevant metrics to the end users, and acknowledging the limitations of the tool [15].

Beyond our focus on AISaT's implementation, but very closely related, difficulties in the use of HEPA devices, such as noise, which had been previously reported in the literature [33], did not preclude their hospital-wide use through ventilation outlets installed in ceilings. This is in line with HEPA filters being the most common mitigation strategy used in hospitals to reduce airborne disease transmission within papers included in a recent review [18], subsequent research [34], and aligned with estates technical guidelines [35]. Although the review reported improvements in patients' health outcomes [18], some stakeholders included in our study stressed the lack of randomized controlled trials proving HEPA devices' effectiveness.

Future Research

This work involved extensive stakeholder engagement, capturing views from the public, subject matter experts, and hospital health care professionals, which helped identify common ground, but also areas of discordance between accounts even among professionals with similar job roles. Hence, it responds to the recommendation to include stakeholders at an early stage to facilitate future acceptability of AI tools [15]. This study is not without limitations; we struggled to access the hospital environment for further ethnographic work, only being able to observe estates work within one building. Difficulties may have been aggravated by the timing of our research during flu season. Furthermore, AISaT was under development at the time of conducting this study, and hence neither researchers nor participants had a tangible idea of what the tool would look like. This may have made it difficult for hospital staff and stakeholders to provide more specific responses and imagine what its implementation could look like in practice. Our formal data collection sample was focused on hospital staff from 2 hospitals, but more so from one of them, due to low response rates and delays in getting the relevant authorizations to do research in the second research site. Hospital staff shared their reservations about the AI tool during interviews; however, there may have been a natural selection bias. Through the wider stakeholder engagement (eg, via a national leaders' workshop and follow-up conversations with national leaders), experts from around the country were involved, which helps reinforce the applicability of our findings to other hospitals with caution. Areas of concern such as impact on costs, workloads, and diverse ways of working were raised by all parties, supporting the transferability of our findings to other hospitals and health systems working under limited resources, staffing pressures, and in old buildings. This approach supported our ability to provide analytical generalization, to aid the development of the AI tool and future trial plans. Future research should involve relevant stakeholders in designing user-friendly AI tools and seeking their feedback with demonstrations of the product to visualize the end-product and think of ways to implement it in their practice.

XSL•FO
RenderX

Conclusions

Even when AISaT and its recommended mitigation strategies are not considered a priority within the hospital environment now, in a climate of tight budgets, staff shortages, and heavy workloads, staff expressed their openness to accommodate AI innovations if the effectiveness and benefits are proven and shared with them. Therefore, when planning implementation across hospitals, it will be important to frame this according to the tenets of NPT to enable understanding at the level of the structure of services as well as people's experiences to engender the flexibility that will be necessary to maximize the likelihood of success across different NHS trusts and associated hospitals.

Acknowledgments

We would like to thank all stakeholders involved in this study, from those involved in wider stakeholder engagement work (via patient advisory group meetings, the National leaders' workshop, and follow-up conversations) to those being observed and interviewed as part of this study. We would like to thank Mr Simon Watt (Public Engagement Manager) for his work in recruiting, managing, and facilitating patient advisory group meetings; Ms Anna Byrne (Air Safety Program Manager) for her work identifying and inviting National Leaders to the workshop; and the Air Safety's Project Team for their collaboration and support through this study. Authors attest that no generative AI was used in the development of this manuscript.

Funding

This study is funded by the National Institute for Health and Care Research (NIHR) under its Programme Grants for Applied Research (Ref: NIHR205439). The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

The datasets analyzed during this study are not publicly available due to their containing information that could identify participants and they did not provide consent to these data being shared outside the research team beyond anonymized quotes in publications. Data supporting the results have been included in this published article. If you would like more information about the nature of the data, please contact the corresponding author.

Abstract

Background: Child-centered care (CCC) is standard practice in pediatrics, emphasizing the child as an individual with rights while acknowledging the child's role within the family. A key aspect of CCC is the involvement of the child in health care decisions alongside parents and professionals. Although this is a right recognized by the United Nations Convention on the Rights of the Child, it may not always be applied in practice.

Objective: The aim of this study is to explore the participation preferences of 3- to 5-year-old children in health care from both their own viewpoint (the child's perspective) and the viewpoint of their parents and health care professionals.

Methods: Q methodology was used to study preferences, comparing responses from 12 children, 14 parents, and 12 health professionals who ranked 25 statements about ways in which children could participate in health care situations. Factor analysis was used to reveal similarities and differences in views on participation preferences. The children's rankings were also analyzed separately for comparison.

Results: Analysis of rankings from children, their parents, and health care professionals identified 3 perspectives with different preferences: direct communication between the child and healthcare professionals; understanding and shared decision-making; and responsive and child-led participation. A separate analysis of children's rankings resulted in 3 perspectives: being included in and setting their own terms for participation; small choices, meaningful outcomes; and trust through familiarity and shared decision-making.

Conclusions: This study suggests that children value shared decision-making and situational control but prefer to leave major decisions to adults. It affirms that preschool-aged children can meaningfully participate in health care when given age-appropriate choices, support, and tools. Children's perspectives must be acknowledged directly rather than adults assuming their views. The findings support CCC principles and reinforce the United Nations Convention on the Rights of the Child mandate to respect children's views regarding all issues relevant to them.

KEYWORDS

children; child participation; child's perspective; health care; Q methodology

Introduction

Child-centered care (CCC) is the standard focus of care in pediatrics [1]. This concept recognizes the individual child at the center of care as a social agent with rights, but also as part of a family [1,2]. The involvement of children in their health care concerns and decisions alongside parents and health care professionals (HCPs) is central to CCC [2]. Child participation can be viewed from 2 different perspectives: the child's perspective and the child perspective [3], which are succinctly different in the person formulating the perspective. The child's perspective refers to a subjective view of a child's understanding of the world through their perceptions and experiences [4]. The child perspective looks at the same situation through the adult's perspective by trying to find the child's point of view, but it is still an adult's interpretation of the child [4]. Both perspectives must be considered when implementing CCC [5,6], including the adult's view of the child's best interest and the child's own preferences for the situation [6].

Despite its common usage, the term "participation" has different meanings in different academic and professional disciplines and settings. It can refer to anything from physical presence to activity, competence, and a sense of self [7]. Participation can also mean children's ability to form and express their opinions and influence matters that affect them [8], which is in line with Article 12 of the United Nations Convention on the Rights of

XSL•FO
RenderX

the Child (UNCRC) [9]. While the declaration does not specify an age limit for children's participation, it does state that their age and maturity should be taken into account. Their opinions should be taken seriously and not dismissed due to their age [9]. In this study, the participation of preschool- and school-aged children in health care situations is defined as deciding how to act, receiving adequate information, making decisions, as well as communicating with HCPs [10].

Previous research shows that children are competent agents who can construct their social worlds in collaboration with others [11,12]. They want to be involved in decision-making processes [13,14], yet they are often unable to participate or express their views [11,15,16]. Parents and HCPs play an important role in facilitating children's participation [10]. However, research has found that parents and HCPs limit children's opportunities to participate in health care [15,17,18], their opinions are not asked for [15], there is no agreement on the level of children's participation [11], or parents protect their children from decision-making instead of allowing shared decision-making [19]. A recent review revealed a knowledge gap concerning preschool-aged children's preferences for participation in health care situations [10]. In accordance with their rights as stated in the UNCRC [9], more research should be conducted into children's perspectives and participation in health care situations, since this area has not been sufficiently explored. Therefore, it is important to better understand how children prefer to participate in health care situations.

The Swedish National Child Health Care (CHC) program provides free, voluntary health care for children from birth to 6 years of age [20]. This study was conducted in Child Welfare Centers, which are part of the program. It explores the ways in which children prefer to participate in health care situations, focusing on preschool-aged children (3 - 5 years old). It examines the topic from 2 perspectives: the child's perspective, that is, the views of the children themselves, and from the child perspective, that is, the views of their parents and HCPs. It explores differences in views expressed by the children themselves, their parents, and HCPs. The research aims to answer the following question: what are the most important ways of participating in health care from the child's perspective and the child perspective?

Methods

Design

The design uses the mixed methods approach of Q methodology. This methodology was developed to examine similarities and differences in participants' views on a specific issue [20,21]. Participants rank statement cards that present different viewpoints on a given issue. Each individual ranking is then compared with the rankings of the other participants using factor analysis. Participants with common views are identified for the same factor [20]. Q methodology studies commonly use approximately 40 statements, but the number of statements can vary from less than 20 to more than 200 in studies with adult participants [22-24]. It is more important to cover all possible opinions on the topic in the statements than to have a fixed number of statements [23].

The Q set for this study, consisting of 25 statements for ranking, was formed based on the results of a literature review on children's participation in health care situations [10]. Initially, 95 statements were formed from the themes of the literature review in English. Some of the statements had similar content and needed to be simplified to make them more accessible to 3- to 5-year-olds. The statements were discussed among all the authors, and duplicate or overlapping statements were removed. Once all the themes from the literature review had been incorporated into the statements, the authors agreed on a set of 25 statements. These statements were the same for all participants but were adapted in their formulation and pictorial representation to reflect the 3 different perspectives from which they would respond: child, parent, and HCP (Table 1). The statements were translated into Swedish by the authors. One of the authors speaks Swedish as a first language, while another speaks English as a first language. The translations of the questions, Q statements, and, later in the data analysis phase, the transcripts were checked and verified by all the authors, who are fully fluent in both languages.

XSL•FO
RenderX

Table . Q statements.

Number	Statements for children	Statements for parents	Statements for health care professionals
1	I want the doctor and nurse to talk to me too	My child wants the doctors and nurses to talk directly to her or him	Children want me to talk directly to them
2	I want the doctor or nurse to use words which I can understand	Doctor or nurse should use words that my child will understand	I should use words the child understands
3	I want to answer questions from doctor or nurse	My child wants to answer questions from the doctor or nurse	Children want to answer questions from me
4	I want to ask questions to the doctor or nurse	My child wants to ask questions from doctor or nurse	Children want to ask me questions
5	I can give my answers by pointing or nodding	My child can use nonverbal communication instead of talking to the doctor or nurse	Children can use nonverbal communication during the visit
6	I want parents and doctor or nurse to make decisions about me	My child wants me to make decisions with doctors and nurses	Children want the parent and me to make decisions during the visit
7	I want to make decisions except for difficult issues	My child wants to make the decisions, except for the difficult issues	Children want to make decisions, except for the difficult issues
8	I have important things to say before decisions are made about me	My child has important things to say before doctor or nurse and I decide on something about her or him.	Children have important information to share before the parent and I make decisions about them
9	As I grow older, I can make decisions on things concerning me	When my child grows older, he or she can decide on matters concerning her or him	When children grow older, they can decide on matters concerning them
10	I should be asked when decisions are made about me	My child should be asked before decisions are made about her or him	Children should be asked before decisions are made about them
11	I want to decide what to do when waiting for the doctor or nurse	My child wants to decide what he or she wants to do during the waiting time for the doctor or nurse	Children want to decide what they want to do during the waiting time to doctor or nurse
12	When I have answered many questions, I want to play	My child stops answering questions when he or she feels he has participated enough	Children stop answering questions when they feel they have participated enough.
13	I will resist things I do not want to do	My child will protest when he or she does not want to participate anymore	Children protest against procedures when they do not want to participate anymore
14	I want to do something else when the doctor or nurse speaks	My child wants to concentrate on something else during the health care visit when I talk with the doctor or nurse	Children want to focus on something else during the health care visit when I discuss with the parent
15	I want to quietly listen to doctor or nurse	My child wants to listen to the doctor or nurse but wants to stay quiet during the visit	Children want to listen to me but stay quiet during the health care visit
16	I want to talk to the doctor or nurse only when my parent is present	My child wants to talk to the doctor or nurse only when I am present	Children talk to me only when the parent is present
17	I want the doctor or nurse to listen to me too	My child wants the doctor or nurse to listen to her or him also	Children want me to listen to them also
18	I want my parents to let me talk like I want with the doctor or nurse	My child wants me to let her or him speak freely with doctor or nurse	Children want to speak freely with me, without the parent interrupting
19	I feel good when I make decisions together with my parents and doctor or nurse	My child feels that she or he is participating greatly when she or he decides something together with me and doctor or nurse	Children feel that they are participating greatly when they decide something together with their parents and me
20	I want the doctor or nurse to speak to me in a nice way	My child wants the health care staff to talk to her or him in a nice way	Children want the staff to talk to them in a nice way

XSL•FO
RenderX

Number	Statements for children	Statements for parents	Statements for health care professionals
21	I want to have choices from which to choose from during my health care visit	My child wants to have choices to choose from during the health care visit	Children want to have choices to choose from during the health care visit
22	I want to think before answering questions	My child needs time before answering questions from doctor or nurse	Children want to have time to think before answering questions
23	I want to make decisions together with the adults (my parents and doctor or nurse)	My child wants to make decisions together with me and doctor or nurse	Children want to make decisions together with their parents and me
24	I like to meet the same nurse or doctor every time I come to the health care center	My child wants to meet the same staff every time we come for a visit	Children want to meet the same staff members at every health care visit
25	I want the doctor or nurse to ask me before they are going to do something to me	My child wants doctor or nurse to ask her or him before they do any procedures with her or him	Children want me to ask them before doing any procedures

Parents and HCPs were asked to respond on behalf of their child or patient, indicating their preferences. To illustrate the meaning of the statements, Microsoft Bing Copilot (version 2024 May) was used to draw pictures for the children's cards (Figure 1). The content of the images and the desired meaning were discussed jointly by the authors during the development of the images. The first author also conducted a preliminary test with a convenience sample of 3 children of the appropriate age for the study to ascertain the images conveyed the intended meaning. The final selection was then made and agreed upon by all authors.

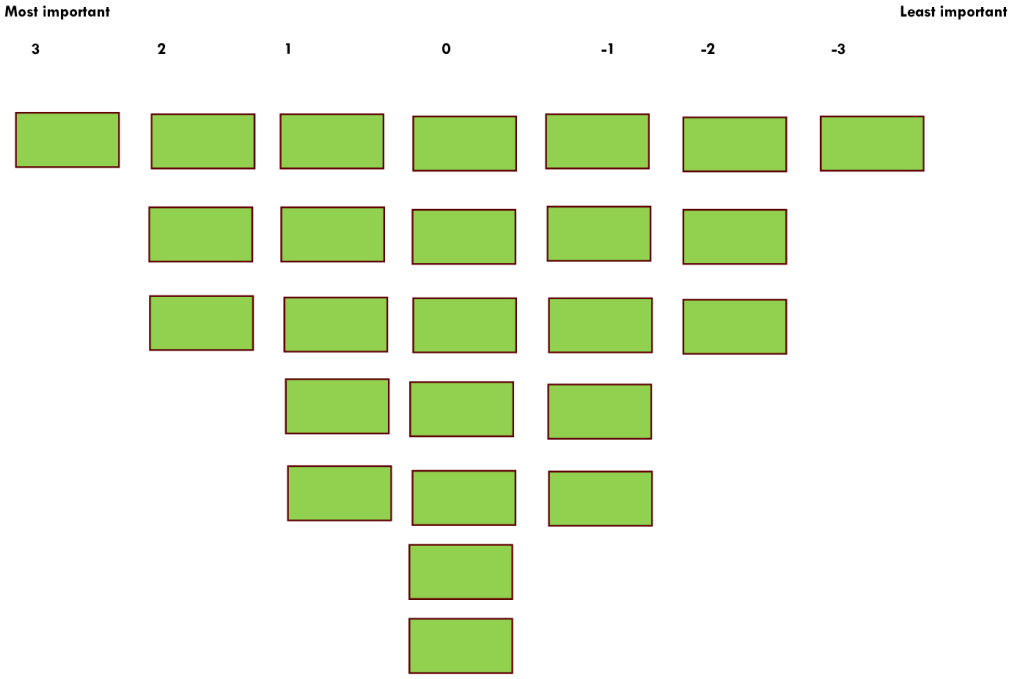

Figure 1. Q statement card for children.

The Q grid, a fixed pattern in the form of a normal distribution for ranking, was chosen to range from least important (−3) to most important (+3), with the extremes of the pattern allowing only 1 statement (Figure 2).

XSL•FO
RenderX

Figure 2. Q grid.

After the participants had ranked the statements, postsorting interviews were conducted for all participants (Textbox 1). The postsorting interviews were conducted to let the participants provide rationale behind the Q sorting and to express their feelings and opinions while conducting the Q sorting [20,25].

Textbox 1. Postsorting interview guide.

Why did you choose to rank the statements in this order?
Why do you think that statement X is more important than statement Y?
Why do you think that statement X is the most or least important?
Are there other ways of involving children that are not mentioned in the statements?

Setting

This study focuses on Child Welfare Centers in Stockholm Region, Sweden. These centers form a part of the national CHC program, which provides free, voluntary health services for children aged 0 to 6 years. The program is widely used and supports child development, parenting, and health promotion [26]. CHC nurses conduct regular health check-ups, including growth monitoring, vision, and balance tests. They also use activities such as drawing and memory games to assess motor skills, communication, and social interaction [27,28]. The goal is to support families and identify the need for further interventions for children [27].

Participants

The participants were recruited via child welfare centers. Three child welfare centers in the Stockholm region participated in the study. One of the centers took part solely through staff interviews in order to obtain the required number of staff members for the study. Nurses from the other 2 centers recruited the child and parent participants through purposive sampling. Participants had to be a child aged between 3 and 5 years, or a parent of a child aged between 3 and 5 years, or a nurse or doctor working with children in this age group in a child welfare center, and they had to be able to understand and speak Swedish. Information about the study was sent to potential participants (children and their parents) prior to their appointment. This included a simplified version with pictures for the child. If a parent agreed to participate in the study, or to allow their child to participate, the nurses contacted the first author to arrange an appointment. Some parents were also asked during the appointment if they wanted to participate in the study, as the nurses and the first author agreed on days when the first author would wait for potential participants at the child welfare center.

XSL•FO
RenderX

The required number of participants was 12 or more in each category. There were no limits on how many participants of a certain age or with a certain amount of work experience needed to be recruited. Seventeen children agreed to be interviewed. However, only 12 of them could complete the sorting task and the subsequent interview. They did not complete the sorting for various reasons: they stopped answering questions, started playing instead of continuing the sorting, or could not concentrate on the questions and directed their attention elsewhere. None of the 3-year-olds (3 persons) who agreed to be interviewed could complete the sorting task. Fourteen parents agreed to be interviewed, but 1 decided not to complete the postsorting interview. Twelve HCPs agreed to be interviewed and completed the sorting and postsorting interviews. This resulted in a convenience sample of 38 participants who were willing to take part.

Data Collection

If a parent agreed to participate in the study, the first author was introduced to them and their child by nurses. Statement ranking and postsorting interviews were conducted immediately after the child's appointment, in a waiting or appointment room at the child welfare center and away from other patients or visitors. Nurses and doctors also conducted the ranking and interview at the child welfare center when their schedules permitted.

All participants were asked to provide the following background information: the age and gender of the child, the age group and gender of the parent, and the work experience and gender of the staff member. Children and parents were also coded together to enable a comparison between how they sorted items.

The child and parent participants completed the Q sorting exercise simultaneously, sitting side by side. The first author verbally explained the sorting procedure to the participants and also provided them with written information about the study. The first author then read and showed the Q statement cards with pictures to the child, while the parent sorted their statements independently. All participants received the same Q statements but written from the different perspectives of the participants (Table 1). After sorting, the final Q grid with the statement cards was photographed for analysis. Participants were interviewed about their motivations for sorting. These postsorting interviews were audio-recorded for the adult participants. The entire ranking situation, including the sorting and postsorting interview, was audio-recorded for pediatric participants. These interviews were transcribed verbatim in Swedish and, during the analysis, translated into English by the authors.

Ethical Considerations

This study does not fall under the Swedish Ethics Review Act since the study does not collect sensitive data and is nonexperimental. However, the Swedish Ethical Review Authority has given an advisory opinion that there are no ethical objections to this study (Dnr 2024-02308-01). The study follows the ethical principles outlined in the Declaration of Helsinki [29]. Participation in the study was voluntary. Adult participants signed a consent form for their participation and an additional form if their child was participating. The children were verbally asked for their assent and were informed that they could withdraw from the study at any time. This study concerns children's preferences and does not collect any identifying information. Any such information provided by participants during postsorting interviews was omitted or anonymized during transcription. Participants were given a cinema ticket as a thank you for taking part.

Analysis

The factor analysis was carried out using the PQMethod software [30], a statistical program. First, data from the ranking of statements were entered into the PQMethod software. Centroid factor analysis, principal component factor analysis, and varimax rotation of factors were performed for each individual sorting. Then, based on the factors obtained, all participants were compared with each other. The common views on each factor were identified by distinguishing the preferred participation methods that the participants in the factor felt most strongly about. These extremes of +3, +2, −2, and −3 were then analyzed to characterize the common views of the factor. The participants associated with the factor were then identified. Several assessments were performed with a variable number of factors, and the optimal balance for most participants was identified when the number of factors was 3. This gave a good balance of most participants associated with the factors. The resulting factors included most adult participants, but only 6 out of the 12 children were identified to be associated with the factors. Therefore, the children's Q sorts were also analyzed separately using the same factor analysis method and analysis of common views characterizing the different factors. Finally, the participants' motivations for sorting from the postsorting interviews were used to corroborate and clarify their preferences for child participation.

Results

Participant Characteristics and Analysis Overview

The sample included 38 participants: 12 children, 14 parents, and 12 HCPs (see Table 2 for participant characteristics). The results of comparing the Q sorts of children, parents, and HCPs are presented as 3 factors representing the children's different preferences for participation, followed by 3 factors from by-person factor analysis of the children's Q sorts only. The Q sort values by factor are presented in Table 3. Finally, the alternative ways of participating, as suggested by the participants during the postsorting interview, are presented.

[a]"Factor all" refers to the factor analysis of all participants' rankings.

[b]"Factor children" refers to the factor analysis of children's rankings only.

This study shows that children and adults have qualitatively different views, as only 1 of the child participants ranked the statements in a similar way to the parent. The perspectives identified in the factor analysis of all the participants' rankings reveal 3 different approaches: involving children in communication during the health care visit, sharing decision-making with children, and, lastly, allowing children to set their own limits for their participation. Adult participants placed particular emphasis on HCPs' communication with children and the establishment of a trusting relationship with them in the postsorting interviews.

Factor All 1: Direct Communication Between the Child and HCPs

Nine parents, 5 HCPs, and 1 child associated with this factor. They felt strongly about HCP communication with children, with the highest-ranked statements concerning how HCPs interact with children as patients and provide children with the possibility to participate in discussions. One parent saw health

XSL•FO
RenderX

care visits as a learning opportunity for children to learn to have a conversation.

> *You should still teach the child that first the doctor has to say something and then they can say it. Not just throw out a bunch of words, but you should still try to learn to have a conversation.* [Parent 4]

Communication was considered important for building a trustworthy relationship and ensuring a positive and comfortable health care encounter for the child. A positive and respectful way of communicating with the children was seen as the basis and an essential condition for the visit, more important than the children taking part in decision-making. Meeting the same staff was not necessary, but the communication skills of the HCP were highlighted for "inviting the child to participate in the visit." Nonverbal communication was not ranked high in importance but was acknowledged during the interviews as an important means of communication for individual children. One HCP described this interpretation of signals as an important part of her communication skills.

> *…it's rather important that I as a healthcare professional can listen to them and see this and interpret their signals, do what they want and don't want, with their body language instead.* [HCP 9]

HCPs felt that most children wanted to participate in the visit. Similarly, parents belonging to this factor described their children as willing to talk and ask questions. Therefore, staying quiet and listening or using nonverbal communication (statements 15 and 5) were not important.

> *She is not so interested in being quiet [laughs]* [Parent 14]

Statements concerning decision-making and choosing from choices were mainly understood to refer to major decisions on treatment options and considered less important. Both parents and HCPs felt that children did not want such responsibility and doubted children's understanding of the consequences of decisions. Some decisions, for example, diet changes for obese children, were not seen as suitable for children. While 1 parent felt that their child with more care needs and experience would need to be more involved in decision-making, other parents and HCPs stated that children were more interested in knowing what would happen during the visit than in making decisions with adults.

> *And this idea that we should be able to make decisions during the care visit, I don't think they care about that in the slightest, they just want to know what's going to happen.* [HCP 12]

Parents and HCPs felt that decisions should be age-appropriate and aligned with children's cognitive levels. Allowing children to choose the order of procedures during a health assessment was considered valuable and within the limits of children's decision-making abilities.

> *… here he got to choose which arm you want the injection to be taken. It's the child's body and I think it's important for the child to say that this arm will feel better to me. You might have pain in some place before.* [Parent 4]

Sometimes procedures had to be done regardless of choice, making mutual understanding between the child and HCP essential. Protesting was seen as a way for children to express emotions, and while protests were respected and could delay care, they did not always change the outcome.

Factor All 2: Understanding and Shared Decision-Making

Three children, 1 parent, and 5 HCPs were associated with this factor. They felt strongly about participating in decision-making and thought it was important for children to understand and follow the events of the health assessment at the child health care center. They also did not think that the parents' presence was necessary for children to talk to the nurse or doctor. HCPs felt they needed to quickly build a relationship with the child and show that they were friendly and not scary. Using translators in the situation hindered this relationship-building, but regular contact with the same HCP helped. Another effective approach was to prepare the children at home before the visit. Like in Factor all 1, a positive and comfortable health care encounter with direct communication with children was considered the foundation for a visit, but this factor emphasized shared decision-making with parents and HCPs. This required understanding of the discussion during the visit.

> *Sometimes certain words become difficult, and she can't quite keep up.… But this thing about making decisions together. It's linked to the fact that if you understand the meaning of it and in the same way, it's important to do it together.* [Parent 12]

Shared decision-making with parents and HCPs was found to be valuable, at the appropriate level of decision-making for children. Even though children might not fully understand what it involved until it was imminent, some decisions were beyond children's capability. Participants associated with this factor felt that children could decide more as they grew older. On the other hand, relevant decision-making for children was seen as children deciding over a range of options presented, giving them a sense of control over the situation.

> *They can choose the color of the paper they draw on, for example, for their drawing. And they can choose the order in which we do things, whether we weigh them first or check their eyesight first. But I don't think the difficult decisions feel important for the child to choose. Instead, they think it's nice that someone else decides. For example, whether to take a vaccine. They can't decide that.* [HCP 6]

Factor All 3: Responsive and Child-Led Participation

Two children, 2 parents, and 2 staff members were associated with this factor. Their preferences are interpreted as the children setting limits on their participation. These limits include consulting them before procedures, sharing decision-making, the possibility of protesting, and the use of nonverbal communication. Asking the children before procedures (statement 25) was motivated by the aim of involving them when possible, allowing them to make decisions based on their age and situation. Participants stated that children would participate for as long as they were interested, after which they

XSL•FO
RenderX

would move on to playing. One parent noted that varying levels of participation meant that offering choices during health assessments was less important.

> *I thought it was like this, yes, sometimes it is important. Sometimes it's a bit varied from day to day. Sometimes it's really important to get him to speak up and tell me about something and ask me something. Sometimes let me sit in a corner.* [Parent 9]

When children grew older, they could make more decisions, but at this age, some decisions on treatments were too complex for children to make. Children's participation was vital for some procedures; therefore, a gentle approach was used, with the possibility of postponing the procedure.

> *…if you take something as concrete as checking vision. You almost have to try somehow to make the child want to do it, because otherwise you might miss vision problems and there will be problems later in school or something, or headaches...* [HCP 7]

HCPs found it important to talk directly to children, even though they felt that children rarely asked questions of them. Similarly, a parent thought that the questions should be directed at children. If the child was unwilling to answer or colored the answer with fantasy, the parent would step in.

> *Yes, but if he wants to answer, he can. And then... we had a visit to the BUM [medical center] and task: does he eat vegetables? Yes, ask him. And then he unraveled the whole vegetable stash as well.* [Parent 9]

The importance of nonverbal communication was recognized. A parent explained that their child was very shy but willing to participate in their own way.

> *…it's very much that if she can respond with body language instead, or she can be quiet if she wants to, and a lot of things like that, as she wants it. She doesn't usually, and neither do her siblings, who want so much... care whether decisions are made with them or not.* [Parent 6]

Factor Children 1: Included in and Setting Their Own Terms for Participation

Three children were associated with this factor. They felt strongly about receiving information, being consulted prior to procedures, participating in discussions, and choosing how long to participate. This gave them a sense of control within the health care situation. As with Factor all 3, the children set their own terms for participation but placed the least importance on making decisions alone or with parents and HCPs. In the following situation, the child suddenly starts playing while still answering questions from the interviewer. She understands the question in a practical way. Furthermore, it can be interpreted that decisions regarding play are important to her. Her actions demonstrate how she sets the terms for her participation, showing agency.

> ***Interviewer:*** *Okay. [child walks away from the table where the interview is being done] Are you going on the slide? Was it hard to make the cards? You turn your head. Was it easy? Mmm. Is there anything that you would like to do when you are with the doctor or nurse that was not included? Is there anything that you would like to do when you are with the doctor or nurse? Apart from going down the slide. Is there anything else you would like to do?*
>
> ***Child:*** *Swing.*
>
> ***Interviewer:*** *Sing?*
>
> ***Child:*** *Swing.*
>
> ***Interviewer:*** *While you are waiting? Or after you have been to the doctor or nurse?*
>
> ***Child:*** *Mmm.*
>
> ***Interviewer:*** *So, is it important what you do while you are waiting?*
>
> ***Child:*** *Mmm.* [Child 3]

This example presents a comfortable level of decision-making for the child. The statement 7 ("I want to decide on easy things but not difficult") illustrated with a child picking a Band-Aid reflects a familiar, practical choice.

> ***Interviewer:*** *We'll take this one which is important, first that pile. I put them on the floor. If you look at them and say what is the most important of all these. Then it's just one card. See, [child's name]? Should I read them all? This one? [reads aloud the card the child is pointing to] I want to decide on easy things but not difficult ones. Is it most important when you come to the nurse?*
>
> ***Child:*** *[inaudible] band-aid.*
>
> ***Interviewer:*** *Yes, to be able to choose band-aids?*
>
> ***Child:*** *Yes.* [Child 9]

Factor Children 2: Small Choices, Meaningful Outcomes

Four children were associated with this factor. They felt strongly about having a choice of options (statement 21) and making decisions about minor issues, while leaving major decisions to parents and HCPs. These choices could be understood as play-related, perceiving the visit as a meeting with HCPs and playtime, and choosing what to play with while waiting as meaningful decisions. Although nurses also use games and play as a method of observing children's development during health assessments, this may explain the child's confusion.

> ***Interviewer:*** *Is it good like this? Is there anything else you would like to do when you come to meet the nurse?*
>
> ***Child:*** *Read a book.*
>
> ***Interviewer:*** *Read a book, okay.*
>
> ***Child:*** *Playing with dolls.*
>
> ***Parent:*** *You want to be in the waiting room.*
>
> ***Interviewer:*** *There are lots of things you want to play with. Mmm. Okay.*
>
> ***Child:*** *Doll. Slide. Read a book.*
>
> ***Interviewer:*** *So, before the visit or after the visit?*

XSL•FO
RenderX

Child: *After the visit.* [Child 17]

The children actively ranked their preferences during the interview but struggled to motivate their choices. One child asked for help from their mother, who then interpreted the child's response.

> ***Interviewer:*** *Why did you choose to sort the statements like this? Was it a...?*
>
> ***Child:*** *Mum.*
>
> ***Interviewer:*** *Wasn't it you who decided?*
>
> ***Child:*** *No.*
>
> ***Interviewer:*** *No?*
>
> ***Parent:*** *It was you who decided all by yourself.*
>
> ***Child:*** *I don't know.*
>
> ***Parent:*** *You don't know why you chose that?*
>
> ***Child:*** *No.* [Child 1]

One parent noted that the child chose opposite preferences, likely due to interpreting the statements differently.

> *…this one sounds like he's going to choose different things when he leaves, but for me it's different choices to choose whether he wants to... start by weighing himself or measuring himself first…* [Parent 1]

In a few cases, participating in the process was more important than the result. One child took over the following postsorting interview and proudly explained her ranking but left out the details of her priorities.

> ***Child:*** *Now you got to make piles.*
>
> ***Parent:*** *I got to make piles too. It is the same as you. What I think is important [talking to the child]*
>
> ***Child:*** *What is important?*
>
> ***Parent:*** *That doctors and nurses listen to... to the child? I don't know what you chose.*
>
> ***Child:*** *I chose all the things that were not important and all the things that were important and in between.* [Parent 4 interview]

Some children associated with this factor were described by parents as talkative and curious, which matched their ranking. They ranked the statements about being quiet, being asked before procedures or decisions affecting them were made, and the possibility of protesting the lowest. These children seem accustomed to expressing their opinions and are unaware of situations in which they cannot do so verbally.

Factor Children 3: Trust Through Familiarity and Shared Decision-Making

Three children were associated with this factor. They prioritized decision-making with parents and HCPs as well as a positive and comfortable health care encounter by HCPs, similar to Factor all 2. However, unlike Factor all 2, participants in this factor considered it important to meet the same HCPs (statement 24) and did not consider it important for HCPs to talk to children as well (statement 1). This suggests the need for parents to be present and supportive during meetings with HCPs, and for children to be willing to build relationships with HCPs. In the following example, the child's wish to repeat the vaccination suggests an optimal level of shared decision-making and trust with the HCP.

> ***Interviewer:*** *Is there anything else you would like to do when you come to the nurse that is not on these cards? Is there anything you absolutely want to do when you come to the nurse?*
>
> ***Child:*** *Hmmm.*
>
> ***Interviewer:*** *That might be a difficult question because we have so many cards here.*
>
> ***Parent:*** *Exactly. Is there anything [child's name]? Is there anything you would like to do?*
>
> ***Child:*** *No.*
>
> ***Interviewer:*** *So, then you're done with it.*
>
> ***Child:*** *Syringe.*
>
> ***Interviewer:*** *What did you say?*
>
> ***Child:*** *Syringe.*
>
> ***Parent:*** *Would you like a shot [vaccine, author's remark]? You've had a shot.*
>
> ***Child:*** *Yes.*
>
> ***Sibling:*** *He really likes syringes now.*
>
> ***Interviewer:*** *Oh, so it went so well that you thought I could do that next time too. That's great. Okay. I think I'm done too. Then, I thank you for the interview.* [Child 16]

Nonverbal communication was ranked as the least important. One child who relied on nonverbal communication during the interviews ranked it low and prioritized decision-making instead. This suggests that the feeling of being involved mattered more than the way of communication, as confirmed by her parent:

> *She just wants to get... So, in her own way, be quiet, respond with thumbs up, thumbs down. Then she's usually happy.* [Parent 6]

Additional Suggested Ways of Participating

In the postsorting interview, participants were asked for other ways children could participate in health care situations. Children mentioned different toys for the waiting room, while adults recommended postponing procedures to a later time if the child was not ready. They highlighted the importance of preparatory information, which helped both children and parents make visits run smoothly. Using pictures to aid communication and allowing children to play with a toy before talking to HCPs were also found to be effective strategies. Reflecting on the visit afterward to assess the child's experience was suggested. The value of the HCP's skills and parental involvement in the process was emphasized, as praise or confirmation from the parent while the child is answering questions promoted their participation, whereas a lack of parental engagement in the situation demotivated children.

> *Or being a parent and looking at the clock all the time and just being stressed and going to work. That doesn't work either. Most often, many times it doesn't work. You have to come back again, so that the child realizes that we don't have time to be here.* [HCP 8]

XSL•FO
RenderX

HCPs also felt that they needed to be flexible and provide options for children. Despite the many obligatory examinations and decisions that children could not influence, HCPs recognized that there were always ways to involve them in the visit

> *I think that in everything we do with children there is always a choice. They can always be allowed to choose which band-aid, which arm.* [HCP 12]

Discussion

Principal Findings

The aim of this study was to understand children's preferences for participation in health care situations and to examine them from the child's perspective as well as from the child perspective. This study sheds new light on the preferences of preschool-aged children. To our knowledge, this is the first study to compare the perspectives of preschool-aged children, their parents, and health professionals on children's participation. The key findings can be summarized as follows.

First, preschool-aged children are happy to leave major decisions to adults, but they want to be in control of health care situations. Similarly, Darcy et al [31] described how children undergoing cancer treatment wanted to control how, when, and at what pace procedures were conducted, and how much they participated in them. According to Moore and Kirk [32], this type of decision, which does not alter the outcome, is considered tokenistic because the planned procedures will be carried out regardless. The current study found that this kind of control is important for preschool-aged children, giving them an opportunity to participate and set their own limits to participation. This relates to the findings by Carlsson et al [33] on how HCPs considered participation as a prerequisite for care. They tried to "make the most of the moment" by involving children at every step, for example, by letting the child choose if they wanted to sit or lie down during the examination. Decosta et al [34] found that actively involving children in the preparation of medical procedures made diabetes education more meaningful, as it engaged them in their own care in an age-appropriate way. Furthermore, positive feedback, play-based approaches, and playful communication encouraged the young (<7) children's participation. These approaches were designed to help children gradually understand and engage more with their care. They are valuable for encouraging children to participate, as the present research supports the idea that some medical examinations depend on children's participation. For example, a vision check requires the child's participation. Children's protests or nonparticipation could postpone the examination to later and result in unnecessary suffering of undetected and treatable vision problems.

Second, a supportive and present parent appears to be important to children. Harlow et al [35] define parental presence in pediatric hospital care as being physically or emotionally present with their child, reducing the child's anxiety and providing emotional support. Besides the emotional support, children seek their parents for advocacy and sense of security during hospitalization [36,37]. Another aspect is learning how to participate with the help of supportive and encouraging adults. In turn, adults need to strike a balance between protecting and encouraging participation [19], or between intervening and giving autonomy [38], in order to provide children with an opportunity to express their views [16]. This means focusing on the child at the center of the care, as outlined in the CCC principles, and giving the child a voice [1,2,16].

Third, participants in the study suggested other ways of involving children, such as providing preparatory information with visual aids or postponing the procedure to a later date. Previous studies have demonstrated the effectiveness of visual aids and digital tools in preparing children for procedures and facilitating their participation in daily discussions about their care in hospital wards [27,39,40]. Digital tools could standardize the information provided to children. A digital application could facilitate children's participation by providing an understanding of what will happen during the procedure [41], while enabling HCPs to identify areas where the child requires further information before the procedure begins. Another suggestion from the participants was to ask children about their experience of the health care situation. This idea is worth exploring further in future research. Asking children at the end of a visit about their experience would provide valuable insight and help HCPs prepare for subsequent encounters with children.

Finally, children and their parents perceive and interpret the world differently. While preschool-aged children are still developing their language skills and abstract thinking abilities [42], they are capable of processing the information presented to them [43] and actively shaping their social environment as competent participants [13,14]. The aim of this Q methodology study was to identify and describe the common perspectives of the participants regarding child participation in health care situations. The results comparing the 3 different views (children, parents, and HCPs) and motivations for the rankings suggest that the resulting perspectives are coherent. Children may not be able to justify their choices, but this should not diminish the importance of their opinions, nor should it be a reason to override them if they differ from the views of adults [16]. Children's preferences identified in this study are in line with the core principles of CCC: trust, respect, autonomy, self-determination, and decision-making regarding their care together with parents and HCPs [2]. The current study showed that parent proxy does not always provide a correct picture of the phenomenon. Therefore, the perspectives of children should be sought in research and health care practice, as well as in other disciplines, and practitioners should be made aware of this perspective, as set out in the UNCRC [9]. This document should be understood as legally binding within state parties [9], ensuring that children are able to express their views. As the children were unable to justify their rankings, it would be interesting to explore this further.

Strengths and Limitations

This study has some limitations. It revealed various perspectives on children's preferences regarding participation in health care situations. However, it does not indicate how prevalent these preferences are among preschool children. The Q statements were developed from themes identified in a literature review, simplified into age-appropriate Swedish, and supported by animations. To minimize potential misunderstandings, only

XSL•FO
RenderX

participants who were fluent in Swedish were included in the interviews and analysis. Prior to the study, the meaning of the images provided with the statements for children was discussed with a convenience sample of children. Nevertheless, misunderstandings regarding the language may still have occurred. Conducting a pilot study could have been helpful. Children and their parents were recruited by nurses at Child Welfare Centers. This may have introduced a bias toward more outgoing children, which could have influenced the study's outcomes. Appointments scheduled late in the afternoon, after a full day at preschool, may have reduced the children's focus, particularly among the 3-year-olds, making it challenging for them to complete the statement ranking task. Conducting the ranking task alongside their child may have influenced some parents' responses if they overheard the interviewer's conversation with their child. Nevertheless, most parents were highly engaged in the ranking process, as they found the number of statements substantial and did not have time to listen to their child's interview.

To our knowledge, no Q methodology studies have been conducted on children younger than 5 years. The number of statements varies greatly from less than 20 to more than 200 in Q-methodology studies [23,24]. In this study, coverage was achieved without redundancy, making additional statements unlikely to expand the viewpoint space meaningfully. Furthermore, Q sorting can be difficult, demanding, and time-consuming [20]. A more concise set reduces participant fatigue. The 25 statements in this study with child participants align with established practice while maintaining methodological rigor.

Conclusion

In this study, 4- and 5-year-olds participated enthusiastically in the ranking process. This method also enabled us to compare the children's perspectives with the efforts of parents and health professionals to understand them and, in some cases, their ability to explain the children's rankings. None of the 3-year-old participants could complete the ranking procedure. It would be interesting to explore whether 3-year-olds share the perspectives identified in this study or whether they have different views, but different methods are needed for this.

Acknowledgments

Microsoft Bing Copilot (version 2024 May) was used to draw pictures for the children's statement cards for illustration of the statements.

Abstract

(JMIR Hum Factors 2026;13:e89669) doi:10.2196/89669

In “Auxiliary Teaching and Student Evaluation Methods Based on Facial Expression Recognition in Medical Education” [1], the authors noted one error in the author affiliation list.

A second affiliation has now been added for author XZ, as follows:

College of Big Data and Artificial Intelligence, Anhui Xinhua University, Hefei, Anhui, China

The correction will appear in the online version of the paper on the JMIR Publications website, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Correction of: https://humanfactors.jmir.org/2026/1/e85816/

(JMIR Hum Factors 2026;13:e111245) doi:10.2196/111245

In "Risk Factors for Noninitiation and Dropout in Blended Therapy in Inpatient Psychiatric Patients: Retrospective Cohort Study" [1], the group definitions underlying the dropout analysis were described incorrectly. The Methods section and Figure 1 state that the dropout comparison was defined as "Group B1: patients who completed 100% of all assigned modules" versus "Group B2: patients who completed <100% of all assigned modules." However, the logistic regression model reported in Table 3 was in fact conducted using a different definition: patients who completed none of their assigned modules (dropout) versus patients who completed at least one assigned module (nondropout).

All statistical analyses and results reported in the article (Tables 2 and 3, including all odds ratios, CIs, and *P* values) were calculated using this correct definition and remain valid and unchanged. The error is limited to the description of the group definitions in the Methods section, Figure 1, and corresponding wording in the Results and Discussion.

The interpretation of the dropout-related findings is refined by the correction: associations reflect the likelihood of completing no assigned modules at all, rather than the likelihood of incomplete module completion, as could be inferred from the original text. The noninitiation analysis is unaffected by this correction.

First, in the Division of Patient Groups section of the Methods, the following statement was revised:

> *Group B1: patients who completed 100% of all assigned modules*
>
> *Group B2: patients who completed <100% of all assigned modules*

The corrected text now reads:

> *Dropout: patients who completed none of their assigned modules*
>
> *Nondropout: patients who completed at least one of their assigned modules*

Second, in the same section, the following statement was revised:

> *...and dropout, the incomplete use of the assigned therapeutic modules.*

The corrected text now reads:

> *...and dropout, defined as the failure to complete any of the assigned therapeutic modules after platform initiation.*

Third, in Figure 1, the lower-level box labels were revised from the following:

> *Group B1: Patients who completed 100% of the assigned modules*
>
> *Group B2: Patients who completed <100% of the assigned modules*

The corrected figure now reads:

XSL•FO
RenderX

Dropout: Patients who completed none of the assigned modules

Nondropout: Patients who completed at least one of the assigned modules

Fourth, in the Distribution of Platform Use Parameters section of the Results, the following sentence was revised:

Notably, only 5 (1.8%) out of 278 patients completed all assigned modules (group B1).

The corrected text now reads:

Notably, only 5 (1.8%) out of 278 patients completed all assigned modules.

Fifth, in the same section, the following sentence was revised:

In terms of group distribution, 94 (33.8%) patients were in group A (noninitiation group), 184 (66.2%) patients initiated the platform, of whom 179 (64.4%) patients did not complete all assigned modules (group B2).

The corrected text now reads:

In terms of group distribution, 94 (33.8%) patients were in group A (noninitiation group), and 184 (66.2%) patients initiated the platform. Among those who initiated the platform, 94 (51.1%) completed none of their assigned modules (dropout), while 90 (48.9%) completed at least one assigned module (nondropout).

Finally, in the Discussion section, the following statement was revised:

...more willing to follow therapeutic guidance and complete assigned modules due to their conscientious traits.

The corrected text now reads:

...more willing to follow therapeutic guidance and continue engaging with assigned modules due to their conscientious traits.

The correction will appear in the online version of the paper on the JMIR Publications website together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: Individuals with *BRCA1/2* germline variants face complex, preference-sensitive medical decisions under psychological distress. Structural constraints in genetic counseling create support gaps during waiting periods, prompting patients to rely on fragmented or misleading online information. Conversational AI may offer low-threshold, continuous informational support, yet methods for its responsible integration into clinical care remain unclear.

Objective: This study identifies and systematizes stakeholder-informed sociotechnical design requirements and governance conditions for a clinically bounded conversational AI system intended to support comprehension, appraisal, and appropriate use of complex hereditary cancer information in *BRCA1/2*-related care.

Methods: We conducted an exploratory, qualitative, predevelopment requirements study using 2 structured participatory workshops with interdisciplinary stakeholders (N=18). Guided exercises included stakeholder analysis, the value proposition canvas, and the sustainability awareness framework. Structured workshop outputs, field notes, and artifacts were analyzed using inductive thematic analysis.

Results: Stakeholder workshops revealed that responsible design was shaped less by consensus around standalone responsible AI principles than by three recurrent cross-stakeholder tensions: (1) accessibility and continuity of support versus clinical role boundaries, (2) simplification and emotional reassurance versus medical precision and epistemic transparency, and (3) technical scalability versus governance, data protection, and institutional accountability. These tensions translated into design requirements for constrained system authority, mandatory human oversight, context-sensitive communication, and integration into clinical and regulatory governance structures.

Conclusions: Conversational AI in this context should be explicitly constrained and embedded within clinical governance structures to be perceived as responsible. Responsible implementation requires transparent design, human oversight, integration into existing care pathways, and early alignment with German/European Union (EU) regulatory requirements concerning data protection, medical device classification, genetic data, and AI transparency.

Introduction

Overview

Individuals carrying pathogenic germline variants in *BRCA1/2* face complex, preference-sensitive medical decisions regarding risk-reducing surgeries and surveillance, often under significant psychological distress with long-term implications for physical and mental health [1,2]. Despite the importance of genetic counseling, clinical pathways often lack continuous support beyond initial disclosure, while limited consultation time constrains the ability to address informational and psychosocial needs [3].

In Germany and internationally, structural bottlenecks and prolonged waiting times for specialized second opinions create a critical informational gap during the decision-making period. Patients frequently turn to online resources, where fragmented or misleading information may distort risk perception and increase uncertainty [4-6].

Conversational agents, particularly chat and voice bots, are increasingly discussed as low-threshold tools in health care. While advances in large language models (LLMs) have improved accessibility, challenges regarding reliability and ethical governance remain [7,8]. This study does not assume that patients lack access to conversational AI through general-purpose systems. Rather, it asks what added value a purpose-built, institutionally governed, and clinically bounded system could provide in *BRCA1/2*-related care. The envisioned conversational AI system is conceptualized as a supportive tool for waiting periods that complements, rather than replaces, human expertise.

Building on responsible AI principles, this study examines how ethical considerations can be translated into concrete design requirements for sensitive clinical contexts. While prior research has focused on the accuracy and usability of medical chatbots, empirical work on how responsibility is operationalized in emotionally sensitive, preference-sensitive decision contexts remains limited. This study therefore investigates how stakeholder perspectives can inform the responsible design and future integration of conversational AI into hereditary cancer care.

Using a qualitative sociotechnical approach, the study combines stakeholder analysis [9], the value proposition canvas (VPC) [10], and the sustainability awareness framework (SusAF) [11] to examine how digital health tools can be ethically integrated into the organizational and relational context of hereditary cancer care and how they shape responsibility, knowledge mediation, and patient autonomy. This study derives actionable design implications for the responsible integration of conversational AI into clinical care pathways, grounded in interdisciplinary stakeholder perspectives.

As an early-stage, stakeholder-informed design inquiry, this study did not include direct patient participation in the initial phase. Patient involvement is addressed as a methodological limitation and as a requirement for subsequent phases of system development.

This study contributes by translating abstract principles of responsible AI into concrete, stakeholder-informed design requirements and governance conditions for conversational AI in sensitive clinical contexts. In particular, it foregrounds legal and regulatory requirements not as external constraints to be addressed after design but as constitutive design conditions shaping system boundaries, data protection, medical device classification, genetic data governance, AI transparency, and institutional accountability in the German/European Union (EU) context.

Background

Clinical Context: *BRCA1/2* Mutation Carriers

Carriers of *BRCA1/2* germline variants face substantially increased cancer risks, requiring complex decisions on prophylactic surgery and surveillance, with implications for psychological well-being, family planning, and quality of life [1,2,12-14].

Standard genetic counseling, often limited to a pretest and disclosure session, frequently fails to meet patients' longitudinal needs. Psychological distress at the time of result disclosure impairs information processing, while limited consultation time constrains clinicians' ability to address psychosocial concerns in depth [3].

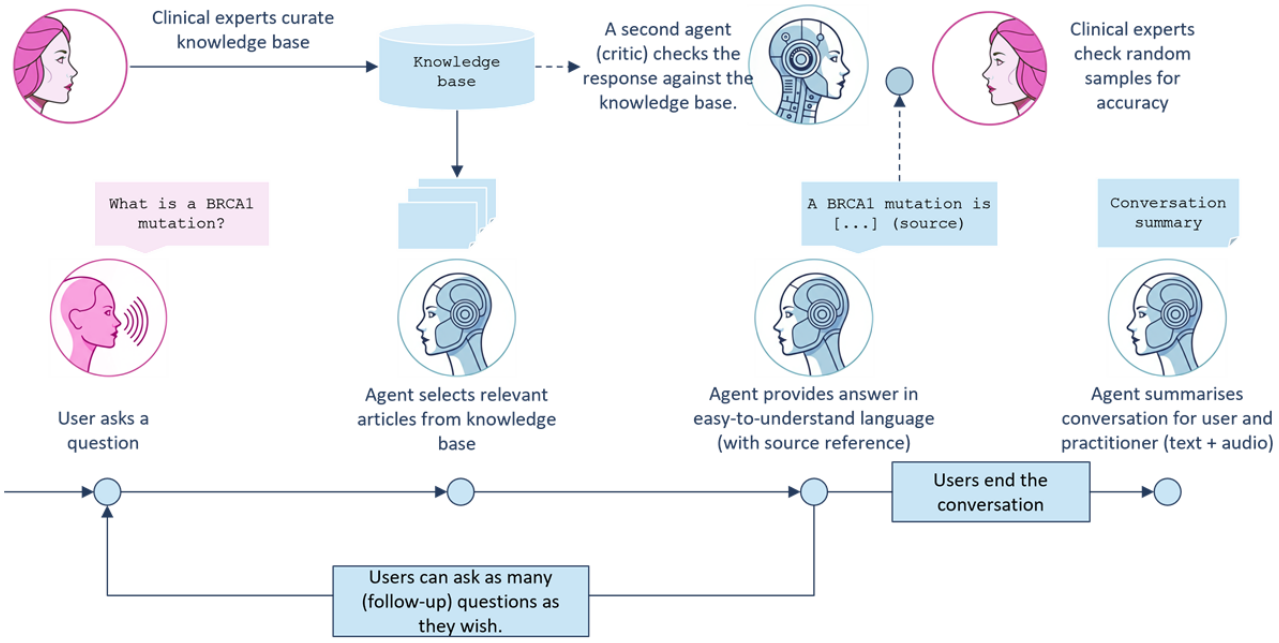
In Germany, specialized second-opinion services exist through the German Consortium for Familial Breast and Ovarian Cancer (FBREK), yet structural bottlenecks result in waiting times of up to 6 to 8 weeks. This gap contributes to patient overload and delayed decision-making, particularly for non-German-speaking individuals [15-17]. International evidence confirms similar deficits; for example, a recent Facing Our Risk of Cancer Empowered (FORCE) survey (n=1261) reported substantial gaps in posttest support, particularly regarding surgical menopause and family risk communication [4].

This "support vacuum" is often filled by online resources, where fragmented, inconsistent, or misleading information can distort risk perception and increase uncertainty [5,18-20]. In *BRCA1/2*-related hereditary cancer care, these risks are amplified by the complexity of decisions involving probabilistic cancer risk, preventive surgery, surveillance, fertility implications, family communication, and psychosocial consequences. Importantly, access to digital health information does not necessarily imply the ability to interpret, evaluate, or apply that information appropriately. Patients' perceived confidence in navigating online resources may diverge from their actual health literacy or eHealth literacy, particularly when information is technical, emotionally charged, or clinically preference-sensitive. Consequently, there is a substantial unmet need for accessible, evidence-based support that strengthens comprehension, appraisal, contextualization, and appropriate use of health information in preparation for clinical decision-making.

Chat and Voice Bots as Support for *BRCA1/2* Mutation Carriers

The evolution of conversational AI began with ELIZA [21] and PARRY [22], early systems rooted in mental health applications.

XSL•FO
RenderX



Today, medical chatbots are deployed across domains, though ethical and implementation challenges remain significant [7,8,23]. In oncology, they support screening, symptom tracking, and risk communication [24,25], with reported high user satisfaction, for example, in breast cancer education [26].

This study addresses the previously described "support vacuum" for *BRCA1/2* mutation carriers during waiting periods for clinical consultations. A conversational chat and voice bot is conceptualized as a supportive tool that provides evidence-based, interactive information to assist in preparing for clinical encounters.

At this stage, the chat and voice bot represents a conceptual system design rather than an implemented prototype. The envisioned architecture would combine an LLM with retrieval-augmented generation (RAG) to ground responses in a curated, evidence-based knowledge base. The proposed content development process would follow established standards such as the International Patient Decision Aid Standards (IPDAS) and would build on materials from the FBREK Consortium and the BRCA Network. The system is envisioned to support multilingual use and varying levels of health literacy.

In the proposed design, system integrity would depend on automated cross-referencing with the knowledge base, regular expert review, and clearly defined content governance processes. These mechanisms should be understood as design requirements derived from stakeholder input rather than as implemented or technically validated system features. Accordingly, Figure 1 illustrates the planned system architecture, not a deployed system.

Figure 1. Planned system architecture: a clinical knowledge base integrated via retrieval-augmented generation (RAG) to provide evidence-based support.

The rationale for such a purpose-built system is not that general-purpose LLMs are unavailable or incapable of conversational interaction. Rather, its added value lies in clinical and institutional governance. In contrast to general-purpose LLMs, the envisioned system would be restricted to a clearly defined *BRCA1/2*-related informational and preparatory role, grounded in a curated and expert-reviewed knowledge base, aligned with established patient decision-aid standards, and connected to escalation pathways for human support. The system is therefore conceptualized not as a more autonomous alternative to existing LLMs, but as a clinically bounded sociotechnical arrangement that limits unsupported interpretation, clarifies accountability, and supports preparation for clinical encounters.

A single example illustrates what this constraint adds. A 28-year-old carrier whose mother died of ovarian cancer at 42 years asks whether a positive BRCA1 result means she will certainly develop the disease. An unconstrained general-purpose system typically answers with cumulative lifetime incidence, approximately 44% by age 80 years [1], names risk-reducing salpingo-oophorectomy without temporal context, and closes with a generic instruction to consult a physician. Each element is accurate in isolation, yet together they equate genetic predisposition with imminence for a user in acute distress. A clinically bounded system would instead be configured to set that figure against the age-stratified incidence for her own age band, which remains an order of magnitude lower over the coming years [1]; to locate the surgical discussion in its guideline-anchored window from about 35 years of age for BRCA1 carriers, adjusted to the earliest diagnosis in her family [13,14]; and to route her to the responsible contact in her own care pathway. The difference lies not in model capability or conversational tone, but in the curated knowledge base, the response constraints, and the escalation rules for which the institution remains accountable.

Functionally, the envisioned system would provide structured summaries in text and audio formats to support clinical consultations and would include escalation pathways to human professionals for users in psychological distress.

From Ethical Principles to Design Practice: Responsible AI

Conversational agents have the potential to improve accessibility and user experience [27-29], but challenges remain regarding inclusivity, reliability, and ethical governance [30-34]. This study adopts a socioinformatics perspective, conceptualizing the system as embedded within social and organizational contexts where design choices shape care practices [35-37]. Responsible AI provides a framework to address these challenges, emphasizing transparency, fairness, and accountability, while highlighting the need to address issues such as explainability and bias [38-43].

In this study, responsible AI is understood as the design, development, and governance of AI systems in ways that are lawful, ethically aligned, technically and socially robust, transparent, accountable, privacy-preserving, and subject to meaningful human oversight. The EU High-Level Expert Group's Trustworthy AI guidance serves as the primary reference point for operationalizing this understanding, particularly through its emphasis on human agency and oversight, technical robustness and safety, privacy and data governance, transparency, diversity, nondiscrimination and fairness, societal and environmental well-being, and accountability [39].

These principles were used as sensitizing concepts rather than as a deductive coding scheme. Human oversight informed the analysis of role boundaries, escalation pathways, and the positioning of medical professionals as primary decision makers. Transparency and explainability guided attention to uncertainty communication, disclosure of system limitations, and prevention of automation bias. Privacy and data governance informed the analysis of genetic data sensitivity, consent, data minimization, and institutional accountability. Technical robustness and safety informed requirements for curated knowledge bases, expert review, and constrained system authority. Fairness and societal well-being informed attention to multilingual access, health literacy, eHealth literacy, accessibility, and the prevention of exclusion.

To operationalize these principles, the study draws on participatory design and value-sensitive design (VSD) to integrate stakeholder perspectives into system development [9,44,45]. Accordingly, responsible AI is treated not as a fixed checklist but as a sociotechnical design task involving the translation of general principles into concrete governance conditions, communication strategies, and role boundaries for a clinically bounded conversational AI system in *BRCA1/2*-related hereditary cancer care.

Research Gap and Research Question

Despite advances in digital health, limited evidence exists on how conversational AI can responsibly support *BRCA1/2* mutation carriers during waiting periods between genetic counseling, second opinions, and clinical decision-making. The underexplored issue is not simply whether conversational AI can provide information in genetic medicine, but how such systems can support the comprehension, appraisal, contextualization, and appropriate use of complex hereditary cancer information in emotionally charged and preference-sensitive contexts.

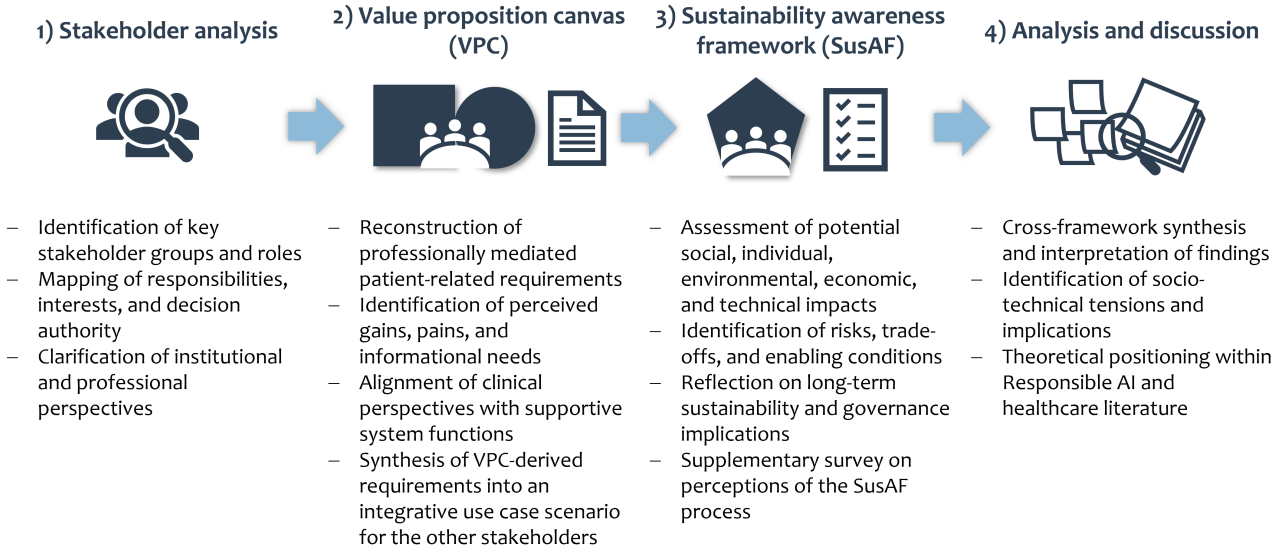
Existing research on medical chatbots has focused primarily on technical accuracy, usability, and user satisfaction, while less attention has been paid to how conversational AI can remain bounded by clinical governance, human oversight, validated content, escalation pathways, and responsible AI principles. In *BRCA1/2*-related care, this is particularly important because users must interpret probabilistic risk information and preventive options without mistaking informational support for clinical decision-making authority.

This study addresses this gap through a stakeholder-informed, sociotechnical perspective. It is guided by the following research question: how can stakeholder-informed design requirements for the responsible design and future integration of a conversational AI system in clinical care pathways be identified?

Methods

Overview

This study used a qualitative, practice-oriented design to identify stakeholder-informed design requirements for the responsible development of a conversational AI system in hereditary cancer care. The system served as an empirical case to examine sociotechnical and ethical dynamics. The study focused on deriving context-sensitive design requirements rather than evaluating system performance or user outcomes.



The conversational AI system examined in this study represents a conceptual design case rather than a fully implemented or deployed product. No prototype was implemented, no technical validation was performed, and no content pipeline was operationalized as part of this study.

The study followed a qualitative exploratory design informed by interpretive research principles and is reported in accordance with established standards, including the COREQ (Consolidated Criteria for Reporting Qualitative Research), to enhance transparency and rigor. In addition, relevant items from the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist were considered where applicable to enhance transparency in reporting digital health research.

The methodology integrated 3 complementary frameworks, including stakeholder analysis [9], the VPC [10], and the SusAF [11], which together structure data collection and analysis across sociotechnical dimensions (Figure 2).

XSL•FO
RenderX

Figure 2. Sequential analytical work steps applied in the study.

Stakeholder Analysis

The stakeholder analysis followed a 4-step process (identification, relevance assessment, interaction, and solution development) based on established participatory design approaches [9].

An interdisciplinary core team identified relevant stakeholders across clinical, technical, and social domains. For each group, key characteristics, including interests, perceived influence (scale 1 - 10), and conflict potential (scale 1 - 10), were assessed (Table 1).

XSL•FO
RenderX

Table . Stakeholder overview (abbreviated) with influence and conflict potential.

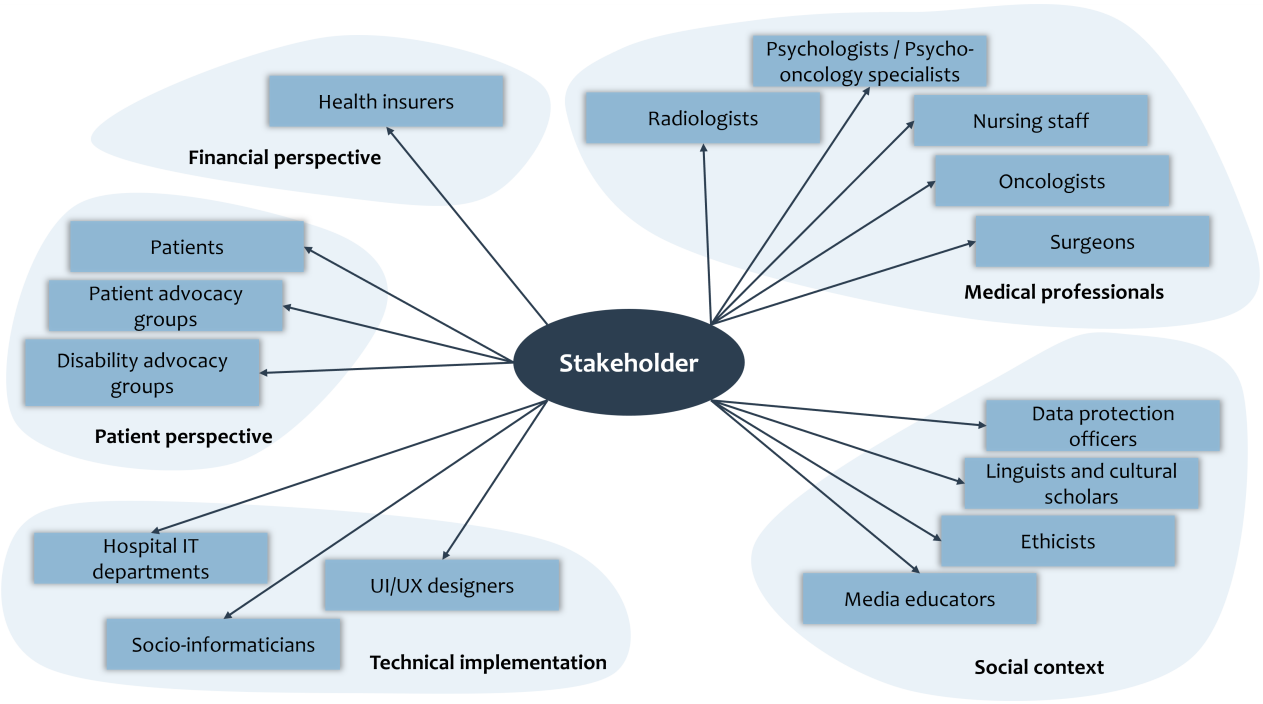
Stakeholder[a]	Known interests	Assumed interests	Perceived influence	Conflict potential	Present in the workshop
Patients	Clear, trustworthy info	Emotional relief; control	10	8	No
Oncologists	Preference-sensitive decisions	Time savings; clarity	10	8	Yes
Surgeons	Safe, aesthetic surgery	Manage expectations	9	7	Yes
Radiologists	Structured screening	Clarify false positive risk	9	7	Yes
Nursing staff	Coordination	Reduce cancellations	9	7	Yes
Patient advocacy	Participation; access	Strengthen autonomy	8	8	Yes
Psychologists	Psychosocial continuity	Early crisis detection	8	7	Yes
Ethicists	Ethical reflection	Influence guidelines	8	6	Yes
Hospital IT	IT security	Integration	7	5	Yes
UI[b]/UX[c] designers	User-centered design	Reduce cognitive load	7	3	Yes
Health insurers	Cost control; quality	Prevent misinformation	7	3	Yes
Disability groups	Accessibility	Avoid digital exclusion	6	4	Yes
Linguists	Cultural sensitivity	Prevent misunderstandings	6	4	Yes
Data protection experts	GDPR[d] compliance	Legal risk reduction	5	5	Yes
Media educators	Explain complexity	Improve transparency	5	3	Yes

[a]For each stakeholder group, perceived influence and conflict potential were assessed on a 1-10 scale through consensus-based discussion by the interdisciplinary core team. These scores represent qualitative assessments specific to the investigated use case rather than empirically measured quantities.

[b]UI:user interface.

[c]UX: user experience.

[d]GDPR: General Data Protection Regulation.



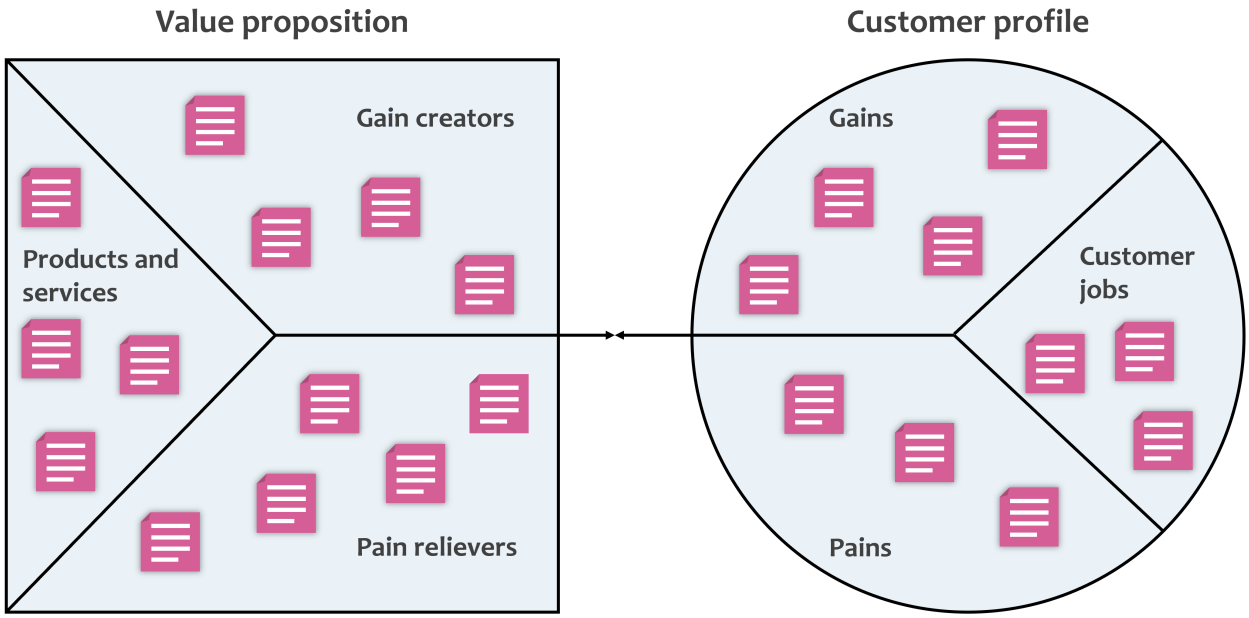
To ensure analytical focus, only stakeholders with an influence score of 5 or higher were included in participatory workshops, while additional stakeholders relevant for later implementation phases were documented but not actively involved. This threshold reflects a balance between inclusiveness and feasibility in early-stage participatory design.

While patients represent the primary end users, direct patient involvement was not included in this initial exploratory phase. This was an ethics-oriented precautionary decision within a phased predevelopment process, rather than an empirically demonstrated indication that patient involvement would have been harmful, inappropriate, or infeasible. To incorporate patient-related perspectives at this stage, psycho-oncology experts and patient advocacy organizations with experience in *BRCA1/2*-related care were included as professional stakeholders. Consequently, the findings reflect stakeholder-mediated interpretations of patient needs rather than direct patient accounts. Direct patient involvement is planned as a necessary next step to validate, refine, and potentially challenge the stakeholder-derived requirements once system boundaries, safeguards, and governance conditions have been further specified.

A stakeholder mapping was conducted to visualize relationships and cluster actors across medical, social, technical, financial, and patient-related domains (Figure 3).

XSL•FO
RenderX

Figure 3. Stakeholder mapping for the medical chat and voice bot.



Participants were recruited using purposive sampling to ensure representation of key stakeholder groups relevant to hereditary cancer care and conversational AI governance, based on professional expertise and practical involvement.

Participatory interactions informed the identification of key tensions, synergies, and unmet needs. Data from workshop outputs, field notes, and artifacts were analyzed iteratively to derive design requirements.

VPC

The VPC [10] was used as a co-design instrument to align the needs of *BRCA1/2* mutation carriers with clinically appropriate and technically feasible system components (Figure 4). The workshop involved medical professionals from relevant disciplines, complemented by technical and socioinformatics expertise.

Figure 4. Value proposition canvas (VPC).

Within the customer segment, the workshop characterized informational needs, emotional burdens, and expectations regarding counseling. The value map translated these into system functionalities and communicative boundaries, positioning the chat and voice bot as a supportive tool rather than a decision-making authority.

The workshop resulted in a consolidated one-page user-case scenario, which served as a shared reference for subsequent

XSL•FO
RenderX

participatory sessions and supported alignment between clinical requirements and system design (see Multimedia Appendix 1).

SusAF

The SusAF was applied as a participatory instrument to examine the broader sociotechnical implications of the chat and voice bot. In contrast to the VPC workshop, the SusAF session involved all identified stakeholder groups (n=18) to capture a wide range of perspectives.

The framework structures analysis across 5 sustainability dimensions and 3 orders of effects, enabling the identification of both immediate and long-term impacts [11] (Tables 2 and 3).

Participants identified and discussed potential positive, negative, and ambivalent effects, which were subsequently prioritized using an impact matrix based on likelihood and significance (Figure 5). This process enabled the identification of key factors that informed design requirements.

Results were further structured using the sustainability awareness diagram (SusAD) to map impacts across dimensions and effect levels, supporting interdisciplinary reflection and making implicit risks explicit (Figure 6).

A final stakeholder survey confirmed the usefulness of the framework and the relevance of the identified implications for system design.

Table . Sustainability dimensions of the SusAF[a].

Dimension	Description
Social	Concerns relationships between individuals and groups, including trust, communication, participation, inclusion, and the balance of potentially conflicting interests
Individual	Addresses individual well-being, autonomy, dignity, privacy, safety, and the capacity to make informed decisions and exercise agency
Environmental	Focuses on the stewardship of natural resources, including energy consumption, material use, and ecological impacts across the system life cycle
Economic	Encompasses financial and organizational aspects such as value creation, cost structures, governance, and long-term economic viability
Technical	Relates to the longevity and evolution of the system, including maintainability, adaptability, security, scalability, and resilience over time

[a]SusAF: sustainability awareness framework.

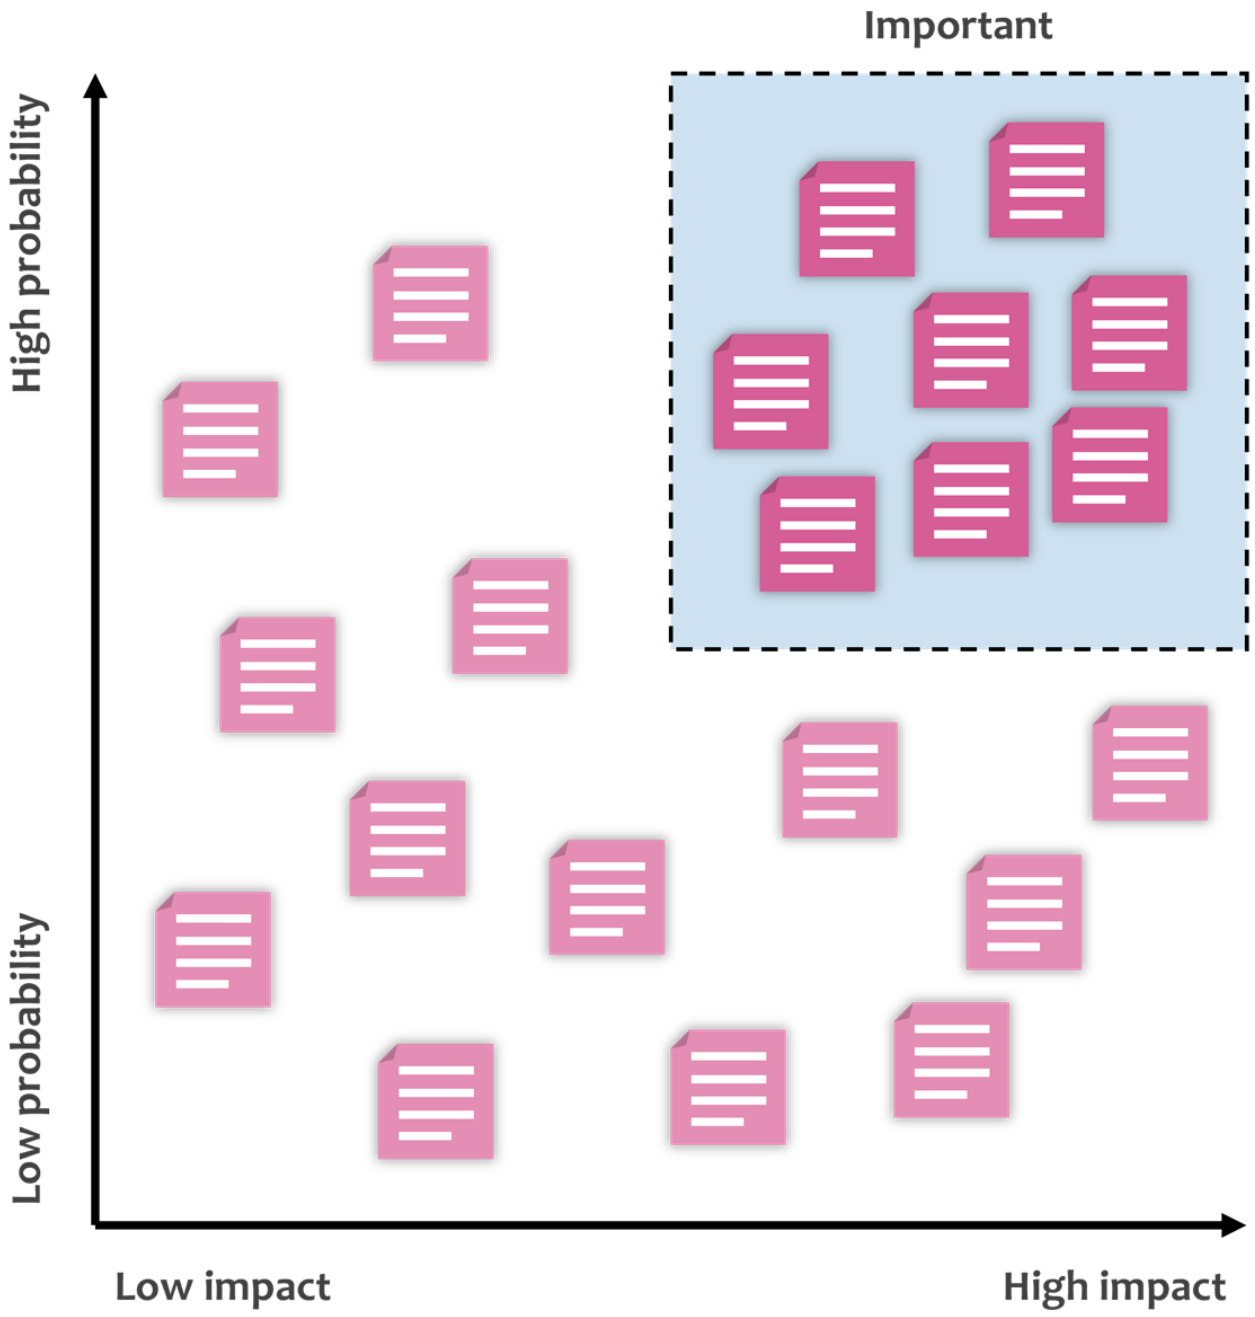


Table . Orders of sustainability effects in the SusAF[a].

Order of effect	Description
Immediate effects	Direct impacts from development, deployment, use, and disposal, including technical features and life-cycle energy consumption
Enabling effects	Indirect impacts emerging over time that induce changes in user behavior, clinical practices, or organizational routines
Structural effects	Long-term, systemic changes at the societal level influencing norms, policies, institutions, or health care infrastructures

[a]SusAF: sustainability awareness framework.

RenderX

Figure 6. Sustainability awareness diagram (SusAD).

Workshop Procedure, Data Collection, and Data Analysis

A total of 2 participatory workshops were conducted between July and September 2025, each lasting approximately 4 hours. Workshop 1 focused on stakeholder analysis and the VPC and included 8 participants from clinical and technical domains. Workshop 2 applied the SusAF and involved all 18 stakeholders. Each workshop followed a structured sequence consisting of (1) introduction and contextual framing, (2) guided individual reflection, (3) small-group work in interdisciplinary subgroups, and (4) plenary discussion and consolidation of results. Workshops were moderated by 2 facilitators with backgrounds in socioinformatics and qualitative research, following a predefined facilitation guide to ensure consistency.

The workshops followed a semistructured format combining individual reflection, collaborative exercises, and framework-based activities. Participants worked both individually and in interdisciplinary groups to generate and reflect on design-relevant insights.

Across both workshops, documented materials (structured outputs, field notes, and artifacts) comprised approximately 45 pages of textual data. No audio recordings were made; discussions were documented in real time and consolidated immediately after each session. The use of multiple data sources enabled triangulation and a comprehensive understanding of stakeholder perspectives.

Data were analyzed using an inductive, codebook-supported form of thematic analysis. The analysis followed a staged procedure consisting of (1) familiarization with structured workshop outputs, field notes, and artifacts, (2) open coding of design-relevant needs, risks, tensions, and safeguards, (3) grouping of codes into preliminary categories, (4) comparison of categories across stakeholder analysis, VPC, and SusAF outputs, and (5) iterative refinement into higher-level design requirements.

XSL•FO
RenderX

The stakeholder analysis, VPC, and SusAF frameworks structured data collection and served as sensitizing lenses during interpretation, but they did not predetermine the final themes. Codes were first generated inductively from the documented workshop materials. They were then compared across the 3 frameworks to identify recurring patterns, contradictions, and cross-stakeholder tensions. For example, codes related to "role boundaries," "medical accountability," "automation bias," and "escalation to human professionals" were consolidated into the higher-level requirement of constrained system authority and mandatory human oversight. Similarly, codes concerning "information overload," "adaptive explanation," "emotional reassurance," and "uncertainty communication" informed the requirement of context-sensitive communication.

Coding was conducted independently by 2 researchers, DL and YS, on the complete set of documented materials. Differences in coding and category assignment were discussed until consensus was reached. Categories were retained as higher-level design requirements only when they were supported by multiple data sources or when contested perspectives could be reconstructed as meaningful stakeholder tensions. This procedure enabled triangulation across data sources, including field notes, structured workshop artifacts, and framework-based outputs, as well as across analytical lenses, including stakeholder analysis, VPC, and SusAF.

Workshops were not audio-recorded due to the sensitive clinical context and to foster an open discussion atmosphere. To mitigate potential loss of nuance and selective documentation, field notes were taken by multiple facilitators in parallel, compared after each workshop, and expanded immediately after each session while the discussion context was still fresh. Structured workshop outputs, including written artifacts, prioritization matrices, stakeholder maps, and framework-based templates, were treated as primary qualitative data rather than as supplementary documentation. Field notes were used to contextualize these artifacts, reconstruct stakeholder reasoning, and identify tensions that were not fully captured in the structured templates.

The research team's dual role as system designers and analysts was addressed through reflexive practices. Researchers documented assumptions and potential biases in analytic memos and revisited them throughout the coding process. Particular attention was given to disconfirming cases and tensions between stakeholder groups. Interpretations were retained only when supported by multiple data sources or when contested perspectives could be reconstructed.

The findings therefore describe stakeholder-informed design and governance requirements rather than evidence of system performance, safety, usability, or clinical effectiveness. Future work should therefore develop and evaluate a prototype, validate the reliability of the RAG-based architecture, and specify the content governance pipeline in detail.

To enhance transparency, illustrative excerpts from field notes and artifacts are reported in the Results section. These are paraphrased for readability and attributed to stakeholder groups to maintain confidentiality.

As the system is in an early conceptual stage, no real-world use data (eg, system logs, user interaction metrics, or adherence data) were collected. Instead, insights are based on structured stakeholder interactions and qualitative analysis.

Ethical Considerations

This study did not involve direct patient participation or the collection of patient-level health data. The study involved professional stakeholders who contributed expert perspectives in participatory design workshops. All participants were recruited based on their professional expertise and provided informed consent prior to participation.

Formal ethical approval was not required for this expert consultation and qualitative design study in accordance with institutional guidelines on good scientific practice at the Technical University of Munich. Nevertheless, ethical safeguards were applied throughout the research process, including voluntary participation, informed consent, confidentiality, anonymized documentation of workshop outputs, responsible data handling, and anonymized reporting of stakeholder perspectives.

No audio recordings were made. Workshop data were documented through structured artifacts, field notes, and summarized outputs without attributing statements to identifiable individuals. All study materials were stored on access-restricted institutional systems and were accessible only to the research team.

Results

The following sections present stakeholder-derived design requirements and sociotechnical tensions identified through the participatory co-design process using the VPC and SusAF.

VPC: Aligning Patient Needs With System Capabilities

The VPC workshop synthesized stakeholder-informed interpretations of the needs of *BRCA1/2* mutation carriers, structured into customer profiles (gains, pains, and customer jobs) and corresponding system responses.

The Mutation Carrier Profile: Gains, Pains, and Customer Jobs

Stakeholders described 2 central phases: understanding genetic risk and evaluating preventive options in relation to life plans.

Gains

Stakeholders emphasized the need for continuous access to reliable, evidence-based information to support decision-making. Key gains include structured action options, individualized risk information, and preparation for clinical consultations. Emotional needs include empathic communication, continuity of care, and reassurance, as well as multilingual and accessible information.

Pains

Fear emerged as a dominant factor, including anxiety related to diagnosis, surveillance, fertility, and family implications. This is compounded by information overload, time pressure, and uncertainty about preventive options. Additional challenges

XSL•FO
RenderX

include limited psychosocial support, lack of trustworthy information, language barriers, and financial concerns.

Customer Jobs

Mutation carriers aim to regain orientation and control, understand individual risk, and make informed decisions regarding prevention, surveillance, and family planning. Stakeholders highlighted the importance of trust in clinical care and access to understandable information, alongside initial skepticism toward digital tools.

Stakeholders emphasized informational fragmentation during waiting periods, as illustrated by one participant, "patients receive pieces of information from different disciplines, but no coherent picture emerges." Emotional burden was closely linked to informational uncertainty, with one expert noting that patients fear "making the wrong decision under pressure." At the same time, clinical stakeholders stressed decision quality and guideline adherence, warning that "simplifying information too much risks misinterpretation." Stakeholder perspectives differed in how needs were prioritized. Clinical stakeholders emphasized decision quality and guideline alignment, while psychosocial and advocacy stakeholders focused on emotional burden and continuity of support. Technical stakeholders highlighted feasibility, scalability, and interaction design.

The System's Value Proposition: Mechanisms for Support

The chat and voice bot was conceptualized as a supportive tool that complements clinical care.

Gain Creation

Adaptive communication tailors information to individual needs and supports preparation for clinical consultations, enhancing perceived autonomy.

Pain Relievers

The system addresses emotional distress through validation and referral to human support while maintaining clear role boundaries and providing structured, evidence-based information.

Trust and Onboarding

Stakeholders emphasized that trust depends on transparent communication, clinical integration, and clear positioning as a non-authoritative informational tool.

Information Support

The system provides continuous access to curated information on prevention, fertility, and psychosocial aspects in multilingual and accessible formats.

Boundary Management and Governance

The system incorporates safeguards against overreliance, including explicit uncertainty communication, encouragement of clinical verification, and expert-reviewed quality assurance. The system is constrained to an informational and preparatory role and includes default escalation pathways to human professionals.

Across stakeholder groups, three requirements were consistently prioritized: (1) clear communication of system limitations, (2) integration into clinical care pathways, and (3) mechanisms for human oversight and escalation. Other features were considered secondary, indicating that trust-building and governance are foundational design conditions.

User Case Scenario as an Integrative Result

A narrative user case scenario was developed to represent a mutation carrier's trajectory from diagnosis to decision-making. It translates abstract requirements into a clinical context, supports alignment on system boundaries (eg, exclusion of longitudinal monitoring and imaging diagnostics), and informs subsequent sustainability and ethical evaluations (see Multimedia Appendix 1).

Cross-Stakeholder Tensions

The analysis revealed several tensions between stakeholder groups, indicating that system design requires balancing competing priorities rather than addressing isolated needs. The most distinctive contribution of the stakeholder workshops was not the identification of responsible AI principles as such, but the reconstruction of how these principles were negotiated, prioritized, and translated into design requirements in the specific context of *BRCA1/2*-related hereditary cancer care. The 3 core requirements should therefore be understood as outcomes of cross-stakeholder tensions rather than as standalone principles.

A central tension concerned the level of system autonomy. Clinical stakeholders emphasized strict role boundaries and the positioning of the system as a nonauthoritative informational tool, whereas advocacy and psychosocial stakeholders highlighted the need for continuity and emotional support, which may increase reliance on the system.

A second tension involved the depth and complexity of information. Medical professionals favored precise and detailed communication to avoid misinterpretation, while communication-focused stakeholders emphasized simplification and progressive disclosure to prevent cognitive overload.

A third tension emerged between technical scalability and ethical safeguards. Technical stakeholders emphasized efficiency and automation, whereas ethicists and data protection experts prioritized transparency, explainability, and strict governance mechanisms.

These tensions were reflected in contrasting stakeholder statements. For example, clinical stakeholders emphasized strict system boundaries ("the system must not be perceived as giving medical advice"), whereas advocacy-oriented participants stressed the need for continuity ("patients need something that feels like ongoing support, not just information"). Similarly, clinicians highlighted the importance of precision ("details matter to avoid wrong conclusions"), while communication-focused stakeholders emphasized simplification ("too much detail overwhelms patients in this situation").

These contrasting perspectives indicate that design requirements emerge from negotiated trade-offs rather than uniform stakeholder agreement. These trade-offs informed the subsequent

XSL•FO
RenderX

interpretation of onboarding, communication design, quality management, and clinical integration as interdependent governance mechanisms rather than isolated design features.

Results From the SusAF

Stakeholders identified sustainability-related impacts across all 5 SusAF dimensions. Rather than treating these dimensions as separate domains, the analysis showed that sustainability in this context depends on whether the system can support *BRCA1/2* mutation carriers during a clinically and emotionally sensitive waiting period without displacing human care or amplifying misinterpretation.

Context-Specific Social and Individual Implications

Across the social and individual dimensions, stakeholders emphasized that 24-hour availability, multilingual access, and the possibility to ask sensitive questions in a low-threshold format could support orientation, self-efficacy, and preparation for clinical consultations. These benefits were considered particularly relevant for topics such as hereditary risk, fertility, preventive surgery, family communication, and psychosocial burden. At the same time, participants warned that decontextualized genetic information could increase anxiety, distort risk perception, or contribute to stigmatization and discrimination. The main design implication was therefore not simply to increase access to information but to provide adaptive, progressively disclosed, and clearly bounded information with transparent escalation pathways to human professionals.

Technical, Data-Related, and Governance Implications

The technical dimension was closely linked to these psychosocial and clinical concerns. Stakeholders viewed a curated knowledge base and RAG as promising mechanisms for source-based information provision, but only if combined with expert review, continuous content maintenance, robust data protection, and explicit communication of uncertainty. Automation bias was identified as a key risk, particularly because users may interpret chatbot responses as medical authority in moments of uncertainty or distress. Technical sustainability therefore depends on maintaining a clear distinction between informational preparation and clinical decision-making.

Environmental and Economic Conditions

Environmental and economic effects were discussed as conditional rather than inherent benefits of digital support. Remote access may reduce unnecessary travel or preparatory consultations, and structured information may help clinical encounters become more focused. However, these potential benefits depend on energy-efficient infrastructure, long-term maintenance capacity, sustainable financing, and regulatory compliance. Stakeholders therefore emphasized that digitalization should not be assumed to be sustainable by default; its value depends on governance, clinical integration, and continued institutional responsibility.

The SusAF analysis showed that the most relevant sustainability concerns in this use case are not generic efficiency gains but the interaction between access, psychological safety, genetic data sensitivity, clinical accountability, and long-term governance. Without clear boundaries, transparency, and integration into clinical workflows, features intended to empower users may also amplify risks such as misinterpretation, overreliance, exclusion, or inequity, underlining the dual-use character of conversational AI in health care contexts.

Stakeholder Reflections on the Process

The postworkshop evaluation (n=14/18) indicates a broadly positive reception of the SusAF process. Ten respondents rated its usefulness as high to very high, and none reported low relevance. Eight participants considered the knowledge gained to justify the time investment, while 6 participants assessed the effort-benefit ratio as moderate.

Participation influenced perspectives, with 8 respondents reporting moderate to strong changes in their understanding of medical chatbot requirements. These shifts reflected increased awareness of heterogeneous user needs and structural constraints of clinical practice, including limited time and the need for interdisciplinary coordination. Interdisciplinary exchange was identified as a key success factor, with 13 participants rating it as highly helpful.

Regarding implementation, stakeholders emphasized that the system should function as a supportive, preparatory tool rather than a standalone solution. Key requirements include transparent communication of system limitations, robust informed consent, and clear positioning of medical professionals as primary points of contact. Participants also highlighted the importance of cultural sensitivity through multilingual and accessible communication.

Discussion

The findings highlight how responsible conversational AI in hereditary cancer care depends on constraining system authority, embedding human oversight, and integrating systems into clinical care pathways.

Onboarding Process and Informed Consent

The stakeholders understood onboarding as a central sociotechnical mechanism for shaping trust and role perception within the care pathway. In the context of hereditary cancer, initial digital interactions appear closely linked to processes of trust formation and emotional safety. A human-mediated onboarding process emerges as particularly important for positioning the chat and voice bot as a supportive tool rather than a replacement for clinical expertise. Introducing the system through medical professionals may therefore contribute to reduced anxiety and clearer role expectations within the care pathway.

From an ethical perspective, informed consent can be understood as a multilayered and ongoing communicative process rather than a one-time procedural step. This includes explicitly communicating system limitations, potential inaccuracies, and the need for human verification. Such transparency is critical for mitigating automation bias and safeguarding individual autonomy, while also reducing cognitive overload and reinforcing clinical responsibility as part of sustainable system use.

XSL•FO
RenderX

The findings further indicated that onboarding should be conceptualized as adaptive and revisitable over time, particularly as patients transition between different phases of decision-making. As individuals move from initial risk assessment to surgical considerations, informational needs and emotional states evolve, requiring corresponding adjustments in how consent and system use are framed.

Linguistic Abilities and Communication Strategies

The findings indicated that linguistic configuration represented a central component of the sociotechnical integration of the chat and voice bot. It could be conceptualized along 3 interrelated dimensions, including sociolinguistic awareness, inclusivity, and strategic communication. The ability to balance an appropriate medical register with adaptive language complexity emerged as particularly critical. This includes adjusting terminology and depth of explanation to individual patient backgrounds, ranging from barrier-free communication for less experienced users to more technical discourse when appropriate. Such adaptability appeared essential for fostering resonance and preventing alienation.

Linguistic inclusivity further extended beyond translation toward a multilingual and multimodal communication architecture. Enabling interaction in a user's preferred language may strengthen accessibility and perceived conversational intimacy. At the same time, bridging the digital–physical divide through multimodal outputs, such as combined voice, text, and structured materials for clinical preparation, appeared to support continuity of care and integration into clinical workflows.

With regard to communication strategies, the findings pointed to the importance of balancing factual clarity with empathic responsiveness. While concise and action-oriented responses are necessary to avoid ambiguity and prevent misinterpretation, acknowledging emotional states remains central to user-centered interaction. In this context, epistemic transparency—including explicit communication of system limitations—emerged as a key mechanism for aligning professional credibility with responsible use.

Taken together, these observations suggest that effective communication design requires the integration of sociolinguistic sensitivity and factual precision. This integration enables the system to address users as individuals rather than as abstract clinical cases, thereby supporting both informational and emotional needs.

Finally, communication must be understood as embedded within broader sociocultural contexts. This includes sensitivity to topics such as fertility, body image, and genetic responsibility, as well as to variations in health literacy, perceptions of medical authority, and attitudes toward preventive interventions. Cultural competence, therefore, extends beyond multilingual support and represents a core condition for responsible system design.

Usability and User Experience

In the workshops, usability and user experience (UX) extended beyond interface design and constituted central conditions shaping the perceived clinical fit of the system. In the context of hereditary cancer risk, UX can be understood as a form of emotional scaffolding, particularly for users experiencing cognitive and emotional overload.

The SusAF analysis indicates that perceived autonomy is closely linked to interaction design. Features such as progressive disclosure and modular content enable users to regulate the depth and pace of information, thereby supporting agency and reducing the risk of disempowerment. In this sense, usability also appears to function as a proxy for institutional trust, as transparent interaction design and explicit cues for escalation to human professionals reinforce confidence in the system's appropriate role.

At the same time, usability must be responsive to heterogeneous user groups. This includes ensuring that voice-based interaction and accessibility features reduce barriers without oversimplifying medically complex information. Technical robustness and error transparency are equally critical, as usability-related failures—such as latency or unmasked hallucinations—carry ethical implications by potentially fostering misplaced trust.

Quality Management

Across the participatory workshops, stakeholders emphasized that quality management for medical conversational agents should be embedded within existing structures of clinical governance rather than treated as a purely technical concern. The chat and voice bot can thus be understood as a preparatory and informational tool whose legitimacy depends on clearly defined institutional responsibilities and explicit role boundaries between automated support and human medical expertise.

Accordingly, quality assurance appears to rely on clinically curated knowledge bases, expert validation processes, and established medical standards, rather than being delegated to the system itself. In this context, quality management emerges as a continuous and iterative process requiring ongoing expert review and system refinement.

With regard to accountability, responsibility was consistently located within the clinical organization rather than attributed to the system. Quality management therefore functions as a mechanism for ensuring traceability, transparency, and professional accountability, supported by clear escalation pathways to human professionals.

This governance perspective also clarifies the added value of a purpose-built system compared with general-purpose LLMs. While general-purpose systems may provide fluent and accessible responses, their use alone does not establish clinical accountability, validated content governance, institutionally defined role boundaries, or reliable escalation pathways. For *BRCA1/2* mutation carriers, these governance conditions were not peripheral safeguards but central design requirements, because users may otherwise mistake conversational fluency for medical authority in moments of uncertainty or distress, as illustrated by the risk-framing and triage example outlined above.

RenderX

Environmental and Economic Trade-Offs of Digital Support

Environmental and economic considerations emerged as secondary but relevant governance concerns. In contrast to the social, individual, technical, and legal issues, these effects were less specific to hereditary cancer care, but they remain important for assessing whether conversational AI can be responsibly sustained in clinical practice.

From an environmental perspective, potential benefits arise primarily through the reduction of physical travel, as remote access to specialized information may decrease unnecessary in-person consultations and associated emissions. However, these benefits are highly dependent on system design. Energy-intensive processes, including model training, inference, and supporting infrastructure, may offset such gains if not carefully managed. Environmental outcomes thus emerge as indirect consequences of architectural and governance decisions, requiring energy-efficient infrastructures and minimized computational overhead.

Similarly, economic implications reflect a tension between potential efficiency gains and structural costs. While shifting preparatory informational tasks to the system may relieve clinical staff and enable more focused patient encounters, the development, certification, maintenance, and regulatory compliance of medical-grade AI systems represent substantial and ongoing financial commitments.

Taken together, sustainability cannot be assumed as an automatic outcome of automation. Instead, both environmental and economic viability depend on governance conditions, including transparent financing structures, institutional responsibility for long-term maintenance, and alignment with health care reimbursement systems.

Data Protection, Privacy, and Legal Requirements

The findings indicated that legal and regulatory compliance is not merely a boundary condition but a central determinant of trust, system acceptance, and responsible integration into clinical care. Data protection requirements, in particular, can be understood as core design conditions that shape system architecture, communication strategies, and governance structures.

The deployment of the chat and voice bot falls within the scope of the General Data Protection Regulation (GDPR; EU) 2016/679, as it involves the processing of personal data (Article 4(1) GDPR; cf. Court of Justice of the European Union [CJEU], Endemol Shine, C-740/22), including chat logs and genetic risk information. The institution determining the purposes and means of processing acts as the controller (Article 4(7) GDPR).

From a design perspective, data minimization and user control emerge as central requirements. An anonymization-oriented approach (Recital 26(5) GDPR) may be implemented through pseudonymized access codes. Where datasets cannot be linked to identifiable individuals by any party, the information is considered anonymized and thus falls outside the scope of the GDPR (cf. CJEU, Single Resolution Board [SRB], C-413/23 P).

Compliance with core principles such as lawfulness, fairness, and transparency (Article 5(1)(a) GDPR) must be operationalized in ways that remain accessible to users. While scientific research may benefit from specific provisions (Article 89 GDPR), deployment in clinical practice requires a valid legal basis, such as a medical contract (Article 6(1)(b) GDPR) or consent ([46], para 48). For special categories of personal data, including genetic and broadly defined health data (cf. CJEU, C-21/23), explicit consent (Article 9(2)(a) GDPR) or Article 9(2)(h) GDPR in conjunction with Section 22 of the German Bundesdatenschutzgesetz (Federal Data Protection Act; BDSG) applies, provided appropriate safeguards are ensured.

At the same time, the findings highlight that extensive legal information may itself contribute to cognitive overload, particularly in emotionally vulnerable situations. This suggests the need for layered privacy communication, combining concise summaries with access to more detailed information, in line with transparency requirements under Article 13 and 14 GDPR [47].

Concerns regarding automated decision-making further underline the importance of clearly defined system boundaries. Although the system was designed to provide informational support without producing legally binding or directly consequential decisions, maintaining this distinction is critical to avoid regulatory risks (Article 22 GDPR; see also CJEU, Schufa, C-634/21) and unintended overreliance.

Beyond data protection, stakeholders pointed to the relevance of the EU AI Act (Regulation [EU] 2024/1689), particularly regarding transparency obligations (Article 50(1)). Clear disclosure of AI interaction was therefore considered essential to support informed use and prevent misinterpretation.

The classification of the system under the Medical Device Regulation (MDR; Regulation [EU] 2017/745) remains context-dependent [48-50]. Maintaining the system's role as an informational and preparatory tool, rather than engaging in monitoring or treatment (Article 2(1) MDR) [51,52] appears critical for avoiding more stringent regulatory requirements. Current legislative developments (the European Commission's proposed COM [2025] 1023 final) [53] may affect the interaction between the MDR and the AI Act.

At the national level, the German Genetic Diagnosis Act (GenDG) requires explicit consent for processing genetic data (Section 11 GenDG). These requirements are closely linked to broader questions of liability and professional responsibility [54]. Rather than attributing responsibility to the system, accountability remains anchored in clinical institutions. In this context, technical safeguards, such as constrained system prompts and conservative response strategies, function as mechanisms to reinforce the system's supportive role and limit potential liability (Sections 280, 823 German Civil Code–BGB).

Overall, legal and regulatory requirements emerged as integral components of system design. Rather than being addressed retrospectively, they shape core design decisions, including system boundaries, communication strategies, and the positioning of human professionals as primary decision makers.

XSL•FO
RenderX

Compared with the informal use of general-purpose LLMs, an institutionally governed system would also allow clearer allocation of controller responsibilities, data minimization strategies, consent procedures, and accountability structures within the clinical setting.

Summary: Reframing Responsibility in Conversational AI for Health Care

Taken together, this sociotechnical analysis suggests that responsibility in conversational AI is not an intrinsic system property but a relational and organizationally situated outcome. Rather than arising from technical accuracy or compliance alone, it emerges from concrete design decisions, including limiting system authority, embedding escalation pathways, and ensuring transparency about uncertainty.

These findings point to a shift in emphasis from optimizing autonomous systems toward designing sociotechnical arrangements that preserve relational care and professional responsibility. More broadly, they indicate that responsibility in medical AI is less a function of model performance than of how system capabilities are deliberately positioned, limited, and governed within clinical contexts.

This study contributes stakeholder-informed insights into how principles of responsible AI can be translated into context-sensitive design considerations for clinical implementation. Rather than proposing new normative frameworks, its central contribution lies in showing how responsible AI requirements are shaped through practical negotiations between competing clinical, psychosocial, technical, and organizational priorities, including accuracy versus accessibility, emotional support versus role boundaries, and scalability versus governance.

Although situated in hereditary cancer care, the identified tensions—including those between autonomy and safety, accessibility and accuracy, and scalability and governance—are likely to extend to other domains of AI-supported, preference-sensitive decision-making in health care.

Limitations

The qualitative and exploratory design prioritizes analytical transferability over statistical generalizability. While this enables in-depth, context-sensitive insights, the findings may not fully represent all clinical settings.

The purposive sampling of stakeholders strengthens practical relevance but introduces potential selection bias. The sample predominantly reflects expert perspectives from the European, specifically German, health care context. Validation in different cultural and regulatory environments is therefore required.

Construct validity may be affected by varying interpretations of abstract concepts such as sustainability. This was addressed through the use of established frameworks (VPC and SusAF) and structured conceptual framing. Nevertheless, reactive bias remains a limitation, as participants in workshop settings may exhibit socially desirable or consensus-oriented responses. Mitigation strategies included neutral facilitation and anonymous postworkshop surveys.

Because workshops were not audio-recorded, the analysis may have missed nuances of interaction, phrasing, or disagreement that would have been available in verbatim transcripts. This limitation was mitigated through parallel field note-taking by multiple facilitators, immediate postworkshop consolidation, triangulation with structured artifacts and framework-based outputs, and consensus-based interpretation by 2 researchers.

Differences in digital literacy among participants likely influenced perceptions of AI-related risks. Although a common baseline was established through introductory explanations, such variation cannot be fully controlled in interdisciplinary settings. In addition, the interpretive subjectivity inherent in qualitative analysis may affect results, despite collaborative coding and iterative validation processes.

The absence of direct patient involvement is a substantive methodological limitation, particularly because the envisioned conversational AI system is intended to support *BRCA1/2* mutation carriers. Patient perspectives were represented indirectly through psycho-oncological and advocacy expertise, which provided clinically and experientially informed approximations of user needs but cannot substitute for direct accounts of lived experience. Future research should therefore involve mutation carriers directly under appropriate ethical and clinical safeguards to validate, refine, and potentially challenge the stakeholder-derived requirements.

The research team's dual role as system designers and analysts may have influenced problem framing and interpretation. While this enabled contextual sensitivity and iterative refinement, it also required continuous reflexive practices to mitigate potential confirmation bias.

The findings are context-dependent and may not be directly transferable to settings lacking institutional oversight, digital literacy, or clearly defined professional responsibility structures.

Although the manuscript discusses key German/EU regulatory considerations, a definitive legal classification of the system under the MDR and the EU AI Act was beyond the scope of this exploratory design study and should be examined in future work together with legal and clinical implementation experts.

Overall, the findings should be understood as context-sensitive rather than definitive, highlighting the need for longitudinal research and broader population-based studies to assess the long-term deployment of responsible AI in health care.

Summary and Conclusion

This study provides a structured account of how established responsible AI principles are negotiated and translated into stakeholder-derived design requirements for conversational AI in *BRCA1/2*-related hereditary cancer care. The findings suggest that effective implementation depends less on increasing system autonomy than on constraining and embedding AI within clinical governance structures.

Across stakeholder groups, responsible use was consistently associated with transparent communication of system limitations, clearly defined role boundaries, and mechanisms for human oversight. Against the backdrop of widely accessible general-purpose LLMs, these findings suggest that the added

XSL•FO
RenderX

value of a purpose-built system lies not in conversational access alone, but in clinically bounded governance, validated content, institutional accountability, data protection, and reliable escalation pathways. These elements emerge as central conditions for trust, appropriate use, and the prevention of over-reliance.

By combining stakeholder analysis, the VPC, and the SusAF, this study demonstrates how abstract principles of responsible AI can be translated into context-sensitive design considerations. Importantly, these considerations arise from negotiated tensions rather than from uniform stakeholder agreement.

Future research should directly involve *BRCA1/2* mutation carriers, evaluate real-world use, and examine how such systems interact with clinical workflows over time. In addition, the findings underline that systematic alignment with evolving regulatory frameworks should not be treated as a downstream compliance task but as an integral part of responsible design, particularly in relation to GDPR, MDR, GenDG, the EU AI Act, and institutional accountability in the German/EU health care context.

Acknowledgments

ChatGPT (OpenAI; model version not documented) was used during manuscript preparation. The tool was used for reference formatting, encompassing standardization of 54 references from heterogeneous source formats. All references were subsequently verified against authoritative sources. The tool was also used for language refinement: ChatGPT suggested minor reformulations of author-written content to ensure consistent use of English throughout the article. Any suggestions were reviewed, accepted, rejected, or modified by the authors. The tool was not used for literature selection, study design, data collection, analysis, interpretation, or the generation of scientific claims. All AI-assisted content was reviewed and verified by the authors, who take full responsibility for the manuscript.

Funding

This research received no external funding.

Conflicts of Interest

JL received honoraria from AstraZeneca GmbH (Germany) and Novartis Pharma GmbH (Germany).

Abstract

Background: Real-world behavioral and physiological functioning, including heart rate, daily mobility, and sleep patterns, may provide information about aging and early neurodegenerative changes that is not captured by periodic clinical visits. Wrist-worn wearable devices offer a promising approach for continuous, passive monitoring of these domains. However, evidence regarding feasibility, usability, and acceptability in real-world observational settings among community-dwelling older adults in China remains limited.

Objective: This study primarily aimed to evaluate the feasibility, usability, and acceptability of using wrist-worn wearable devices to monitor behavioral and physiological function in community-dwelling older adults under naturalistic conditions. As a secondary objective, the study descriptively characterized wearable-derived behavioral and physiological measures among participants with minimal consecutive valid monitoring.

Methods: We enrolled 486 community-dwelling older adults from the Beijing region of the China-Aging cohort, each of whom received a Huawei Band 8 commercial wrist-worn wearable device. A valid monitoring day was defined as 10 or more hours of wear time. Participants were classified into three monitoring-pattern categories based on predefined wear-time criteria: no valid monitoring day, nonconsecutive valid monitoring, and minimal consecutive valid monitoring (≥3 consecutive valid monitoring days). Demographic characteristics, health status, and cognitive and functional measures (Mini-Mental State Examination and Barthel Activities of Daily Living Index) were compared across groups. Usability, acceptability, and perceived barriers were assessed using a structured user experience survey.

Results: Of 486 participants, 224 (46.1%) achieved minimal consecutive valid monitoring, 156 (32.1%) had nonconsecutive valid monitoring, and 106 (21.8%) had no valid monitoring day. Self-rated health differed significantly across monitoring patterns (P=.005), whereas no significant differences were observed for the other measured baseline characteristics. Among participants with minimal consecutive valid monitoring, mean daily heart rate was 72.1 (SD 8.6) bpm, median daily step count was 6177 (IQR 4249 - 8872) steps/day, and sleep data were available for 211 out of 224 (94.2%), with a median sleep duration of 7.23 (IQR 6.48 - 8.04) hours. The user experience survey was completed by 106 out of 486 (21.8%) participants, with higher participation among those with more sustained monitoring. Respondents generally reported favorable usability and acceptability; common barriers included device discomfort, data synchronization issues, and battery life.

Conclusions: Wrist-worn wearable monitoring was feasible under naturalistic conditions for a substantial proportion of community-dwelling older adults in China, with generally favorable usability and acceptability among survey respondents. However, monitoring patterns varied considerably across individuals, highlighting challenges for long-term use and large-scale implementation. These findings support the potential of wearable technologies for longitudinal monitoring outside clinic-based assessments. Further research is needed to establish the stability and clinical relevance of wearable-derived behavioral measures over longer monitoring periods.

Introduction

Population aging is a major global demographic trend that is reshaping public health priorities and increasing demands on health care systems worldwide [1]. As life expectancy increases, a growing proportion of older adults experience age-related declines in functional ability, reflecting gradual changes in physical and cognitive capacities that are essential for maintaining independent living [2]. Functional decline is strongly associated with increased morbidity, mortality, health care utilization, and societal burden [3,4].

Functional deterioration in later life rarely occurs abruptly. Accumulating evidence indicates that subtle and progressive changes in daily-life behaviors, such as alterations in walking patterns [5], physical activity levels [6], and sleep characteristics [7,8], often precede clinically detectable impairment by several years. Longitudinal and meta-analysis studies further suggest that increased variability in routine behaviors, particularly sleep and activity patterns, is associated with emerging cognitive and functional vulnerability, even in the absence of overt clinical symptoms [8-10].

Despite growing recognition of early functional change, current assessment approaches remain largely limited to episodic clinic-based assessments and self-reported measures [11]. Standard assessments typically rely on brief performance tests administered during scheduled clinical visits, retrospective questionnaires, or caregiver reports, providing only snapshots of functioning at isolated time points [11,12]. As a result, these approaches are limited in their ability to capture gradual trajectories of functional change, particularly during preclinical or early stages when deviations from individual baselines are subtle, heterogeneous, and context-dependent [12,13]. Moreover, self-reported and proxy-reported measures are vulnerable to recall bias and reporting inaccuracies, constraining sensitivity to small but clinically meaningful behavioral alterations [14,15].

Wearable sensing technologies have emerged as a promising approach to addressing these limitations. Wrist-worn devices can passively and continuously capture daily behaviors, including physical activity [16], sleep [17], and heart rate dynamics [18], using embedded accelerometers and photoplethysmography (PPG) sensors with minimal user burden [16,19]. Beyond passive data collection, accumulating evidence suggests that these continuously monitored behaviors carry prognostic significance [5,7,10].

Wearable-derived behavioral and physiological patterns show strong clinical associations in older adults. Lower daily step counts, reduced activity, and more sedentary profiles are associated with higher all-cause mortality and cardiovascular risk [4,20-22]. Similarly, sleep characteristics, including shorter duration, greater night-to-night variability, and longitudinal deterioration, are associated with subsequent cognitive impairment and neurodegenerative risk [7,8,23]. Recent work suggests that real-world behavioral measures derived from wrist-worn devices, including walking speed, activity patterns, and sleep timing, can predict incident dementia years before clinical diagnosis [5]. In particular, gait-related measures have been developed as digital biomarkers [24] and can distinguish mild Alzheimer disease from cognitively normal controls in community settings [25]. Beyond observational associations, wearable technologies are increasingly being applied in intervention studies and structured remote monitoring programs in clinical research [26-29]. Together, these findings support the potential value of wearable-derived measures for longitudinal health monitoring in older adults. However, their use depends in part on whether adequate monitoring can be achieved under real-world conditions [30,31].

However, important gaps remain in understanding real-world feasibility among older adults. Most feasibility studies have been conducted over short durations or under controlled conditions, often involving intensive researcher support, structured onboarding, frequent follow-up, or incentives [16,32]. Study samples are also frequently highly selected, excluding individuals with lower digital literacy, comorbidities, or functional limitations, thereby limiting generalizability [30,33]. While such approaches are appropriate for early-stage validation, they may not reflect feasibility under naturalistic, everyday conditions, where ongoing researcher support may be limited and users vary in their capabilities and support needs [32,34]. Additionally, feasibility data from Chinese community settings remain particularly limited, despite China's rapidly aging population and increasing policy interest in digital health monitoring for older adults.

Accordingly, this study aimed to evaluate the feasibility, usability, and acceptability of wearable monitoring among community-dwelling older adults under naturalistic conditions by examining (1) the initiation and maintenance of wearable monitoring, (2) the proportion of participants achieving the predefined minimum criterion for consecutive valid monitoring, (3) measured participant characteristics associated with different wearable monitoring patterns, and (4) usability experiences and perceived barriers reported by participants who completed the user experience survey.

Methods

Study Design

This study was conducted within the China Healthy Aging Cohort Study (China-Aging; ClinicalTrials.gov identifier: NCT06472674), an ongoing longitudinal, multicenter cohort of community-dwelling older adults across several regions in China [35]. The China-Aging study aims to investigate the prevalence and risk factors of disability and cognitive impairment and to develop predictive models by integrating traditional clinical measures with technology-derived data.

The wearable monitoring component was established within the Beijing center of the China-Aging cohort to collect longitudinal, real-world behavioral and physiological data using wrist-worn wearable devices. The present study reports the feasibility, usability, and acceptability of this monitoring approach under naturalistic conditions. A mixed methods design was used, combining quantitative wearable monitoring data with user experience survey data, including open-ended responses analyzed thematically. Baseline demographic and

XSL•FO
RenderX

clinical assessments were conducted by trained researchers as part of the China-Aging cohort procedures.

Ethical Considerations

The study was approved by the Ethics Committee of Xuanwu Hospital, Capital Medical University (approval number 2024214001), and all participants provided written informed consent prior to participation.

Participants

Participants were recruited from the Beijing region of the China-Aging cohort through the Baizhifang Community Health Centre. Eligible participants were invited to take part in this wearable monitoring study after completing baseline assessments within the cohort.

Inclusion criteria were (1) age 55 years or above, (2) residence in the local community for at least 1 year, (3) ability to independently use a wrist-worn device, (4) ownership of a compatible Android smartphone for successful device pairing, and (5) ability to install and use the Huawei Health app with regular access to Wi-Fi or mobile data for data synchronization. Exclusion criteria included (1) unstable medical conditions or acute illness at the time of recruitment, (2) severe cervical or lumbar spine disease or advanced osteoarthritis substantially limiting routine daily activity, and (3) incomplete baseline assessment.

Baseline assessments included demographic characteristics (age, sex, education level, marital status, living arrangement, care arrangement, and self-rated health status), cognitive function assessed using the Mini-Mental State Examination (MMSE) [36], and functional status assessed using the Barthel Activities of Daily Living (ADL) Index [37]. All enrolled participants demonstrated sufficient cognitive and functional capacity for independent device use at baseline.

Study Procedure

Wearable devices were distributed beginning in December 2023, with rolling enrollment following the completion of baseline assessments. Devices were offered consecutively to eligible and willing participants after the confirmation of smartphone compatibility and successful completion of device pairing, connection testing, and data transmission. Participants were not selected based on demographic characteristics, self-rated health status, or prior technology experience.

Participants received the wearable device at no cost and were instructed to wear it during daily life without restrictions, including during sleep, removing it only when necessary (eg, for charging). The monitoring start date was defined as the day on which participants completed device activation and first wore the device following study onboarding procedures. No predefined monitoring duration or mandatory wear requirements were set, and participants were allowed to discontinue device use at any time without affecting their participation in the China-Aging cohort. Monitoring continued until the last successful data synchronization or the end of November 2025, whichever occurred first.

In-person technical support was provided during initial device setup, with subsequent troubleshooting available through a WeChat group. Brief reminders were sent approximately every 2 days during the first 2 weeks to support device activation and data synchronization and to identify early technical issues. Thereafter, no proactive reminders or adherence-enhancing contact were provided, although participant-initiated technical support remained available through WeChat. This limited-support approach was intended to approximate real-world wearable use under naturalistic conditions.

Wearable Device and Data Acquisition

Participants were provided with a commercial wrist-worn wearable device (Huawei Band 8; Huawei Technologies Co) designed for the continuous monitoring of heart rate, physical activity, and sleep. The device incorporates a PPG sensor for heart rate monitoring and a triaxial accelerometer for activity tracking. Proprietary onboard algorithms generate summary measures of heart rate, step counts, and sleep parameters as implemented by the device manufacturer.

Participants paired the device with the Huawei Health app on their personal smartphones, through which wearable data were transmitted via Bluetooth and synchronized to the Huawei Health Research Platform. Data available through the research platform were pseudonymized and identified by wearable device ID. The linkage between wearable device ID and participant number was maintained separately by the research team. Data exported for analysis were stored on a secure research laptop accessible only to the study team.

Wear-Time Definition and Monitoring Criteria

Minute-level heart rate data were used as the primary indicator of wear-time, as heart rate is recorded only during direct skin contact [17,38]. Brief data gaps may occur due to transient loss of sensor contact or motion-related artifacts. Consistent with the improved nonwear detection algorithm proposed by Choi et al [39], which extended the foundational approach of Troiano et al [40], short interruptions of 1 - 2 minutes were treated as continuous wear, whereas longer gaps were considered potential nonwear periods. In the present study, nonwear was defined as intervals of 90 or above consecutive minutes without valid heart rate data, and subsequent data were treated as a new wear period. This approach was further reviewed and confirmed through consultation with Huawei technical engineers. Accordingly, daily wear-time was calculated as the sum of all valid wear periods within each calendar day.

A valid monitoring day was defined as a day with 10 or more hours of wear time, consistent with definitions used in wearable and accelerometry research [33,41]. A minimum of 3 valid monitoring days has been used in previous wearable research [33]. In the present feasibility study, we additionally required these 3 valid days to be consecutive as a pragmatic operational criterion for identifying short-term monitoring continuity under naturalistic conditions.

Based on these criteria, participants were classified into three monitoring-pattern categories:

XSL•FO
RenderX

1. No valid monitoring day: no day met the ≥10-hour valid-day criterion.
2. Nonconsecutive valid monitoring: 1 or more valid monitoring days, but no sequence of 3 or more consecutive valid monitoring days.
3. Minimal consecutive valid monitoring: 3 or more consecutive valid monitoring days.

User Experience Survey

User acceptability and usability were assessed using a self-administered questionnaire following a period of real-world wearable use. The questionnaire was developed for this study, informed by existing wearable usability instruments [32,42], and designed to capture multiple dimensions of usability, acceptability, and perceived impact in real-world use. It comprised 16 items, including 13 Likert-scale questions covering device comfort, ease of use, display readability, charging, app connectivity, data recording and accuracy, perceived lifestyle impact, and willingness for continued use and data sharing, as well as 3 open-ended questions exploring perceived benefits, barriers, and suggestions for improvement.

All Likert-scale items were rated on a 5-point scale, with higher scores indicating more positive evaluations. The questionnaire was originally developed in Chinese and translated into English for reporting. It was distributed to all participants after an initial period of device use, and responses were collected for subsequent analysis. Full details of the questionnaire are provided in Multimedia Appendix 1.

Statistical Analysis

All analyses were conducted using R (version 4.5.1) [43]. Descriptive statistics were used to summarize participant characteristics, monitoring metrics (eg, wear-time and valid days), and wearable-derived measures (eg, heart rate, physical activity, and sleep). Continuous variables are reported as mean (SD) for normally distributed data and median (IQR) for nonnormally distributed data.

Group comparisons were performed to examine potential differences in demographic, self-rated health status; cognitive function; and functional characteristics associated with wearable monitoring patterns. The distributions of continuous variables were assessed using the Shapiro-Wilk test. Continuous variables were summarized using median (IQR) and compared across monitoring-pattern groups using the Kruskal-Wallis test, with epsilon-squared (ε^2) reported as the effect size. Categorical variables were compared using Pearson chi-square tests or exact tests where appropriate, with Cramér *V* reported as the effect size. These analyses were exploratory and intended to characterize potential differences associated with monitoring patterns. Statistical significance was defined as a 2-sided $P<.05$.

For survey data, responses to Likert-scale items were summarized descriptively using median (IQR) and mean (SD). Open-ended responses were analyzed using an inductive thematic approach. Two researchers (YB and YZ) independently reviewed the responses and developed initial thematic categories related to perceived benefits, barriers, and suggested improvements. They then compared their categorizations and discussed disagreements, refining the categories until consensus was reached on the final coding and thematic structure.

To assess the robustness and potential sources of selection bias, we examined alternative monitoring thresholds and continuous monitoring measures, compared baseline characteristics between enrolled and nonenrolled participants, and compared baseline characteristics and monitoring measures between survey respondents and nonrespondents. Details of these analyses are provided in Multimedia Appendix 2.

Results

Participant Characteristics

All 710 participants approached for the wearable study owned a smartphone. Of these, 147 used a phone that was incompatible with the Huawei Health app (eg, iOS devices or unsupported Android versions), 64 did not proceed because stable data transmission could not be established during connection testing, and 13 did not enroll for other reasons that were not systematically recorded. Refusal was not recorded as a separate category and may therefore have been included among these 13 participants. Ultimately, 486 participants received a Huawei Band 8 and entered the wearable study, with wearable data available for all enrolled participants.

Baseline comparisons between the 486 enrolled and 224 nonenrolled participants showed no significant differences in age, sex, education, marital status, or self-rated health. Enrolled participants had higher MMSE scores and differed in living arrangement and care arrangement; a statistically significant but small difference was also observed in ADL. Full results are provided in Multimedia Appendix 2.

Among the 486 enrolled participants, 224 (46.1%) achieved minimal consecutive valid monitoring (≥3 consecutive valid monitoring days), 156 (32.1%) had nonconsecutive valid monitoring, and 106 (21.8%) had no valid monitoring day. Among participants with no valid monitoring day, 97 of 106 (91.5%) participants had a maximum observed daily wear time of less than 1 hour, while the remaining 9 of 106 (8.5%) participants had a maximum daily wear time of 1 to less than 5 hours. Within the nonconsecutive valid monitoring group, 119 of 156 (76.3%) participants had 1 valid monitoring day, 29 of 156 (18.6%) participants had 2 valid monitoring days, and 8 of 156 (5.1%) participants accumulated 3 or more valid monitoring days but never achieved 3 consecutively. Overall, 148 of 156 (94.9%) participants in this group had only 1 or 2 valid monitoring days. Full results are provided in Multimedia Appendix 2.

Baseline demographic, self-rated health status, cognitive, and functional characteristics across the 3 monitoring patterns are summarized in Table 1. The observed age range among enrolled participants was 59 to 86 years. Age, sex, education level, marital status, living arrangement, care arrangement, MMSE score, and Barthel ADL score did not differ significantly across monitoring patterns (all $P>.05$). Self-rated health was the only measured baseline characteristic that differed significantly across groups (Cramér $V=0.114$; $P=.005$), with better self-rated health

XSL•FO
RenderX

more frequently reported among participants with minimal consecutive valid monitoring.

XSL•FO
RenderX

Table . Baseline characteristics by wearable monitoring pattern (N=486). Effect sizes are reported as ε^2 for Kruskal-Wallis tests, and Cramér V for chi-square tests.

Characteristic	No valid monitoring day (n=106)	Nonconsecutive valid monitoring (n=156)	Minimal consecutive valid monitoring (n=224)	*P* value	Effect size

Wearable Monitoring Patterns and Data Availability

Among the 224 participants with minimal consecutive valid monitoring, the median total number of valid monitoring days was 60.5 (IQR 19 - 94.3; range 3 - 409), while the median maximum consecutive valid-day streak was 16 days (IQR 8 - 34; range 3 - 168), indicating substantial heterogeneity in both monitoring extent and continuity (Figure 1).

Figure 1. Monitoring extent and continuity among participants with minimal consecutive valid monitoring. (A) Distribution of total valid monitoring days. (B) Distribution of the maximum consecutive valid-day streak. Histograms show the number of participants across monitoring durations, with dashed blue lines indicating the median. Boxplots show the median, IQR, and distributional spread; circles indicate outliers.

Sensitivity analyses were conducted to examine the robustness of the findings to the primary ≥3-consecutive-valid-day criterion. Among the 380 participants with 1 or more valid monitoring days, 224 (58.9%), 211 (55.5%), 196 (51.6%), and 178 (46.8%) achieved 3 or more, 4 or more, 5 or more, and 7 or more consecutive valid monitoring days, respectively. The association between better self-rated health and consecutive valid monitoring remained directionally consistent across these alternative thresholds. Full results of the sensitivity analyses are provided in Multimedia Appendix 2.

Among participants with minimal consecutive valid monitoring, heart rate and step-count data were available for all 224 participants. Mean daily heart rate was 72.1 (SD 8.6) bpm, and median daily step count was 6177 (IQR 4249 - 8872) steps/day. Sleep data were available for 211 of 224 (94.2%) participants, with a median sleep duration of 7.23 (IQR 6.48 - 8.04) hours (Table 2).

Table . Summary of wearable-derived signal availability and characteristics among participants with minimal consecutive valid monitoring.

Signal	Participants with available data, n (%)	Summary metrics
Heart rate	224 (100)	72.1 (8.6; 49.4 - 93.1)[a] bpm
Sleep	211 (94.2)	7.23 (6.48 - 8.04; 3.22 - 10.39)[b] hours
Step count	224 (100)	6177 (4249 - 8872; 269 - 19,067)[b] steps/day

[a]Mean daily heart rate (SD; range).

[b]Median (IQR; range).

User Experience Survey

User acceptability and experience were assessed using a self-administered questionnaire completed by 106 of 486 (21.8%) participants after a period of real-world device use. Survey response rates were higher among participants with minimal consecutive valid monitoring (74/224, 33%) than among those with nonconsecutive valid monitoring (21/156, 13.5%) or no valid monitoring days (11/106, 10.4%). Although respondents and nonrespondents were broadly comparable in measured baseline characteristics (Multimedia Appendix 2), respondents demonstrated greater monitoring continuity and persistence. The survey findings therefore primarily reflect the

XSL•FO
RenderX

experiences of participants who maintained greater wearable use.

Across the 13 Likert-scale items (n=106), ratings were generally above the neutral midpoint (score=3), indicating overall favorable usability and acceptability (see Multimedia Appendix 3 for full item-level results). Median scores were 4 for most items, with IQRs ranging from 3-4 to 4-5, and mean values ranging from 3.51 to 4.22, with SDs ranging from 0.59 to 1.09. The highest rating was observed for independence of use (Q6; mean 4.22, SD 0.96), suggesting that most participants were able to operate the device without assistance. Items related to usability and data perception, including comfort, ease of use, readability, charging, connectivity, accuracy, and trust (Q1-Q8), also showed consistently positive ratings.

Perceived impact on health behavior was more varied. While participants reported increased health awareness (Q9) and greater willingness to engage in physical activity (Q10), perceived changes in daily habits (Q11) were more modest (median 3), indicating greater variability in responses. This suggests that although respondents reported greater awareness and motivation, perceived changes in daily habits were more limited. Willingness for long-term use (Q12) and data sharing with health care providers (Q13) remained high (median 4, IQR 4-4), indicating generally favorable acceptability among respondents.

For the open-ended questions, participants reported both perceived benefits and barriers to device use. The most commonly reported benefits included improved sleep monitoring (38/106, 35.8%) and activity or exercise tracking (37/106, 34.9%), followed by increased awareness of heart rate and oxygen saturation (29/106, 27.4%) and greater attention to overall health management (29/106, 27.4%). Only a small proportion (4/106, 3.8%) of participants reported no perceived benefits.

Reported barriers included device discomfort (18/106, 17%), data synchronization issues (12/106, 11.3%), and limited battery life (12/106, 11.3%). Some participants noted that removing the device for charging or showering disrupted routines and increased the likelihood of forgetting to put it back on. Others reported difficulty using functions beyond basic activity tracking. In contrast, 36 of 106 (34%) participants reported no inconvenience and were satisfied with device use.

Suggestions for improvement focused on both functionality and usability. The most common suggestions included adding additional health monitoring features (35/106, 33%), such as blood pressure or glucose tracking, simplifying device operation and guidance (17/106, 16%), and improving device comfort and battery performance (12/106, 11.3%). Approximately one quarter (27/106, 25.5%) of respondents reported no additional suggestions and were satisfied with the current device. A detailed breakdown of thematic categories is provided in Multimedia Appendix 3.

Discussion

Principal Findings

This study evaluated the real-world feasibility, usability, and acceptability of using a consumer wearable device for continuous health monitoring in community-dwelling older adults under limited-support, naturalistic conditions. The findings indicate that wearable monitoring was feasible for a substantial proportion of participants, with many achieving consecutive valid monitoring and maintaining device use beyond the initial monitoring period. At the same time, monitoring patterns varied considerably across individuals, with substantial heterogeneity in both monitoring extent and continuity, highlighting challenges for sustained real-world monitoring and large-scale implementation.

The observed monitoring patterns should be interpreted in the context of the limited-support design. Participants received support during initial device setup and brief reminders during the first 2 weeks but no proactive adherence support thereafter. This differs from previous studies using structured follow-up, training, prompting, or incentives and reporting relatively high adherence [16,32,44,45]. For example, Paolillo et al [45] reported wearable use on an average of 95% of study days during a supported 30-day protocol, while Holmqvist et al [44] reported a mean daily wear time of 21 hours during a structured 4-week study involving training and automated prompting. Although direct comparisons are limited by differences in study design and monitoring definitions, the present findings provide an estimate of wearable use under conditions with limited ongoing support. The substantial variation in monitoring extent and continuity also aligns with broader patterns of digital health use, in which sustained engagement depends on the integration of technology into everyday routines [46,47]. Together, these findings suggest that wearable feasibility is influenced by implementation context and support intensity and that supported and naturalistic studies provide complementary evidence for understanding real-world use.

Implementation Challenges and Associated Factors

From an implementation perspective, participants with nonconsecutive valid monitoring may represent an important target for improving sustained wearable use. Most participants in this group accumulated only 1 or 2 valid monitoring days, suggesting that initial device use did not consistently develop into sustained monitoring [48,49]. Practical barriers identified in the user experience survey, including data synchronization, battery management, and interruptions associated with device removal, may contribute to difficulties in incorporating wearable use into everyday routines [29,32,50]. Previous research suggests that sustained wearable use can be supported by the development of routine behaviors, such as integrating device wear and charging into established daily activities [50,51]. Additional support during the early monitoring period may therefore be one strategy for facilitating the transition from initial to more sustained use.

Participants with no valid monitoring day may represent a different implementation challenge. Although all participants in this group generated some wearable data, observed wear was

XSL•FO
RenderX

extremely limited: among the 106 participants, 97 (91.5%) participants had a maximum daily wear time of less than 1 hour, and none reached 5 hours on any observed day. This pattern suggests that the predominant challenge was establishing meaningful wearable use after initial setup, rather than wear that narrowly fell below the ≥10-hour valid-day criterion. Notably, this occurred despite successful device pairing, connection testing, and data transmission before enrollment, suggesting that successful technical onboarding alone may not be sufficient to ensure subsequent wearable use. Potential barriers may include technical and usability challenges, perceived usefulness, and difficulties integrating the device into everyday activities [29,32,52,53]. However, the specific reasons for limited monitoring in this group could not be determined because survey participation was particularly low, and barriers reported by survey respondents may not reflect the experiences of participants with little valid monitoring. Further research is therefore needed to identify the factors contributing to limited early-stage monitoring and determine whether targeted technical or usability support could facilitate continued device use.

Taken together, these findings suggest that different monitoring patterns may require different implementation strategies. Participants with some valid monitoring but limited continuity may benefit from support focused on establishing consistent monitoring routines, whereas those who do not achieve a valid monitoring day may require greater attention to barriers occurring earlier in the monitoring process. Distinguishing between these patterns may therefore help inform more targeted approaches to supporting wearable monitoring.

Self-rated health was the only measured baseline characteristic significantly associated with monitoring pattern, with better self-rated health more frequently reported among participants achieving minimal consecutive valid monitoring. This association remained directionally consistent across alternative consecutive-day thresholds, suggesting that the finding was not dependent on the primary ≥3-day criterion. Similar associations between health status and digital health use have been reported previously, with greater health burden potentially increasing the practical demands of device use [34,48,49]. Self-rated health is a multidimensional measure that may reflect aspects of physical and psychological well-being, perceived control, and health-related self-efficacy, which have also been associated with technology adoption and health behaviors [52,54]. However, the mechanisms underlying the observed association were not assessed in the present study, and the finding should therefore be interpreted as exploratory rather than causal.

The absence of significant associations between monitoring patterns and age, education, cognitive function, or functional status is also informative, suggesting that these measured characteristics did not substantially differentiate monitoring patterns within the enrolled cohort. However, these findings should be interpreted in the context of the relatively cognitively and functionally intact study population. The high and narrow range of MMSE and Barthel ADL scores limited the ability to examine the effects of greater cognitive or functional impairment. In addition, comparisons between enrolled and nonenrolled individuals identified differences in cognitive function, living arrangement, and care arrangement, indicating that selection may occur before wearable monitoring begins. Therefore, the absence of associations within the enrolled cohort should not be interpreted as evidence that cognitive or functional characteristics are not important for wearable adoption more broadly [52,53,55]. Further research including older adults with more diverse cognitive, functional, and digital capabilities is needed.

Among participants with minimal consecutive valid monitoring, wearable-derived heart rate and step-count data were available for all participants, while sleep data were available for 94.2% (n=211) of the participants. This indicates that multiple behavioral and physiological measures could be obtained among participants who achieved minimal consecutive valid monitoring. The slightly lower availability of sleep data may reflect the additional requirements of overnight wear, including charging and device removal. More broadly, these findings indicate that successful wearable monitoring does not necessarily result in equivalent data availability across monitoring domains, an important consideration when consumer wearables are used for longitudinal health monitoring.

The user experience survey also provided insight into practical aspects of device use. While some participants reported no inconvenience, others identified barriers related to comfort, data synchronization, and battery life, and 33% (35/106) of the respondents suggested additional health-monitoring functions, such as blood pressure or glucose monitoring. These findings suggest that both practical burden and perceived relevance may influence continued wearable use and that greater alignment between device functionality and users' health priorities may enhance acceptability [29,32,46,47]. However, these findings should be interpreted with caution because the respondents demonstrated greater monitoring continuity and persistence than nonrespondents, indicating that the usability, acceptability, and barrier findings disproportionately reflect the experiences of participants who maintained greater wearable use.

Strengths, Limitations, and Future Directions

The principal strength of this study lies in its community-based design under naturalistic conditions, which captured variability in wearable use with limited ongoing support. The combination of objective monitoring data and user experience responses also enabled feasibility to be examined from complementary perspectives. Several limitations should be considered. First, recruitment from an urban community setting and requirements for smartphone compatibility and successful data transmission may limit generalizability, particularly to older adults with lower digital capability or greater cognitive or functional impairment. Differences between enrolled and nonenrolled participants further indicate potential preenrollment selection. Second, the ≥3-consecutive-valid-day criterion was a pragmatic operational definition rather than a validated threshold, although sensitivity analyses using alternative thresholds and continuous monitoring measures supported the overall findings. Third, the relatively low user experience survey participation rate (106/486, 21.8%) and greater monitoring persistence among respondents may have resulted in more favorable estimates of usability and acceptability. In addition, individual-level use of technical support was not systematically recorded, limiting our ability to

XSL•FO
RenderX

assess whether support use differed across monitoring patterns or influenced monitoring continuity. Finally, the study used a single consumer wearable ecosystem with proprietary algorithms that were not independently validated against research-grade reference measures in this population. Future research should therefore examine longer-term monitoring patterns, identify barriers to sustained use, evaluate targeted technical and behavioral support, and validate wearable-derived measures against reference standards. Longitudinal associations with cognitive, functional, and health outcomes should also be investigated to establish the potential clinical relevance of these measures.

Conclusions

In conclusion, this study demonstrates that wrist-worn wearable monitoring is feasible for a substantial proportion of community-dwelling older adults in China under limited-support, naturalistic conditions, although monitoring extent and continuity varied considerably. Usability and acceptability were generally favorable among survey respondents. Future research should identify strategies to support sustained monitoring and establish the clinical relevance of wearable-derived measures for longitudinal changes in cognitive and functional health.

Acknowledgments

This study was conducted within the China Healthy Aging Cohort Study (China-Aging). The authors would like to thank all participants for their time and contribution, as well as the staff at participating community health centers for their support with recruitment and data collection. They also thank Dr Xiaolong Zhang (Beijing Anding Hospital, Capital Medical University) for his helpful comments and suggestions from digital health and psychological perspectives, which informed the interpretation of the findings and the discussion.

The authors did not use generative AI in any portion of the preparation of this manuscript.

Funding

This study was funded by Noncommunicable Chronic Diseases-National Science and Technology Major Project (2025ZD0546200) and Beijing Outstanding Young Scientist Program (JWZQ20240101023). The funders had no role in the study design; data collection, analysis, or interpretation; manuscript preparation; or the decision to submit the manuscript for publication.

Data Availability

Deidentified data supporting the findings of this study are available to qualified researchers upon reasonable request, subject to approval by the Ethics Committee of Xuanwu Hospital, Capital Medical University. Requests should be directed to the corresponding author.

Abstract

Background: Cardiovascular diseases (CVDs) remain a leading cause of morbidity and mortality. In primary prevention, effective communication of individual risk and support for behavior change are crucial. Interactive risk visualizations can enhance understanding and engagement, while continuous glucose monitoring (CGM) offers immediate feedback on the physiological effects of daily choices.

Objective: This study aimed to explore how patients at increased CVD risk and family medicine nurses perceive CVD risk visualization (Petal-X) and the integration of real-time glucose monitoring, with a focus on perceived person-centered care (PCC), motivation, and lifestyle change. This manuscript reports the qualitative phase of a larger sequential mixed methods study; the quantitative randomized controlled trial is reported separately.

Methods: Using total population (census) sampling within a closed, predefined trial cohort, we invited every eligible patient who had completed the intervention arm of a parallel randomized controlled trial and every eligible registered nurse providing preventive consultations at the same single community health center in central Slovenia who had been familiarized with the intervention and with the Petal-X dashboard; 6 patients at increased CVD risk who had used the Petal-X dashboard in combination with CGM, and 6 nurses familiar with the intervention, took part, and interviews were conducted between September and December 2024. Data were collected through individual, face-to-face semistructured interviews that explored perceptions of the visualization, real-time glucose monitoring, and lifestyle change. Interviews were audio-recorded, transcribed verbatim, and analyzed by inductive qualitative content analysis within a qualitative descriptive design; coding continued until code saturation and data adequacy were judged to have been reached.

Results: The analysis produced 11 subcategories, which were grouped into 4 categories, with an overarching theme running across them: visualization and digital tools as support for PCC to enhance motivation and lifestyle change in individuals at risk of CVD. Patients and nurses reported that personalized visual displays improved understanding of risk factors, facilitated dialogue and shared decision-making, and increased patients' sense of involvement, responsibility, and control, although the 2 groups differed in emphasis: patients foregrounded personal meaning and self-regulation, whereas nurses foregrounded communication and fit with the consultation workflow. CGM was perceived as particularly motivating by linking behavior (food, activity, and stress) to real-time glucose changes, encouraging dietary and activity adjustments that some participants maintained after the intervention. Key barriers included variable digital literacy (especially among older users), fear or mistrust of technology, the attentional burden of continuous monitoring, potential information overload, workflow integration needs, and affordability or accessibility of CGM.

XSL•FO
RenderX

Conclusions: Interactive CVD risk visualization Petal-X, especially when complemented by CGM, was perceived as a meaningful support for PCC and a driver of motivation and lifestyle change in primary prevention. Implementation should address training, usability, integration into routine workflows, and equity of access.

Introduction

Primary health care in Slovenia is based on a network of 63 community health centers organized into 10 administrative regions, with approximately 900 teams of which around 200 operate privately under concession [1]. Family medicine practices offer both preventive and curative services. The preventive services are focused on individuals aged 30 years and older with no chronic disease, where registered nurses (RNs) assess the risk of developing chronic conditions [2,3]. In this process, prognostic models are used, which combine multiple predictive factors into a mathematical equation to estimate the likelihood of an outcome [4,5]. One of these is the SCORE2 (Systematic Coronary Risk Evaluation 2) model for estimation of cardiovascular disease (CVD), validated on the European population, which includes age, sex, smoking status, systolic blood pressure, total cholesterol, and high-density lipoprotein cholesterol [6]. Such models enable the early identification of high-risk individuals and guide the allocation of limited health care resources where they can achieve the most significant impact [7,8].

Nevertheless, CVDs remain the leading cause of death worldwide, accounting for over 20 million deaths each year [9]. Many individuals do not recognize how their daily habits (diet, physical activity, and smoking) directly influence their long-term CVD risk [10]. Therefore, effective communication of risk and the potential benefits of lifestyle change play a critical role in CVD prevention [11].

Visual tools are becoming an increasingly important approach in health care communication, as graphical and interactive representations of data improve understanding and foster motivation for lifestyle modification [9]. Digital health solutions that present personalized risk and the potential effects of change can help patients perceive their health status more tangibly. The growing digitalization of health care offers new possibilities for integrating real-time data with personalized risk assessment [12,13]. Continuous glucose monitoring (CGM) devices, for example, provide patients with immediate feedback on how their dietary and behavioral choices affect their blood glucose levels [14,15]. When combined with visualizations of long-term CVD risk, such as those provided by digital tools, this integration can support shared decision-making, enhance patient engagement, and promote more timely and sustainable lifestyle changes [16,17].

In this context, we examined the Petal-X visualization tool, which is based on the Petal Product Plots visualization and an explanation layer on top of the SCORE2 model. Its accuracy is comparable with the graphical score charts used in clinical practice. The developers of Petal-X conducted a study with nursing students, finding that its use improved understanding of risk factors and stimulated reflection on possible lifestyle changes [18].

The aim of our qualitative study was to explore how visualization of CVD risk, combined with the possibility of real-time blood glucose monitoring, influences the perception of person-centered care (PCC) among patients at increased risk of CVD. Furthermore, we sought to understand how RNs and patients perceive the use of these digital tools, as well as the opportunities and challenges they identify for their integration into everyday clinical practice.

Methods

Research Design

This research forms the qualitative phase of a sequential mixed methods design [19], carried out after the quantitative phase. The results of the quantitative analysis reported by Svenšek et al [20] indicated certain patterns that we wanted to explore in more detail. For this phase, we used a qualitative descriptive design [21], with data analyzed by inductive qualitative content analysis [22,23]. This approach was chosen because the aim of the study was descriptive and evaluative rather than theory-generating: we set out to characterize how patients who had completed the intervention arm, and the nurses working in the same preventive service who had been familiarized with it, experienced the Petal-X dashboard and CGM, including perceived usability, the perceived contribution to PCC and to motivation, and the barriers to implementation in routine practice. The study was not designed to develop a theory of a social or clinical process, and no theory-generating claims are made. We collected the data through individual semistructured interviews. We ensured the rigor of the qualitative study by adhering to Lincoln and Guba's [24] criteria of credibility, dependability, confirmability, and transferability. Procedures are reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) 32-item checklist [25].

Setting, Participants, and Recruitment

The study was conducted at a single community health center in central Slovenia that delivers preventive family medicine services. It was nested within a parallel randomized controlled trial (ClinicalTrials.gov NCT06226948) evaluating interactive

XSL•FO
RenderX

digital visualization counseling for patients at risk of CVD [20]. Recruitment for the interviews was open to individuals across Slovenia, although the promotional campaign and study implementation were concentrated at this center. Patients were drawn from the trial intervention arm (n=30 at baseline), in which participants had a mean age of 51.9 (SD 7.2) years, 70% (21/30) were women, and the mean baseline 10-year SCORE2 risk was 4.87 (SD 2.61) and the highest of the 4 trial arms [20].

Patients were eligible if they were aged 40 years or older, had no diagnosed CVDs, and had at least 1 CVD risk factor (elevated systolic blood pressure, elevated fasting glucose, elevated blood lipids, or elevated BMI); nurses were eligible if they provided preventive consultations at the participating center, had been familiarized with the Petal-X dashboard and with CGM-based monitoring during the study period, and had at least 5 years of professional experience as a nurse, which was verified individually for each nurse before inclusion. Eligible patients who had completed the trial intervention arm were identified from the trial records by the study team, and eligible nurses were identified through the participating center; potential participants were then contacted individually by the first author (AS), in person or by telephone, informed about the aim and the voluntary nature of the study, and, if they agreed, gave written informed consent before an interview was scheduled. Recruitment was not purposive. We used a total population (census) approach within the closed, predefined cohort created by the parent trial: every patient who had completed the trial intervention arm and every nurse at the participating center who had been familiarized with the intervention was invited, and no further selection step was applied within this eligible pool, either on the basis of participant characteristics (eg, age, sex, and baseline risk category) or on the basis of the content of their experience. The size and composition of the sample were therefore determined by the boundaries of the parent trial and by willingness to participate, rather than by deliberate selection for particular characteristics, by maximum variation, or by an emergent analytic rationale. No more than 2 interviews were conducted per week so that each interview could be analyzed before the next. The final sample comprised 6 nurses and 6 patients.

Definition of Intervention Completion and Extent of Exposure

Because eligibility for interview depended on having completed the intervention arm, we define here what completion involved in this study, independently of the report of the parent trial [20]. The intervention arm did not consist of a single encounter with the dashboard. Each patient attended a face-to-face preventive consultation, delivered by the first author (AS), an RN and PhD candidate, during which the patient's individual 10-year SCORE2 risk was calculated and explored interactively using the Petal-X dashboard (duration of consultation: 30 minutes). Each patient was then fitted with a CGM sensor, which was worn during everyday life for 10 days, with real-time access to their own glucose readings through the associated smartphone app, and attended a further study visit 6 months later, at which the glucose record and the risk profile were reviewed together. The intervention therefore comprised both a nurse-led visualization consultation and a defined period of CGM-based self-monitoring. Patients were counted as completers of the intervention arm and were therefore eligible to be approached for an interview if they attended all 3 scheduled study visits (the baseline assessment, blood sampling at 3 months, and the final assessment at 6 months), wore the CGM sensor for at least 5 of the 10 intended days, and completed the final study assessment. Patients who withdrew, who discontinued sensor wear before this threshold, or who did not attend the final assessment were not counted as completers and were not invited to interview. Of the 30 patients randomized to intervention group 1 (Petal-X visualization combined with CGM), 27 met this definition of completion and were invited, and 6 agreed to be interviewed. Interviews were conducted a median of 5 weeks after the end of each patient's participation, so that all patients described a completed rather than an ongoing experience of the intervention.

For nurses, participation did not involve delivering the intervention. All trial consultations, including the presentation of the Petal-X visualization and the application and explanation of the CGM sensor, were carried out by the first author (AS), and the participating nurses had no formal delivery role in the trial. They were RNs providing routine preventive consultations at the same center who had been familiarized with the intervention during the study period: each nurse took part in a single structured familiarization session of approximately 30 minutes, in which the Petal-X dashboard was presented and explored with example risk profiles, the rationale of the SCORE2-based visualization was explained, and the principles and practical use of CGM-based monitoring were demonstrated. Within this session, the nurses also used the dashboard themselves on example profiles, so that their appraisals were based on direct, if brief, hands-on contact with the tool rather than on observation alone. They also worked alongside the trial in the same preventive service and were therefore familiar with how it was organized and with the patients taking part. At the time of the interview, each nurse had approximately 7 months of familiarity with the tool and the intervention, which was delivered between May and December 2024, and the dashboard was displayed again at the start of the interview so that the discussion could refer to specific features of the visualization.

In this study, therefore, "completion" has a different meaning for the 2 groups. For patients, it denotes completion of the intervention arm as defined in the section Setting, Participants, and Recruitment; for nurses, it denotes completion of this familiarization and continuous presence in the setting for the whole intervention period, rather than a threshold of sessions delivered. Their accounts should accordingly be read as the informed appraisal of experienced preventive care nurses who knew the intervention and the tool well, and who work daily with the paper-based SCORE2 charts that the dashboard is intended to replace, rather than as the reflections of practitioners who had themselves delivered it in routine care; this distinction is revisited in the Limitations section.

Data Collection

Interviews were conducted by the first author (AS), a female RN holding a master's degree (MSc), who was trained in qualitative research methods and was a doctoral researcher at

XSL•FO
RenderX

the University of Maribor and teaching assistant at the time of the study. The interviewer had no prior clinical or supervisory relationship with the participants before the study commenced. Participants were informed of the researcher's professional and academic background and that the interviews formed part of a doctoral research project on digital tools for cardiovascular risk communication and prevention. The researcher's background in nursing and digital health shaped an interest in PCC and technology-supported prevention; to limit the influence of these assumptions, reflexive memos were kept, and the developing interpretation was discussed in regular peer-debriefing meetings within the research team.

We conducted interviews with RNs who had been familiarized with the Petal-X dashboard for CVD risk visualization and with the potential for real-time blood glucose monitoring during the study period; at the start of each interview, the dashboard was displayed again so that the discussion could refer to specific features of the visualization. The patients we interviewed had all taken part in the intervention arm that combined the Petal-X dashboard with real-time monitoring of blood glucose levels. We were interested in the participants' perceptions of the intervention and the use of new technologies. We used semistructured interviews to preserve certain concepts [24]. With the help of semistructured interviews, we obtained all the necessary information for the research, allowing participants as much freedom as possible in their responses. We opted for semistructured interviews because we did not want to stray from our topic and wanted to obtain an accurate description and perception of the participants' involvement in interventions and visualizations related to CVD risk. With semistructured interviews and semi–open-ended questions, we also aimed to gather information about the experiences, feelings, and advice of RNs and research participants regarding the visualization of the risk of CVD using Petal-X and the potential for real-time monitoring of blood glucose levels. The interview guides for nurses and for patients are provided in Multimedia Appendices 1 and 2.

Data Analysis

All interviews were audio-recorded, transcribed verbatim, and anonymized prior to analysis. Interviews were conducted and transcribed in Slovenian, and all coding and analysis were carried out in Slovenian to stay close to participants' original wording; the illustrative quotations presented in the Results section were subsequently translated into English by the bilingual research team and checked against the original transcripts for accuracy and meaning. Data were analyzed by inductive qualitative content analysis [22,23]. Analysis proceeded alongside data collection, so that preliminary observations could inform the emphasis given to particular questions in later interviews.

Each transcript was first read repeatedly to obtain a sense of the whole. Meaning units relevant to the aim of the study were then identified and condensed, and each condensed meaning unit was labeled with a code that stayed close to participants' own wording. The first transcripts were coded independently by 2 researchers (AS and LG), who compared their code lists and agreed on a shared coding frame; this frame was applied to the remaining transcripts and revised whenever new codes were added. Codes were compared systematically within and across the 2 participant groups and sorted, on the basis of similarity in content, into subcategories and then into categories. Finally, an overarching theme expressing the thread of meaning that ran across the categories was formulated. The developing category structure was reviewed and refined together with a senior researcher (GS) in peer-debriefing meetings until consensus was reached. Categories were refined iteratively by writing analytic memos, revisiting transcripts, and actively searching for discrepant accounts (eg, accounts of CGM worry or of limited benefit for some users). An audit trail (coding memos and versioned code lists) was maintained. To strengthen credibility, verbatim transcripts were returned to participants for review and possible correction (member checking).

Because the sample was bounded by the closed intervention arm of the parent trial, the size of the sample was fixed in advance rather than determined by the progress of the analysis. We therefore considered code saturation and the adequacy of the data for the descriptive aim of the study [26]. Toward the end of data collection, later interviews were adding few, if any, new codes, and the research team judged the material sufficient to describe the categories reported. We present this as an assessment of data adequacy rather than as a formal claim of saturation, since the number of available participants was fixed by the parent trial. In the Results section, quotes are attributed using participant identifiers to preserve anonymity: P denotes patients and N denotes RNs (eg, P1, N2). Each quotation is additionally accompanied by brief, nonidentifying contextual information about the speaker, namely, sex, age, and baseline 10-year SCORE2 risk category for patients, and years of professional experience for nurses, so that readers can interpret each quotation in relation to the individual speaking rather than only in relation to the participant group.

Qualitative Rigor

Qualitative rigor was addressed using established criteria for qualitative rigor: credibility, dependability, confirmability, and transferability. Credibility was supported by verbatim transcription, systematic comparison of codes within and across the 2 participant groups, member checking (returning transcripts to participants for review and possible correction), regular peer-debriefing meetings within the research team, and the deliberate search for and analysis of negative cases. Dependability and confirmability were supported by maintaining an audit trail of coding memos and versioned code lists, so that the development of the codes, subcategories, and categories could be traced back to the underlying data. Transferability was supported by providing a thick description of the setting, participants, and context, enabling readers to judge the applicability of the findings to other primary care settings.

Ethical Considerations

The study was approved by the Ethics Committee for Nursing Research at the Faculty of Health Sciences, University of Maribor (approval number 02/7K-2023), and the National Medical Ethics Committee of the Republic of Slovenia (approval number 0120-217/2023/4). We have also registered the research protocol of the clinical trial (ClinicalTrials.gov ID:

XSL•FO
RenderX

NCT06226948) [27]. All participants were informed that their data would be used exclusively for research purposes. All participants received written and oral information about the study and gave written informed consent before their interview, including explicit consent to audio-recording and to the use of anonymized verbatim quotations in publications. Recordings were transcribed verbatim and deidentified; direct identifiers were removed and participants are referred to only by coded identifiers (P for patients and N for nurses). Data were stored securely, were accessible only to the research team, and were used exclusively for research purposes. Participants did not receive any financial compensation for taking part in the study.

Results

Participant Characteristics

The sample comprised 6 RNs and 6 patients at increased CVD risk, all from a single community health center in central Slovenia. All patients had taken part in the intervention arm of the parallel randomized controlled trial [20] that combined the Petal-X dashboard with CGM; they were aged 40 years or older, had no diagnosed CVD, and had at least 1 CVD risk factor. Among the 6 patients interviewed, 4 were women and 2 were men, aged 46 - 67 (mean 57.8, SD 7.8) years; at baseline, 1 was at low, 2 at moderate, and 3 at high 10-year SCORE2 risk. The interviewed patients were therefore somewhat older than the intervention arm as a whole, in which the mean age was 51.9 (SD 7.2) years [20]. All 6 participating nurses were women, aged 26 - 50 (mean 33.3, SD 10.2) years, and each had at least 5 years of professional experience as a nurse and worked in preventive family medicine consultations at the participating center throughout the trial period. To avoid duplication, participant characteristics are reported in the text only; brief individual descriptors accompany each quotation so that quotations can be read in relation to the individual speaker.

The analysis produced 11 subcategories, which were grouped into 4 categories (Table 1). Running across all 4 categories was an overarching theme, formulated as “Visualization and digital tools as support for PCC to enhance motivation and lifestyle change in individuals at risk of CVD.”

XSL•FO
RenderX

Table . Display categories and subcategories with codes.

Categories and subcategories	Codes
Person-centered care	
Goal-oriented care and individual approach	Time devoted to the patient; patient-centered care; tools as a means of improving treatment; individualized approach, and treatment; daily routine; meal planning; recommendations for the use of technology; involvement of family members; faster task completion; and ease of treatment.
Involvement in treatment	Patient involvement, treatment planning, increased sense of responsibility, sense of control, active role of the patient, and quality of treatment.
Knowledge and monitoring of risk factors for the development of CVD[a]	
Monitoring of vital functions and detection of changes or deviations	Real-time monitoring of blood glucose levels, monitoring of risk factors, changes in monitored vital signs, immediate monitoring of condition, detection of changes, and faster identification of risks.
Risk factors	Tool for identifying variable risk factors, raising awareness of risk, reducing risk, visualizing risk, incorporating relevant risk factors, transparency and relevance of factors, link between data and risk, and link between food and sugar.
Understanding of impacts	The impact of risk factors on disease vulnerability, visual representation of health status, understanding vulnerability, understanding necessary changes, understanding through visualization, simplicity and clarity of visualization, and understanding lifestyle changes.
Visualization and interpretation of results and the impact of technology use on lifestyle changes	
Personalized graphical display of results	Interactivity of visualization, real-time data visualization, visualization without explanation is not always informative enough, graphical representation of data, decision-making based on visualization, visual presentation as an advantage, color visualization, connection between colors and risk, display of changes, visual type, visualization as a communication tool, facilitating conversation.
Improved understanding of the interpretation of results	Easier understanding of data; simplification of complex data, visualization as a tool for clear presentation, advantage of images over numbers, awareness and impact on results, advantage of visualization over SCORE2[b] tables, graphical representation of risk, visual displays enable faster and more accurate understanding without complicated procedures, transparency of visualization, ease of presentation for patients, and easier interpretation of results for patients.
Technology and usability	Significant impact of technology, usefulness of CGM[c] for people with diabetes, self-monitoring and prevention, disease prevention, benefits for patients, and practicality.
Motivation and lifestyle changes	Patient motivation, changes in physical activity, motivation of the older adult population, motivation to change lifestyle, dietary changes, maintaining lifestyle changes, connection with meals, increased awareness, and control over food intake.
Identification of problems and challenges and recommendations for improvement	
Identification of problems or deviations	Identifying problems, realizing deviations, recognizing patterns, linking to results, reservations about use and lack of trust in technology, patients' fear of using technology, negative interpretation of technology, and the challenge of affordability.
Opportunities for improvement and recommendations	Opportunities for improvement and emphasis on improvements, recommendation for wider implementation, link between decisions and health, potential for the future, application in other areas of health care, lack of education and knowledge and its inclusion, and improvement of visual tools.

[a]CVD: cardiovascular disease.

[b]SCORE2: Systematic Coronary Risk Evaluation 2.

[c]CGM: continuous glucose monitoring.

XSL•FO

Overview of the Findings

The 4 categories describe complementary aspects of participants' experience rather than stages of a process. PCC describes the character of the consultation as participants experienced it: goal-oriented, individualized, and involving the patient in decisions. Knowledge and monitoring of risk factors describes what participants reported learning and noticing through Petal-X and CGM, including the recognition of deviations and the connection between everyday behavior and measurable indicators. Visualization and interpretation of results and the impact of technology use on lifestyle changes describes how the display itself was used and appraised, together with the dietary and physical activity changes that patients associated with it. Identification of problems and challenges and recommendations for improvement gathers the limitations that both groups reported, fear or mistrust of technology, the burden of continuous monitoring, variable digital literacy, information overload, and the cost of CGM, alongside their suggestions for addressing them.

Across all 4 categories, patients and nurses converged on the perceived usefulness of the visual display but differed consistently in emphasis. Patients spoke primarily about personal meaning, reassurance, and self-regulation; nurses spoke primarily about communication, the efficiency of the consultation, and the fit of the tool with existing workflows. Where the 2 groups diverged, this is made explicit in the sections that follow.

Category 1: Person-Centered Care

Goal-Oriented Care and Individual Approach

Participants described consultations as more individualized and goal-focused than usual encounters, with more time for dialogue and tailoring recommendations to daily routines (eg, meal planning, physical activity, and family support). Nurses emphasized that visual displays supported more transparent communication and helped patients identify personally salient risk factors. Interpreted within the core category, these accounts suggest that the value of the consultation lay less in the visual tool itself than in how it reorganized the encounter around the individual: by making risk personally legible, the visualization created a shared reference point that shifted the interaction from information delivery toward negotiated, goal-oriented care. Patients and nurses agreed that a consultation supported by the visualization differed from a routine preventive encounter, but they located that difference in different places. For patients, the difference was one of attention and time: the consultation was experienced as being about them rather than about a presenting complaint. One participant contrasted it directly with her usual visits, noting that "the consultation was dedicated to me. We talked about me, my lifestyle and my habits. It took more time than my usual healthcare visits, where I normally go only because of specific problems," and adding that she "felt more involved and received more information about my health" (P1; woman, aged 67 years, baseline SCORE2 risk 4%). Nurses rarely framed the change in terms of time; their emphasis fell on what the display did for the structure of the conversation, describing it as a way of making the assessment legible to the patient, in that "visualization is very useful in terms of transparency...easier to present to patients" (N2; ≥5 years of professional experience).

Read together, the 2 accounts suggest that the perceived value of the consultation lay less in the visual tool itself than in how it reorganized the encounter around the individual. By giving both parties a shared reference point, the visualization shifted the interaction away from the delivery of a risk figure and toward a negotiated discussion of daily routines, meal planning, and physical activity, which in several accounts extended to the involvement of family members. This is the sense in which participants described the care as goal-oriented: the goals were formulated during the consultation, and the display supplied the common ground on which they were agreed.

Involvement in Treatment

Both groups linked this reorganization of the consultation to a more active patient role, again with a difference of emphasis. Patients framed involvement in terms of partnership, control, and responsibility, describing a shift from recipient to interlocutor: one participant said that with this kind of care she "felt like a real conversation partner. We discussed what I could improve, and I had not experienced something like that before," and connected seeing and understanding her data in real time with a "stronger sense of control over my health" (P3; woman, aged 58 years, baseline SCORE2 risk 7.8%). Nurses described the same shift from the outside, as a lowering of the threshold for participation, since with the visual display it was "easier for patients to get involved...easier to understand" (N3; ≥5 years of professional experience). Patients in turn linked this sense of control and responsibility to their willingness to follow the recommendations agreed during the consultation. It is worth noting that none of the reservations raised in the interviews concerned the shared discussion of results itself; where patients reported burden, it related to continuous self-monitoring, described under category 4, rather than to their involvement in decisions about their care.

Category 2: Knowledge and Monitoring of Risk Factors for the Development of CVD

Monitoring Vital Functions and Detecting Deviations

Real-time monitoring (particularly CGM) was described as enabling rapid feedback and earlier recognition of deviations. Participants highlighted the importance of continuous access to data; nurses emphasized increased awareness and perceived patient independence. This pattern indicates that real-time monitoring did more than supply data; by compressing the interval between behavior and feedback, it appeared to support a sense of agency and self-regulation, which participants linked to sustained motivation rather than to a single moment of insight. Real-time monitoring, and CGM in particular, was the element of the intervention that patients raised most spontaneously. What they valued was less the data themselves than the continuous availability of feedback and the short interval between an action and its visible consequence. One participant described the sensor as a constant companion that also allowed retrospective reflection: "Those data were always on my side...when I saw that the glucose level was high, or when it increased, I was a little more careful to eat less...I could look back over the last

XSL•FO
RenderX

10 days and reflect on my state over time" (P1; woman, aged 67 years, baseline SCORE2 risk 4%). The color coding of the display was repeatedly described as doing interpretive work that numbers alone did not: "Numbers do not tell you enough, because you do not know exactly where the threatened area is. When it is visualized and turns orange or red, you experience it almost like a silent alarm, and then you approach lifestyle change more seriously" (P4; woman, aged 58 years, baseline SCORE2 risk 5.8%).

Nurses observed the same behavior from a professional standpoint but described it as a change in patients' attentiveness and independence rather than as a personal experience, reporting that "patients monitor their condition more closely...more aware" (N2; ≥5 years of professional experience). Across both groups, therefore, monitoring was described as doing more than supplying data: by compressing the interval between behavior and feedback it appeared to support self-regulation, which participants linked to sustained attention to their habits rather than to a single moment of insight. The contrast with the annual preventive checkup, in which feedback arrives once and well after the behavior it reflects, was implicit in several patient accounts.

Identifying Risk Factors

Whereas CGM was associated with day-to-day feedback, Petal-X was associated with making the composition of long-term risk visible. Patients described the dashboard as the first occasion on which their risk profile had been presented in a form they could interpret; one participant recalled being able to "see for the first time how high my risk [was]...and what that means" (P3; woman, aged 58 years, baseline SCORE2 risk 7.8%). Nurses' accounts converged with this, describing the display as making the contribution of individual modifiable factors transparent and relevant, and therefore easier to connect to a concrete recommendation within the consultation. What patients added to the nurses' account was the personal meaning of that transparency: the value they described lay in relating the displayed factors to their own everyday behavior, rather than in the precision of the estimate itself.

Understanding Impacts

Participants described visualization as enhancing comprehension of how lifestyle factors influence risk and what changes are needed. Nurses similarly described visual feedback as supporting awareness and action. Taken together, these accounts frame comprehension as a mechanism rather than an outcome: translating abstract, probabilistic risk into a concrete visual form appeared to make the link between everyday choices and long-term risk actionable, consistent with the core category that connects visualization and digital tools to motivation and lifestyle change. Both groups described comprehension as the mechanism through which the visualization worked, rather than as an end point in itself. Patients contrasted the visual display with the numerical formats they had encountered previously: "Before, when I received results only as percentages, I could not fully imagine what those numbers actually meant for me. The visualization tool allowed me to see how my everyday decisions, such as diet and physical activity, directly affected my health. It was not just a number on paper, but a clear picture of how my choices influenced my risk" (P2; man, aged 63 years, baseline SCORE2 risk 10%). Nurses described the same effect in terms of its immediacy within the encounter, observing that with the visual display "patients immediately become aware" (N2; ≥5 years of professional experience). The difference between the 2 perspectives is largely one of timescale: nurses referred to comprehension achieved during the consultation, whereas patients described an understanding that persisted afterward and informed subsequent choices. Taken together, the accounts indicate that translating an abstract, probabilistic estimate into a concrete visual form was what made the link between everyday choices and long-term risk actionable for participants.

Category 3: Visualization and Interpretation of Results and the Impact of Technology Use on Lifestyle Changes

Personalized Graphical Display and Interpretation

Interactivity was described as the feature that turned the display from a presentation into a discussion. Patients reported that reviewing the graphs together created an opening for asking questions and for proposing changes themselves: "When we reviewed the graphical displays of my results together, I could ask questions and suggest changes to my care plan. In the past I was often just a listener, but now I was truly involved in deciding about my health" (P2; man, aged 63 years, baseline SCORE2 risk 10%). Nurses valued the same interactivity for a different reason, namely, the speed with which it surfaced where change was possible; one nurse noted that the tool "very clearly illustrates deviations...opportunities for improvement" (N4; ≥5 years of professional experience). Nurses qualified this in an important respect: several observed that a visualization presented without accompanying explanation was not in itself sufficiently informative, and therefore the professional's interpretation remained necessary. That qualification locates the benefit in the combination of display and dialogue rather than in the display alone, and it is consistent with the patients' own emphasis on the conversation that the graphs made possible.

Technology and Usability

Appraisals of usability were broadly positive in both groups but were expressed in group-specific terms. Patients spoke of the technology as unproblematic in use, one stating simply that she was "very satisfied with the technology we used" (P3; woman, aged 58 years, baseline SCORE2 risk 7.8%). Nurses assessed usability against the tools they currently use, and it was in this comparison that the perceived advantage was most clearly articulated: "The table we use in the clinic is very comprehensive and time-consuming, because you have to look for each piece of data separately and compare it. With this tool, everything is together, explained and shown in one place, and it is visually simpler" (N3; ≥5 years of professional experience). The nurses' positive appraisal was nevertheless conditional. They regarded the tool as practical and promising for preventive family medicine provided that it could be fitted into existing consultation workflows and that additional support was available for patients with lower digital literacy, conditions to which they returned when discussing implementation barriers.

XSL•FO
RenderX

Motivation and Lifestyle Changes

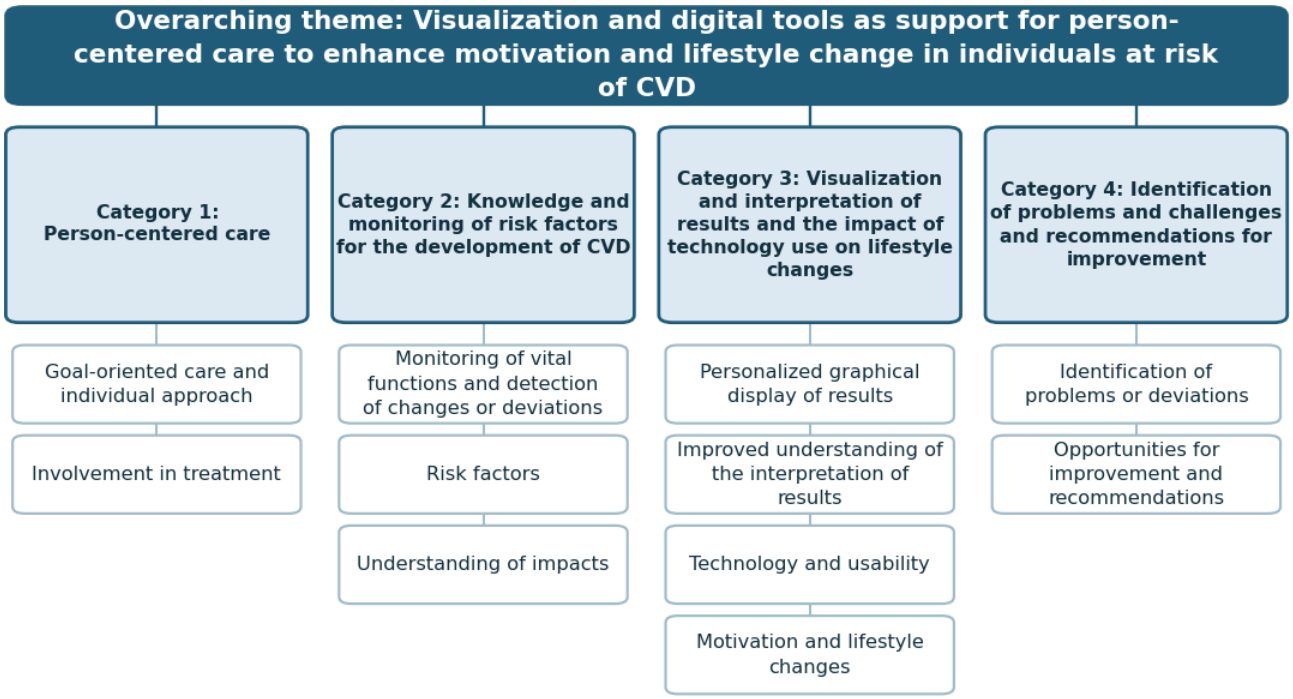
Patients' accounts of behavior change were concrete and specific, and in several cases extended beyond the intervention period. One participant reported that he still followed certain guidelines and remained motivated, having "realised that my wellbeing has improved a lot and that I have much more energy than before" (P2; man, aged 63 years, baseline SCORE2 risk 10%). Another described a gradual rather than an abrupt change: "I changed the way I eat, especially sweets and fructose. I started to be very selective about what I eat. I also started going to the swimming pool and try to maintain walking as much as I can. The change was not sudden, but gradually I changed my diet a lot" (P4; woman, aged 58 years, baseline SCORE2 risk 5.8%). Nurses did not report outcomes of this kind, which they were not in a position to observe; their contribution was an account of why the tool might be motivating, namely, that it renders the room for improvement visible and concrete rather than abstract. Nurses were also more cautious than patients about how far this effect would reach, anticipating that motivation would be easier to elicit in younger, digitally confident patients than in older ones, a reservation examined in the next category.

Category 4: Identification of Problems and Challenges and Recommendations for Improvement

Problems and Deviations

Implementation barriers included fear or mistrust of technology, the risk of negative interpretation, usability challenges for older users, affordability (especially for CGM), and the time burden of conventional tools. The barriers described by the 2 groups were largely distinct, reflecting their different positions in relation to the intervention. Patients described difficulties arising from continuous self-monitoring. These ranged from an initial apprehension about what the results would show, "I was a little scared of reality...maybe it is a little scary to compare it with reality, but on the other hand I would say it is more positive" (P1; woman, aged 67 years, baseline SCORE2 risk 4%), to the practical and attentional burden of wearing and following the sensor: "Constant monitoring was at times somewhat burdensome and stressful, because I was paying attention to the numbers the whole time...because my work is very active and I usually do not have my phone with me, it was a burden to always watch where my phone was so as not to lose the signal with the sensor" (P2; man, aged 63 years, baseline SCORE2 risk 10%). A related concern was the fear of overlooking something (P3; woman, aged 58 years, baseline SCORE2 risk 7.8%), and one participant described the monitoring becoming compulsive before settling: "it can quickly become an obsession. When I was wearing the glucose device, during the first few days I was constantly checking it. It was almost like a teenager who cannot get away from the phone. You have to find a balance" (P4; woman, aged 58 years, baseline SCORE2 risk 5.8%). Importantly, these accounts were not offered as reasons to reject the technology; the same participants also described the monitoring as motivating, and the difficulty they identified was one of calibration rather than of value.

The nurses' concerns lay elsewhere, in feasibility and equity. They contrasted the tool favorably with the existing paper-based procedure, noting that with "SCORE2 tables, you need a lot of time and it is more likely that you make a mistake and then start over. Here it is much simpler and faster" (N5; ≥5 years of professional experience), but identified the digital divide as the principal limitation on who could benefit: "For the older population, it may be harder to motivate them to use this tool, whereas younger people, who are more digitally advanced, would probably understand more easily why it is useful" (N1; ≥5 years of professional experience). Nurses further raised the affordability and accessibility of CGM, which is not routinely reimbursed for people with no diabetes, and the risk that a patient might interpret a display negatively in the absence of professional support. Taken together, the patient-reported and nurse-reported barriers point in different directions for implementation: the former concerns how continuous monitoring is introduced and framed for the individual, whereas the latter concerns whether the approach can be delivered equitably within routine services.



Opportunities for Improvement

Suggested improvements focused on training and support, avoiding information overload, preserving the intuitive visual metaphor (flower), and extending use to other clinical areas. The suggestions made by each group followed from the barriers they had identified. Patients proposed extending the scope of what is measured and consolidating it in one place: "Maybe in the future it would be possible to measure something else, not only glucose. It would be useful if the same sensor or application could also include movement, steps and other aspects, so that everything would be visualized in one application" (P4; woman, aged 58 years, baseline SCORE2 risk 5.8%). The nurses' recommendations were oriented toward wider adoption and the conditions for it, encompassing training and support for both staff and patients, the avoidance of information overload, and the preservation of the intuitive flower metaphor, which they regarded as central to the accessibility of the tool. Several also saw application beyond cardiovascular prevention: "I think this is a big bright spot for the future. It could also be used in other areas of health care, or in other fields, to motivate patients" (N2; ≥5 years of professional experience). Across the 2 groups, the recommendations were complementary: patients focused on the completeness and integration of the information they receive, and nurses focused on the organizational preconditions for using that information in routine practice.

Figure 1 presents a conceptual map of the categories and subcategories identified in the analysis, together with the overarching theme that runs across them. The map summarizes the descriptive structure of the findings; the layout does not imply a causal, temporal, or hierarchical sequence between the categories.

Categories and subcategories are shown as a descriptive structure; the layout does not imply a causal, temporal, or hierarchical sequence between categories. CVD: cardiovascular disease.

Relation to the Parallel Quantitative Study

This paper reports the qualitative phase of a sequential mixed methods study; the quantitative randomized controlled trial is reported separately. We did not statistically integrate the 2 datasets in this paper. Instead, consistent with sequential mixed methods designs, the qualitative findings are connected to the trial at the level of interpretation: they help explain the mechanisms that may underlie the trial results, namely, greater understanding, involvement, self-perceived control, and motivation supported by visualization and real-time feedback. The literature review informed the selection of technologies and risk factors incorporated into the intervention.

Discussion

Principal Findings

In this qualitative study, both nurses and patients experienced interactive CVD risk visualization (Petal-X), particularly when combined with CGM, as a meaningful support for PCC. Across 4 categories and 11 subcategories, participants described a clearer understanding of risk factors, more individualized and shared consultations, a greater sense of involvement and control, and stronger motivation for dietary and physical activity change, which some patients reported maintaining after the study. At the same time, participants and nurses highlighted important barriers, including variable digital literacy among older users, fear or mistrust of the technology, the burden of continuous self-monitoring, potential information overload, workflow and training needs, and the affordability and accessibility of CGM. Qualitative analysis of interviews with nurses and participants reveals key aspects of PCC that were identified during the introduction of new technologies in the family medicine practice. The participants expressed satisfaction with the individualized approach, which includes adapting care to the needs and wishes of individuals and actively involving patients in the treatment process.

The perceptions of nurses and participants regarding the use of cardiovascular risk visualization (Petal-X) and CGM are crucial for understanding how effectively these technologies improve management and motivation for lifestyle changes. The categories that enable us to answer the research question are the following: goal-oriented care and an individual approach, involvement in treatment, monitoring of vital functions and technology, motivation and lifestyle changes, understanding of impacts and risk factors, and opportunities for improvement. The category that most strongly organized participants' accounts was PCC.

PCC, supported by technologies that enable personalization and visualization of health data, emerged in our study as an effective strategy for encouraging lifestyle changes among patients in the family medicine setting. Such an approach not only enhances the quality of care but also fosters collaboration between patients and health care professionals, ultimately contributing to improved long-term health outcomes. These findings are consistent with previous interventions that have focused on patient education, structured follow-up and enhanced support for self-management, such as programs for disease self-management education [28,29], structured discharge plans with tailored follow-up [30], and lifestyle counseling, home visits, and telephone support led by health care professionals [31].

Our results suggest that interventions that combine education, personalized care plans, and lifestyle adaptation to the individual's cardiovascular risk could be further strengthened by incorporating visual risk displays [9,32-35], mobile apps [36-39], and additional biometric measurements. CVDs remain a leading cause of morbidity and mortality worldwide, and early

XSL•FO
RenderX

identification and engagement of at-risk individuals are crucial for effective prevention. In this context, digital tools that translate complex prognostic information into intuitive, patient-friendly formats align strongly with the principles of PCC and offer a promising route to more effective preventive strategies.

A central finding of our qualitative analysis is that goal-oriented care and an individualized, data-driven approach are key to tailoring care for patients at risk of CVD. Participants consistently reported that they experienced the consultation as more holistic, with more time for conversation and shared decision-making about their health. This tailored approach took into account specific needs, values, and goals, and included adjustments to diet, physical activity, and daily routines, often with the support of family members. New forms of visualization, such as interactive graphs and personalized analyses of risk factors, were perceived as particularly helpful. They improved communication, enhanced understanding of patients' health status, and encouraged them to participate actively in planning their care.

The Petal-X visualization dashboard, developed and used in our study, represents a concrete step toward augmenting SCORE2 with an explanation layer and operationalizing PCC in routine practice. By providing a clear, structured overview of individual CVD risk factors, Petal-X made the risk profile more transparent and easier to interpret for both patients and nurses. Visualizations increased the sense of overview and control among participants, allowing them to see how different risk factors contribute to their overall risk and what might change if they modify certain behaviors [9,27,32,34,35]. Nurses emphasized that this approach improved the quality of consultations, simplified workflows, and made it easier to involve patients in setting realistic, personalized goals, findings that echo positive outcomes reported in other technology-supported interventions [40-43].

In addition to visualization, the use of CGM, typically reserved for people with diabetes, introduced a dynamic and highly engaging element to lifestyle counseling. Participants carried the CGM device with them and were able to observe real-time changes in their glucose levels in response to food intake, physical activity, stress, and other daily situations. This immediate feedback created a direct link between behavior and physiological response, which several participants identified as a strong motivator for changing and maintaining healthier habits. Similar benefits of real-time monitoring and digital feedback loops have been documented in studies using mobile apps and wearable technologies to support self-management and lifestyle modification [28,29,36-39,41].

Overall, our qualitative findings indicate improvements in patients' understanding of their health status, awareness of CVD risk, satisfaction with the integration of technologies, and willingness to participate in planning their lifestyle changes. Participants reported an increased motivation to continue monitoring and adjusting their lifestyle even after the study ended. From the perspective of nurses, the combined use of Petal-X and CGM supported more structured, person-centered consultations and facilitated the integration of preventive interventions into everyday practice. These experiences are consistent with evidence from other technology-enhanced interventions, which have demonstrated positive outcomes when new tools are embedded in supportive, PCC models [42-44].

The Slovenian context adds an important system-level dimension to these findings. Currently, there is no standardized digital tool that integrates multiple solutions for both nurses and patients, nor is there a unified national electronic health record system that would seamlessly support such approaches. Our implementation of Petal-X and CGM within this fragmented digital environment underscores the potential of these tools to enhance care even in the absence of a comprehensive national infrastructure. At the same time, it underscores the necessity for national guidelines on integrating new technologies into health care, particularly in the areas of prevention and chronic disease management.

Finally, lifestyle modification remains one of the most important modifiable risk factors for reducing the prevalence of CVD risk, making research and innovation in this area especially valuable in Slovenia. Our results suggest that lifestyle change is closely linked to patients' perception of PCC, especially the experience of an individualized approach, personalized visualization of risk, and a holistic, respectful consultation process. The inclusion of new technologies in lifestyle interventions can increase patient motivation, enable real-time monitoring of health status, and support higher-quality PCC. Further research should explore how such tools can be scaled up, integrated into national digital ecosystems, and combined with established interventions, such as education, structured follow-up, and community-based support [28,30,31], to strengthen prevention and long-term management of CVD risk.

Future Research

Several directions for future research follow from these findings. First, larger studies across multiple primary care settings are needed to test whether the perceived benefits of risk visualization and CGM extend to more diverse populations and to evaluate how the tools can be scaled and embedded in routine workflows and in national digital health infrastructure, including electronic health record systems. Second, because CGM carries nontrivial costs, future work should include an affordability and risk-benefit analysis from a public health perspective, so that decisions about wider adoption weigh the added value of continuous monitoring against its cost and its equity implications for patients who cannot afford such devices. Third, given the focus on secondary prevention and PCC, future studies should more explicitly incorporate patients' own preferences, needs, and values, for example, through a structured "What Matters to You?" approach, so that digitally supported risk communication is aligned with what patients themselves consider important. Finally, longer follow-up is needed to determine whether the motivation and behavioral changes that participants described translate into the long-term sustainability of lifestyle change and into measurable cardiovascular risk reduction over time.

Limitations

Several limitations should be considered when interpreting these findings. First, this was a qualitative descriptive study based on

XSL•FO
RenderX

semistructured interviews with a small sample of nurses (n=6) and intervention participants (n=6) recruited by total population sampling from a closed, predefined trial cohort, which supports depth of description but limits transferability to broader primary care populations and settings. Second, although recruitment was open across Slovenia, the promotional campaign and implementation were concentrated in a single Community Health Centre in central Slovenia, so local organizational routines and context may have shaped participants' experiences and perceptions. In addition, recruitment from a single center, combined with the small sample size, resulted in a relatively homogeneous sample, which may further limit the transferability of the findings. Third, the study relied on self-reported experiences, which may be influenced by recall bias and social desirability. Finally, perceptions of Petal-X and CGM may reflect novelty effects and practical implementation constraints; importantly, participants and nurses also reported barriers such as variable digital literacy (particularly among older users), fear or mistrust of technology, potential information overload, workflow integration needs, and affordability or access limitations of CGM, which may affect scalability and equity of implementation.

A further limitation, and one that follows directly from the sampling strategy described, concerns who was eligible to be interviewed. Both samples were restricted to individuals who had completed their part of the intervention: patients who had completed the intervention arm, as defined in the Methods section, and nurses who had completed the familiarization with the intervention and remained in the preventive service throughout the trial period. Patients who withdrew, who discontinued sensor wear, or who did not attend the final assessment were by definition unavailable for interview, and their reasons for discontinuing, which may include precisely the burdens, anxieties, and usability problems that an intervention of this kind is most likely to generate, are therefore not represented in our data. Completer-only sampling plausibly selects for higher engagement with digital tools, greater tolerance of continuous self-monitoring and of the practical and attentional demands of wearing a sensor, and a degree of comfort with self-quantification that may not be typical of the wider primary prevention population. The barriers reported here, including the initial apprehension about what the results would show, the compulsive checking described by one participant, and the burden of keeping a smartphone within range of the sensor, should therefore be read as difficulties reported by people who nevertheless persisted to the end of the intervention, and they are likely to understate both the frequency and the intensity of the problems that would arise in an unselected population.

A related but distinct consideration applies to the nurses. As described in the Methods section, all trial consultations were delivered by the first author (AS), and the nurses interviewed had been familiarized with the intervention and the Petal-X dashboard rather than having used them with their own caseload in routine practice. Their appraisals of usability, workflow fit, and feasibility are therefore the anticipatory judgments of informed prospective users rather than reports of sustained delivery, and they may not capture the frictions that would emerge once such a tool is embedded in everyday consultations, nor the adaptations that practitioners make over time. Equally, the nurses who agreed to be interviewed were those who had engaged with the familiarization offered at the center, which may again select for interest in digital tools. Research in which nurses themselves deliver visualization-supported consultations over a sustained period is needed before conclusions about routine implementation can be drawn. It should also be noted that the interviewed patients were somewhat older than the intervention arm as a whole (mean 57.8 vs 51.9 years), so that the older group whose digital literacy the nurses identified as a barrier was, if anything, overrepresented among the interviewees, although these were older adults who had nonetheless completed the intervention successfully. Studies that deliberately sample noncompleters, partial users, and individuals who decline such interventions are needed to characterize the full range of responses to visualization-supported and CGM-supported cardiovascular prevention.

Conclusions

This qualitative study demonstrates that interactive CVD visualization (Petal-X), particularly when combined with real-time glucose feedback via CGM, can enhance key elements of PCC in primary prevention. Both patients and nurses described that those personalized visual displays improved comprehension of risk factors, supported shared decision-making, and increased patients' sense of involvement and control, mechanisms that were perceived as essential drivers of motivation and lifestyle change.

At the same time, implementation challenges were identified, including variable digital literacy (particularly among older users), concerns about information overload, the need for training of health care professionals, and affordability and accessibility of devices such as CGM. Future work should evaluate how these tools can be integrated into routine workflows and national digital infrastructure, and how they can be scaled in a way that preserves usability, equity, and sustained lifestyle benefits.

Acknowledgments

The authors want to thank all participants who took part in this research. The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: translation and reformatting. The GAI tool used was Chat GPT 5.1. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the outcomes.

Abstract

Background: Body image dissatisfaction, disordered eating, and eating disorders represent significant public health concerns; however, many affected individuals never access evidence-based support. We co-designed and developed a rule-based chatbot, JEM, which conducts conversations addressing evidence-based psychoeducation and psychotherapeutic microinterventions. We previously demonstrated the feasibility, acceptability, and preliminary satisfaction of the JEM chatbot in a research setting. However, broader satisfaction, experiences, and user-reported outcomes in real-world settings have not yet been investigated.

Objective: This study aims to conduct a real-world evaluation of the JEM chatbot in Australia and Canada, the two countries that have hosted a deployment of the chatbot to date. Specifically, we aim to explore user satisfaction and experiences with the chatbot and within-session differences in user mood and body image satisfaction when completing the chatbot's microinterventions.

Methods: Respondents were users of the JEM chatbot aged 13 to 64 years who self-selected to complete a web-based overall evaluation survey (N=230; n=122 in Australia and n=108 in Canada) over a 6-month period. This evaluation survey included user demographic characteristics, satisfaction measures, and the System Usability Scale. Respondents for the within-session pre-post analyses were JEM chatbot users who chose to complete brief web-based surveys immediately before and after completing one of the chatbot's microinterventions during the same 6-month period. Sample sizes varied across microinterventions, ranging from 75 to 276 respondents overall (Australia: n=34 - 146; Canada: n=39 - 130). These surveys included validated visual analog scales (VAS) measuring mood (anxiety, depression, happiness, confidence) and body image satisfaction (body size satisfaction, body shape satisfaction, physical attractiveness).

Results: Demographic characteristics showed that survey respondents were commonly young adult cisgender women and nonbinary individuals across Australia and Canada. Respondent satisfaction with the chatbot was high in both countries (Australia: mean 76.1, SD 22.7; Canada: mean 78.8, SD 14.3), and the usability of the chatbot was rated as "excellent" in both countries (Australia: mean 86.5, SD 16.9; Canada: mean 89.5, SD 11.6) according to the System Usability Scale. Across completed microintervention surveys, patterns of within-session pre-post ratings were broadly similar in Australia and Canada, with effect sizes generally ranging from very small to large across VAS-measured mood and body image outcomes.

Conclusions: The JEM chatbot achieved high satisfaction and usability ratings. Among respondents who completed pre-post surveys, immediate within-session differences in mood and body image ratings were observed following the completion of chatbot microinterventions. The study findings were broadly similar across Australia and Canada. These results provide evidence of user experience and within-session differences following engagement with JEM and support continued evaluation in future studies.

KEYWORDS

eating disorder; body image; mental health; chatbot; conversational agent; artificial intelligence; digital health; psychoeducation; microintervention; evaluation; survey

Introduction

Eating disorders are characterized by disruptions in eating or feeding behaviors that negatively impact an individual's physical and psychosocial functioning [1]. These disorders are present across ages, genders, and backgrounds, and their prevalence and impact are increasing [2,3]. Eating disorders are complex and involve a combination of biological, psychological, sociocultural, and environmental factors [2]. Body image concerns and body dissatisfaction have a significant association with the development of some eating disorders and extreme weight-loss behaviors [4]. Body image dissatisfaction and eating disorders are major public health concerns contributing to substantial economic and health burdens [5-7]; however, many

XSL•FO
RenderX

affected individuals cannot access psychoeducation, early intervention, or timely support.

In response to the growing demand for accessible mental health support, digital mental health interventions have increased in popularity, including artificial intelligence (AI) chatbots. Chatbots offer advantages such as accessibility, instantaneous responses, and being free of cost to users, and they can act as a pathway to more individualized services [8,9]. They can also be helpful in overcoming barriers such as mental health stigma, which is particularly common in body image distress and eating disorders, or having a lack of services available [8,9]. An expanding body of research is supporting chatbot usage and efficacy in the mental health care sector [10-13]. However, despite the rapid growth in chatbot development, relatively few have been rigorously evaluated in real-world eating disorder or body image–specific contexts, with most evidence derived from controlled or early-stage pilot studies [14]. This limits understanding of how such tools perform under naturalistic conditions, including voluntary use, more diverse user populations, and nonresearch settings. As a result, there remains limited evidence regarding engagement, acceptability, and short-term outcomes of body image– and eating disorder–focused chatbots when deployed at scale.

To date, a small number of chatbots with eating disorder– and/or body image–focused evidence-based components have been reported in the literature, including Tessa [15], Topity [16], Alex [17], an early-stage unnamed chatbot for adolescents at risk of eating disorders [18], ED ESSI [19,20], and JEM [21] (formerly KIT), which is the focus of the current study. These systems differ in their primary aims and intervention focus, spanning prevention and early intervention (Tessa, Topity), support for individuals on treatment waitlists (ED ESSI), and early-stage or partially evaluated tools (Alex). Only Tessa, Topity, and ED ESSI have demonstrated effectiveness in randomized controlled trials (RCTs), with Tessa reducing weight and shape concerns in young women [15], Topity improving body image outcomes in adolescents [16], and ED ESSI reducing eating disorder pathology and mood-related outcomes in adolescents and adults awaiting treatment [19]. Certain components of Alex have also been evaluated in controlled settings, although the optimized system has not yet been fully tested [22]. Overall, despite promising early findings, there remains a lack of large-scale real-world evaluations of eating disorder and body image–focused chatbots that combine psychoeducation with brief evidence-based skill-building interventions.

JEM is a rule-based chatbot (ie, operating using predefined conversational pathways rather than generative AI) developed using the Google Dialogflow platform [23]. The chatbot was designed to deliver evidence-based eating disorder–focused psychoeducation alongside brief skills-based microinterventions [21]. The psychoeducation component provides structured information on eating disorders, including prevalence, types, warning signs, health effects, causes, and help-seeking, while the microinterventions focus on brief cognitive behavior therapy (CBT), acceptance and commitment therapy (ACT), and mindfulness-informed exercises targeting cognitive and emotional processes. These microinterventions include education on cognitive distortions or unhelpful thinking styles (CBT), practicing detaching from unhelpful thoughts via cognitive defusion exercises (ACT), and mindful breathing. Both the psychoeducation and microintervention components are delivered using multimodal formats, including text, audio, video, and graphics.

JEM was co-designed with young people aged 13 years and older with lived experience of body image concerns and/or eating disorders, parents/carers, and health professionals [21]. The co-design process provided iterative feedback on content, tone, and usability, which informed the refinement of both the psychoeducation and microintervention components. Overall, co-design findings supported the acceptability and feasibility of JEM and informed its final structure and delivery format [21]. The efficacy of JEM was not tested in an RCT setting before wider scale deployment within Australia because the development timing coincided with the COVID-19 pandemic when demand for support was high and many health initiatives were decided to be fast-tracked [24,25].

While it can be argued that RCTs are ideal for establishing evidence of efficacy as they offer structured environments for rigorous hypothesis testing and reduce the influence of external factors, their findings may not always be generalizable [26]. Evaluating a chatbot in a real-world setting is advantageous in this regard. Naturalistic evaluations are beneficial for understanding user experiences, engagement, and outcomes as they offer increased ecological validity by enabling more natural interactions and outcomes [27-29]. Moreover, they can involve a diverse user base, allowing for a better understanding of the chatbot's usability and effectiveness across various demographics [28,29]. Additionally, real-world evaluations may capture more accurate long-term engagement, as users are not confined by the structured timeframe or artificial environment of an RCT, making it easier to evaluate the chatbot's sustainability and broader impact [26,27]. However, such designs also introduce limitations including self-selection bias, lack of control conditions, and challenges in causal inference.

Real-world evaluations of mental health–specific chatbots are seemingly quite rare [30]. For instance, a study of Wysa, a mobile app for mental resilience and well-being, involved 129 voluntary users [31]. Data were collected via anonymous in-app feedback and assessment questionnaires from users across 23 time zones. High Wysa users showed significantly greater improvement in major depression symptoms with a moderate effect than low users, with 67.7% reporting the app as helpful and encouraging. The authors noted that these results aligned with prior RCTs on conversational agents for mental well-being [32,33] and emphasized that the naturalistic design offered scalable, real-time insights into engagement and effectiveness.

A single-session "mini-course" version of the Tessa chatbot, focused on eating disorders, was studied in users prompted via social media searches [34]. This mini-course improved body image (moderate effect) and motivation to change (small effect), but the study was not fully naturalistic due to researcher screening before mini-course access. When Tessa was deployed in a real-world US setting in June 2023, it shifted from

XSL•FO
RenderX

rule-based responses to offering "off-script" dieting and weight-loss advice, which can be very harmful in eating disorder contexts. This issue was reported by users, not researchers, and attracted global attention [35,36]. Since 2023, Tessa has not been implemented in any public forums to the best of our knowledge. Overall, real-world evaluations of body image– or eating disorder–specific chatbots and mental health chatbots in general remain scarce.

The objective of the current study was to conduct a novel real-world evaluation of our body image and eating disorder education chatbot, JEM, in Australia and Canada, the 2 countries (representing 2 continents) that have hosted a deployment of the chatbot to date. Exploring both settings provided an opportunity to examine whether similar patterns of user experiences and outcomes were observed across different implementation contexts.

Given the exploratory nature of this real-world evaluation, no a priori directional hypotheses were specified. However, the microinterventions were grounded in CBT, ACT, and mindfulness approaches and were examined as within-session pre-post changes in self-reported mood and body image satisfaction following engagement with the microinterventions. The primary aim of the study was to examine user satisfaction and experiences and explore within-session pre-post changes in body image satisfaction and mood for the microinterventions. No specific eating disorder symptoms or behavioral outcomes were assessed. A secondary aim was to explore and describe any differences between the Australian and Canadian JEM deployments.

Methods

Ethical Considerations

This study was approved by the Monash University Human Research Ethics Committee (ID 26129), which encompassed research conducted in both Australia and Canada. Chatbot users were offered the opportunity to complete web-based surveys throughout their conversation with the JEM chatbot; however, the surveys were framed as completely optional, and users could ignore the survey and continue using the chatbot without consequence. When users clicked on a survey weblink, they were presented with detailed study information. Users were informed of their right to withdraw from the survey at any time without any negative impacts. After the detailed information, users were asked to consent by clicking on a button that they had read the information and consented to proceeding to the survey. For users aged 13 to 15 years, ethics-approved procedures required them to confirm that they had obtained parental or guardian consent via an online acknowledgment. Given the fully anonymous and low-risk nature of the research, this approach was deemed appropriate and proportionate by the approving committee. The lower age threshold of 13 years was selected in line with common minimum ages for digital platform access and social media use and to capture early adolescent users who may engage with online eating disorder–related content. Users aged 16 and 17, like those aged 18 and over, were considered to be sufficiently mature to consent for themselves without parent or guardian consent required according to our ethics approval. Users completed the surveys anonymously—they were not required to provide their name or any potentially identifying information at any point. No compensation was offered for completing surveys or using the chatbot.

Study Design

This study used a naturalistic mixed methods design comprising 2 complementary data structures: (1) cross-sectional user evaluation surveys and (2) within-session pre-post microintervention assessments embedded within chatbot interactions. A minimum of 34 completed responses per microintervention was used as a pragmatic threshold intended to support estimation of moderate effect sizes [37], consistent with prior work [31,34], and the exploratory nature of this real-world design [38].

Participants

Participants were individuals aged 13 years and older residing in Australia or Canada who engaged with the JEM chatbot from January 2023 to June 2023 in Australia or September 2024 to March 2025 in Canada. Geographic location was based on self-reported residence and deployment platform context within an anonymous web-based design. These time periods covered the first 6 months of JEM deployment in each country for optimal comparability, particularly in terms of the novelty of the chatbot service to the users in the respective countries [39]. In this 6-month period, system-level usage included 6862 total chatbot sessions and 39,184 interactions in the Australian deployment and 1332 sessions and 5370 interactions for the Canadian deployment according to Google Dialogflow analytics definitions [40], which are distinct from individual-level survey respondents analyzed in this study. Study participants were recruited from individuals already engaging with the JEM chatbot. All surveys (overall evaluation and microintervention surveys) were open surveys, and a self-selection sampling method was used, representing a convenience sample. No direct contact with potential participants was made by any members of the research team. Recruitment occurred in writing through the chatbot's "Provide Feedback/Feedback Survey" and "Skill Survey" conversation options, which users could select voluntarily. These options led to web-based surveys hosted by Qualtrics [41]. Surveys were administered with standard Qualtrics platform-level fraud-prevention settings applied to reduce duplicate responses (eg, cookie-based controls) [42,43], although these do not fully eliminate the possibility of repeat submissions in anonymous online settings. Only completed questionnaires were analyzed. Due to the fully anonymous design of the chatbot and surveys, individual users could not be tracked across sessions or timepoints. Therefore, engagement is reported at the session level, and survey participation represents voluntary, self-selected responses from the overall user base (see Multimedia Appendix 1 for aggregate study flow). For users who initiated the overall survey, completion rates were 80.1%, and for users who initiated microintervention surveys, completion rates ranged from 70.2% to 75.0%. There were no significant differences between the Australian and Canadian chatbot deployments for these completion rates (all *Ps*>.05).

XSL•FO
RenderX

Intervention

JEM was a web-based and rule-based chatbot powered by the Google Dialogflow platform [23]. The chatbot was available 24 hours per day, 7 days a week to users in Australia via a Monash University website (Figure 1) and in Canada via the National Eating Disorder Information Centre website (Figure 2). These deployment characteristics are reported to contextualize accessibility and real-world use; however, the primary focus of the intervention is the structure and content of the psychoeducational and microintervention pathways delivered within the chatbot. The chatbot was free of charge to access and users could converse with the chatbot as long as they wished to do so. There was no login or authentication required to use JEM, and usage was completely anonymous. Users were cautioned on these websites that the JEM chatbot was not monitored by any humans, and if they were experiencing an emergency, they should contact country-specific emergency services with contact details provided.

Figure 1. Australian version of the JEM chatbot hosted on a Monash University webpage. Users clicked on the blue speech bubble icon to start the conversation.

XSL•FO
RenderX

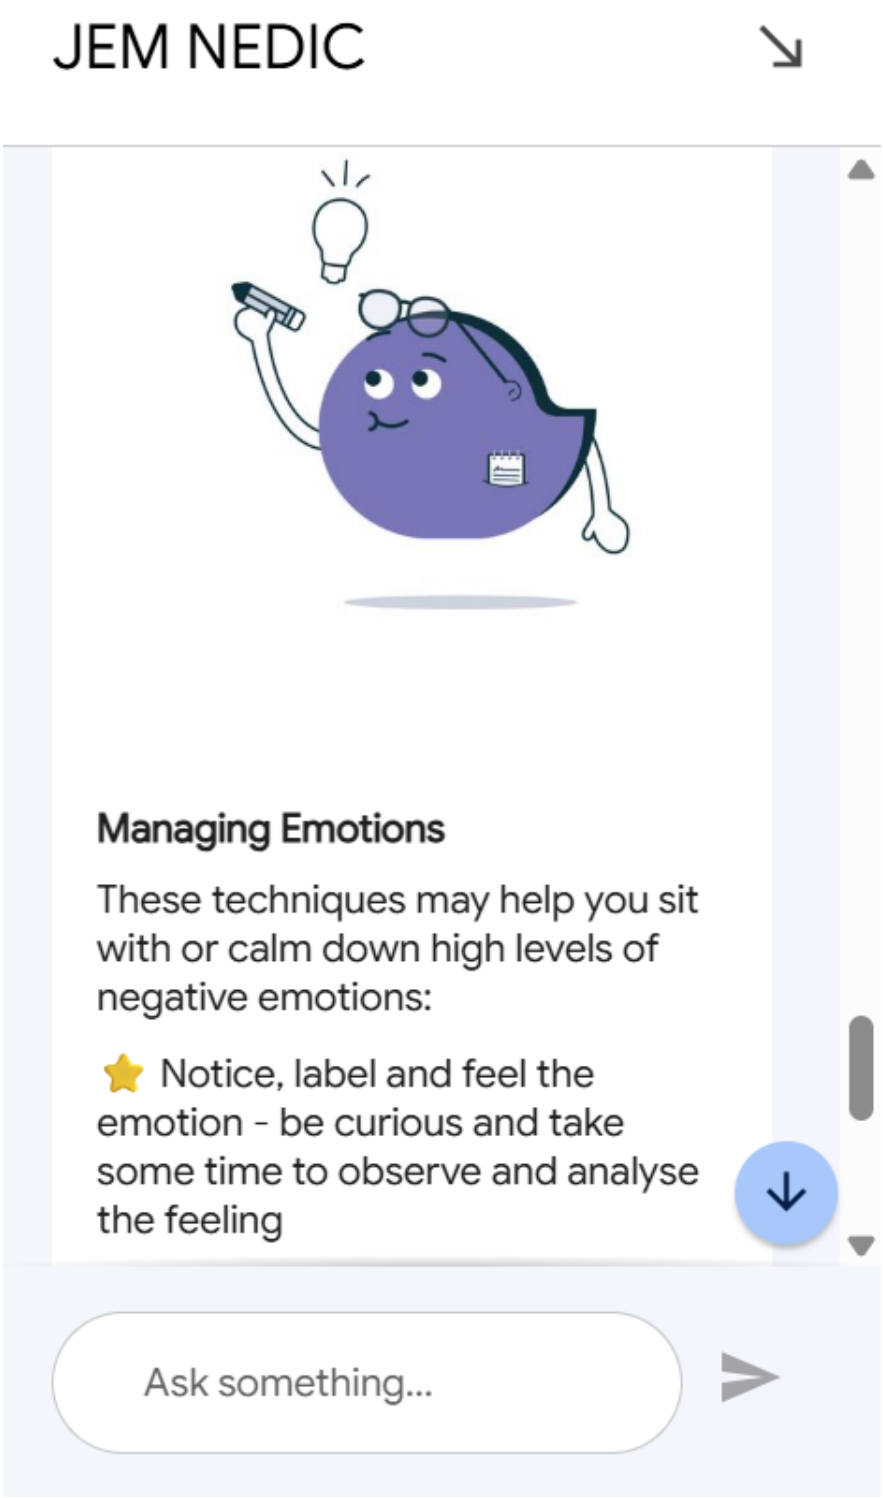

Figure 2. Canadian version of the JEM chatbot hosted on the National Eating Disorder Information Centre website. Users clicked on the purple JEM icon to start the conversation.

The chatbot's conversation content was based on evidence-based information or interventions for eating disorders, specifically psychoeducation, CBT, ACT, and mindfulness (for detailed information, see Beilharz et al [21]). Owing to the short conversational style of the JEM chatbot, the microinterventions taught by JEM were carefully selected, such as for CBT, education on cognitive distortions, for ACT, cognitive defusion exercises, and mindful breathing for mindfulness (see Figures 3 and 4 as examples). All microinterventions were estimated to take less than 5 minutes to complete. The chatbot operated through a rule-based decision-tree structure, where user inputs were matched to predefined intents that triggered specific conversational pathways. Users engaged with JEM via either free-text inputs or menu-based options, which routed them to psychoeducation content or presented a set of available microintervention scripts. The 10 microintervention scripts were discrete, standardized conversational pathways that users could actively select from a menu of available skills. Each microintervention followed a fixed sequence of prompts and responses with no within-script branching. These scripts were delivered in multimodal formats, including text, images, audio, and video. Users self-selected into microinterventions during their interaction with the chatbot, and each script could be completed within a single session or revisited multiple times. Completion was operationalized as reaching the end of the scripted conversational pathway.

XSL•FO
RenderX

Figure 3. Example conversation from the JEM chatbot for the "Managing Emotions" microintervention (Canadian version).

There were no major conceptual differences in intervention content and technical delivery between the Australian and Canadian deployments. In terms of safety, natural language processing was used for JEM to detect user-typed risk phrases such as "I want to kill myself," and "I wish I was dead," and JEM responded with 24/7 crisis support services specific to Australia or Canada. Specifically, risk detection was implemented using Google Dialogflow's intent classification and entity extraction [44] to identify free-text inputs indicative of self-harm and suicidality. When a high-risk intent or entity was detected, the system immediately triggered a predefined response flow that bypassed standard conversational pathways and directed users to country-specific 24/7 crisis support services. There was also a "Get Urgent Help Now" option for users to select where the chatbot responded with these same crisis support services. If a user was to type a prompt that the chatbot could not match to a preprogrammed answer, the chatbot responded with "I'm just a simple bot so I'm still learning how

XSL•FO
RenderX

to respond to your typed message. Try using my buttons to have a conversation with me" along with crisis support service contacts. There were no adverse events reported by users during the study period.

XSL•FO
RenderX

Measures

Surveys

There were 2 types of web-based surveys, hosted by Qualtrics [41], where the survey weblinks were included within the JEM chatbot's conversation: (1) overall evaluation survey accessed via the "Provide Feedback" option and (2) skill surveys presented for every microintervention conversation (10 in total). There were no "back" options on any of the surveys for people to change their earlier responses.

Overall Evaluation Survey

The content and structure of this survey were based on our previous chatbot co-design research [20,21]. These items were designed as brief, study-specific indicators of user experience within an embedded chatbot context and were not intended as stand-alone psychometric instruments. In the first section of the survey, demographic characteristics were asked, particularly age, gender identity, LGBTIQA+ community membership (lesbian, gay, bisexual, transgender, intersex, queer, asexual people, or people otherwise diverse in gender, sexual orientation, and/or innate variations of sex characteristics), and ethnicity. Note that ethnicity was asked in a different format in Australia compared to Canada to suit the standard ethnicity demographics of the country [45]. The second section of the survey included categorical items addressing (1) reasons for using the chatbot, (2) whether the user found the information they were looking for, and (3) whether they intended to seek further support. The third section involved a single-item user satisfaction sliding scale ranging from 0 ("not at all satisfied") to 100 ("completely satisfied"). This satisfaction item was followed by an optional open-text question: "Please let us know your reason(s) for your satisfaction rating." The fourth and final section of the survey used the validated System Usability Scale (SUS) [46], which comprised 10 items that reflected various statements related to system usability (eg, "I thought the system was easy to use"). Responses were recorded on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree"). The SUS score yielded a single number between 0 and 100, with higher scores representing higher perceived usability of the system. The SUS demonstrated high reliability in this study's sample (Cronbach α=0.89 for both Australian and Canadian samples).

Microintervention Survey

For every microintervention included in the JEM chatbot (10 in total, see Beilharz et al [21] for comprehensive descriptions), there was a web-based survey offered. If the user decided to complete the survey, they were asked for their current mood ratings for how happy, confident, anxious, and depressed they felt, with each being rated on a visual analog scale ranging from 0 ("not at all") to 100 ("very much"). The respondents were then asked to similarly rate for body image satisfaction on visual analog scales ranging from 0 ("not at all") to 100 ("very much"), specifically physical attractiveness, body size satisfaction, and body shape satisfaction. Note that we did not ask demographic characteristics of respondents in the microintervention surveys. Single-item visual analog scales were used to assess momentary mood and body satisfaction to minimize respondent burden and enable repeated, brief assessments within a chatbot-based design. Single-item visual analog scale measures are widely used for capturing transient, state-level affective and body image experiences and have been shown to be sensitive to within-person changes over time [47-50]. Importantly, prior research indicates that single-item measures of body satisfaction are responsive to short-term changes in both observational and online intervention contexts [51-53]. Respondents were instructed to complete the microintervention and then return to the survey immediately afterward, where they were then presented with the same mood and body image satisfaction visual analog scales again. Thus, the before and after microintervention ratings were completed within the same survey for each microintervention.

Data Analysis

The Statistical Package for Social Sciences (SPSS; version 31; IBM Corp) [54] was used for quantitative statistical analysis. Descriptive statistics were used to analyze demographic characteristics and user satisfaction and experiences. To explore if there were differences between countries, 2-tailed independent samples *t* tests were used for continuous data and Fisher's exact tests for categorical data (2-tailed). To examine within-session pre-post microintervention changes in mood and body image, Cohen *d* was calculated as a measure of effect size [37], with 95% CIs reported. Analyses were conducted at the survey or session level due to the fully anonymous design of the chatbot, which did not allow the linkage of responses across users or timepoints. Any missing data were handled with listwise deletion, acknowledging that missingness in optional, anonymous web-based surveys may not be completely at random. Given the exploratory and hypothesis-generating nature of these analyses, no formal correction for multiple testing was applied [55]. Applying such corrections in this context may have increased the risk of type 2 error and obscured potentially meaningful signals warranting further investigation. The results were therefore interpreted cautiously, acknowledging the increased risk of type 1 error associated with multiple comparisons. The open-ended qualitative text responses addressing reasons for chatbot satisfaction ratings were analyzed using an abbreviated content analysis approach [56], given the brevity of the responses (30 words maximum). GS conducted initial coding, with HH independently reviewing and refining codes. All authors agreed on the final content interpretations.

Results

User Characteristics

Across all analyses, reported Ns refer to completed survey instances (survey responses). As shown in Table 1, from the overall evaluation surveys, respondents were, on average, in their early 20s, but age distribution varied substantially, particularly in the Australian sample. The respondents predominantly identified as girls or women, followed by nonbinary individuals. Around two-thirds of respondents did not identify as LGBTIQA+; however, when they did, queer was the most common identity. There were no differences between Australian and Canadian-based respondents for any of these demographic characteristics (all *P* values >.05). The majority of respondents were European or White in Canada, and around

XSL•FO
RenderX

a quarter identified as culturally and linguistically diverse (CALD) in Australia. Owing to the different style of questioning required, ethnicity was not compared between countries.

Table . Respondent demographic characteristics for overall evaluation survey by country (N=230 total).

Demographic characteristic	Australia (n=122)	Canada (n=108)
Age (y), mean (SD; range)	21.0 (12.0; 13 - 64)	22.8 (6.8; 14 - 43)
Gender, n (%)		
Girl or woman	99 (81.1)	87 (80.6)
Boy or man	7 (5.7)	6 (5.6)
Nonbinary	14 (11.5)	12 (11.1)
Transgender woman	0 (0)	0 (0)
Transgender man	1 (0.8)	0 (0)
Prefer not to answer	1 (0.8)	3 (2.8)
Ethnicity		
Australia CALD[a], n (%)		
No	89 (73.0)	—[b]
Yes	31 (25.4)	—
Prefer not to answer	2 (1.6)	—
Canada, n (%)		
European or White	—	81 (75.0)
African or Black	—	3 (2.8)
Latin, South or Central American	—	3 (2.8)
East Asian	—	3 (2.8)
“Mixed”	—	6 (5.6)
Prefer not to answer	—	12 (11.1)
LGBTIQA+[c] n (%)		
No	81 (66.4)	72 (66.7)
Bisexual	4 (3.3)	6 (5.6)
Lesbian	5 (4.1)	3 (2.8)
Queer	17 (13.9)	15 (13.9)
Gay	10 (8.2)	6 (5.6)
Asexual	0 (0.0)	3 (2.8)
Prefer not to answer	5 (4.1)	3 (2.8)

[a]CALD: culturally and linguistically diverse.

[b]Ethnicity was assessed using country-specific response categories. Blank cells indicate categories that were not applicable to that country.

[c]LGBTIQA+: lesbian, gay, bisexual, transgender, intersex, queer, asexual people, or people otherwise diverse in gender, sexual orientation, and/or innate variations of sex characteristics.

Experiences and Satisfaction

As indicated in Table 2 from the overall evaluation surveys, the most common reasons in both countries for using JEM chatbot were that the respondents thought they may have an eating disorder, had issues finding information, and were simply curious about the chatbot. Respondents found the information they were looking for the vast majority of the time, and the majority intended to seek or maybe seek further support after using the chatbot. The overall satisfaction rating for the JEM chatbot was high on average, and the SUS rating was in the “excellent” category for both Australia and Canada [46]. There were no country-based significant differences for any of these findings (all *P* values >.05).

For the open-ended qualitative responses to reasons for the satisfaction ratings, this question was completed by a self-selected subset of respondents (Australia n=16; Canada n=12), which did not significantly differ between countries (all *P* values>.05). Given the lower response rates, responses were analyzed in aggregate rather than by country (Table 3). The response themes were mostly positive in nature, with the most

XSL•FO
RenderX

common focused on JEM chatbot providing helpful information and being easy to use.

Table . Responses to overall evaluation survey by country (N=230 total).

Measure	Australia (n=122)	Canada (n=108)
Reasons for using the chatbot, n (%)[a]		
May have an eating disorder	71 (58.2)	61 (56.5)
Trouble finding information via other sources	32 (26.2)	29 (26.9)
Curious about the chatbot	29 (23.8)	27 (25.0)
Chatbots do not judge	13 (10.7)	12 (11.1)
Not ready to speak to a real person	10 (8.2)	9 (8.3)
Find information, n (%)		
Yes	112 (91.8)	100 (92.6)
No	10 (8.2)	8 (7.4)
Seeking further support, n (%)		
Yes	79 (64.8)	77 (71.3)
Maybe	15 (12.3)	14 (13.0)
No	14 (11.5)	12 (11.1)
I already have support	14 (11.5)	5 (4.6)
Satisfaction rating, mean (SD; range)	76.1 (22.7; 20.0 - 100)	78.8 (14.3; 30.0 - 100)
SUS[b] rating, mean (SD; range)	86.5 (16.9; 20.0 - 100)	89.5 (11.6; 40.0 - 100)

[a]Percentages add up to greater than 100% as respondents could choose multiple responses.

[b]SUS: System Usability Scale.

Table . Themes for open-ended qualitative responses for reasons for satisfaction ratings by country (N=28 total).

Theme	Category	Total, n (%)[a]	Australia, n	Canada, n
Chatbot provided helpful information	Positive	18 (64.3)	10	8
Chatbot was easy to use	Positive	16 (57.1)	10	6
JEM character was fun or cute	Positive	7 (25.0)	3	4
Prefer a chatbot over a helpline	Positive	6 (21.4)	6	0
Chatbot had a friendly tone	Positive	4 (14.3)	0	4
Difficult to find the information sought	Negative	2 (7.1)	2	0
Chatbot conversation was targeted at too young an audience	Negative	1 (3.6)	0	1

[a]Percentages add up to greater than 100% as qualitative responses could be classified into multiple themes.

Changes to Mood and Body Image

Four of the 10 total microinterventions included in the JEM chatbot's conversation yielded sufficient completed survey responses (n≥34) from either country to conduct suitable within-session pre- or postchange analyses (Table 4). These 4 microinterventions were (1) Managing unhelpful thoughts (CBT and ACT strategies), (2) Managing emotions (ACT strategies), (3) Challenging beauty (CBT strategies), and (4) Feeling worthy (CBT strategies). Sample sizes for individual microintervention analyses varied and were modest for some subgroups; therefore, the findings should be interpreted with appropriate caution.

Across microinterventions, the within-session pre-post ratings were broadly similar in Australia and Canada, with effect sizes ranging from very small to large. The Managing unhelpful thoughts microintervention showed very small or small effect sizes across most measures, with moderate effects observed for anxiety. The Managing emotions microintervention showed the largest within-session effect sizes for depression, with moderate

XSL•FO
RenderX

effects observed for body size satisfaction and the remaining measures showing very small-to-small effects. The Challenging beauty microintervention showed very small-to-moderate effects across measures, with confidence and physical attractiveness showing the largest effect sizes. The Feeling worthy microintervention showed very small-to-moderate effects across measures, with confidence, physical attractiveness, body size satisfaction, and body shape satisfaction showing the largest effect sizes.

Discussion

Principal Findings

This study provides one of the first real-world evaluations of a mental health–focused chatbot deployed at scale across 2 countries and continents, providing insight into chatbot use under naturalistic conditions. Overall, the findings indicated that the JEM chatbot was well accepted by respondents who completed surveys in both Australia and Canada, demonstrated excellent usability, and showed immediate within-session differences in mood and body image ratings. Satisfaction was high, information needs were largely met, and most survey respondents reported an intention to seek or consider further support after using the chatbot, suggesting that JEM may function as a supportive resource that could potentially facilitate consideration of further support.

Across microinterventions, patterns of within-session pre-post ratings were broadly similar in Australia and Canada, with effect sizes generally ranging from very small to large. While the magnitude of effect sizes varied across microinterventions and outcomes, the largest effects were typically observed for depression, anxiety, confidence, and body size satisfaction outcomes. These findings reflect immediate within-session pre-post changes and should not be interpreted as evidence of causal or sustained intervention effects.

In contrast, effect sizes for happiness ratings were generally very small across the microinterventions included in the analyses. This may reflect the brief nature of the interventions, which are designed to reduce distress and maladaptive cognitions rather than induce immediate positive affect, and is consistent with theoretical expectations of CBT and ACT informed strategies [57-59].

Gender identity beyond the binary was represented in the sample, with approximately 11% of respondents identifying as nonbinary. All study analyses included these respondents within the overall sample rather than stratifying by gender. Overall, JEM's nongendered and inclusive framing of content [21] suggests potential applicability across gender identities, although future work should directly examine differential experiences among gender diverse users, particularly their responses to psychotherapeutic microinterventions.

Comparison With Prior Work

These findings extend the very limited literature on eating disorder– and body image–specific intervention chatbots, particularly in real-world contexts. Previous RCTs have demonstrated efficacy for Tessa, Topity, and ED ESSI under controlled conditions [15,16,19], while other chatbots have been evaluated only partially or at early stages of development [17,18]. This study extends this work by demonstrating that a rule-based chatbot can be deployed with high user satisfaction and usability in naturalistic settings. Furthermore, the patterns of within-session pre-post differences observed among JEM users aligned in direction with findings reported in more controlled trials, while recognizing the differences in study design.

Compared with prior naturalistic evaluations of mental health chatbots such as Wysa [31], this study focused on a more specific population and set of outcomes. The patterns of within-session pre-post differences in anxiety, depression, and body image satisfaction observed among JEM survey respondents were mostly consistent with those reported in broader mental health chatbot evaluations. These observations are consistent with the literature suggesting that well-designed conversational agents may be associated with positive user-reported outcomes in real-world observational settings [31,60] and align with broader discussions about the promise and fragility of AI-mediated mental health care in real-world settings [61].

Importantly, the present findings contrast with concerns raised following the real-world deployment of the Tessa chatbot in 2023 in the United States, where the chatbot deviated from its rule-based design and provided dieting and weight loss advice [35]. No adverse events or harmful outputs were reported by users during the study period. JEM's rule-based architecture and co-designed content were intended to minimize such risks; however, all safety outcomes were not assessed in this study.

The very small effects on happiness from microinterventions also align with previous digital intervention research, where reductions in negative symptoms are often more readily observed than increases in positive affect, particularly following brief, single-session interventions [59,62]. Together, these findings suggest that JEM performs in a manner consistent with existing evidence while addressing a notable gap in real-world evaluations of body image– and eating disorder–specific chatbots.

Recent RCTs of generative AI-based conversational agents further suggest both the promise and the complexity of chatbot-delivered mental health interventions, reinforcing the importance of safety-focused design and careful real-world evaluation [63]. While the vast majority of qualitative feedback in this study was positive, with respondents reporting helpfulness, ease of use, and an engaging conversational style, a minority had negative feedback. More broadly, rule-based

XSL•FO
RenderX

chatbot systems are often perceived as less flexible than emerging large language model (LLM)–based approaches, which offer more naturalistic dialogue [64]. This highlights an important design trade-off between maintaining clinically safe, structured responses and meeting evolving user expectations for more adaptive and personalized conversational experiences. Future JEM iterations could explore hybrid architectures that combine rule-based safety constraints with controlled generative or retrieval-based components to enhance conversational flexibility while maintaining clinical safety and content fidelity [65].

Limitations and Future Research

Several limitations should be acknowledged for this study. First, the absence of a control group precludes causal inference and means changes cannot be definitively attributed to the chatbot alone. Second, outcomes were assessed immediately before and after individual microinterventions, limiting conclusions about the durability of effects. The immediate pre- and postintervention design may also be susceptible to demand characteristics and expectancy effects. However, differences were not uniform across outcomes or microinterventions, suggesting variability in within-session responses across measures and intervention content. Third, sample sizes varied across microinterventions, with 4 yielding sufficient data for analysis, which may have influenced the pattern of the findings based on differential engagement. Additionally, reliance on self-report measures and voluntary survey completion introduces potential response bias and means that the results reflect only a subset of users. Due to the fully anonymous design of JEM, which did not include login, authentication, or persistent user identifiers, individuals could not be tracked across sessions or over time. As a result, it was not possible to construct a participant-level CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) style flow diagram [66] tracking individuals through the chatbot content or determine precisely where attrition occurred within the chatbot journey. Engagement data are therefore reported via text and diagram at the session level, limiting the assessment of repeat usage and longitudinal engagement. Furthermore, this study did not assess changes in specific eating disorder symptoms, eating behaviors, or clinical outcomes.

Future research should examine longer-term outcomes associated with repeated or sustained chatbot use, including whether these immediate within-session differences are associated with longer-term outcomes, such as eating disorder risk or engagement with formal care. Hybrid designs combining real-world deployment with comparison conditions may help balance ecological validity with internal rigor. Further investigation into engagement patterns, personalization, and differential effects across demographic subgroups is also warranted.

Conclusions

This study demonstrated that a co-designed evidence-based chatbot, JEM, can be deployed at scale across multiple countries, achieving high usability and user satisfaction. Immediate within-session differences in mood and body image ratings were observed following the completion of the microinterventions investigated. However, further controlled research is needed, and the longer-term effects are yet to be determined. The study findings were broadly similar across Australia and Canada. These results extend the limited real-world evidence for mental health and body image– or eating disorder–specific chatbots, demonstrating that rule-based systems with co-designed content can be acceptable to users. As digital mental health interventions evolve, future research should explore how different approaches, including rule-based and generative AI chatbots, can complement each other to provide scalable, safe, and personalized support. Collectively, these findings suggest that chatbots such as JEM may represent a feasible and acceptable low-barrier resource for individuals seeking information and support related to body image and eating disorder concerns.

Acknowledgments

The authors would like to thank the JEM chatbot users in Australia and Canada for their valuable study involvement.

ChatGPT (OpenAI) was used to assist with language editing and improving clarity and flow of the manuscript. The authors take full responsibility for the content.

Funding

The authors declared no financial support was received for this work.

Data Availability

The datasets generated and analyzed during the current study are not publicly available under the participant confidentiality conditions of ethics approval from the Monash University Human Research Ethics Committee (ID 26129). The corresponding author can be contacted with queries about the data.

Abstract

Background: Despite the growing importance of social media in mobile health (mHealth) communication, we lack a clear understanding of how emotional elements like emojis shape message effectiveness. Furthermore, since emojis are inherently tied to text, their impact may be highly dependent on the relevance and context of the accompanying written content.

Objective: This study aimed to investigate how the valence of emojis affects the effectiveness of mHealth messages and to determine the role of emoji-text congruence in shaping message outcomes.

Methods: A mixed-method approach was used, encompassing 3 complementary studies. First, an analysis of real-world health-related tweets (N_1=257,648) quantified social media engagement in relation to positive, negative, and absent emojis. Building on these insights, 2 controlled experiments (N_2=220; N_3=190) further explored how negative emojis influence preventative health behaviors under varying levels of text congruence.

Results: The automatic content analysis revealed that messages containing negative emojis generated significantly higher social media engagement than those with positive emojis (β=0.24, SE=0.03, $t_{257,593}$=9.59; P<.001). Subsequently, experimental findings indicated that negative emojis can effectively promote preventative health behaviors (t_{218}=−4.15; P<.001). However, messages with high negative emoji-text congruence are more persuasive in promoting preventive behavior than those with low congruence ($F_{1,186}$=5.46, η^2=.028; P<.05), highlighting the complex interplay between emotional signaling and message consistency.

Conclusions: These findings advance our theoretical understanding of emoji-based health communication and provide practical guidelines for public health organizations seeking to optimize their mHealth messaging strategies. Our results highlight the need for careful consideration of both emotional valence and message coherence when designing health communications in the digital age.

KEYWORDS

emojis; preventive behavioral intention; emotional valence; congruence; mobile health communication; social media engagement

Introduction

Background

In mobile health (mHealth), disseminating accurate, comprehensible, and persuasive health information is crucial [1]. Campaigns, whether in the form of health posts or advertisements, aim to foster positive attitudinal and behavioral shifts, which is especially important when conveying protective measures against infectious diseases such as Ebola, COVID-19, and Monkeypox, or promoting routine practices like physical examinations [1]. Given the vast reach and interactive nature of social media, public health advocates increasingly leverage these platforms to communicate vital information [2-5]. Within these digital interactions, emojis have become ubiquitous, functioning as paralinguistic cues that supplement textual content and amplify emotional expression [6-8]. Scholarly attention has thus turned to understanding how emojis support messaging-based interventions in mHealth, particularly since research indicates that their inclusion can evoke more intense emotional responses compared to text alone, potentially enhancing behavioral intentions [9-17].

While several studies have demonstrated that the presence of emojis generally benefits health communication [13,16,18,19], most have focused on their mere presence versus absence, without delving into the nuanced effects of specific emoji characteristics. Emojis are not monolithic; they vary in

XSL•FO
RenderX

emotional valence and serve as potent social cues in online interactions [6]. In the context of health communication, positive emojis (eg, ,) are conceptually defined as symbols that convey approach-oriented or supportive emotions, signaling safety or encouragement to cope [15,20]. By contrast, negative emojis (eg, ,) express avoidance-oriented, alarming, or aversive emotions, signaling risk or concern [16,17]. The emotions as social information (EASI) model provides a foundational framework by suggesting that emotional expressions influence behavior via two main pathways: a direct affective reaction (eg, emotional contagion) and a cognitive inferential process (eg, deducing meaning or intent) [21]. Despite its strengths, scholars call for more comprehensive testing of the EASI model across digital contexts to better understand the specific persuasive impact of emoji valence in health messaging [6,21]. A clear grasp of how emoji valence operates is essential for designing more effective public health interventions.

Beyond shaping attitudes and behavioral intentions, a cornerstone of health communication efficacy [22-24], the success of health messages on social media is reflected in engagement metrics. Social media engagement is the extent to which users interact with online content through behaviors such as liking, commenting, and sharing [25-27]. These metrics indicate that a message has captured audience interest, stimulated discussion, and achieved widespread dissemination. Moreover, the congruence between a message's components—specifically, the emotional tone of an emoji and the accompanying text—is a known predictor of message credibility and persuasiveness [28,29]. Incongruence between emoji valence and textual content could compromise message clarity and reduce persuasive effectiveness.

This study addresses these gaps by examining the strategic use of negative emojis in public health communication through messaging-based interventions on social media. We integrate three complementary theoretical perspectives: the EASI model [21], which explains how emotional expressions shape behavior; emotional contagion theory [30], which details how negative emotions can rapidly spread within social networks; and schema-congruity theory [31,32], which elucidates how congruence between emojis and text facilitates multimodal cognitive processing. Guided by these theoretical underpinnings, we address the following hypotheses:

Effectiveness of Emoji Valence on Social Media Engagement

The affective pathway of the EASI model posits that observed emotions can induce similar feelings in recipients, while Emotional Contagion Theory [30] indicates that negative emotions tend to spread more rapidly, serving as potent threat signals [33,34]. Previous research has shown that negative emotional cues, even when conveyed through emojis, can heighten risk perception and, in turn, drive user engagement as audiences seek, share, or discuss the information [35-37]. In the context of health communication, negative emojis act as digital "alarm signals," motivating engagement through two complementary processes: (1) individual-level contagion (unconscious adoption of fear or concern) [30] and (2) social-level diffusion (sharing messages to alert others) [38]. Critically, negative emojis exhibit stronger contagion effects than positive ones.

Hypothesis 1: compared to positive emojis, using negative emojis in health-related social media posts will generate higher social media engagement.

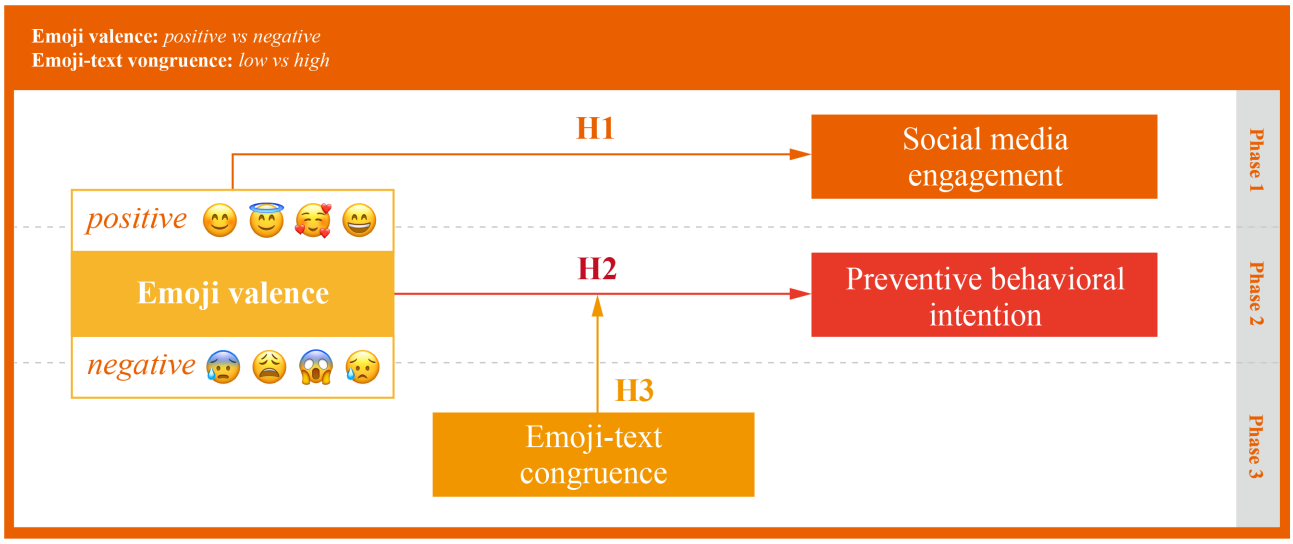
Effectiveness of Emoji Valence on Preventive Behavioral Intention

Previous studies have leveraged emoji valence to inform individuals' perceptions and behaviors, such as emotional responses to food [39] and intentions to receive vaccination [16]. Preventive behavioral intention refers to the deliberate motivation to adopt health-protective actions and serves as a critical precursor to actual health behavior change [16,40-42]. Persuasive messaging often leverages emotional valence to amplify risk perception and motivate action [22,43]. Negative emojis (eg, ,) serve as condensed emotional cues that trigger a "risk-as-feelings" response, making abstract health risks more tangible and activating defensive motivations [43]. This process is consistent with the affective pathway anticipated by the EASI model and the human predisposition to give priority to negative signals as survival-relevant warnings [33,35].

Hypothesis 2: Compared to positive emojis, using negative emojis in health-related social media posts will increase individuals' preventive behavioral intentions.

Moderating Role of Emoji-Text Congruence on Preventive Behavioral Intention

In messaging-based health interventions on social media, emojis are often conveyed to users alongside textual messages. Schema-congruity theory [31,32,44] suggests that messages aligning with an individual's existing schemas are processed more smoothly. People tend to have more positive attitudes toward messages that exhibit high internal congruity [32,44]. For example, in high-risk contexts, recommendations are more effective when the visual content, textual message, and information source are mutually consistent [1,16]. Erle et al [6] assert that although emojis enhance the comprehensibility of information on social media, this effect is not realized solely through perceived valence. According to the EASI model's inferential pathway, the alignment between the emotional tone of emojis and the textual narrative builds a cohesive communicative schema. Negative emojis can enhance preventive intentions when they are congruent with risk-oriented text, whereas positive emojis may backfire when they are perceived as incongruent with the seriousness of the message. Although some degree of incongruence may introduce novelty effects [45,46], in health communication, a mismatch (eg, pairing positive emojis with severe warnings or negative emojis with overly reassuring texts) could undermine message credibility and clarity [38].



Hypothesis 3: the impact of emoji valence on preventive behavioral intentions is moderated by emoji-text congruence; specifically, negative emojis will be most effective when paired with text that is congruent in conveying risk or threat, while the

XSL•FO
RenderX

persuasive effectiveness of positive emojis may be diminished if this text conveys negative emotional framing.

The conceptual model of this study is presented in Figure 1.

Figure 1. The conceptual model and phase hypotheses.

Methods

Overview

To systematically test these hypotheses, we used a multimethod approach comprising an automated content analysis of real-world social media data and 2 online simulation experiments. To enhance the ecological validity of the study, we examined or simulated three phases of messaging-based health communication interventions across different social media platforms (Twitter, Facebook, and WeChat). These three phases cover both emergency public health crises and regular physical examination scenarios. This robust approach enables a comprehensive examination of how emoji valence and congruence impact both social media engagement and preventive behavioral intentions in health communication.

Ethical Considerations

This research received approval from the Academic Ethics Review Committee of the College of Fine Arts, Guangdong Polytechnic Normal University (approval number GPNU-GD25YYS34). Before participation, all participants were presented with an electronic informed consent form on the Credamo [47] platform describing the study purpose, voluntary nature of participation, data use, and compensation. Only those who provided digital consent were allowed to proceed. Participants were informed that they could withdraw from the survey at any time without penalty. All responses were collected anonymously (or de-identified before analysis) and analyzed in aggregate form only, and no personally identifiable information was retained by the research team. Those who completed the survey received compensation of 3 RMB (about US $0.44 as of July 16, 2026). The study complied with applicable institutional and national ethical guidelines for research involving human participants.

Phase 1

Data Collection

To examine how the emotional valence of emojis relates to public engagement with health messages, we collected 320,151 tweets from 48 prominent Twitter (now “X”) accounts specializing in health communication, including the World Health Organization, NPR Health, and NBC News Health (see Multimedia Appendix 1 for the full list). Data were retrieved using the academic research product track of the Twitter application programming interface (API) v2, which provides full-archive access to public tweets. Using the academictwitteR package in R (version 4.3; R Foundation for Statistical Computing), an automated script retrieved all tweets posted by each account between January 1, 2019, and December 31, 2021. This 3-year window was selected to capture health communication dynamics spanning the prepandemic period, the onset of COVID-19, and the ongoing pandemic, thereby enhancing temporal generalizability. For each tweet, the script extracted textual content, posting timestamp, originating account, and engagement metrics (likes, retweets, replies, and quote tweets). During data processing, 2 accounts contributing fewer than 10 tweets over the study period were excluded, yielding a final analytic sample of 46 accounts. Several preprocessing steps were applied to ensure data quality and analytic consistency. First, duplicate tweet records arising from API pagination were removed. Retweets (identified by the “RT @” prefix) were excluded, as their engagement metrics reflect the original author’s content rather than the retweeting account’s communication choices. Tweets in languages other than English were filtered out using the language metadata provided by the Twitter API, and tweets with fewer than 10 characters or empty text fields were discarded. Finally, to mitigate the influence of viral outliers on model estimates, tweets exceeding the 99th percentile on any individual engagement metric (likes, retweets, replies, or quote tweets) were trimmed. After these steps, 257,648 tweets remained for analysis (See Multimedia Appendix 2 for detailed documentation).

XSL•FO
RenderX

Sentiment Classification

The emotional valence of emojis within each tweet was classified using a three-stage automated cascade. First, each emoji character was scored using the VADER (Valence Aware Dictionary and Sentiment Reasoner) sentiment analyzer via the *VADER R* package, similar to the Emoji Sentiment Ranking [15]. When VADER could not assign a nonzero score to the raw character, the emoji's standardized Unicode name was retrieved using the emoji R package and re-scored through VADER. For the remaining unscored emojis, a keyword-matching heuristic compared the emoji name against curated lists of positive and negative semantic patterns. Emojis scoring above +0.05 were labeled positive, below −0.05 negative, and between these thresholds neutral. At the tweet level, tweets were then categorized into five groups based on the composition of their emoji labels: positive (n=16,861), negative (n=1312), neutral (n=13,470), mixed (containing emojis of differing valences; n=528), or none (no emojis present; n=225,477).

Measures and Variables

The dependent variable was social media engagement, operationalized as the sum of likes, retweets, replies, and quote tweets [26,27]. This composite score was log-transformed using log (x+1) to address the pronounced right-skew typical of engagement distributions [27]. We additionally analyzed each component—log likes, log retweets, and log replies—separately to assess consistency across engagement types. The independent variable was emoji valence, coded as a five-level categorical factor (negative, positive, neutral, mixed, or none). To strengthen internal validity, five tweet-level covariates were included: tweet character length, URL presence (binary), hashtag count, mention count, and a weekend posting indicator. Variance inflation factors ranged from 1.02 to 1.31, indicating no multicollinearity (Multimedia Appendix 2).

Analytical Approach

Because tweets are nested within accounts that vary in audience size, topical focus, and credibility, we used hierarchical linear models (HLM) with random intercepts for accounts. This approach partitions engagement variance into within-account and between-account components, preventing the conflation of emoji effects with account-level characteristics (see Multimedia Appendix 2 for model equations). The intraclass correlation coefficient (ICC) was computed from null (intercept-only) models to quantify between-account variation. We followed a sequential model-building strategy: Model 1 (M1) included a binary emoji presence indicator; Model 2 (M2) replaced this with the five-level valence factor; Model 3 (M3) added covariates to M1; and Model 4 (M4) combined the valence factor with all covariates. M4 served as the primary model for hypothesis testing. Models were estimated via restricted maximum likelihood (REML) using the *lme4* package, with Satterthwaite-approximated degrees of freedom from lmerTest. Model fit was compared using AIC and BIC (Multimedia Appendix 2).

Phase 2

Design and Procedure

This phase aimed to investigate the influence of different emoji valence in health messages on the intention to engage in preventive behaviors. An online experiment was conducted in November 2022, simulating a health message when a booster shot of the COVID-19 vaccine had been made available to the public. While ensuring the consistency of the message text, the health message introduced and persuaded participants about the vaccine booster shot by categorizing the emojis into two emotional valences (positive vs negative). Participants were sent a link to a survey in which they were invited to browse a webpage and sign an informed consent form. They were then exposed to one of two stimuli (ie, a positive emoji or a negative emoji). A piece of health information published by a fictitious health organization was displayed to the participants. Participants were asked to carefully read the information and evaluate their intention to receive the booster shot for COVID-19. Finally, the participants reported their demographic information, such as sex, age, and education.

Stimulus Material

The selection of several representative emojis was based on the Emoji Sentiment Ranking developed by Kralj Novak et al [15]. We invited four visual design professionals, including two visual designers and two design department teachers from universities. Four experts selected candidate emojis from the list of Apple-device emojis in the Emojipedia database [48]. The selection was based on three criteria: (1) the official descriptions and meanings displayed in the database; (2) the Emoji Sentiment Ranking developed by Kralj Novak et al [15]; and (3) the quality of their semantic and visual representativeness [49]. Ultimately, experts selected  and  as representatives of positive emojis, and  and  as representatives of negative emojis. After determining the four emoji representatives, we conducted a pretest for manipulation check purposes. The pretest was conducted online using Credamo, and participants were asked to evaluate whether "this message uses positive (or negative) emojis?" using a Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). We recruited 120 participants for the pretest (mean 29.39, SD 6.58), and 65 (54.2%) of them identified as women. The results of a *t* test showed that, compared to participants who saw negative emojis (mean 2.17, SD 1.77), participants in the positive emoji condition were more likely to believe that the emojis used in the information tended to express positive emotions (mean 6.20, SD 1.15, t_{118}=−14.8; P<.001). In addition, participants who received health information with negative emojis (mean 6.15, SD 1.52) were more likely to believe that the emojis were negative than those in the positive emoji condition (mean 1.67, SD 1.08, t_{118}=18.6; P<.001). These results provide convincing evidence for the manipulation, demonstrating that participants can correctly identify the emotional value of emojis.

We created a fictitious organization named "Health Online" and designed a Facebook post using Adobe Illustrator (Multimedia Appendix 3). The post was displayed in traditional Chinese characters, with the headline and content arranged

XSL•FO
RenderX

sequentially from top to bottom. The publishing unit, publishing time, and the body of the information were designed sequentially below. The content presented an overview of COVID-19 vaccine booster shots along with corresponding vaccination recommendations aimed at promoting immunization. Finally, emojis were incorporated into the messages, and the emotional valence of the emojis was manipulated to be either positive or negative. The emojis were positioned within the text, both in the middle and at the end. Apart from the manipulation of emojis, all other content remains consistent.

Participants

Phase 2 recruited 220 participants from Hong Kong, Macau, and Taiwan online via Credamo, and assigned them equally to one of the four scenarios. All participants were users of traditional Chinese characters, and 135 (61.4%) of them were women. Participants' ages ranged from 18 to 45 years old (mean 27.42, SD 6.32). Among them, 180 individuals (81.8%) hold bachelor's degrees or higher. All participants reported having prior experience reading Facebook posts.

Measurement Instrument

The scale to measure vaccination intention was adapted from Gerend and Shepherd's research [40] and was measured using a 7-point Likert scale. The first four items were anchored from 1 (strongly disagree) to 7 (strongly agree). The last two items were anchored from 1 (very unlikely) to 7 (very likely). These questions examined participants' willingness to receive the COVID-19 vaccine booster shot in the short and long term ()(Textbox 1). Higher scores indicate stronger preventive behavioral intention. We examined the reliability of the scale in this experiment (α=0.919).

Textbox 1. The reliability of the measurement.

Construct: Preventive Behavioral Intention (Adapted from Gerend & Shepherd [40])

Items:

- I will get more information about the COVID-19 vaccine booster shot
- I will consider getting a booster shot
- I will try the booster shot
- I will actually accept the booster shot
- How likely are you to accept the vaccine if hospitals or medical facilities offer the booster shot?
- Will you actively accept the vaccination if the time limit of the booster shot is every 6 months or 8 months?

Cronbach alpha: 0.919

Phase 3

Overview

The objective of study 3 was to further demonstrate the interaction effect of emoji valence and emoji-text congruence on health behavioral intentions. Study 3 is a 2 (emoji valence: positive versus negative) by 2 (emoji-text congruence: low versus high) between-subject experiments design.

Design and Procedure

Participants were informed that this study was conducted to evaluate information about physical examinations. We used scenarios related to physical examinations for the online experiment in April 2023. After signing the informed consent form, participants were provided with and read a health message about regular blood tests. The emojis embedded in the health message could be either negative or positive. Additionally, the message text was manipulated to have high or low congruence with the negative emojis while ensuring the meaning remained consistent (ie, positive emoji and low congruence, positive emoji and high congruence, negative emoji and low congruence, or negative emoji and high congruence). Participants were first prompted to assess the congruence between the emojis and the text in the health message (ie, "I feel that the emojis in the message are not consistent with the text"). Then their preventive behavioral intention was also assessed (ie, If hospitals or medical institutions offer regular check-up services, how likely am I to undergo regular physical examinations?). At the end of the experiment, participants reported their demographic information.

Stimulus Material and Participants

To enhance the generalizability of emojis and the robustness of cross-context in this study, 4 additional representatives, different from those in study 2, were selected for this phase of the experiment.  and  were chosen as positive emojis, while  and  were selected as negative emojis. Selecting additional emojis serves to strengthen external validity. The emotional valence of these emojis was ensured as they were also derived from previous studies [13,16,50]. In addition, to simulate the public's reception of health messages, we created a fictitious WeChat public account named "Health Smart Butler." The visualization of its health tweets was designed using Adobe Illustrator (Multimedia Appendix 4). All stimuli were displayed in Chinese, with components such as the title, the message publisher, message release date and time, the purpose of regular physical examination, and the role of blood tests. Next, the congruence of the body content with the negative emojis was categorized into "high" and "low" expressions. The content highlighted the benefits of regular physical examination, providing assurance for one's life. Moreover, the importance and usefulness of blood tests in these examinations were presented (specific stimulus texts are shown in the table below). To manipulate the emoji-text congruence, we placed the emoji in different locations. For the high fit with negative emojis

XSL•FO
RenderX

condition, emojis were placed after negative words such as risks, problems, lacking. In contrast, in the low fit with negative emojis condition, emojis were displayed next to neutral or positive words such as tests, healthy, crucial, testing. Please see Table 1 for detailed information.

A total of 190 online participants from mainland China were recruited through Credamo and randomly assigned to each experimental group. Participants' ages ranged from 19 to 57 years (mean 30.19, SD 6.62), with 113 (59.5%) identified as women. Among them, 174 individuals (91.6%) had completed a bachelor's degree or higher. All participants reported having prior experience reading health messages through WeChat public account posts.

Results

Phase 1

The final dataset comprised 257,648 tweets from 46 health-focused Twitter accounts. Of these, 32,171 (12.5%) contained at least one emoji: 16,861 positive (6.5% of all tweets), 13,470 neutral (5.2%), 1312 negative (0.5%), and 528 mixed-valence (0.2%). Overall, tweets received a median of 12 total engagements (mean 32.22, SD 49.96). Descriptively, tweets with negative emojis received higher mean likes (mean 39.5, SD 49.5) than tweets with positive emojis (mean 16.4, SD 36.4) or no emojis (mean 20.6, SD 32.5). Full descriptive statistics are presented in Multimedia Appendix 2.

Null-model ICCs indicated that between-account differences explained 48.5% of the variance in log total engagement, 46.1% in log likes, 45.4% in log retweets, and 28.4% in log replies, confirming the necessity of multilevel modeling.

Table 2 presents the primary hypothesis-testing model (M4), incorporating emoji valence and all covariates, for each engagement outcome. For log total engagement, tweets containing negative emojis received significantly higher engagement than tweets without emojis (β=0.25, *SE*=0.02, $t_{257,596.35}$=10.44; *P*<.001). Neutral (β=0.23, *SE*=0.01; *P*<.001) and mixed (β=0.36, *SE*=0.04; *P*<.001) emojis were also positively associated with engagement, whereas positive emojis showed no significant difference from emoji-free tweets (β=0.01, *SE*=0.01, $t_{257,610.93}$=1.52; *P*=.13). Critically, a planned contrast confirmed that negative-emoji tweets generated significantly higher engagement than positive-emoji tweets (Δβ=0.24, *SE*=0.03, $t_{257,595.11}$=9.59; *P*<.001), directly supporting H1. These patterns were consistent across engagement sub-metrics: negative emojis outperformed positive emojis in log likes (Δβ=0.17, $t_{257,595.36}$=6.70; *P*<.001), log retweets (Δβ=0.29, $t_{257,595.71}$=13.90; *P*<.001), and log replies (Δβ=0.14, $t_{257,599.22}$=9.24; *P*<.001). Among covariates, URL presence was the strongest predictor (β=0.93; *P*<.001), followed by weekend posting (β=0.11; *P*<.001), hashtag count (β=0.07; *P*<.001), and tweet length (β=0.01; *P*<.001), while mention count was negatively associated with engagement (β=−0.09; *P*<.001). The inclusion of covariates in M4 improved model fit substantially over M2 (ΔAIC=−47,903 for log total engagement), yet the negative emoji advantage persisted, indicating that the effect is not attributable to the tweet-level characteristics examined.

XSL•FO
RenderX

Table . Sequential model results for log total engagement. Reference category for emoji valence is "No Emoji." M4 is the primary hypothesis-testing model. The notable sign change for the positive-emoji coefficient from M2 (−0.243) to M4 (+0.012, n.s.) indicates that the apparent negative association of positive emojis in M2 was confounded with tweet characteristics (eg, positive-emoji tweets tended to contain fewer URLs and be shorter).

Predictor	M1: emoji presence	M2: emoji valence	M3: presence+ covariates	M4: valence + covariates
Intercept, β (SE)	1.93 (0.14)[b]	1.92 (0.14)[b]	0.51 (0.14)[b]	0.53 (0.14)[a]

[a]*P*<.05.

[b]*P*<.001.

Although the pooled multilevel models show a clear average advantage for negative emojis, the account-specific patterns are not perfectly uniform. To address this heterogeneity, we examined per-account estimates of the negative-emoji coefficient (relative to positive or to no-emoji, depending on the model specification). Most accounts showed a positive association consistent with the pooled effect (Figure 2), but a small subset diverged from this pattern. Specifically, the negative-emoji effect was statistically indistinguishable from zero for accounts such as the "Health," "Arthritis Foundation," and "CDC," and it was directionally reversed for accounts like "WHO" and "National Psoriasis Foundation," where negative-emoji tweets were associated with lower engagement than comparable posts with positive emojis.

XSL•FO
RenderX

Figure 2. The multilevel effect of emoji valence on engagement. Four accounts were excluded from the figure due to the absence of tweets containing both negative and positive emojis.

Phase 2

A series of 2-tailed *t* tests were used to analyze the results. The result of the manipulation check showed that, compared to information with negative emojis (mean 2.32, SD 1.76), receivers perceived a post with positive emojis to contain positive emotions (mean 4.78, SD 1.75, t_{218}= −10.4; *P*<.001). Therefore, the manipulation of emojis in the experiment was successful.

We conducted another independent-sample 2-tailed *t* test to determine the effects of emoji valence on the intention to receive a booster shot. The results (Table 3) indicated a significant main effect of emoji valence on booster shot intention (t_{218}= −4.15; *P*<.001). Specifically, using negative emojis (mean 5.61, SD 0.99) increased participants' intention to receive booster shots more than using positive emojis (mean 4.88, SD 1.53). These findings support hypothesis 2 and, simultaneously, supplement the conclusions of study 1. The use of negative emojis in health messages not only enhances social media engagement but also increases people's willingness to receive booster shots.

Table . The results of *t* test.

Group	Mean (SD)	*t* test (*df*)
Preventive behavioral intention		218 (−4.15)[a]
Negative emojis (N=110)	5.61 (0.99)	
Positive emojis (N=110)	4.88 (1.53)	

[a]*P*<.001.

XSL•FO
RenderX

Phase 3

The results of a *t* test revealed that participants who received the messages with positive emojis (mean 6.34, SD 0.82) were more likely to perceive the emoji as conveying more positive emotional valence than did those in the negative emojis condition (mean 1.43, SD 0.72, $t_{186.89}$= −43.85; *P*<.001). Compared with participants who received messages containing positive emojis (mean 1.44, SD 0.77), those exposed to messages with negative emojis perceived the emotional valence communicated by the emojis as more negative (mean 6.55, SD 0.67, $t_{186.72}$=48.70; *P*<.001). Another manipulation check to assess whether emojis in messages matched the text was appropriately manipulated suggested that in messages with negative emojis, content that was perceived to be low in congruence with negative emojis (mean 4.02, SD 1.73) mismatched negative emojis more than those that were high in congruence with negative emojis (mean 3.11, SD 1.66, $F_{1, 186}$=7.62; *P*=.006). Additionally, among messages using positive emojis, content with high congruence to negative emojis (mean 2.82, SD 1.29) was perceived to have a lower match to positive emojis than content with low congruence to negative emojis (mean 3.52, SD 1.64, $F_{1, 186}$=4.81; *P*=.03). Therefore, both manipulations were successful.

We conducted a 2-way ANOVA analysis to test hypothesis 3. The results indicated that there was no significant main effect of emojis on preventive behavior intentions ($F_{1, 186}$=0.01, η^2<.001; *P*=.91), regardless of whether the health message contained positive (mean 6.03, SD 0.87) or negative emojis (mean 6.01, SD 0.87). On the other hand, the main effect of emoji-text congruence on preventive behavior intentions was also not significant ($mean_{low}$ 5.97, SD 0.87; $mean_{high}$ 6.07, SD 0.87, $F_{1, 186}$=0.58; *P*=.45). However, interestingly, a significant interaction effect on preventive behavior intentions was observed ($F_{1, 186}$=5.46, η^2=.028; *P*<.05), as shown in Table 4 and Figure 3. It showed that in health messages with negative emojis, messages with high negative emoji-text congruence (mean 6.11, SD 0.75) enhance people's intentions to engage in preventive behaviors more than those with low congruence (mean 5.83, SD 0.95). In contrast, when the emojis in the health messages are positive, participants' intention to undergo regular physical examinations became less favorable as the negative emoji-text congruence increases ($mean_{low}$ 6.22, SD 0.74 versus $mean_{high}$=5.91, SD 0.97). These findings support hypothesis 3 and, simultaneously, supplement the conclusions of studies 1 and 2. The use of negative emojis in health messages not only enhances social media engagement but also increases people's preventive behavior intentions, especially when negative emojis have high congruence with the text.

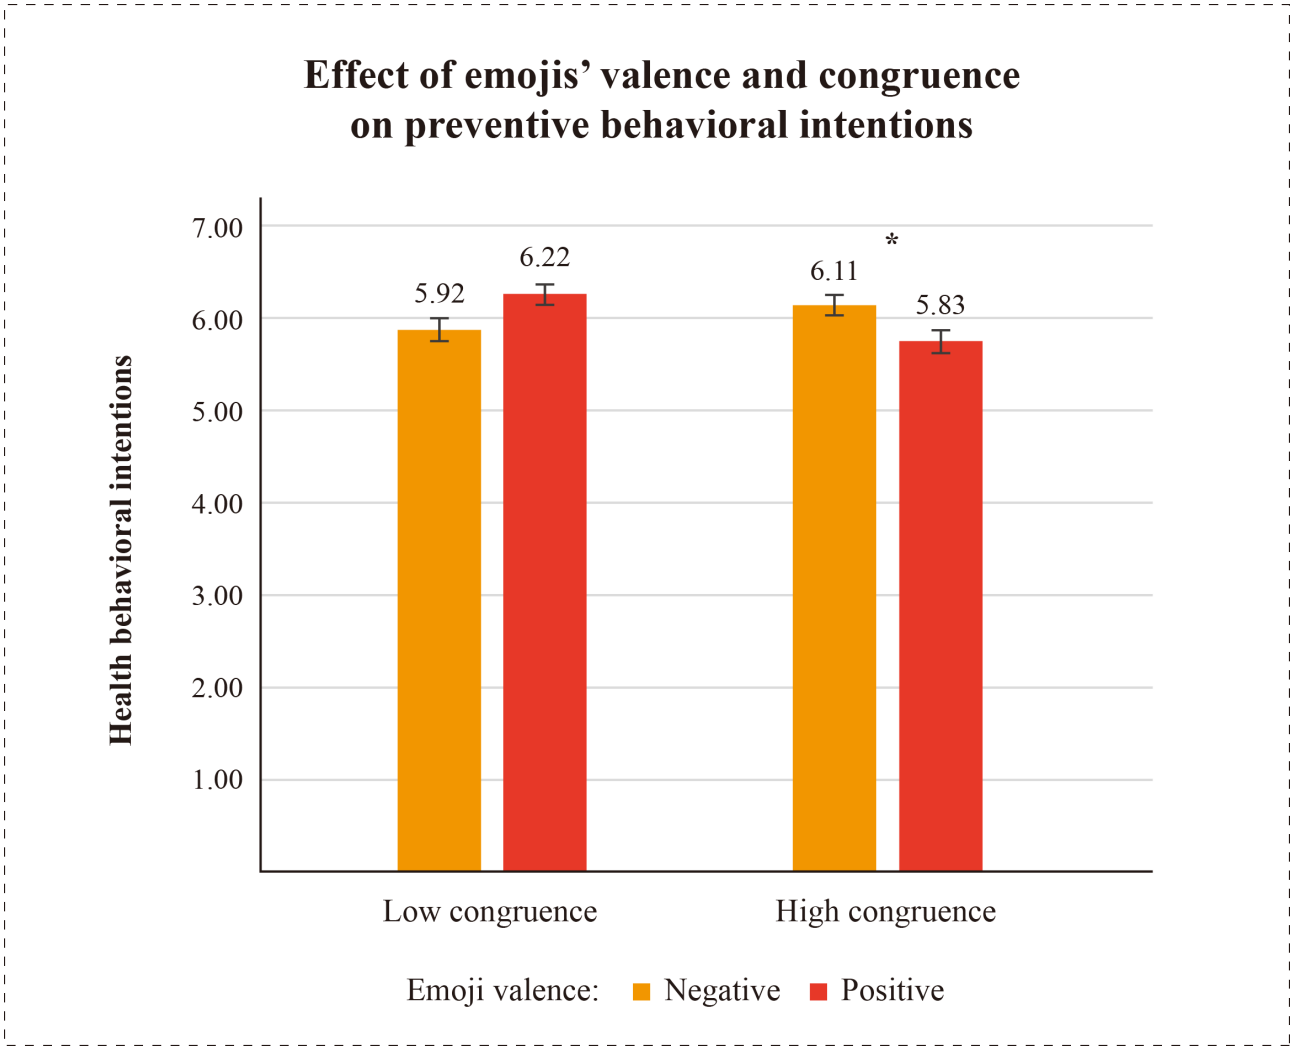

Table . Descriptive statistics of ANOVA.

Source	*F* (*df*)	*P* value	η^2
Intention to take regular physical examinations			
Emoji valence	0.01 (1, 186)	.91	<.001
Emoji-text congruence	0.58 (1, 186)	.45	.003
Emoji valence × emoji text congruence	5.46 (1, 186)	.02[a]	.028

Discussion

Principal Findings

This study used automated content analysis and experimental methods to examine the role of emojis in health communication. Specifically, we investigated the effects of emojis with different emotional valence on social media engagement, as well as how their congruence with text influences preventive behavioral intentions. Compared to positive emojis, the use of negative emojis in health messages generated more social media engagement and preventive behavioral intentions. Negative emojis demonstrated significantly stronger persuasive effectiveness than positive emojis or the absence of emojis in text-based mHealth interventions during the pandemic. However, this advantage depends on the congruence between the emojis and the accompanying textual message.

Comparison With Prior Work and Theoretical Contributions

We first indicate that the valence of emojis used in tweets has a significant impact on the social media engagement that tweets receive, even after accounting for the nested data structure through a random-intercept HLM. This finding was also robust when examined using an OLS model with account fixed effects and clustered standard errors. Specifically, tweets that used negative emojis received more social media engagement than tweets that used no emojis or positive emojis. Furthermore, the ICC of approximately 0.49 indicates that a substantial proportion of the variation in social media engagement is attributable to differences between Twitter accounts, underscoring the importance of accounting for this multilevel structure. Consistent with previous studies, unlike daily interactions on social media, negative visuals tend to capture individuals' attention and interest in health communication [16,35,37,51]. Users tend to interact and share health information with negative emojis, and these visuals with negative emotions evoke rich emotional experiences, including fear [52,53]. This result confirms that the information processing of emojis in health communication on social media provides users with a pathway for emotional reactions. Public health organizations can use emojis in health message design and disseminate them via social media to obtain more comments, likes, and shares, and to increase information coverage.

The findings of further experiments show that the use of negative emojis in health messages can elicit higher preventive behavioral intentions compared to positive emojis. This extends the view of previous research that the valence of emojis can guide individuals' perceptions and behavioral intentions

XSL•FO
RenderX

[16,19,39]. Compared with positive emojis, negative emojis may be more effective in motivating the public to engage in low-risk actions because they have the potential to activate heightened perceptions of risk and fear [14,16,17]. Also, this finding further demonstrates the effectiveness of using emojis for emotional contagion and health persuasion on social media [35,51]. We do not believe that the use of negative emojis in health messages is intended to immerse recipients in negative emotions. Instead, the negative emotions triggered by these emojis should be transformed by individuals into feelings of hope [52,53], thereby emphasizing the importance and necessity of preventive behaviors. This result further complements the emotional pathways provided by emojis in health communication and addresses the need, as proposed by Erle et al [6], to test the applicability of the EASI model within digital communication contexts.

In a postpandemic, regular physical examinations context, emoji valence alone is not sufficient to shape preventive behavioral intentions. The effect of emojis depends on their congruence with the textual framing. The use of negative emojis in health messages can increase preventive behavioral intentions, as demonstrated in the framework of high negative emoji-text congruence. According to the EASI model, the inferential process serves as the primary determinant of the subsequent behavioral effects of emotional expressions when the meanings of emojis are relatively vague and unclear [6]. Our findings also qualify previous work suggesting that a moderate level of incongruity in the schema can enhance evaluations by increasing novelty [45,46]. In the context of preventive health communication, the valence of negative emojis with low congruence to text presentation may appear less likely to be experienced as “interesting” and more likely to be interpreted as confusing or misaligned, thereby weakening individuals’ preventive intentions. Negative emojis in health messages with high emoji-text congruence maximize the consistency among the visual, emotional, and content elements conveyed to the user [16,19,54]. Naturally, individuals are more likely to positively and smoothly accept the emotions elicited by an object with high internal consistency, thereby translating those emotions into preventive behavior intentions. However, when negative emojis are replaced with positive ones, the effects of emotional inference become counterproductive due to the inconsistency in the schema. Negative emojis in a textual context of high negative emoji-text congruence may prompt the audience to devote more cognitive effort in processing the information, thereby increasing preventive behavior intentions. In real-world health communication, it is common for message design components to yield only small-to-moderate effect sizes because outcomes are shaped by multiple influences. However, when health messages are repeatedly delivered to large populations, even modest effects can accumulate and become highly consequential at the population level. Emojis, similar to facial expressions, provide two pathways—emotional reactions and inferential processes—in the dissemination of health information on social media platforms. More specifically, we build on the “emojis as social information” model proposed by Erle et al [6] and extend its applicability to the context of messaging-based interventions in mHealth. Emojis, as multimodal cues that convey both social information and visual semantics, interact with textual health messages to form multimodal content. This integration facilitates the interpretation, interaction, and acceptance of information by individuals on social media platforms.

Practical Implications

In addition to theoretical refinement, this study also offers several practical recommendations. First, health organizations and online health accounts are encouraged to use emojis as an interactive tool for health communication on social media. Second, using negative emojis not only increases audience engagement but also enhances individuals’ intentions to engage in preventive and health behaviors. Beyond the communication and interaction of health knowledge in daily life, the use of negative emojis is particularly effective for health messages that require strong public attention. For instance, during urgent health crises such as monkeypox or COVID-19 outbreaks, negative emojis can encourage individuals to adopt preventive behaviors like vaccination or promote the spontaneous communication of health messages. Finally, when using negative emojis in health messages, it is crucial to ensure congruence with the textual content. Properly placing emojis can maximize the persuasive power of health messages in mHealth and social media.

Limitations and Further Research

This study was deliberately designed to span multiple time points, demonstrating that emojis have influence on health communication across different phases of the pandemic and beyond, especially negative emojis. The first 2 phases were conducted in a high‐threat context (COVID-19), but the findings should not be interpreted as evidence that negative emojis are more persuasive than positive emojis across diverse health contexts. By contrast, in postpandemic settings such as regular physical examination scenarios, the persuasive impact of emoji valence depends on its congruence with the accompanying text. These results reveal the boundary conditions for generalizing beyond the pandemic period and highlight the need to explore the role of emojis across a broader range of health risks and cultural contexts. Further research should consider additional specific health contexts, such as sexual and reproductive health, depression, and anxiety. Currently, the study only compares the effects of positive and negative emojis, without examining neutral emojis and combinations of mixed valences. On social media, users often use emojis with different emotional valences to supplement their emotions and textual meanings [25,55,56]. Combinations of emojis with different emotional valences may become a direction for further research. This study relies on social media engagement and preventive behavioral intention as observed outcome indicators. The limitation highlights the need for future research to further test the applicability of the EASI model by incorporating mediating variables (eg, arousal and perceived ambiguity) and simultaneously represents an issue that the field of emoji research seeks to address. In addition, the visual stimuli used in this study were selected from the “Smileys” series of emojis. Future work should consider nonfacial expression emojis, such as gestures, occupations, and actions, to expand the applicability of emoji categories in health communication. Moreover, the

XSL•FO
RenderX

study participants focused on the Chinese-speaking region; future studies may investigate the effect of emoji valence in different cultures. Furthermore, the effect of emoji valence may also depend on different languages and texts, as well as the complexity of the information. Future studies may investigate how these contextual factors influence the effect of emoji valence on the public's perception, understanding, and attitudes.

Conclusions

This study demonstrates that emojis are not merely decorative elements in digital health communication, but persuasive multimodal cues that can shape both audience engagement and preventive behavioral intentions. Across the pandemic and post-pandemic contexts, negative emojis were found to be especially effective in attracting social media engagement and motivating preventive responses. However, their persuasive advantage is not universal; in lower-threat contexts, such as regular physical examinations, their effectiveness depends on congruence with the accompanying textual framing. These findings extend the applicability of the EASI model to mHealth and social media by showing that emojis influence health communication through both emotional reactions and inferential processing. Overall, this study highlights the strategic value of emoji use in health message design and underscores the importance of aligning visual and textual cues to maximize persuasive impact.

Acknowledgments

The study expresses its gratitude to the journal editors and reviewers.

Abstract

Background: Mental health challenges such as stress and depression are prevalent among employees. Mobile health platforms that deliver exercise or yoga interventions offer a promising approach to improve mental health outcomes in this population.

Objective: This study aimed to assess the effectiveness of 12-session adaptive moderate-intensity exercise and yoga programs delivered via a motion-detecting digital platform in reducing stress and depressive symptoms among employees.

Methods: This was an unblinded, 3-arm, parallel-group, randomized controlled trial conducted at Seoul National University Bundang Hospital and Boramae Medical Center between November 2023 and January 2024. Eligible participants were full-time employees. Seventy-five participants were randomly assigned to an exercise, a yoga, or a cognitive behavioral therapy–based self-care control group using computer-generated randomization. The exercise and yoga groups engaged in motion-detecting, adaptive physical activity training, whereas the control group accessed mobile-based, self-directed stress management educational materials. The intervention was largely automated, with no individualized therapeutic guidance provided. Allocation was concealed until trial entry. All recruitment and outcome assessments were conducted in person at the hospitals. The primary outcomes were perceived stress and depressive symptoms, whereas the secondary outcomes included posttraumatic stress, insomnia severity, cognitive stress response, occupational stress, and burnout. Physiological outcomes were assessed using heart rate variability and electroencephalography. Measurements were collected at baseline, immediately after the intervention, and at 4-week follow-up. Data were analyzed using a multivariate linear model to evaluate the main effects of time, group, and time×group interactions.

Results: Of the 75 randomized participants (exercise: n=24, 32%; yoga: n=25, 33.3%; and control: n=26, 34.7%), 71 (94.7%) who completed at least 9 of the 12 sessions (≥40 min each) were included in the outcome analysis (exercise: n=21, 29.5%; yoga:

XSL•FO
RenderX

n=24, 33.8%; and control: n=26, 36.6%). For the coprimary outcomes, the group×time interaction for depressive symptoms (Patient Health Questionnaire-9) approached but did not reach the Bonferroni-corrected threshold ($F_{4,136}$=2.71; P=.03; adjusted α=.025); however, planned pairwise comparisons revealed significantly greater improvement in the yoga group compared to the control group at 4-week follow-up (β=−3.67; adjusted P<.001). For the Perceived Stress Scale, the interaction was not significant (P=.29), although a significant main effect of time (P<.001) indicated overall stress reduction across all groups. For secondary outcomes, a significant group×time interaction was found for the Cognitive Stress Responses Scale (P=.003), indicating differential trajectories of improvement. The yoga group showed a consistent linear decrease, whereas the exercise group showed immediate but less sustained gains.

Conclusions: Digitally delivered adaptive yoga programs demonstrated superior and sustained improvements in depressive symptoms and Cognitive Stress Responses Scale scores compared with the active cognitive behavioral therapy–based self-care control group. However, the exercise program showed more modest and less sustained effects, warranting further investigation using larger samples.

Introduction

Mental health issues, including stress, depression, and anxiety, are major global health concerns, particularly among employees. Pressures in modern work environments, compounded by sedentary lifestyles, have led to an increased prevalence of psychological distress [1]. These mental health conditions not only affect individual well-being but also contribute to broader societal effects, including reduced productivity and increased health care costs [2]. Studies have shown that poor mental health among employees is associated with absenteeism, presenteeism, and lower workplace efficiency, highlighting the need for effective, accessible, and sustainable interventions [3]. Considering these challenges, there is growing interest in identifying effective, accessible, and sustainable interventions to improve mental health, particularly among the working population.

Physical exercise is associated with numerous mental health benefits, particularly in alleviating anxiety and depressive symptoms. Recent systematic reviews and meta-analyses have confirmed that physical activity can reduce psychological distress, improve mood, and enhance cognitive function [4,5]. These effects are believed to be mediated by various physiological mechanisms, including endorphin release, improved neuroplasticity, and regulation of the hypothalamic-pituitary-adrenal axis [5]. Despite these benefits, busy employees find adherence to regular exercise challenging, with time constraints and fatigue after long workdays being cited as common barriers [6].

Yoga has been shown to offer substantial mental health benefits as a mind-body intervention. Yoga integrates physical posture with breath control and mindfulness to provide a holistic approach to promoting physical and psychological well-being. Studies have suggested that yoga reduces stress and anxiety while enhancing mindfulness and relaxation [7]. Recent studies have demonstrated that yoga can significantly reduce symptoms of stress, anxiety, and depression while improving emotional regulation and social connectedness [8,9]. A 2024 randomized controlled trial (RCT) found that yoga can benefit mental health, with participants reporting improved self-compassion, extrinsic affect, and personal and communal spiritual well-being compared with control groups [10]. Moreover, yoga's flexibility allows practitioners to choose options ranging from gentle meditative practices to more intense forms, thus aligning with their time constraints and physical capabilities. This makes yoga particularly well-suited to individuals with busy schedules, potentially addressing some of the challenges associated with adherence to more physically demanding exercise routines [11].

Although physical exercise and yoga have been validated as effective mental health interventions, they offer distinct benefits and challenges, particularly for busy employees. Yoga, owing to its low impact and flexible nature, may be more accessible and sustainable for individuals with limited time. In contrast, moderate-intensity exercise boosts vitality and energy, which may be particularly beneficial for individuals experiencing fatigue or low energy [12]. However, lack of motivation, busy work schedules, and family commitments can pose significant barriers to adherence [13].

Recently, the integration of digital tools, including mobile apps, into health care has expanded the scope of health interventions. Mobile health platforms are increasingly being used to deliver exercise and wellness programs, offering convenience and personalization [14]. Mobile technology can provide access to personalized training programs at the user's convenience, overcoming traditional barriers to participation such as location, time, and access to expert instruction [15]. Wang et al [16] demonstrated that real-time feedback using smart wearable devices could improve postural control precision during balance training, suggesting that such systems enhance user engagement by providing immediate and actionable insights into movement accuracy.

This study evaluated the effects of a 12-session yoga program and an adaptive moderate-intensity physical exercise program using a mobile platform on employees' mental health outcomes compared to those of an active control group based on cognitive behavioral therapy (CBT). The primary hypothesis was that

XSL•FO
RenderX

yoga and physical exercise would positively influence mental health outcomes, such as reduced stress and depressive symptoms, compared to the control group. Furthermore, we hypothesized that these interventions induce beneficial changes in physiological markers, such as heart rate variability (HRV) and electroencephalography (EEG), and that differential effects may exist between the yoga and exercise groups on specific outcomes. By incorporating a mobile platform, we aimed to enhance the feasibility of the intervention by allowing participants to engage in programs at home and monitor their progress using real-time feedback.

Methods

Participants

The participants were enrolled via advertisements at Seoul National University Bundang Hospital and Boramae Medical Center between November 2023 and January 2024. The inclusion criteria were as follows: (1) employed adults aged 19 to 49 years; (2) individuals experiencing moderate-to-high levels of stress, defined as a Perceived Stress Scale (PSS) score of ≥14 at baseline; (3) individuals undergoing pharmacological treatment for psychiatric conditions, such as depression, anxiety disorders, or insomnia, who were eligible if their symptoms were stable and their medication dosages were not expected to change during the clinical trial; and (4) individuals who fully understood the clinical trial protocol and voluntarily consented to participate.

The exclusion criteria were as follows: (1) individuals aged <19 or >49 years; (2) those with dementia, intellectual disabilities, or other cognitive impairments; (3) individuals with seizure disorders, stroke, or other neurological conditions; (4) those with a history or current diagnosis of psychotic disorders, such as schizophrenia or bipolar disorder; (5) individuals with active suicidal ideation; (6) those using medications or having medical conditions (eg, heart or lung disease) that could affect the reliability of HRV testing; (7) individuals who received nonpharmacological psychiatric treatment or counseling within the past 6 months; and (8) individuals with physical limitations preventing them from participating in the exercise or yoga program.

The presence of psychiatric disorders was assessed using the Mini International Neuropsychiatric Interview, a short, structured psychiatric interview designed to identify a broad spectrum of psychiatric disorders as outlined in the *DSM-IV* (*Diagnostic and Statistical Manual of Mental Disorders* [Fourth Edition]), and the *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*). The Korean version of the Mini International Neuropsychiatric Interview has been shown to have good validity and reliability. The interviews, which typically took 15 to 30 minutes to complete, were conducted by 2 qualified psychologists with master's degrees who were familiar with the tool.

The total sample size was calculated a priori using the G*Power software (version 3.1.9.4; Heinrich-Heine-Universität Düsseldorf). On the basis of previous meta-analyses of digital mental health interventions [17], we anticipated a large effect size (f=0.40). To achieve a statistical power of 0.80 with a significance level (α) of .05 for a 3-group ANOVA, a minimum of 66 participants (22 per group) was required. This provided a conservative power estimate for the multivariate linear model (MLM) used in the primary analysis. After accounting for a potential dropout rate of 10%, 75 participants were recruited.

Measures and Assessments

Overview

The participants who provided consent underwent a baseline assessment. This assessment included demographic information, such as age, sex, marital status, education level, and occupation. It also included an evaluation of psychiatric diagnoses, medical history, and mental health–related questionnaires.

Changes in the PSS and Patient Health Questionnaire-9 (PHQ-9) scores for depressive symptoms were used as the primary psychological outcome measures. The secondary psychological outcomes included changes in the scores of scales assessing insomnia (Insomnia Severity Index), occupational stress (Korean Occupational Stress Scale [KOSS]), burnout (Maslach Burnout Inventory-General Survey), positive and negative affect (Positive and Negative Affect Schedule-Revised), posttraumatic stress symptoms (Posttraumatic Stress Disorder Checklist-5 [PCL-5]), interoceptive awareness (Multidimensional Assessment of Interoceptive Awareness [K-MAIA]), mindfulness (Five Facet Mindfulness Questionnaire [FFMQ]), and cognitive stress responses (Cognitive Stress Response Scale [CSRS]).

Originally developed by Cohen et al [18], the PSS is a 14-item scale; however, a modified 10-item version is commonly used [19,20]. This scale measures the degree to which individuals have perceived their lives as unpredictable, uncontrollable, or overwhelming in the past month. Higher scores indicate greater perceived stress. Total scores range from 0 to 40, with each item rated on a 5-point Likert scale, ranging from 0 (never) to 4 (very often).

PHQ-9 is a self-report depression screening tool that assesses the severity of depressive symptoms [21]. It comprises items based on 9 diagnostic criteria for major depressive disorder from DSM-IV. Total scores range from 0 to 27, with higher scores indicating more severe depressive symptoms.

Insomnia Severity Index was developed by Morin [22] to assess insomnia severity based on the diagnostic criteria of *DSM-IV* and the International Classification of Sleep Disorders. It comprises 7 items that examine the type and severity of insomnia over the past 2 weeks, satisfaction with sleep, daytime functioning, impact of sleep disturbances, and distress caused by sleep difficulties. Total scores range from 0 to 28, with higher scores indicating more severe insomnia.

The KOSS-Short Form is a shortened version of the KOSS consisting of 19 items reduced from the original 43. Each item is rated on a 4-point Likert scale, ranging from 1 (not at all) to 4 (very much). Higher scores indicate greater job stress experienced in the past month. The scale comprises 8 domains: physical environment, job demands, lack of job control, insufficient social support, job insecurity, organizational

XSL•FO
RenderX

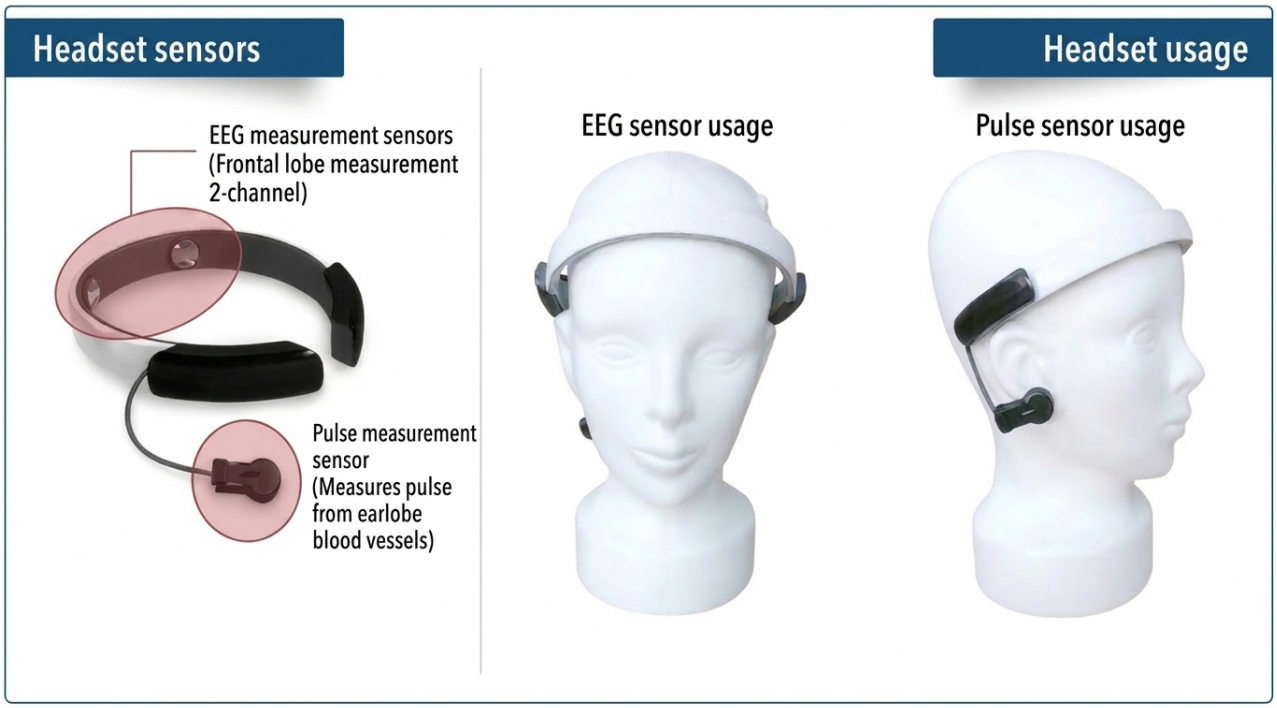
injustice, inappropriate rewards, and work-life imbalance. It was designed for easy field application [23].

The Maslach Burnout Inventory-General Survey, developed by Schaufeli et al [24] and adapted by Shin [25], was used to measure participants' current levels of job burnout. This scale assesses 3 core aspects of workplace burnout: exhaustion, cynicism, and professional efficacy. Each item is rated on a 7-point Likert scale, ranging from 0 (strongly disagree) to 6 (strongly agree). Higher scores on the exhaustion and cynicism domains and lower scores on the professional efficacy domain indicate higher degrees of job burnout.

To measure the participants' positive and negative affect, we used the Positive and Negative Affect Schedule developed by Watson et al [26] and adapted by Park and Lee [27]. It assesses the emotions experienced over the past week using 20 items, with participants rating their affective experiences on a 5-point Likert scale.

We used the PCL-5 to measure the severity of posttraumatic stress disorder (PTSD) symptoms. The original PCL was developed by Weathers et al [28] and revised by Weathers et al [29] to align with the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) diagnostic criteria. The Korean version of the PCL-5 was validated by Lee et al [30]. The PCL-5 assesses the severity of symptoms experienced in the past month in relation to traumatic events. It comprises 20 items rated on a 5-point Likert scale, ranging from 0 (not at all) to 4 (extremely). Higher scores indicate more severe PTSD symptoms. PCL-5 includes 4 subscales: intrusion, avoidance, negative alterations in cognition and mood, and hyperarousal.

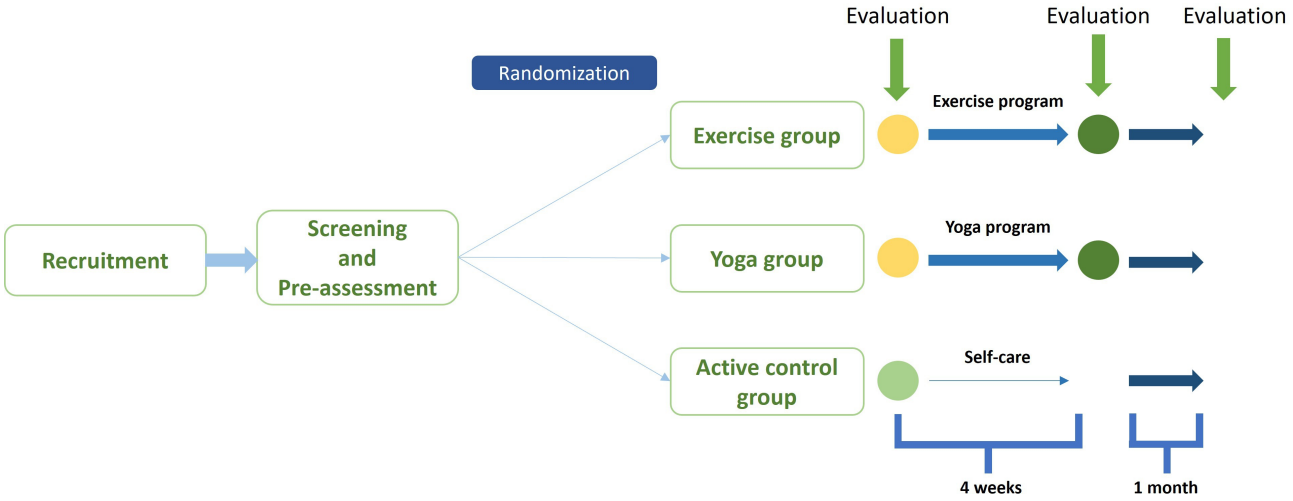
To assess participants' habitual body awareness, we used the K-MAIA, which was validated by Gim et al [31] based on the original scale developed by Mehling et al [32]. K-MAIA consists of 32 items rated on a 7-point Likert scale, ranging from 0 (not at all) to 6 (always). It comprises 6 subscales: noticing, accepting, attention regulation, mind-body connection awareness, returning to the body, and trusting. Noticing assesses awareness of positive, negative, and neutral bodily sensations by measuring sensitivity to physical sensations. Accepting evaluates the tendency to neither avoid nor divert attention from physical discomfort or the ability to not experience emotional distress from such discomfort. Attention regulation refers to the ability to control and maintain focus on bodily sensations. Mind-body connection awareness measures recognition of the connection between bodily sensations and emotions. Returning to the body refers to the ability to manage distress through attention to bodily sensations, leading to internal insight. Trusting reflects the extent to which one's body is experienced as safe and trustworthy.



To measure participants' habitual mindfulness levels, we used the Korean version of the FFMQ (K-FFMQ) validated by Won and Kim [33] and based on the original scale developed by Baer et al [34]. K-FFMQ includes 39 items rated on a 7-point Likert scale, ranging from 1 (not at all) to 7 (always). Mindfulness is defined as observing the flow of internal and external stimuli as they occur without judgment and is considered an adaptive response that helps prevent automatic, impulsive, and maladaptive behaviors [34]. This scale comprises 5 factors. Nonreactivity refers to the ability to refrain from immediate reactions to internal experiences without becoming overwhelmed. Observing means attending to and noticing internal phenomena (eg, bodily sensations, thoughts, and emotions) and external stimuli (eg, sounds and smells). Description measures the ability to label and describe observed experiences in words. Acting with awareness refers to fully engaging in the present activity without distraction. Nonjudgment refers to refraining from making evaluations such as good or bad, right or wrong, or valuable or worthless.

To assess participants' cognitive stress responses, we used the CSRS developed by Koh and Park [35]. This scale evaluates 3 dimensions of the cognitive stress response: extreme negative, aggressive-hostile, and self-depreciative thoughts. It comprises 21 items rated on a 5-point Likert scale, ranging from 0 (not at all) to 4 (very much). The test-retest reliability ranges from 0.87 to 0.95, and the internal consistency is 0.94.

In addition, we measured physiological variables, including HRV and EEG, which are widely used as stress-related physiological biosignals [35-37]. EEG and HRV were measured using the neuroNicle FX2 (OMNI C&S, Inc) [38]. The device was equipped with 2 EEG monopolar electrodes positioned over the left and right prefrontal areas (FP1 and FP2, respectively), along with ground and reference electrodes attached to a clamp on the right earlobe (Figure 1). Additionally, one pulse wave sensor (photoplethysmograph [PPG]) was attached to the same clamp to measure HRV. EEG and PPG data were simultaneously recorded. The device was approved by the South Korean Ministry of Food and Drug Safety (authorization 16 - 4837). EEG and HRV measurements were recorded over a 5-minute period in a resting state with eyes closed, and the results were analyzed.



XSL•FO
RenderX

Figure 1. neuroNicle FX2 device. EEG: electroencephalography.

Throughout the study, all self-reported psychological, cognitive, and physiological indices were measured at 3 time points: during enrollment (baseline assessment), immediately after training (post-training assessment), and 4 weeks after training (1-mo follow-up assessment; Figure 2). Although psychological outcome measures (eg, PSS, PHQ-9, and CSRS) are typically validated for self-report, their administration in this study was conducted in person at the hospital during assessment visits, rather than purely online or remotely. This approach was used to ensure data quality and minimize potential technical issues or self-report bias often associated with unproctored web-based questionnaires. In addition, participants completed a structured user satisfaction and usability questionnaire, comprising four 4-point Likert-scale items and 6 closed-ended items (3 single-response and 3 multiple-response items in which up to 2 options could be selected), at their final visit (Multimedia Appendix 1).

Figure 2. Assessment process of the study.

Apparatus

The reliability of the prefrontal EEG marker from the neuroNicle FX2 device [38] was previously established by Choi et al [39], who reported no significant differences in the means of the tested variables between the prefrontal and occipital regions.

The raw data collected by the equipment were processed using TeleScan (OMNI C&S, Inc). Ocular, muscular, and other types of artifacts were detected using an automatic removal algorithm, and contaminated periods longer than 10 seconds were removed. For EEG, the band-pass filter (infinite impulse response Butterworth filters, high-pass filter: first order with fc=2.6 Hz; low-pass filter: eighth order with fc=43 Hz), with the 3 to 43 Hz range, was applied to the data. All data were digitized in continuous recording mode (5 min of recording, 250-Hz sampling rate, and 15-bit resolution). For HRV, the PPG

XSL•FO
RenderX

waveform and heartbeat time interval of 4 ms for each heartbeat were detected using the pulse wave sensor. Raw EEG and PPG data were transmitted to the host device in real time. In the host device, a fast Fourier transform was applied to calculate the power spectrum of the EEG and HRV data.

The power spectra of the θ (4 - 8 Hz), α (8 - 12 Hz), low β (12 - 15 Hz), β (15 - 20 Hz), high β (20 - 30 Hz), and γ (30 - 40 Hz) frequency bands were calculated from the EEG data. In addition, relaxation (ratio of α to high β power) and concentration (ratio of low β to θ power) indices were calculated from the EEG data. For HRV parameters, the power of the low-frequency (0.04 - 0.15 Hz) and high-frequency (0.15 - 0.4 Hz) bands was calculated. All variables were normalized according to sex and age.

Platform of Fitness and Yoga

A fitness platform was developed to enable participants to engage in exercise or yoga programs. To improve motion recognition accuracy, usability testing was conducted in 3 phases: the first phase involved office workers, the second included medical professionals, and the third targeted the general public in home settings. The evaluation focused on key performance indicators, including user interface intuitiveness, functional accessibility, system stability, and latency. The tests identified specific areas for improvement, such as menu complexity, ambiguity in instructional text, and suboptimal user inteUser Interface intuitiveness. Recognizing that these issues could increase user-entry barriers and adversely affect adoption rates, corrective refinements were implemented prior to this clinical trial. Furthermore, the testing phases revealed that environmental variables, such as background interference and camera positioning, affected motion recognition accuracy. Consequently, the recognition algorithm was further optimized, and a comprehensive user manual was developed to ensure consistent performance across diverse environments. To ensure accuracy and quality of information, this study used Redmine, an open-source project management and defect-tracking platform, to oversee the development lifecycle. White box testing methodologies were used for logical defect detection and structural verification. We used a suite of automated testing tools, such as unit, Pytest, and SonarQube, to ensure the precision of the software's internal logic. The version of the platform evaluated was the initial release (version 1.0, "frozen" during the trial period). No major content or functional changes, bug fixes, or downtimes occurred that might have influenced the study results. Institutional affiliations were not displayed on the digital intervention platforms and were disclosed only during the consent process.

Randomization and Intervention Conditions

Overview

This study used a parallel-group randomized controlled design. Participants were assigned to 3 groups by 1:1:1 block randomization (stratified by organization and sex) with randomly selected block sizes (3, 6, or 6) using REDCap (Vanderbilt University) tools hosted at the Medical Research Collaborating Center of Seoul National University Bundang Hospital. REDCap generates randomization codes with SAS (SAS Institute). Owing to the nature of the intervention, participants and intervention providers were not blinded; however, the allocation sequence was concealed from participants until they entered the trial and from the investigators until the end of the study. Participants were aware of the 3 intervention types but were not informed about the intervention of interest or the comparators.

Participants accessed the platform via mobile devices or online and followed the instructed movements displayed on the screen (Multimedia Appendix 2). Participants' joint movements were recorded and analyzed in real time during the sessions. They were also provided feedback on their exercise performance during relaxation and transitions between movements to ensure and enhance their participation and engagement. Only participants' skeletal movement data (body movement) were collected to check the accuracy of their movements, without facial recognition or screen recording. Participants' movements were tracked, and they were alerted with pop-up notifications of any deviations from the prescribed exercise or yoga movements, encouraging adherence. Motivational pop-up messages were displayed at the end of each session. Participants were instructed to access a designated internet address via a web browser using their unique ID to engage in the exercise, yoga, or CBT-based self-care program specifically developed for this study. During the study period, participants were advised to refrain from engaging in any exercise beyond the prescribed program. The program was conducted in a quiet and comfortable location of the participant's choosing. To minimize environmental influences, participants were instructed to use the same location for each session, ensuring that it was a space where they could engage in exercise or yoga without interruption. Notably, participants did not need to visit the hospital to complete the exercise or yoga sessions.

The control group participants who practiced CBT-based self-care were instructed to access a designated website through a web browser to view educational materials based on CBT. This paper covers the definition of stress, its signs and symptoms, and strategies for its management.

Participants accessed the intervention platforms free of charge using their own devices and internet connections and received 300,000 KRW (US $231) after completing the 4-week study. The intervention itself (exercise and yoga sessions) was fully automated, relying on motion detection technology to provide real-time objective feedback. Human involvement during the trial was limited to recruitment, in-person baseline or outcome assessments at the hospital, and basic technical support, as needed. This minimal human involvement was designed to reflect the potential for low-cost routine applications (see section *Discussion*). The use of the interventions was defined and measured by the completion of prescribed 12 sessions within the 4-week study period. This adherence metric was monitored using the platform's backend log file analysis. The ultimate measure of usage intensity had a high completion rate (71/75 randomized participants). During the intervention period and follow-up, no significant harmful or unintended effects were reported in any of the groups (exercise, yoga, and control).

XSL•FO
RenderX

Exercise Program

The exercise program was designed by the Korea Association of Sports Culture and Industry, an expert exercise organization involved in this study. On the basis of a literature review, the program was designed to alleviate the symptoms of conditions, such as depression, anxiety, and posttraumatic stress, by considering the intensity, frequency, duration, and type of exercise. These exercises included adaptive moderate-intensity exercises. Each session comprised warm-up, training, and cool-down phases. The program was conducted over 12 sessions, with each session lasting 50 minutes, held 3 times a week for 4 weeks.

- Warm-up (8 min): Stretching, which focuses on flexibility and balance, was incorporated to enhance joint mobility before the main exercise. This phase, which included self-stretching exercises, lasted for 8 minutes.
- Training (26 min): The main exercises focused on core strength and balance, with strength exercises being conducted for 26 minutes.
- Cool down (16 min): Designed to calm the sympathetic nervous system, this 16-minute phase included balance stabilization, static stretching, breathing exercises, mindset focus, and relaxation movements.

The protocol also incorporated expert recommendations from a researcher in the Rehabilitation Medicine Department at the Boramae Medical Center, ensuring a comprehensive approach to the exercise regimen. Multimedia Appendices 3 and 4 present the detailed protocols for the exercise program.

Yoga Program

An example of the movements in the program protocol is presented in Multimedia Appendix 5, and the schedule of the 4-week yoga program is presented in Multimedia Appendix 6.

CBT-Based Self-Care Program

The CBT-based active control group received educational materials aimed at stress management delivered via the platform through either web or mobile access. This occurred 3 times per week over 4 weeks, for a total of 12 sessions. The materials were based on CBT principles, with a focus on applying the content learned in the “Let’s Take a Moment” section to actionable behavior. This group served as an active control intervention to control for the nonspecific effects of attention, time, and digital platform access. The program was designed to encourage CBT-based self-care practices appropriate for an active control group. Multimedia Appendix 7 presents the protocol for the CBT-based stress management educational materials.

The CBT-based self-care control group was advised to refrain from exercising during the study period.

Adherence was monitored using the platform’s backend log file analysis. A minimum completion threshold of 9 of 12 sessions (≥75%), each lasting at least 40 minutes, was required for inclusion in the outcome analysis. The mean number of completed sessions did not differ significantly between groups. The quality of the exercise and yoga performance was ensured through the platform’s real-time motion detection system, which provided automated corrective feedback when movement deviations were detected.

Statistical Analysis

Demographic variables and baseline psychological measurements were analyzed using ANOVA or Kruskal-Wallis tests for continuous variables, whereas chi-square or Fisher exact tests were used for categorical variables to compare the 3 groups.

The primary analysis followed the intention-to-treat principle using an MLM for repeated measures [40,41], accommodating potential missing data points. This model evaluated the effects of group, time, and their interaction across 3 time points: baseline, post-training (4 wk), and follow-up (8 wk). A first-order autoregressive (AR(1)) correlation structure was specified to account for within-subject correlations, and baseline PSS scores were included as covariates to minimize confounding effects.

To control for the family-wise error rate (FWER), a hierarchical testing strategy was adopted for the 2 co-primary outcomes (PSS and PHQ-9). First, the group×time interaction was evaluated at a Bonferroni-corrected significance level of 0.025 (0.05/2 outcomes). Regardless of the interaction significance, prespecified planned pairwise comparisons (yoga vs control, exercise vs control, and yoga vs exercise) were performed at each post-baseline time point using a Bonferroni-adjusted alpha of 0.0083 (0.025 per 3 groups) to test our a priori hypotheses. For secondary outcomes, although treated as exploratory, a Bonferroni-adjusted alpha of 0.0167 (0.05 per 3 groups) was applied for pairwise comparisons to maintain statistical stringency.

In accordance with CONSORT (Consolidated Standards of Reporting Trials) reporting standards, results of group comparisons were reported as mean differences (β), adjusted 95% CIs, and adjusted *P* values. These CIs were calculated to align with corrected α levels (.0083 and .0167, respectively) to ensure a transparent interpretation of both statistical significance and clinical magnitude. The overall model parameters (eg, *F*, df_1, and df_2) are reported in the table.

Frontal θ power was defined as the primary physiological outcome of interest. All other EEG frequency bands (α, β, and γ) were treated as secondary or exploratory outcomes. Consequently, no formal adjustment for multiple testing was applied to these exploratory measures, and the results should be interpreted as hypothesis generating.

For the user satisfaction and usability questionnaire administered at the final visit (Multimedia Appendix 1), the four 4-point Likert-scale items were compared between the 2 active intervention groups (exercise vs yoga) using 2-tailed independent samples *t* tests, with Cohen *d* as the effect size because these items referred specifically to the assigned exercise or yoga program. The 6 closed-ended items—3 single-response items and 3 multiple-response items in which participants could select up to 2 options—were summarized as frequencies and percentages, and between-group differences in the endorsement of each response option were examined using Fisher exact tests.

XSL•FO
RenderX

These analyses were exploratory and were not adjusted for multiple comparisons.

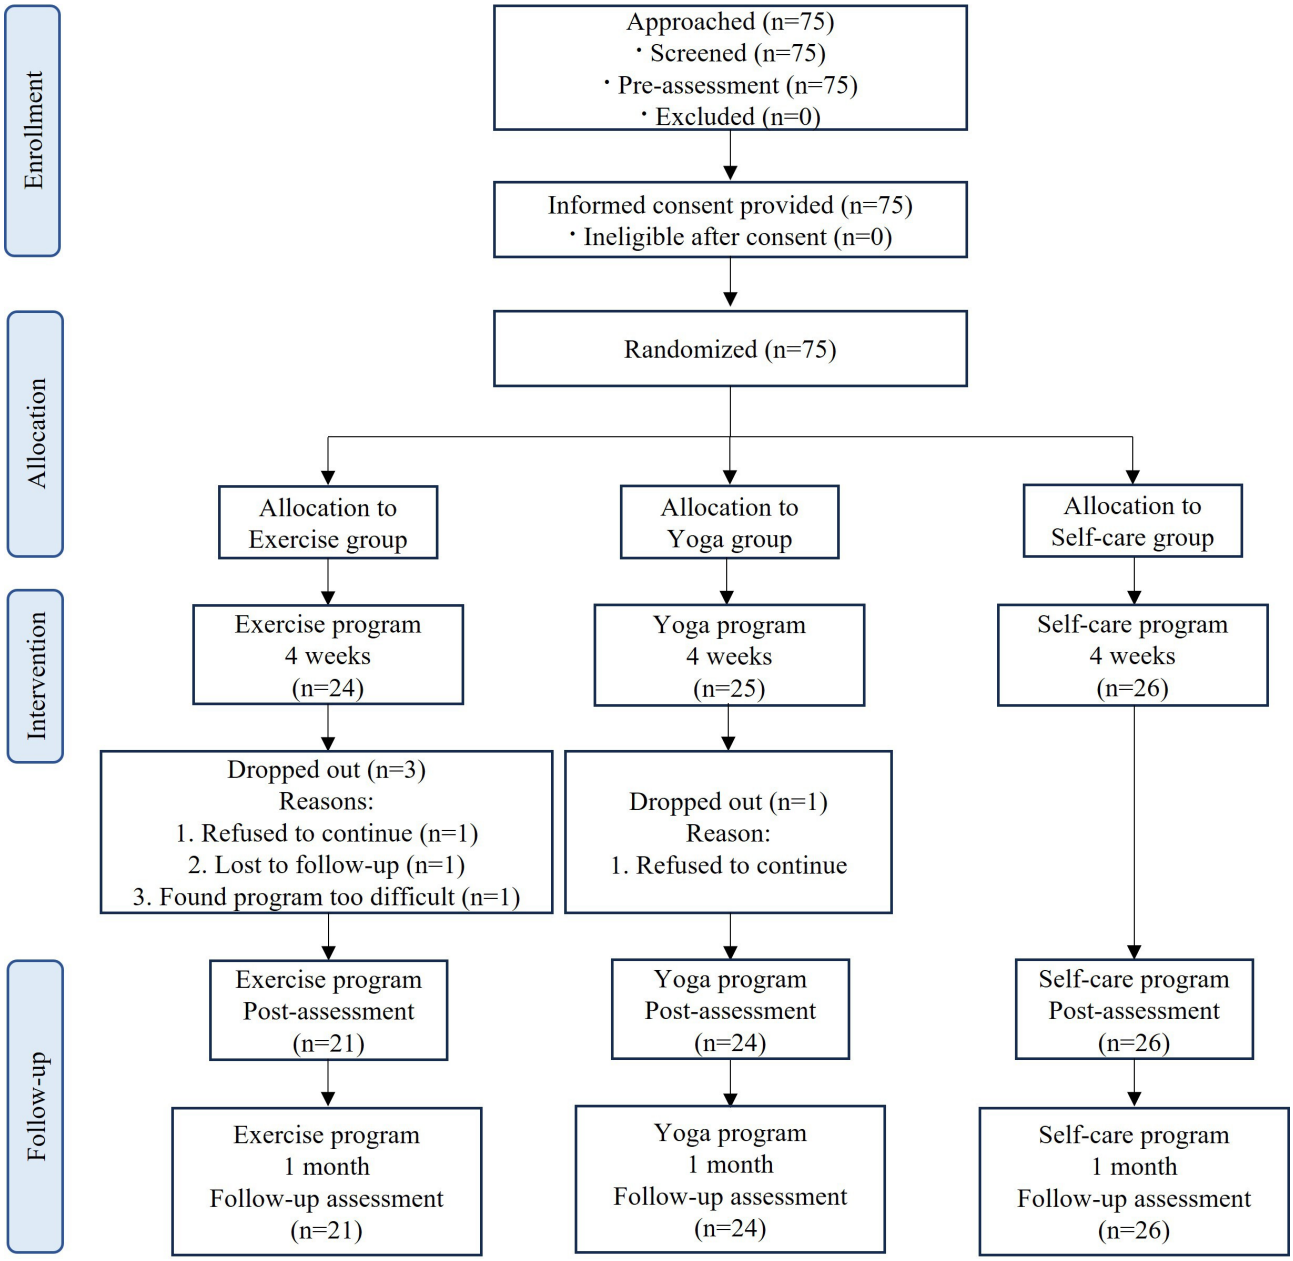
All statistical analyses were performed using SAS (version 9.4).

Ethical Considerations

The study protocol for this RCT was approved by the institutional review boards of Seoul National University Bundang Hospital (approval B-2309-855-301) and Boramae Medical Center in South Korea (approval 30-2023-106), and the trial was registered at ClinicalTrials.gov (NCT06620783). At their initial onsite visit, all participants were provided with comprehensive written and verbal information regarding the study purpose, procedures, and interventions and subsequently provided written informed consent in person prior to participation. Participants were informed of their right to withdraw from the study at any time without penalty, and the original consent also covered secondary analyses without the need for additional consent. All data collected, including self-reported psychological, cognitive, and physiological indices, were handled with strict confidentiality; data were deidentified and stored using unique research IDs. Participants received compensation of KRW 100,000 (US $77) for their time and travel expenses at each of the 3 required evaluation visits (baseline, post-intervention, and 4-week follow-up), amounting to a maximum total compensation of KRW 300,000 (US $231).

During the intervention period and follow-up, no significant harmful or unintended effects were reported in any of the groups (exercise, yoga, and control).

Results



Overview

Of the 75 randomized participants (exercise, 24/75, 32%; yoga, 25/75, 33.3%; and control, 26/75, 34.7%), 71 who completed at least nine of the 12 sessions, with a minimum duration of 40 minutes per session, were included in the outcome analysis (exercise, 21/71, 29.6%; yoga, 24/71, 33.8%; and control, 26/71, 36.6%). Figure 3 presents a flow diagram of participant enrollment and retention. Specific reasons for attrition included personal time constraints (2/75, 2.67%), exercise program difficulty (1/75, 1.33%), and inability to establish follow-up contact (1/75, 1.33%). Participants' average age was 34.14 (SD 6.18) years, and 77.3% (58/75) were women. No significant group differences were observed in demographic characteristics, such as age, sex, marital status, or education level at baseline (all P>.05; Table 1).

Both the exercise and yoga interventions led to improved mental health outcomes over time. The yoga group demonstrated the most pronounced and sustained benefits, while the exercise group showed immediate gains in some cognitive measures.

Primary Outcomes

The group×time interaction for PHQ-9 did not reach the prespecified Bonferroni-corrected significance level of 0.025 ($F_{4,136}$=2.71; P=.03). However, planned pairwise comparisons revealed a significant reduction in depressive symptoms for the yoga group compared to the control group at the 4-week follow-up (β=−3.67, 95% CI −5.64 to −1.69; adjusted P<.001). No significant differences were observed between the exercise and control groups at any time point (Figure 4A).

We also analyzed changes in another primary outcome: the PSS. The MLM showed that the group×time interaction was not statistically significant ($F_{4,136}$=1.27; P=.29), indicating that the trajectory of stress reduction did not differ significantly between the yoga, exercise, and control groups. However, a significant main effect of time was observed ($F_{2,136}$=38.56; P<.001), confirming a general reduction in perceived stress across all participants from baseline to the 4-week follow-up. The main effect of group was not significant ($F_{2,68}$=1.13; P=.33). The results, including the F statistics and P values, are summarized in Table 2, while Table 3 presents between-group differences and within-group changes in items from baseline (adjusted 95% CI).

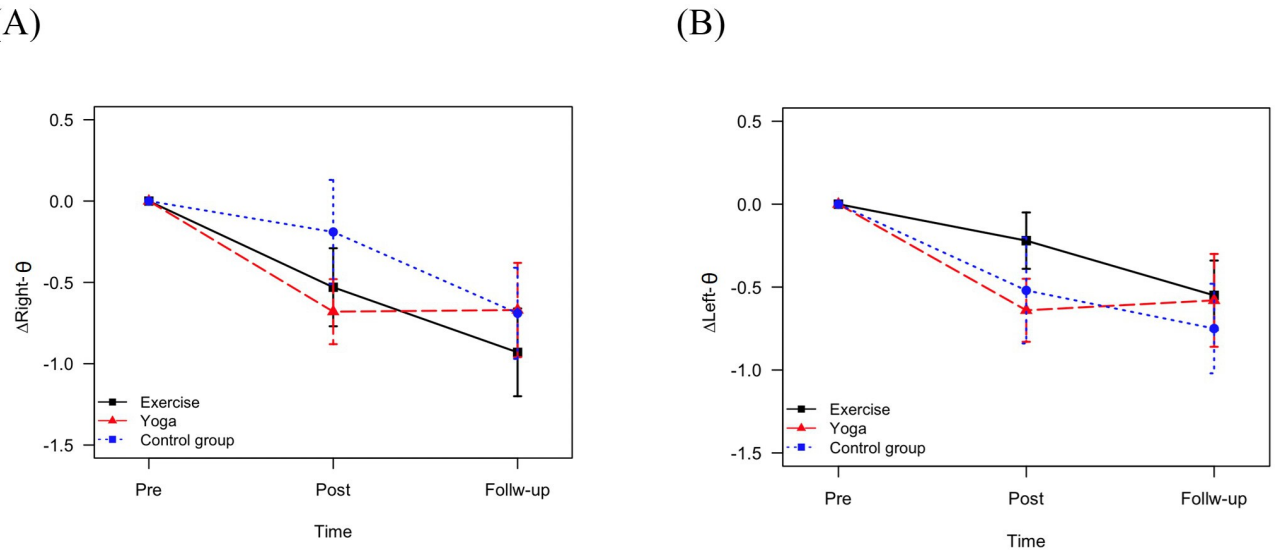
Secondary Outcomes

Overview

Similarly, a significant time×group interaction effect ($F_{4,136}$=2.61; *P*=.04) was observed for hyperarousal symptoms, as measured by the PCL-5 subscale (Figure 4). Although pairwise comparisons did not show significant between-group differences at specific time points, a trend analysis indicated that the yoga group exhibited a significant linear decrease in hyperarousal symptoms over time, with an average reduction of 0.854 points per month (95% CI 0.18-1.52; *P*=.01). The exercise group showed a nonsignificant downward trend, whereas the control group showed no significant change. These findings suggest that the yoga intervention led to a continuous decrease in hyperarousal symptoms during the study period.

Cognitive stress responses, as measured by the CSRS total scores, showed a significant time×group interaction effect ($F_{4,136}$=4.28; *P*=.003; Figure 4). At the post-training assessment, the exercise group showed the most substantial reduction in total CSRS scores; however, this effect diminished at the 1-month follow-up. In contrast, both yoga and control groups demonstrated significant linear decreases in CSRS scores over time. Notably, the yoga group exhibited a more pronounced average reduction of 2.81 points per month (95% CI 1.27-4.36; *P*<.001), while the control group showed an average reduction of 1.923 points per month (95% CI 0.54-3.30; *P*=.007). The exercise group showed significant improvements immediately post-training (post vs pre: β=−7.62, 95% CI −13.18 to −2.06; P_{adj}<.01); however, some of this gain was lost by follow-up. Conversely, the yoga and control groups showed a continuous and significant decrease in CSRS scores during the study period.



As a subscale of CSRS, extreme negative thoughts showed a significant time×group interaction effect ($F_{4,136}$=4.04; *P*=.004; Figure 4), indicating that changes in extreme negative thoughts over time differed across groups. The exercise group showed a substantial reduction in extreme negative thoughts post-training; however, this effect was not sustained at 1-month follow-up. In contrast, the control group demonstrated a significant decrease between the post-training and follow-up assessments, with an average reduction of 1.192 points (95% CI 0.42-1.97; *P*=.003). The yoga group showed no significant changes over time. These findings suggest that the exercise intervention led to an immediate decrease in extreme negative thoughts, although this effect diminished over time. Conversely, the control group experienced a delayed yet significant reduction, whereas the yoga group did not exhibit notable changes on this subscale.

Aggressive hostile thoughts also showed a significant time×group interaction effect ($F_{4,136}$=3.05; *P*=.02; Figure 4). The exercise group showed the greatest reduction in aggressive hostile thoughts post-training. The control group showed a decreasing trend over time (β=.269, 95% CI 0.02-0.52; *P*=.04). However, the yoga group showed a decreased effect after the post-training point. The self-depreciative thought subscale of the CSRS also had a significant time×group interaction effect ($F_{4,136}$=3.03; *P*=.02), with the yoga group showing the greatest sustained reduction (β=1.146, 95% CI 0.50- 1.79; *P*=.006; Figure 4). The exercise group showed a significant change immediately post-training, which was reversed after the training intervention ended.

Regarding biological markers, significant time effects were observed for both right and left EEG θ power (right θ: $F_{2,135}$=12.06; *P*<.001; and left θ: $F_{2,135}$=10.37; *P*<.001). As shown in Figure 5A, for right θ power, post-training levels were significantly lower than baseline levels (β=.45, 95% CI 0.15-0.76; *P*=.004), with a further decrease observed at the 1-month follow-up compared to baseline (β=.753, 95% CI 0.43-1.07; *P*<.001). However, the difference between post-training and follow-up θ power was not statistically significant (β=.302, 95% CI −0.04 to 0.65; *P*=.09). A comparable pattern was observed for the left θ power, as depicted in Figure 5. Post-training levels significantly decreased compared to baseline (β=.47, 95% CI 0.19-0.75; *P*=.001). This reduction remained significant at follow-up (β=.631, 95% CI 0.33-0.93; *P*<.001). No significant differences were found between the post-training and follow-up measurements (β=.16, 95% CI −0.15 to 0.48; *P*=.31). Other frequency bands, including α, β, and γ, did not show significant changes between pre- and post-training assessments. Furthermore, no significant group effects or group×time interactions were observed for any frequency band, including θ. Expanding on previous findings, no statistically significant changes were observed in the main HRV indices across time points.

Figure 5. Changes in the power of the θ frequency band of (A) the right and (B) the left electroencephalogram channel at 3 time points.

User Satisfaction and Usability

Responses to the user satisfaction and usability questionnaire are summarized in Multimedia Appendix 1. For the 4 Likert-scale items, the yoga group rated their assigned program as significantly more helpful than the exercise group for stress relief (mean 2.83, SD 0.70 vs mean 2.33, SD 0.66 on a 4-point scale; t_{43}=−2.45; *P*=.02; Cohen *d*=0.73) and for mental health management (mean 2.88, SD 0.61 vs mean 2.48, SD 0.60; t_{43}=−2.20; *P*=.03; Cohen *d*=0.66). Perceived helpfulness of the platform for overall health management (*P*=.10) and ease of use of the platform (*P*=.47) did not differ significantly between the 2 groups.

For the 6 closed-ended items, response distributions were largely comparable between the exercise and yoga groups, and no between-group differences reached significance for desired improvements (Q5), perceived inconveniences (Q6), prior and intended platform use (Q7), main reasons for using the program (Q8), or main barriers to engagement (Q10). The only significant difference was for preferred platform functions (Q9), where participants in the exercise group more frequently endorsed "referring to a variety of exercise programs" than those in the yoga group (57.1% vs 25.0%; Fisher exact *P*=.04). Descriptively, the most frequently endorsed inconvenience in both groups was a preference for compatibility across multiple devices (76.2% and 75.0% in the exercise and yoga groups, respectively), and the most frequently endorsed barrier to sustained engagement was insufficient personal motivation to continue (45.5% and 62.5%, respectively). Full item-level frequencies, percentages, and test statistics are provided in Multimedia Appendix 1.

Discussion

Principal Findings

This study aimed to assess whether a 12-session mobile-delivered exercise and yoga programs could effectively reduce stress and depressive symptoms among employees. An RCT demonstrated that both an adaptive moderate-intensity exercise program and a yoga program delivered via a digital platform significantly improved mental health outcomes among employees with moderate-to-high stress compared with a CBT-based self-care control condition. Both interventions decreased depressive symptoms, hyperarousal, and maladaptive CSRS scores. In particular, the yoga intervention showed the most pronounced and sustained benefits across a range of psychological measures. The significant group×time interactions for depressive symptoms, hyperarousal, and CSRS indicated that the trajectories of improvement differed by group, with the yoga group often showing the greatest improvement over time. This is consistent with research on the mental health benefits of mindfulness-based practices, such as yoga, which have been shown to alleviate anxiety and depressive symptoms [10]. A significant main effect of time was observed on frontal θ power; however, no significant group or group×time interaction effects were found. The exercise group also showed improvements in most outcomes, although in some cases, these were not as large or sustained as those in the yoga group. The yoga group demonstrated the greatest and most sustained improvements, whereas the exercise group showed immediate but less sustained gains in secondary cognitive measures. These results suggest differential efficacy patterns among the intervention modalities.

Furthermore, CSRS scores, particularly for extreme negative, aggressive hostile, and self-depreciative thoughts, decreased more prominently in the yoga and exercise groups than in the control group. These findings suggest that physical activity and mind-body interventions can effectively reduce cognitive distortions associated with stress. Such decreases in negative thought patterns may have contributed to the overall improvement in mental health observed in this study.

In addition to psychological outcomes, this study explored brainwave activity, focusing specifically on θ power in the prefrontal cortex, which is commonly associated with cognitive processes, such as attention and memory. We observed a significant decrease in θ power after both interventions across all groups. Elevated θ power in resting states has been associated with poor cognitive functioning [42], including deficits in attention and executive function. The overall reduction in resting frontal θ power over time may be consistent with changes in

XSL•FO
RenderX

neural markers associated with stress and arousal regulation. However, given the absence of cognitive performance measures, this interpretation is exploratory and should be viewed with caution [43]. This interpretation is supported by the results of previous studies. Thornberry et al [43] demonstrated that decreases in θ power are associated with improved spatial learning. Brzezicka et al [44] reported that reduced θ power in the dorsolateral prefrontal cortex, especially under a high cognitive load, predicts better task performance, which allows the brain to manage cognitive demands more effectively. The overall reduction in θ power observed across all groups may reflect improved arousal and attention regulation, possibly enhanced by the mindfulness components inherent in the yoga sessions. However, the absence of a significant group×time interaction precludes attributing this effect specifically to yoga.

Comparison With Previous Studies

Our results are consistent with those of a growing body of literature highlighting the mental health benefits of exercise and yoga interventions. A recent systematic review by Singh et al [45] found that physical activity interventions can significantly reduce depression, anxiety, and psychological distress in various populations. Similarly, our exercise intervention reduced depressive symptoms and stress-related outcomes. The observed improvements in the exercise group align with the findings of Arida and Teixeira-Machado [46], who noted that exercise contributes to neuroplasticity and cognitive reserve, which are crucial for brain resilience to cognitive impairment.

Our findings on cognitive resilience and stress responses complement those of Shields et al [47], who found that collegiate athletes exhibited cognitive resilience through adaptations in mood and stress responses during a competitive season, suggesting that regular physical activity supports mental health and cognitive flexibility. Furthermore, Brush et al [48] showed that 8 weeks of moderate-intensity aerobic exercise can reduce depressive symptoms and influence neural indicators of reward and cognitive control in young adults with major depression, indicating potential neurobiological pathways for exercise effects and paralleling our EEG findings.

Bouthillier and Asmundson [49], Tseng et al [50], and Soteriades et al [51] demonstrated the efficacy of physical exercise (including aerobic and resistance training) in reducing anxiety, PTSD symptoms, and occupational stress in patients with anxiety disorders, middle-aged adults with poor sleep, and firefighters, respectively. By including physiological stress measures (HRV and EEG), our study provides additional evidence that such interventions can induce favorable changes in stress-related biomarkers, although our HRV results did not reach significance, possibly because of the relatively short intervention period.

Previous studies conducted on trauma-exposed and high-stress populations have supported the benefits of combining mind-body practices with exercise. Goldstein et al [52] reported that an integrative exercise program for veterans with PTSD reduced symptoms, whereas Rosenbaum et al [53] observed that an exercise program tailored to police officers with PTSD improved psychological outcomes. Similarly, our yoga program, which included mindfulness and relaxation components, produced notable improvements in hyperarousal and negative thought patterns, reflecting outcomes particularly relevant to stress and trauma-related conditions. McKeon et al [54] also showed that a mental health–informed physical activity intervention delivered via social media was feasible for first responders, suggesting that digital delivery can be effective, a finding echoed by the high adherence and engagement observed via our digital platform.

Our results on physical activity and stress align with epidemiological findings such as those of LeardMann et al [55], who observed an association between regular vigorous exercise and a lower incidence of PTSD symptoms in military personnel. In our study, participants in the exercise and yoga groups engaged in structured physical activity and showed corresponding decreases in stress and hyperarousal, supporting the protective and ameliorative effects of exercise on stress-related outcomes. Schuch et al [4] and Mikkelsen et al [5] found that physical exercise reduces anxiety and depression, likely through endorphin release and enhanced neuroplasticity. The decreases in depressive symptoms and improvements in hypervigilance and cognitive responses observed in our study align with these physiological mechanisms.

Our findings emphasize the importance of exercise intensity and enjoyment. Paolucci et al [56] noted that both high-intensity interval training and moderate continuous training could reduce depression and inflammation, although intensity matters and high intensity may increase perceived stress. In the exercise program, we chose moderate-intensity exercise and observed mental health benefits without evidence of increased stress, suggesting that a tolerable intensity level is crucial for psychological benefits. Similarly, the yoga program, which was generally low-to-moderate intensity, yielded strong benefits, consistent with the idea that the optimal intensity for mental health improvements might not necessarily be maximal.

The general improvements in mental health observed in this study are supported by large-scale data, such as those of Chekroud et al [57], who found that individuals who exercise have a significantly lower mental health burden. In that study, all exercise types were associated with better mental health, with decreases in mental health burden ranging from 12% to 22% compared to nonexercisers. We observed robust improvements in the exercise and yoga groups, reinforcing the idea that regular physical activity, whether traditional exercise or yoga, can substantially improve mental well-being. Notably, Chekroud et al [57] also found that certain group-based exercises and mindfulness practices (eg, yoga and tai chi) had larger effects than some other forms of activity, a trend mirrored in our study in which the yoga group often experienced equal or greater benefits than the conventional exercise group.

Our study adds to existing evidence on the efficacy of yoga in occupational contexts. Rhodes et al [58] demonstrated the benefits of yoga in women with treatment-resistant PTSD, and Shohani et al [59] demonstrated its positive effects on stress, anxiety, and depression in women. Jeter et al [60] found that a yoga program for police trainees improved mood and stress, whereas Weathers-Meyer et al [61] reported that firefighters who participated in an 8-week yoga program experienced

XSL•FO
RenderX

reduced PTSD symptoms, negative affect, and trait anxiety. Similarly, our yoga program improved mood and stress (depressive symptoms and CSRS). Fang and Li [62] found that nurses who regularly practiced yoga reported better sleep quality and lower work stress, highlighting the broad benefits of yoga.

The comparable effectiveness of the CBT-based self-care control and yoga intervention groups may reflect the active psychological mechanisms embedded in both interventions. Self-guided CBT and psychoeducation, even in brief, have significantly reduced depressive symptoms in occupational populations [63]. This suggests that the control group did not serve as a passive comparator but instead offered evidence-based psychological tools with known antidepressant efficacy. Furthermore, stress regulation and mindfulness-based practices in yoga may overlap with CBT techniques through shared mechanisms of emotion regulation, attentional control, and cognitive reappraisal [64]. These parallels could account for the similar symptom reduction observed in both groups.

In contrast, the relatively weaker performance of the exercise group may be attributable to several pragmatic and methodological factors. First, the intervention was delivered remotely, without live supervision. Prior meta-analyses suggest that structured and professionally supervised exercise interventions tend to be associated with greater improvements in depressive symptoms compared to structured formats [65]. Second, real-world barriers, such as fatigue after long workdays and time constraints, may adversely affect engagement with exercise sessions [66]. Finally, the 4-week intervention duration may not have been sufficient to produce robust antidepressant effects from exercise [67], whereas the cognitive and emotional benefits of CBT-based self-care or yoga may manifest more quickly.

The user satisfaction findings converged with the primary outcome results. The yoga group, which showed the most pronounced and sustained improvements in depressive symptoms and cognitive stress responses, also rated their program as significantly more helpful for both stress relief and mental health management than the exercise group. This concordance between subjective perceptions of benefit and objective changes in psychological outcomes supports the internal consistency of our findings and suggests that the superior efficacy of the yoga intervention was accompanied by a correspondingly favorable user experience. The usability feedback also carries practical implications for future platform development. Across both groups, the most frequently endorsed request was for compatibility across multiple devices, and the most frequently reported barrier to sustained engagement was insufficient personal motivation to continue. These observations indicate that broadening device support and incorporating motivation-enhancing features (eg, progress reports, reminders, and social or gamified elements) may further improve adherence and engagement when such digitally delivered programs are scaled to routine workplace settings.

Suggestions and Limitations

These findings have important clinical implications. First, yoga is a viable and accessible intervention, and exercise may complement it in reducing workplace stress and improving employee mental health. Given that these programs were delivered via a mobile platform, our study supports the potential of digital health solutions to reach employees with time or accessibility constraints. Employers and health professionals should consider incorporating such programs into workplace wellness initiatives to address stress and mental health proactively.

Second, the distinct advantages of yoga suggest that mind-body exercises may be particularly useful for individuals who struggle with stress-related cognitive distortions or heightened arousal. However, the exercise program showed meaningful improvements in vitality and energy, consistent with findings indicating that exercise boosts energy levels. A combined approach that offers both traditional exercises and yoga can cater to personal preferences and target a broader range of outcomes.

Despite these promising results, this study had several limitations. First, the relatively short intervention period (12 sessions over 4 wk) may limit the generalizability of the findings. Although this study demonstrated short-term improvements in mental health outcomes, it remains unclear whether these benefits can be sustained in the long term. Future studies should include longer follow-up periods to assess the durability of the observed effects. Second, our sample size (N=75, three groups) was calculated to detect large effects (f=0.40). A larger sample size would increase statistical power. Third, the study relied on self-reported measures of psychological outcomes, which could be subject to response bias. Objective measures of stress, such as cortisol levels, were not obtained in this study but could strengthen future research. Fourth, although we attempted to control for participant behavior outside the interventions (eg, advising against extra exercise), we cannot fully rule out external factors influencing the outcomes (eg, changes in work stress or personal life events during the study). Fifth, the control group received a CBT-based self-care program that, while intended to be minimal, might have provided some benefits (eg, stress management education). This may have diluted between-group differences. Nevertheless, the inclusion of basic psychoeducation in the control condition made our findings more applicable to real-world settings in which doing nothing is often unethical or impractical. More importantly, by comparing the interventions to active digital control, the study successfully isolated the differential impact of physical and mind-body components (yoga and exercise) from the nonspecific effects of general engagement and digital access. The observed significant group×time interactions validate that the specific mechanisms of the active interventions produced differential trajectories of mental health improvement compared to CBT-based self-care control. Sixth, the homogeneity of the sample—predominantly female, young, urban, and well-educated employees—may limit the applicability of the findings to other populations, such as men, older adults, rural workers, and those with lower digital literacy. The Korean cultural context may also influence intervention uptake. Seventh, the stringent exclusion criteria ensured participant safety but may limit applicability to employees with comorbid psychiatric or physical conditions. Eighth, several elements of this RCT may differ from routine application.

XSL•FO
RenderX

In-person assessments and follow-ups conducted at the hospital provided a level of accountability and reduced loss to follow-up, which might not exist in purely remote routine applications. Additionally, the use of unique IDs and concealed allocations, when necessary, would be streamlined in a real-world scenario. The omission of in-person assessments in a routine setting might affect retention rates, underscoring the need for future studies on effective remote engagement strategies (eg, gamification or peer support). Ninth, EEG analyses were exploratory, and we did not apply formal corrections for multiple comparisons across frequency bands. As such, the observed time-related reductions in θ power should be considered hypothesis generating and require replication in future studies with preregistered EEG outcomes and appropriate controls for multiple testing. Finally, although the study successfully used a digital platform to deliver interventions, technical issues or user proficiency may have influenced engagement and outcomes. In addition, the analyses of the user satisfaction and usability questionnaire were exploratory and were not corrected for multiple comparisons; given the small subgroup sizes, these results should be interpreted with caution and regarded as hypothesis generating.

Despite these limitations, this study highlighted several unmet needs and areas for future research. First, further investigations are required to explore the long-term effects of digital mental health interventions, particularly in diverse workplaces. Understanding how different populations engage with digital platforms and whether the benefits of yoga and exercise persist beyond the initial intervention period is crucial for upscaling these programs.

Future research should focus on refining the digital delivery of mental health interventions. For example, incorporating gamification or social support elements may motivate users to adhere to the programs. Finally, studies comparing these interventions across different psychological distress levels are required. Although this study primarily focused on individuals with moderate-to-high stress, future research should investigate whether these findings hold true for individuals with lower baseline stress or severe mental health conditions. This could help tailor interventions for specific mental health needs, ensuring that the most appropriate treatment is provided.

Conclusions

This study provides evidence that digitally delivered adaptive yoga programs demonstrate superior and sustained improvements in depressive symptoms and CSRS compared to an active CBT-based self-care control. However, the exercise program showed more modest and less sustained effects, which warrant further investigation using larger samples. The use of a motion-detecting digital platform demonstrated high feasibility and engagement, suggesting that mobile health interventions can overcome common barriers to exercise (eg, time and accessibility) in employee populations. Our findings support the integration of regular physical activity, including mind-body practices such as yoga, into workplace wellness programs to promote mental well-being. Large-scale studies with longer follow-up periods are warranted to confirm these results, examine the long-term maintenance of benefits, and evaluate the cost-effectiveness of such interventions. Employers and health care providers should consider leveraging digital health platforms to deliver structured mind-body programs, particularly yoga, to reduce workplace stress and enhance overall mental health among employees; however, the role of exercise warrants further investigation.

Acknowledgments

We would like to thank Nankyung Lee, a professional yoga teacher, for her invaluable assistance in designing the yoga program. We also extend our gratitude to the participants for their commitment and time during the trial. The authors declare the use of generative AI (GenAI) in the research and writing process. According to the GAIDeT (Generative AI Delegation Taxonomy; 2025), the following tasks are delegated to GenAI tools under full human supervision: literature search and systematization, proofreading, and editing. The GenAI tool used was ChatGPT 4.5. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

This research was supported by the Culture, Sports, and Tourism R&D Program through the Korea Creative Content Agency funded by the Ministry of Culture, Sports, and Tourism in 2022 (Project Name: K-Total Force Fitness Sports Care Service Process Development, Project R-2022 - 020114).

Data Availability

The deidentified datasets generated and analyzed in this study are available from the corresponding author upon reasonable request. Access will be granted following a review of the research proposal by the study team to ensure that the data use aligns with the original consent and ethical approval. No data were deposited in a public repository due to restrictions under the institutional review board approval concerning sensitive health information.

Abstract

Background: Anxiety and depressive disorders remain highly prevalent and insufficiently treated, with many individuals experiencing persistent or untreated symptoms, limited access to evidence-based care, or insufficient support between clinical encounters. Adults with disabilities represent a particularly underserved subpopulation, often facing compounded barriers to mental health care and higher rates of anxiety and depression. Digital therapeutics offer a scalable opportunity to address these gaps by extending structured, evidence-based interventions beyond traditional care settings.

Objective: This pilot study evaluated Rauha, a novel digital therapeutic created by Toivoa Inc, that integrates cognitive behavioral therapy (CBT)–based modules with live weekly sessions led by a National Board-Certified Health and Wellness Coach (NBC-HWC), delivering structured, smartphone-based psychoeducation and interactive therapeutic exercises combined with personalized mental health coaching to support behavior change.

Methods: Thirteen adults with mobility and/or hearing disabilities and clinically elevated anxiety and/or depression were enrolled in a single-arm, within-participants design. Participants completed 8 weeks of CBT modules delivered via smartphone, accompanied by synchronous virtual mental health coaching. Anxiety and depression were assessed using the Hamilton Anxiety and Hamilton Depression Rating Scales, respectively, at baseline, post treatment, and at the 4-week follow-up.

Results: Mean reductions were significant for both anxiety (−13.05, SD 2.51; $P<.001$) and depression (−12.83, SD 1.55; $P<.001$), exceeding thresholds for clinical significance and sustained through follow-up. Post treatment, 84.6% (11/13) of participants showed clinically significant improvement in both anxiety and depression. At follow-up, 76.9% (10/13) and 92.3% (12/13) of participants showed clinically significant improvement in anxiety and depression, respectively. Between baseline and follow-up time points, these reductions corresponded to mean shifts from moderate to mild anxiety on the Hamilton Anxiety Rating Scale and from moderate to mild/nondepressed on the Hamilton Depression Rating Scale. Participants reported strongly favorable acceptability, experience, and usability ratings for the Rauha treatment program, demonstrating 100% treatment retention and an average replay rate of 5.5 for personalized smartphone content.

Conclusions: The findings suggest that a combined digital CBT and NBC-HWC approach can yield clinically meaningful and durable symptom reductions in depression and anxiety, coupled with high user acceptability and engagement, for adults with disabilities. These findings provide preliminary evidence supporting Rauha as a scalable, evidence-informed mental health intervention with the strong potential to improve access and address key barriers to care.

Introduction

Digital Interventions for Adults with Disabilities

About 18.2% and 21.4% of adults reported symptoms of anxiety and depression, respectively [1]. These conditions are often undertreated, partly due to many obstacles prohibiting treatment initiation and engagement, resulting in a substantial unmet need for effective and accessible mental health interventions [2]. Among underserved populations are adults with physical disabilities or functional limitations, who comprise a large proportion of the US population, with over 40% of those aged 45 to 64 years reporting such limitations, a 21% increase in prevalence from 2002 to 2016 [3]. This growing population faces compounded barriers to care, including limited access to evidence-based therapies, highlighting the critical need for scalable interventions tailored to both mental health and functional challenges. Additionally, this population is at higher risk of mental health difficulties than those without a disability, with recent data showing that 32.9% of those with disabilities report significant mental distress as compared with 7.2% of those without disabilities [4].

Unfortunately, individuals with disabilities and functional impairments also face significant barriers in accessing adequate treatment, including limited treatment options, a lack of adequate training among providers concerning the unique needs of those with disabilities, and limited transportation capabilities [5,6]. Further worsening this public health problem is a severe shortage of mental health providers. On average, within the United States, only 26.4% of all mental health care needs are being met based on provider volume and availability [7]. These provider shortages strongly contribute to the 2023 finding that 46% of US adults with a mental disorder did not receive care for their condition [8].

Fortunately, evidence suggests that these obstacles are surmountable. For example, research has shown that cognitive behavioral therapy (CBT) and mindfulness-based therapies are strong approaches for this population [9-11]. Furthermore, virtual mental health interventions for those with disabilities can address obstacles related to mobility or transportation [12,13], reduce wait times, and increase overall access [14-16]. Self-guided CBT has shown significant promise in treating adults with mild-to-severe mental health symptoms without requiring a licensed provider [17,18].

In response to the rapid expansion of digital health technologies, the digital therapeutics (DTx) category has emerged as a distinct class of evidence-based interventions. Although definitions vary, DTx is largely characterized as a digital, evidence-based medical intervention delivered directly to patients to prevent, treat, or manage a disease or disorder using validated clinical frameworks [19]. As it relates to mental health, DTx and closely related evidence-based digital interventions demonstrate significant promise in reducing symptom severity across multiple conditions [20-24]. However, there are notable limitations, including high rates of attrition [25], often attributed to symptom severity beyond the scope of self-guided DTx capabilities, technological limitations, and insufficient personalization or support [26,27]. Importantly, evidence suggests that attrition can be reduced and adherence improved through the inclusion of human support elements that enhance accountability, personalization, and timely response to changes in treatment needs [28,29]. However, despite their promise, many existing digital platforms remain inadequately accessible for individuals with disabilities, inadvertently reproducing the very barriers they aim to reduce [26,30]. As such, designing DTx in alignment with established accessibility standards, such as the Web Content Accessibility Guidelines (WCAG) 2.2 [31], is therefore not a peripheral design consideration but a foundational requirement for equitable delivery of evidence-based care.

Beyond digital solutions, another step in expanding mental health care has been the significant increase in health and wellness coaches, such as National Board-Certified Health and Wellness Coaches (NBC-HWC). Health and wellness coaches are professionals who support patients in making behavioral changes according to self-chosen health goals and needs [32]. In terms of efficacy, a recent meta-analysis supports the use of health and wellness coaches as a stand-alone behavioral intervention in improving mental health outcomes among those with medical and psychological conditions [33]. In addition, adding a health coach to self-guided CBT significantly improves mental health outcomes over and above self-guided CBT alone [34]. At a systemic level, the use of health and wellness coaches is a promising avenue for improving flexible access to mental health care, given that these sessions are significantly shorter than traditional psychotherapy, typically around 30 minutes [32,35], allowing for more patients to receive care per single coach when compared to licensed mental health providers.

In summary, although adults with disabilities face significant mental health concerns and obstacles to accessing adequate care, ongoing innovations in technology, treatment delivery, and types of care show promising results in better reaching and treating this underserved population.

Development of the Rauha Mental Health Program

Rauha is a smartphone-based DTx developed to deliver flexible, accessible, and evidence-based mental health care for adults with anxiety-related and depression-related symptoms, including those with functional or sensory limitations. The Rauha DTx is a Health Insurance Portability and Accountability Act (HIPAA)–compliant software, certified with WCAG 2.2 AA accessibility standards. This certification ensures usability for individuals with functional, sensory, or other accessibility challenges, as only 5.2% of the top 1 million websites pass WCAG accessibility testing [36]. Per WCAG principles, Rauha is perceivable, operable, understandable, and robust [31]. Therapeutic content is delivered across text, audio, and video, with captions, transcripts, and high-contrast scalable text to support perceivability. The platform allows full keyboard navigation and works with assistive technologies, avoiding reliance on time-sensitive interactions. Content is written in plain language and presented in a consistent, structured format. The system was tested across devices and browsers and designed to work with common accessibility tools.

The clinical program of Rauha consists of 2 integrated components: (1) asynchronous, self-guided, interactive modules

XSL•FO
RenderX

and exercises rooted in standard CBT [37], delivered digitally via recorded sessions by a licensed psychologist, allowing users to listen, review, and engage with content multiple times at their convenience; and (2) weekly live virtual coaching sessions with an NBC-HWC focused on implementing evidence-based behavior change strategies to support patients' chosen goals. The use of NBC-HWCs rather than licensed therapists was intentional to support scalability, expand access to care, and align the live treatment component with a structured behavior change model that complements the asynchronous CBT content.

This clinical program is meant to serve as an intermediary treatment option, balancing the benefits of both self-guided, smartphone-based CBT programs and traditional one-on-one care offered by clinicians (Table 1). Traditional psychotherapy is often constrained by provider availability and extended wait times [38,39], whereas self-guided CBT offers immediate access but may be limited by engagement and adherence challenges [40], as well as rarely, if ever, meeting WCAG standards [41]. Hybrid models that combine digital content with human support can address these limitations by maintaining scalability while incorporating structured support, which has been associated with improved engagement and more efficient use of clinical resources [42].

Table . Comparison of cognitive behavioral therapy (CBT) delivery models and access characteristics.

Feature	CBT delivery model		
	Self-guided CBT applications	Traditional provider care	Rauha CBT model
Clinician involvement	Little to none	Direct	Psychologist-developed and guided
Delivery format	Asynchronous	Synchronous	Combined
Wait times	Immediate	48-day average	3-day average
Scalability	High	Low	High
Consistency of care	Standardized content	Clinician-dependent	Standardized content with personalized coaching
Meets WCAG[a] standards	Rare	Not applicable	Yes
Flexible to patient needs	Limited	High	High
Clinical standards	Variable	High	High
Cost efficiency[b]	Low cost, variable engagement	High cost, resource-intensive	Moderate cost, scalable support

[a]WCAG: Web Content Accessibility Guidelines.

[b]Cost efficiency reflects relative resource utilization and scalability rather than absolute cost.

Study Objectives

The central aim of this study was to evaluate Rauha in the treatment of moderate-to-severe symptoms of anxiety and depression in adults with a hearing and/or mobility-related disability. We hypothesized that there would be (1) at least 80% treatment retention among those who initiated the intervention and (2) a statistically and clinically significant reduction (CSR) in anxiety and depressive symptoms between baseline and the end of the treatment period through a 4-week follow-up. As an exploratory aim, we assessed user acceptability, experience, and usability of the Rauha program.

Methods

Study Design

This study used a single-arm, within-participants design to measure the clinical impact of Rauha on symptoms of anxiety and depression, as measured by the Hamilton Anxiety Rating Scale (HAM-A) [43] and Hamilton Depression Rating Scale (HAM-D) [44], respectively. Patients were assessed with the HAM-A and HAM-D at baseline (preintervention), immediately after completing treatment (post intervention), and 4 weeks after completing treatment (follow-up). Participation from baseline to follow-up lasted approximately 12 weeks.

Participants

Participants were recruited through approved study flyers at Endeavors Programs in San Antonio, Texas, as well as through other approved recruitment channels, including clinical and community referrals. Inclusion criteria for participation were a self-reported mobility or hearing disability, age 22 years or older, a minimum score of 10 on the Patient Health Questionnaire-9 (PHQ-9) [45] or Generalized Anxiety Disorder-7 (GAD-7) [46], access to a stable internet connection via Wi-Fi or mobile data, access to an iPhone or iPad (optionally, an iPhone could be provided by the research team), English fluency, resident of the United States for the duration of the study, no changes in psychotropic medication or psychotherapy treatment in the 30 days before study entry, and comprehension of and willingness to sign informed consent and complete all study procedures.

Exclusion criteria were a diagnosis of psychotic or bipolar disorder, active participation in another treatment trial, nontobacco substance use disorder within the past 12 months, any suicidality beyond passive ideation in the past 12 months, and currently pregnant or planning to become pregnant during the treatment period.

XSL•FO

Ethical Considerations

This study was approved by the Advarra Institutional Review Board (Protocol 79652). All participants provided informed consent prior to participation in any study-related activities. Participation was voluntary, and participants were informed that they could withdraw from the study at any time without penalty. Participant privacy and confidentiality were protected throughout the study. All study data were collected, transmitted, and stored within a HIPAA-compliant digital platform and secure data management dashboard with restricted access limited to authorized study personnel. Appropriate administrative, technical, and physical safeguards were implemented to protect participant information. Data were deidentified prior to analysis and reporting. Participants received US $125 in compensation for their participation in the study in accordance with the institutional review board–approved protocol and were not contingent upon study outcomes.

Materials

Patient Health Questionnaire-9

The PHQ-9 is a 9-item self-report measure corresponding to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) [47] criteria for major depressive disorder and is used as an inclusion criterion in this study [45]. Each item is rated on a 4-point Likert scale ranging from 0 (“not at all”) to 3 (“nearly every day”), yielding total scores ranging from 0 to 27, where higher scores reflect more severe levels of depressive symptoms. The PHQ-9 has established cutoff scores of 5, 10, 15, and 20, representing mild, moderate, moderately severe, and severe depression, respectively. It has demonstrated good internal consistency (α=.85) [45].

Generalized Anxiety Disorder-7

The GAD-7 is a 7-item self-report measure of anxiety symptoms corresponding to the DSM-5 [47] criteria for GAD, used as an inclusion criterion in this study [46]. Each item is rated on a 4-point Likert scale ranging from 0 (“not at all”) to 3 (“nearly every day”), yielding total scores ranging from 0 to 21, with higher scores indicating greater anxiety symptoms. The GAD-7 has established cutoff scores of 5, 10, and 15, representing mild, moderate, and severe anxiety, respectively. It has demonstrated good internal consistency (α=.89) [48].

Columbia Suicide Severity Rating Scale

The Columbia Suicide Severity Rating Scale (C-SSRS) is a 6-item suicide risk screening tool that assesses suicidal ideation and behavior and is used as an exclusionary criterion in this study [49]. It was administered in an interview format, first at baseline and then at the start of each coaching session. The baseline C-SSRS assessed past-month suicidality (with the exception of item 6), whereas the subsequent weekly C-SSRS was used to assess any suicidality between each coaching session. The C-SSRS has demonstrated excellent internal consistency (α=.94) [49].

Hamilton Anxiety Rating Scale

The HAM-A is a structured interview for examiners to rate anxiety severity, and it was used as a primary outcome measure in this study [43]. It assesses anxiety symptoms based on 14 items, each rated from 0 (“not present”) to 4 (“severe”), with scores ranging from 0 to 56. It uses established cutoff scores, where a score of 7 or lower indicates no or minimal anxiety, 8 indicates mild anxiety, 15 indicates moderate anxiety, and 24 or higher indicates severe anxiety [50]. The HAM-A has demonstrated good internal consistency (α=.89) [51].

Hamilton Depression Rating Scale

The HAM-D is a structured interview for examiners to rate depression severity, and it was used as an outcome measure in this study [44]. It assesses depression symptoms based on 17 items, which range from 0 (“not present”) to 4 (“severe”) with total scores ranging from 0 to 54. Among these 17 items, 8 items are rated on a 0 to 2 scale and 9 items are rated on a 0 to 4 scale. In terms of established cutoff scores, a score of 7 or lower suggests no depression, 8 indicates mild depression, 17 indicates moderate depression, and 24 or greater indicates severe depression [52]. The HAM-D has demonstrated good internal consistency (α=.81–.89) [53].

Participant-Reported Surveys

Three exploratory surveys comprising 35 questions were created to assess the acceptability, usability, and user experience of the Rauha DTx.

User Acceptability Survey

This 10-item scale measured overall satisfaction, perceived value, and personal relevance of the Rauha DTx, including how useful and worthwhile participants found its content and structure. Items were rated on a 5-point Likert scale ranging from 1 (“strongly disagree”) to 5 (“strongly agree”). Example items include “My participation on this app was worth the time” and “I am satisfied with the help I received on the app.”

System Usability Survey

This 10-item scale measured users’ perceptions of ease of use, efficiency, and learnability of the Rauha DTx, evaluating whether participants found the interface intuitive and consistent. Items were rated on a 5-point Likert scale ranging from 1 (“strongly disagree”) to 5 (“strongly agree”). Example items include “I think that I would like to use this system frequently” and “I feel very confident using this app.”

User Experience Survey

This 15-item scale measured qualitative aspects of user experience within the Rauha program, including the perceived helpfulness of program features, engagement with multimedia content, and support from mental health coaches. It captured both functional and interpersonal satisfaction with the DTx and coaching components. Items were rated on a 5-point Likert scale ranging from 1 (“strongly disagree”) to 5 (“strongly agree”). Example items include “My mental health coach was critical to my completion of the program” and “I found the mental health coaches to be a useful part of the program.”

Procedures

Recruitment and Screening

Adults interested in participating in the study first initiated contact with study personnel at Endeavors Programs. All

XSL•FO
RenderX

interested adults then preconsented to an initial screening with the GAD-7 and PHQ-9 to establish appropriateness for study inclusion based on anxiety and/or depressive symptoms, respectively, and a self-reported disability. Those who met these initial eligibility criteria were then invited to the study consent process, where the full study details were outlined, including verification of remaining inclusion and exclusion criteria. After signing the consent form, participants were scheduled to complete the baseline HAM-A and HAM-D. Importantly, the HAM-A and HAM-D were administered by licensed clinicians who received the same training to standardize assessment procedures and scoring to maximize interrater reliability. These clinicians were independent from the intervention team, and each participant was evaluated by the same clinician at baseline, post treatment, and follow-up to ensure consistency in assessment and minimize variability due to differences in raters across time points. Upon completion of the structured interviews, participants were invited to download the Rauha smartphone DTx, assigned a coach, and booked for their virtual coaching orientation appointment. This orientation appointment was not part of the treatment but rather was used as an introduction to assist with registering the participant on the Rauha DTx and to help prepare the participant for the treatment itself. Registration for Rauha included a brief disability and demographic screening, a program introduction video by a licensed psychologist, and a coach-led onboarding session to orient participants to the program.

Treatment

The Rauha program targeted both anxiety and depressive symptoms using an 8-week intervention, combining the smartphone-based, self-guided component with weekly sessions led by an NBC-HWC and implementing evidence-based behavior change strategies. The selection of an 8-week intervention period was informed by prior work on both traditional CBT and digitally delivered CBT, as well as practical considerations related to the structure of the DTx and coaching model. CBT is typically delivered as a structured, time-limited intervention, with standard protocols often spanning on the order of 6 to 12 weeks depending on the target condition and setting [54,55]. Internet-based and guided CBT programs follow a similar pattern, with many interventions delivered within a defined multiweek window and a substantial proportion clustering around approximately 7 to 9 weeks [56,57]. An 8-week duration was therefore chosen as a balance between providing sufficient time for skill acquisition and consolidation while maintaining a format that is feasible and consistent with established CBT and digital intervention models.

Each week, the CBT-based smartphone program focused on a new, overarching topic comprising multiple lessons that fulfill that topic (Multimedia Appendix 1). These lessons consist of psychoeducational videos featuring a licensed psychologist, animated videos illustrating therapeutic concepts from an example patient perspective, infographics, and brief reading lessons to teach psychoeducation and various CBT concepts, as well as interactive quizzes and exercises that allow participants to apply the skills being taught. Each weekly digital topic is designed to take approximately 60 minutes to complete and can be divided into smaller segments, allowing participants to engage with the material according to their schedule and preferences.

In addition to the 60 minutes spent in the smartphone program, participants also met with an assigned NBC-HWC for 30 minutes each week. In accordance with board certification training, coaches used a client-centered approach to support participants in identifying mental health–related goals, using behavior change strategies consistent with motivational interviewing, behavioral activation, values identification, and solution-focused behavioral therapy. At the start of each coaching session, coaches administered the C-SSRS to assess suicidality and ensure participant safety. A safety escalation protocol was put in place in the event a participant endorsed any item on the C-SSRS beyond item 2, which would entail a same-day warm transfer back to their referring clinician for further risk management and appropriate treatment planning in the event of nonimminent suicidal concerns. In the case of imminent suicidal intent, emergency services would be activated, followed by notifying the original referring provider for follow-up once immediate safety was confirmed. Following the initial safety assessment, each session proceeded according to a semistructured approach that entailed (1) a brief mood check-in, (2) review of digital CBT content according to that week, (3) reviewing and reinforcing past skills (eg, behavioral activation, values clarification), (4) setting goals for the upcoming week, and then (5) identifying and troubleshooting any barriers to continued skills practice or weekly goals. While this semistructured approach was standardized across participants, coaches were permitted to tailor certain aspects of coaching according to individual needs, so long as it aligned with the framework of the CBT program. Specifically, this tailoring was restricted to the examples used to illustrate CBT concepts, pacing of skill learning based on participant comprehension or engagement, and goal refinement based on individual readiness and unique contextual barriers. NBC-HWC coaching is standardized to support engagement, goal attainment, and real-world application of CBT skills, without providing psychotherapy or modifying CBT content.

Steps were taken to ensure coaching fidelity both before participant enrollment and throughout active intervention, trained by a licensed clinician. Before participant enrollment, coaches were required to complete standardized training in the intervention protocol, undergo ongoing supervision, and adhere to rigorous quality assurance processes, ensuring consistent and reproducible delivery across all participants. This systematic approach was used in order to provide evidence-based support with high fidelity, minimizing between-participants variability and maximizing confidence in outcomes.

Upon completion of the intervention, anxiety and depressive symptoms were assessed using the clinician-administered HAM-A and HAM-D, respectively. These assessments were then administered at 4 weeks post intervention (ie, follow-up) to evaluate the durability of symptom changes. Importantly, even after the 8-week coaching component ended, participants retained access to the smartphone-based CBT program through the 4-week follow-up period, allowing them to revisit any clinical content or exercises.

XSL•FO
RenderX

Statistical Approach

Clinical Outcome Analysis

Regarding the first hypothesis, the retention rate was calculated as the proportion of participants who completed the full 8-week intervention to include all smartphone-based CBT modules and all 8 coaching sessions. All analyses related to the second hypothesis used the sample of participants who initiated treatment. Clinical measures are summarized with means and SDs for continuous measures and percentages for categorical and binary measures. Mixed-effects modeling (MEM) [58] was used for analyses focusing on symptom change. MEM accommodates the within-participant correlation over time for repeated measures, which was fit through a compound symmetry design for the variance-covariance matrix. MEM does not require balanced data per person, where missed assessments are excluded from the analysis. Time was measured discretely by assessment point corresponding to baseline, post treatment, and follow-up and treated as a fixed effect in the MEM. Linear contrasts of the model parameterization allowed us to estimate change from baseline to post treatment corresponding to the intervention effect, as well as change from baseline through follow-up, which allowed us to quantify the durability of the intervention effect. We used partial eta as an indication of within-person change. Following Cohen conventions [59], partial eta squared values of 0.1, 0.3, and 0.5 represent small, medium, and large effect sizes, respectively. Jacobson and Truax [60] criteria informed CSR calculations. Percentages with 95% CIs using the Clopper-Pearson exact CI formulas were used to calculate the proportion of participants achieving a CSR. Additionally, we calculated percent change in symptoms ranging from 10% to 90% for both anxiety and depression with 95% CIs.

Scoring and Analysis of Participant-Reported Surveys

Responses to the user acceptability, usability, and experience surveys were summarized descriptively at both the item and scale levels. For each item, we calculated the proportion of participants selecting each Likert-scale response option, with primary emphasis on the percentage endorsing “agree” or “strongly agree” as an indicator of a positive response. At the scale level, we computed for each participant the percentage of items endorsed as “agree” or “strongly agree,” and then averaged these values across participants to generate overall acceptability, usability, and user experience scores (reported as percentages with SDs). This approach was used given the exploratory nature of the measures and small sample size, prioritizing depth of user perspectives.

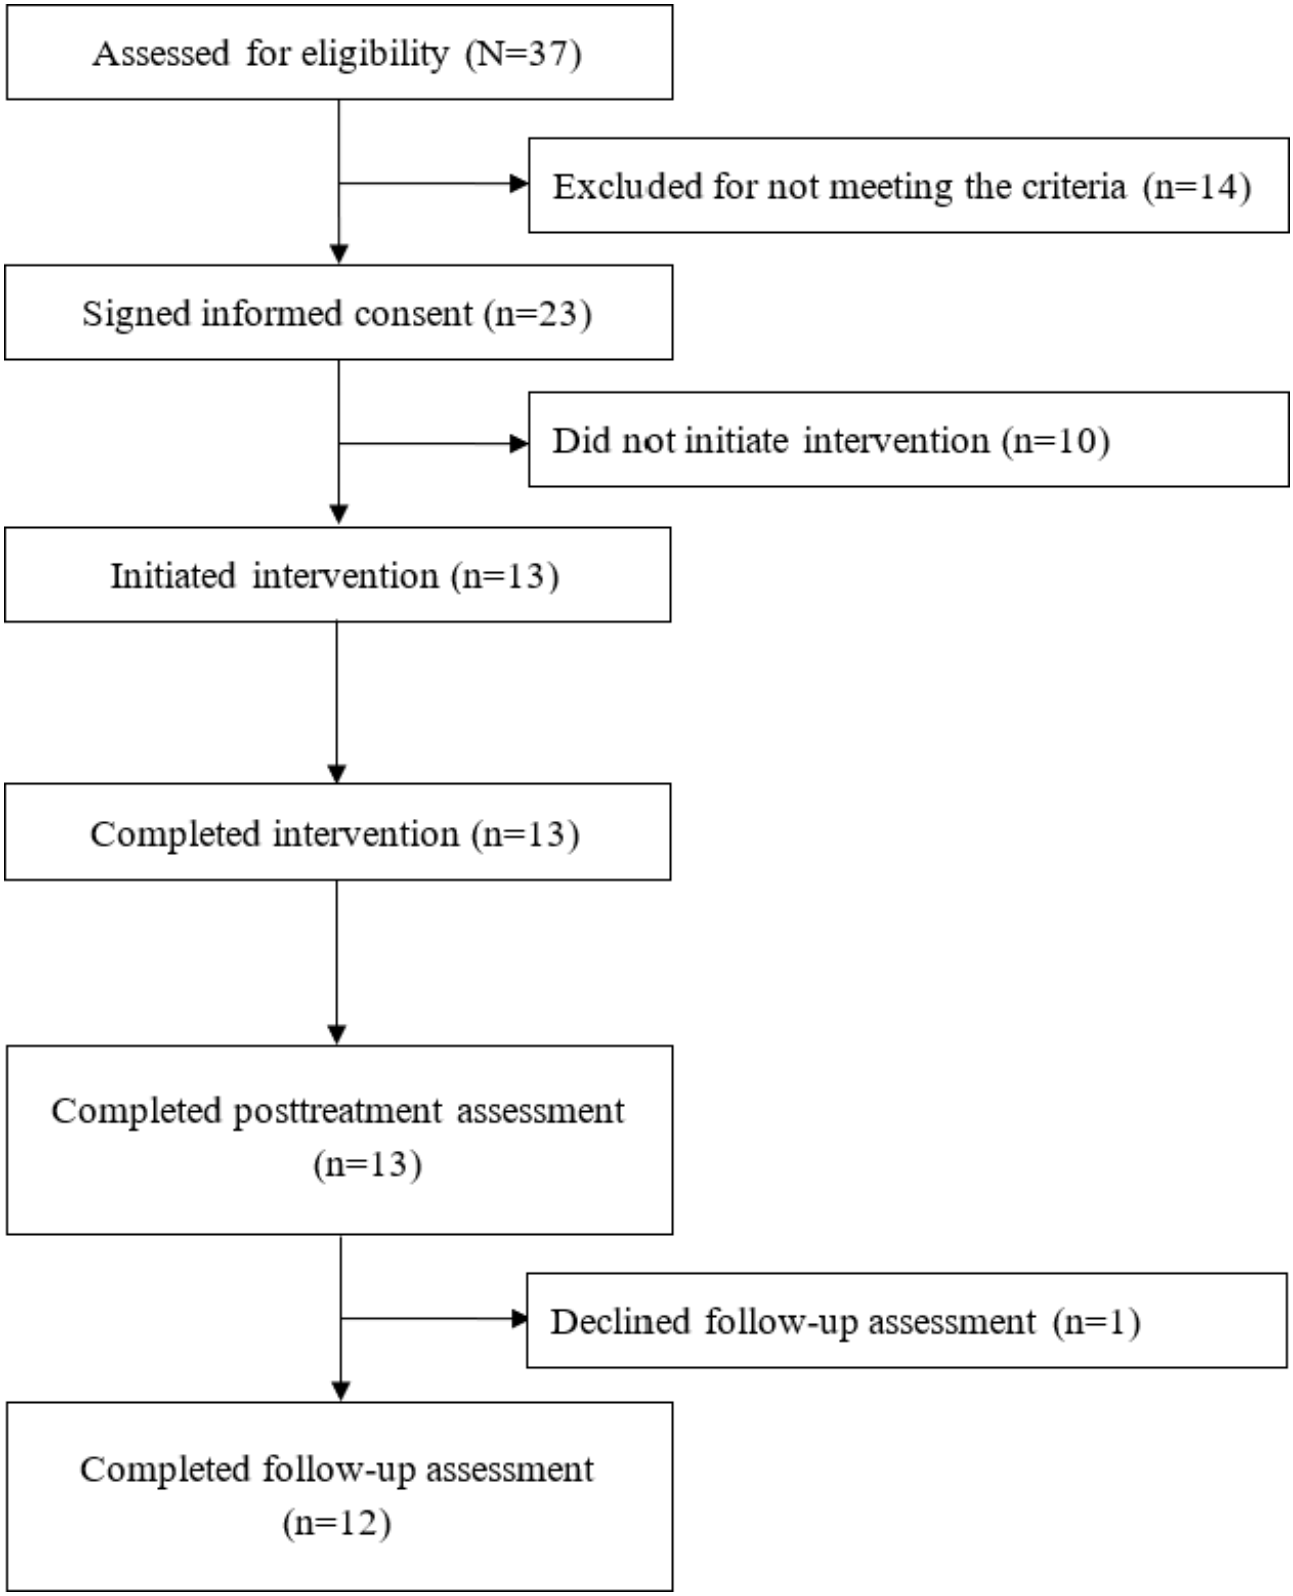
Replay Rate

We examined the replay rate as an exploratory indicator of engagement using platform analytics. The system passively tracks user interactions at the lesson level, including instances where participants returned to previously completed smartphone-based CBT content. A replay event was defined as any access of a completed lesson beyond the initial viewing. For each participant, replay events were summed across the 8-week intervention, and the average replay rate was calculated across participants.

Power Analysis

Prior to the start of the study, preplanned power calculations were based on a 2-tailed test with an α level of .05. Using a subgroup of 72 participants with disabilities reported in previous work [61], baseline HAM-D and HAM-A SDs were 9.1 and 5.5, respectively. Using these SDs with our treatment sample, there was 82.9% and 87.1% power to detect reductions of 8 and 8.5 points, respectively, on the HAM-D. Similarly, there was 78.8% and 85.6% power to detect reductions of 4.5 and 5, respectively, on the HAM-A. As such, the proposed data analysis is proof-of-concept with the goal to serve as initial evidence for a future larger study. With the exploratory nature of our investigation, corrections for multiple comparisons are generally not needed [62]. As such, the level of significance was set at .05 for all analyses.

Results



Study Flow and Retention

A total of 37 individuals were assessed for eligibility, of whom 14 were excluded for not meeting inclusion criteria. Twenty-three participants provided informed consent. Of these, 10 did not initiate the intervention: 1 declined to participate and did not complete baseline HAM-A or HAM-D assessments, and 9 elected not to continue due to preference for live clinician therapy, time-commitment requirements, discomfort with recorded sessions, or inability or unwillingness to complete the intervention on an iOS device. The remaining 13 participants initiated and completed the intervention, with no attrition during treatment, and all 13 completed the post treatment assessment. At follow-up, 12 participants completed the follow-up assessment, with 1 participant declining follow-up participation. Participant flow of the study is shown in Figure 1 (CONSORT [Consolidated Standards of Reporting Trials] diagram), detailing screening, enrollment, intervention initiation and completion, post treatment assessment, and follow-up assessment.

The final analytic sample consisted of 13 adults, of whom 53.8% (n=7) were female participants and 46.2% (n=6) were male participants. Reporting of age and race or ethnicity was optional; 12 of 13 participants reported age and 9 of 13 reported race or ethnicity. Among those reporting age, the mean age was 34.42 (SD 13.51) years. Of the 9 participants reporting race or ethnicity, 5 identified as White, 2 as two or more races, 1 as Hispanic, and 1 as Black or of African descent. With respect to disability status, 6 participants reported a mobility-related disability, 2 reported a hearing-related disability, and 5 reported both mobility-related and hearing-related disabilities. Based on baseline HAM-A and HAM-D scores, 10 participants exhibited clinically elevated levels of both anxiety and depression, 2 exhibited elevated depression only, and 1 participant did not demonstrate clinically elevated anxiety or depression despite meeting inclusion criteria. No participants endorsed any suicidal symptoms.

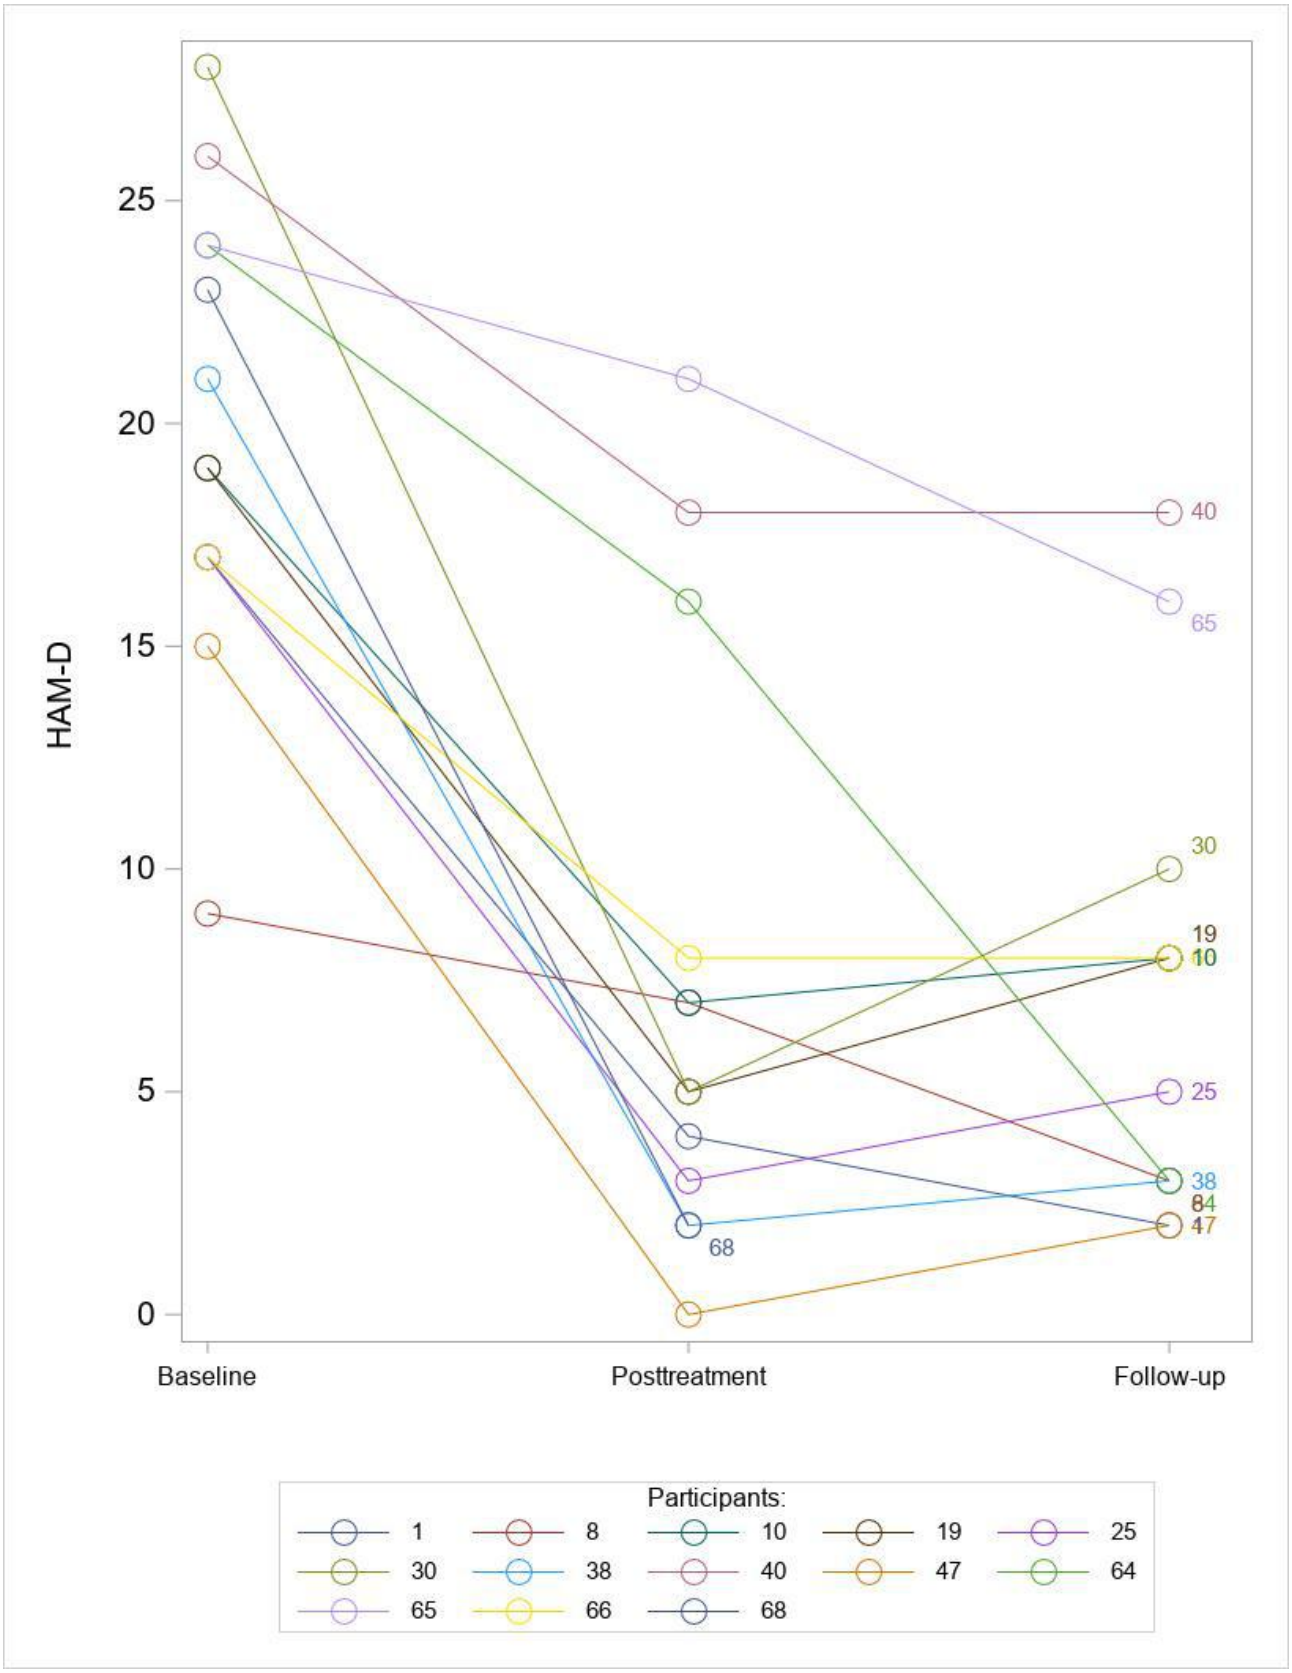
Table . Clinical descriptives by assessment time point (N=13).

Assessment	HAM-D[a], mean (SD)	HAM-A[b], mean (SD)
Baseline	19.92 (5.14)	21.69 (9.35)
Post treatment	7.54 (6.63)	9.85 (8.9)
Follow-up	7.17 (5.36)	9 (7.01)



[a]HAM-D: Hamilton Depression Rating Scale.

[b]HAM-A: Hamilton Anxiety Rating Scale.

Individual spaghetti plots are illustrated in Figure 2 for HAM-D and in Figure 3 for HAM-A. Both figures illustrate 2 major findings in our study: (1) the majority of participants improved over the observational period and (2) the completeness of the data, where all participants except 1 (ID=68, who did not provide follow-up assessment) completed all 3 assessments. Figure 4 illustrates the mean profile over time for both anxiety (HAM-A) and depression (HAM-D).

Figure 4. Mean profile for Hamilton Anxiety (HAM-A) and Hamilton Depression (HAM-D).

With respect to anxiety, we observed a significant average reduction of 11.84 (SE 2.44) from baseline (mean 21.69, SD 9.35) to post treatment (mean 9.85, SD 8.90; t_{13}=4.85, P<.001). From post treatment (mean 9.85, SD 8.90) to follow-up (mean 9.00, SD 7.01), we observed a nonsignificant reduction of 1.24 (SE 2.51; t_{13}=0.48, P=.64). Cumulatively from baseline (mean 21.69, SD 9.35) to follow-up (mean 9.00, SD 7.01) for anxiety, we observed a significant average reduction of 13.05 (SE 2.51; t_{13}=5.21, P<.001), corresponding to a mean shift from moderate to mild anxiety between baseline and follow-up. Partial η estimates quantifying the size of the effect for the change from baseline to post treatment and follow-up were η^2_p=0.80 (95% CI 0.48-0.90) and η^2_p=0.82 (95% CI 0.52-0.91), respectively, corresponding to large effects. Similarly, for depression, we observed a significant average reduction of 12.39 (SE 1.50) from baseline (mean 19.92, SD 5.14) to post treatment (mean 7.54, SD 6.63; t_{13}=8.24, P<.001). From post treatment (mean 7.54, SD 6.63) to follow-up (mean 7.17, SD 5.36), we observed a nonsignificant reduction of 0.44 (SE 1.55; t_{13}=0.29, P=.78). Cumulatively from baseline (mean 19.92, SD 5.14) to follow-up (mean 7.17, SD 5.36), we observed a significant average reduction of 12.83 (SE 1.55; t_{13}=8.30, P<.001), corresponding to a mean shift from moderate to mild/nondepressed between baseline and follow-up. Partial η estimates quantifying the size of the effect for the change from baseline to post treatment and follow-up were η^2_p=0.92 (95% CI 0.76-0.95) and η^2_p=0.92 (95% CI 0.76-0.96), respectively, corresponding to large effects.

Based on published research, we define CSR as a 4-unit change in both HAM-A [63] and HAM-D [64]. Using all 13 participants, with nonresponse corresponding to not achieving CSR, at post treatment, 84.6% (95% CI 54.5%-98.0%) achieved CSRs for both anxiety and depression. At follow-up, 76.9% (95% CI 46.2%-95.0%) achieved a CSR in anxiety and 92.3% (95% CI 74.0%-99.0%) in depression. Interestingly, 1 participant (ID=8) started the study without an elevation in the HAM-A or HAM-D but still displayed a CSR in both. As CSR can depend on initial measurement score, the percentage of participants achieving a symptom reduction ranging from 10% to 90% (in 10% increments) from baseline to post treatment and baseline to follow-up are shown in Tables 3 and 4, respectively.

XSL•FO
RenderX

Table . Percentage of participants reaching percentage thresholds of symptom reduction from baseline to post treatment (N=13).[a]

Symptom reduction[a]	HAM-D[b], percentage of participants (95% CI[c])	HAM-A[d], percentage of participants (95% CI[c])
10% reduction	100 (75.3 - 100)	84.6 (54.6 - 98.1)
20% reduction	92.3 (64.0 - 99.8)	76.9 (46.2 - 95.0)
30% reduction	84.6 (54.6 - 98.1)	69.2 (38.6 - 90.9)
40% reduction	69.2 (38.6 - 90.9)	61.5 (31.6 - 86.1)
50% reduction	69.2 (38.6 - 90.9)	61.5 (31.6 - 86.1)
60% reduction	61.5 (31.6 - 86.1)	53.8 (25.1-80.8)
70% reduction	53.8 (25.1 - 80.8)	46.2 (19.2-74.9)
80% reduction	38.5 (13.9 - 68.4)	46.2 (19.2-74.9)
90% reduction	23.1 (5.04 - 53.8)	7.69 (0.19-36.0)

Figure 5 summarizes the acceptability, experience, and usability of the Rauha smartphone platform. Among participants who agreed or strongly agreed based on direct DTx experience, 85.6% (SD 10.4%) reported positive acceptability, 87.7% (SD 8.3%) reported positive experience, and 85.0% (SD 6.3%) reported positive usability. The most highly endorsed items (>90%) highlight the aspects of the program driving the positive user experience: overall satisfaction with the treatment program, relevance of treatment strategies to daily life, the central role of mental health coaches in treatment success, use of video and text delivery within Rauha, ease of understanding digital content, and confidence in using the platform. Importantly, there was no negative feedback on any item across these self-report surveys and no accessibility issues, given the WCAG 2.2 AA standards of the smartphone program. These findings underscore that participants valued not just general satisfaction but specific program components that supported engagement, skill application, and confidence in using Rauha effectively.

XSL•FO
RenderX

Figure 5. Ratings of acceptability, user experience, and usability of the Rauha program. UAS: User Acceptability Scale; UEQ: User Experience Questionnaire; SUS: System Usability Scale.

Regarding replay rate, participants revisited previously completed CBT lessons multiple times over the course of the intervention, with an average replay rate of 5.5. Replay behavior was derived from platform usage analytics, with some modules showing higher repeat access based on user interaction patterns (eg, repeated entry and time spent within lessons). In the context of consistently high acceptability, experience, and usability ratings, this pattern of re-engagement is more consistent with voluntary reuse of content than with difficulty understanding the material.

Discussion

Principal Findings

The central aim of this study was to evaluate Rauha—a mental health DTx intervention combining an asynchronous, CBT-based treatment with a synchronous NBC-HWC implementing behavior change strategies—in treating symptoms of moderate-to-severe anxiety and depression in adults with hearing and/or mobility-related disabilities. We hypothesized that (1) there would be a treatment retention rate of at least 80%, and (2) there would be a CSR in internalizing symptoms from pretreatment to post treatment and through follow-up. The data supported both hypotheses, with a retention rate of 100% and a statistically and clinically significant decrease in both anxiety and depression symptoms on average that was sustained during the 4-week follow-up. Furthermore, this average decrease in symptoms far exceeded the minimum threshold for clinical significance by a magnitude of 3, such that participants had even more benefit than expected.

This is the first known study to assess the treatment effect of a WCAG 2.2 AA–certified platform-aligned DTx combined with a weekly, virtual NBC-HWC to treat moderate to severe symptoms of anxiety and depression in adults with disabilities. In addition, as noted previously, 1 participant with subclinical baseline levels of both anxiety and depression nevertheless achieved a CSR despite a generally lower capacity for symptom change among those with lower baseline severity [9]. Given these results, this study offers strong preliminary data to support this novel approach to treatment. In addition, the 100% retention rate also speaks to the acceptability and engagement of the treatment itself, given that treatment retention is often an issue both in research [65] and clinical [66] settings. These findings extend the overall evidence of CBT-based interventions to less-used treatment modalities while also being applied to an underserved clinical population, adults with disabilities and functional limitations. The clinically significant outcomes from this study are either commensurate with or exceed many previous outcome studies, including internet-based CBT [18,67,68], traditional CBT delivered as weekly individual

XSL•FO
RenderX

therapy [69-71], combined internet-based and individual face-to-face CBT [70,72-74], and CBT combined with pharmacotherapy [75].

At a systems level, and as it relates to barriers prohibiting access to adequate treatment, both of the Rauha treatment components can increase overall access to care, as self-guided treatment does not require time from a provider for a patient to receive care, and there are over 12,000 NBC-HWCs that can be considered part of the otherwise limited mental health resources to drastically expand treatment options [76]. Thus, CBT and other evidence-based approaches can be highly scaled with this approach without sacrificing clinical impact.

Strengths and Limitations

This study has several notable strengths. First, it evaluated a novel, digitally delivered CBT intervention targeting an underserved population with nuanced physical and mental health needs, addressing a critical gap in accessible mental health care. These findings extend our understanding of the potential for nontraditional treatment modalities and suggest that CBT can remain clinically impactful even when delivered through a smartphone-based DTx. Second, the use of clinical significance, in addition to statistical significance, provides a richer assessment of treatment impact, highlighting the clinical meaningfulness of Rauha for patients. Third, the inclusion of a 4-week postintervention follow-up allowed for a preliminary assessment of the durability of symptom improvements. While this time frame provides early support for the maintenance of treatment effects, longer follow-up periods are needed to fully characterize sustained outcomes in anxiety and depression. Interestingly, there was an increase in clinically significant improvement in depression between post treatment and follow-up, which may be attributable to participants having continued access to the smartphone-based CBT program to revisit relevant clinical content, though the robustness of such a finding would require further research. Finally, assessing user acceptability, experience, and usability offers greater insight into the participant's experience with the DTx, demonstrating highly positive views regarding the ease of use, DTx content, and coaching sessions. Together, these elements underscore the potential of Rauha as a scalable, accessible, and evidence-informed treatment.

This study has several limitations that should be considered when interpreting the findings. First, the sample size was small, which limits statistical power, the precision of estimates, and the generalizability of findings. Accordingly, the observed large effect sizes should be interpreted with some caution and considered preliminary support for proof-of-concept requiring replication in higher-powered clinical studies. Second, the participant population was limited to individuals with hearing and mobility disabilities, and researchers allowed certain demographic disclosures to be optional for participant comfort. Future efforts could expand representation across a broader range of functional and accessibility challenges and require demographic reporting, which would enhance generalizability. Third, the study did not include a control condition, which limits formal causal inference such that results may reflect uncontrolled factors (eg, natural symptom fluctuation, placebo effects, regression to the mean, or untracked changes in medication during the intervention). Given this, future studies incorporating a control condition are planned to rigorously assess causal treatment effects. Fourth, participants were recruited in part through a mental health clinic, which may introduce selection bias, as the individuals referred may differ from the broader population in terms of treatment readiness, clinical profiles, and motivation to engage in care. Future studies can address this by using more diverse recruitment strategies to strengthen generalizability. Finally, because Rauha combines a self-guided digital component with NBC-HWC support, it is not possible to attribute the observed outcomes to either component alone. That is, the present design does not allow for attribution of effects to either the digital CBT component or the coaching component independently. Future studies using component analyses or factorial designs are needed to isolate the mechanisms of change and optimize the intervention itself by identifying the most impactful factors. Collectively, these limitations highlight the need for continued research while underscoring the promising potential of Rauha to improve outcomes in this population.

Conclusions

To our knowledge, this is the first study to evaluate a hybrid digital CBT intervention—combining self-guided, smartphone-delivered CBT with live weekly sessions led by a NBC-HWC—for adults with disabilities experiencing anxiety and/or depression. The findings provide preliminary support for clinical benefit of Rauha, high engagement, accessibility, and scalability, while identifying important directions for future research. Importantly, this work supports the potential of a coordinated digital CBT and coaching model to address persistent barriers to care and deliver flexible, clinically meaningful support to populations historically underserved in mental health services. Overall, Rauha represents a promising, evidence-informed approach that extends the reach of CBT and highlights the value of integrating DTx with coaching to improve mental health outcomes among adults with functional and accessibility challenges.

Abstract

Background: Digital health technology enables collection of continuous physiological and behavioral data from participants in clinical trials. This supports hybrid trial designs, potentially reducing clinic visits and participant burden for patient monitoring. Interstitial lung disease (ILD) is characterized by an unpredictable clinical course, creating a need for new treatments and more sensitive approaches to assessing treatment effectiveness, disease progression, and clinically meaningful trial end points.

Objective: This study aimed to explore the experiences of individuals with ILD using digital tools in a clinical study to inform digital health–enabled clinical research.

Methods: This qualitative study was conducted within the PRODIGY-ILD (Predicting Outcomes using Digital Technology in Interstitial Lung Disease) cohort, a prospective observational study using wearable devices and electronic patient-reported outcome measures for a planned 3 years of longitudinal monitoring. Participants were recruited from a specialist outpatient ILD clinic. A topic guide was developed iteratively, and individual semistructured interviews were conducted remotely via Zoom (Zoom Video Communications, Inc) and/or telephone, audio-recorded, and transcribed. Data were analyzed using reflexive thematic analysis with NVivo software (Lumivero).

Results: Fifteen of the final 20 participants recruited to the PRODIGY-ILD study consented and completed interviews. Four key themes were identified, highlighting how trust, digital literacy, participant-initiated engagement with data, and illness burden shape sustained participation in digital health–enabled clinical research: (1) trust and altruism override data concerns: confidence in researchers' data handling and a desire to contribute enabled data sharing; (2) navigating digital tools: friction and flexibility: digital literacy, usability, and device compatibility varied, but participants were able to use workarounds to maintain engagement; (3) participant-initiated engagement with wearable data: participants moved from passive to active engagement, in many cases integrating devices into daily routines; and (4) life-limiting illness as a constraint on digital trial participation: managing symptoms and severe comorbidities reduces motivation and engagement with study technology.

Conclusions: Despite participants' motivations to contribute data to research, engagement was shaped by usability, participant-initiated engagement, and the constraints of living with chronic illness. There is a need for patient-centered design, tailored support, and flexible trial procedures to optimize adherence in digital health–enabled clinical research.

KEYWORDS

digital technology; interstitial lung disease; remote monitoring; clinical trials; qualitative thematic analysis

Introduction

Interstitial lung diseases (ILDs) are a heterogeneous group of chronic respiratory conditions characterized by significant symptom burden and progressive declines in lung function typical of fibrotic phenotypes [1]. The clinical course of ILD is often unpredictable, with periods of stability punctuated by episodes of deterioration that can be difficult to identify early using traditional, clinic-based measures [1]. Recent studies on the feasibility and acceptability of home monitoring to provide real-world data for patients have been promising [2-9]. Advances in digital technology, including smartphone apps and wearables,

XSL•FO
RenderX

offer opportunities to collect continuous and timely data on physical activity, symptoms, and physiological parameters to augment outpatient clinical data and to monitor participants in clinical trials [10].

Although digital monitoring in ILD has shown promise, a mixed methods study by Althobiani et al [11] suggested that patients may experience both reassurance and burden when engaging with self-management using digital monitoring, with engagement shaped by symptom severity, treatment effects, and uncertainty around how monitoring data are interpreted or acted upon clinically. However, existing studies have largely assessed the acceptability of digital monitoring using cross-sectional surveys [11] or short-term evaluations; little is known about how patients experience sustained engagement with these technologies over time. This study addresses this gap by examining the lived experience of participating in a longitudinal digital monitoring program for ILD, capturing how engagement evolves across differing clinical trajectories. Understanding how patients experience, perceive, and adapt to digital monitoring in real-world contexts is essential to ensure that these technologies are acceptable, feasible, and responsive to patient needs, facilitating sustained engagement and data quality.

PRODIGY-ILD [12] (Predicting Outcomes using Digital Technology in Interstitial Lung Disease) is a prospective cohort study designed to examine whether remotely collected electronic patient-reported outcome measures (ePROMs) and wearable-derived physiological data can identify early indicators of disease trajectory in people living with ILD, for a planned 3-year follow-up. In this study, participants completed regular symptom-based ePROMs, including weekly and monthly measures, and wore a smartwatch that passively captured behavioral and physiological data throughout follow-up, as described in the study protocol [12]. The primary quantitative analysis focus was on identifying candidate digital biomarkers and understanding temporal patterns in symptoms and physiology across the disease course. What remains underexplored is how participants live with, interpret, and adapt to digital monitoring over time, particularly when technologies are embedded within life-limiting illness. This qualitative substudy, nested within the PRODIGY-ILD study, aimed to explore participant experiences, attitudes, and perceptions of using the MyCap app (Vanderbilt University Medical Center), the companion app to REDCap (Vanderbilt University) research software for ePROMs and the Apple Watch wearable device, to inform the development of future digital health design for clinical trials [13,14].

Methods

Design and Theoretical Approach

Overview

This study was designed as a qualitative study with individual interviews. A qualitative design with individual interviews was selected to capture the depth, nuance, and lived experience of participants in a one-to-one setting, enabling a rich and contextualized understanding that cannot be fully represented through quantitative measures alone. The COREQ (Consolidated Criteria for Reporting Qualitative Research) [15] 32-item checklist (Checklist 1) informed the study design and was used for transparency and completeness of reporting interviews.

Positioning

This study was informed by an experiential critical realist stance [16], recognizing that while ILD and associated physiological changes represent real underlying phenomena, participants' experiences of symptoms and digital health technologies are subjectively perceived and socially mediated. Knowledge was therefore understood as being generated through participants' accounts of lived experience, coconstructed through interaction with the researcher and shaped by the analytical framework applied.

This epistemological position has important analytic implications, particularly given the researcher's prior involvement in the wider PRODIGY-ILD study. Rather than treating prior relationships as a source of bias to be eliminated, they were understood as a contextual feature of the research process that could shape both data generation and interpretation. Familiarity between participants and the researcher may have influenced what participants chose to disclose, how experiences were framed, and the assumptions embedded within accounts.

Reflexive thematic analysis was therefore used, explicitly acknowledging the active role of the researcher in meaning-making. Reflexivity was operationalized through ongoing critical self-reflection throughout data collection and analysis, including the use of reflexive memo-writing to document assumptions, emotional responses, and evolving interpretations, and regular revisiting of analytic decisions to consider how the researcher's positionality and prior knowledge may have shaped theme development. Themes are understood as analytic constructions rather than emergent truths, and interpretations were iteratively refined through engagement with the data and discussion within the research team, ensuring that themes remained grounded in participants' accounts while recognizing the interpretive nature of qualitative analysis.

Development of Interview Guide

The interview guide was developed through a comprehensive process that drew upon existing literature, team discussions, and pilot testing with 2 participants. The approach was iterative, allowing for continual refinement to ensure the guide was both relevant to the study objectives and responsive to participant feedback. Key topic areas included onboarding, usability, perceived usefulness, impact on daily life, privacy concerns, and suggestions for improvement. The guide consisted of open-ended questions, supplemented with targeted prompts, to facilitate in-depth exploration of participant experiences. Further details of the interview template and question structure are provided in Multimedia Appendix 1.

Participant Recruitment and Sampling

Participants were recruited from the existing PRODIGY-ILD study cohort (n=20 final number onboarded between April 30 and November 22, 2024) attending the specialist ILD outpatient clinic. The inclusion criteria were as follows: (1) age ≥18 years,

XSL•FO
RenderX

(2) diagnosis of idiopathic pulmonary fibrosis or progressive pulmonary fibrosis, and (3) ability to provide written informed consent. The exclusion criteria were as follows: (1) patients who are unwilling to wear a smart watch for the duration of the study and (2) cognitive impairment or inability to understand and follow instructions that would limit the patient's understanding of the project or the measurement.

A purposive sampling approach was used, whereby individuals were invited to participate based on their direct experience of living with ILD and engagement with wearable and app use as part of the parent study. All eligible participants were sent a text message and a hard-copy patient information leaflet and informed consent form to inform participants of the qualitative substudy (Multimedia Appendix 2). Reasons for nonparticipation included death, withdrawal from the parent study, being too unwell, or personal reasons.

Data Collection

One-on-one semistructured interviews were conducted between July 16 and August 20, 2025, using the Zoom online platform (Zoom Video Communications, Inc) to conduct and record the semistructured interview using Zoom's autotranscription function. Three participants were unable to log on to Zoom and were interviewed by phone, the audio of which was recorded and autotranscribed by Zoom. Patient A's wife was present and Patient B's son was present during the interviews; however, both answered all questions independently. Participants were interviewed once. Interviews lasted between 18 and 51 minutes and were recorded with permission. Notes were taken after each interview to document details and initial impressions. Transcripts were checked against the recordings for accuracy after each interview. All transcripts were anonymized according to COREQ. Member checking was not performed to reduce participation burden.

Data Analysis

Reflexive thematic analysis was conducted in line with Braun and Clarke's 6-phase approach [17,18], using an inductive approach, allowing patterns of meaning to emerge from participants' accounts, such that theme development was not constrained by predefined categories.

Thematic analysis proceeded through the following stages, once audiochecked anonymized transcripts were imported into NVivo qualitative data analysis software (Table 1).

Table . Practical workflow.

Step	Activity	Tool or platform
Interview and record	Semistructured interviews	Zoom and/or phone call
Transcription	Auto + manual cleaning	Word
Coding and theme generation	Manual and NVivo and Word	NVivo and Word
Reflection and reporting	Summarize and contextualize	Word and Word tables

Researchers familiarized themselves with the transcripts by reading them multiple times. They then generated initial codes, which included usability domains such as onboarding and reminders, as well as inductive codes that emerged directly from the data. These codes were subsequently grouped into candidate themes, which were reviewed and refined iteratively to ensure coherence and distinctiveness, reflecting the principles of reflexive thematic analysis. Analytic credibility was supported through the maintenance of a detailed audit trail documenting iterative theme development. Regular discussions among the research team provided a forum for reflexive dialogue, in which interpretations were questioned, alternative readings considered, and analytic decisions refined, recognizing that themes represent informed analytic judgment rather than objective consensus. Consideration was also given to the inclusion of deviant cases and contrasting viewpoints, with divergent perspectives actively sought and incorporated to ensure a comprehensive understanding of participants' experiences.

Once the themes were finalized, they were defined and named, and the findings were reported with illustrative participant quotes to provide context and depth.

NVivo was used for parent and child coding; the coding structure is detailed in Multimedia Appendix 3. Themes are presented alongside tables of relevant participant quotes, and divergent perspectives are highlighted to reflect a range of experiences. The clinical trial context is also provided to aid the interpretation of themes within the broader study framework.

Research Team and Reflexivity

Interviews were conducted by EG pursuing a PhD in digital technology for clinical trials at the time of the study. All participants were known to the researcher through their enrollment in the PRODIGY-ILD study prior to the interviews. The interviewer introduced herself in the context of her research role and explained that the interviews sought to explore participants' experiences and perspectives on wearable technology use and apps for patient-reported outcomes. Participants were aware of the overarching study aims but were not provided with the specific interview questions in advance.

This prior familiarity between the interviewer and participants may have fostered a sense of trust and openness, encouraging participants to share their honest experiences and perspectives more freely. Additionally, the interviewer's background and expertise in clinical trials and digital health may have shaped the direction of the interviews, with her insights and probing questions encouraging deeper exploration of topics related to digital technology use in health care. Overall, these factors likely contributed to a data collection process that was more attuned to the study setting, while also necessitating reflexivity to account for potential influences on participants' responses.

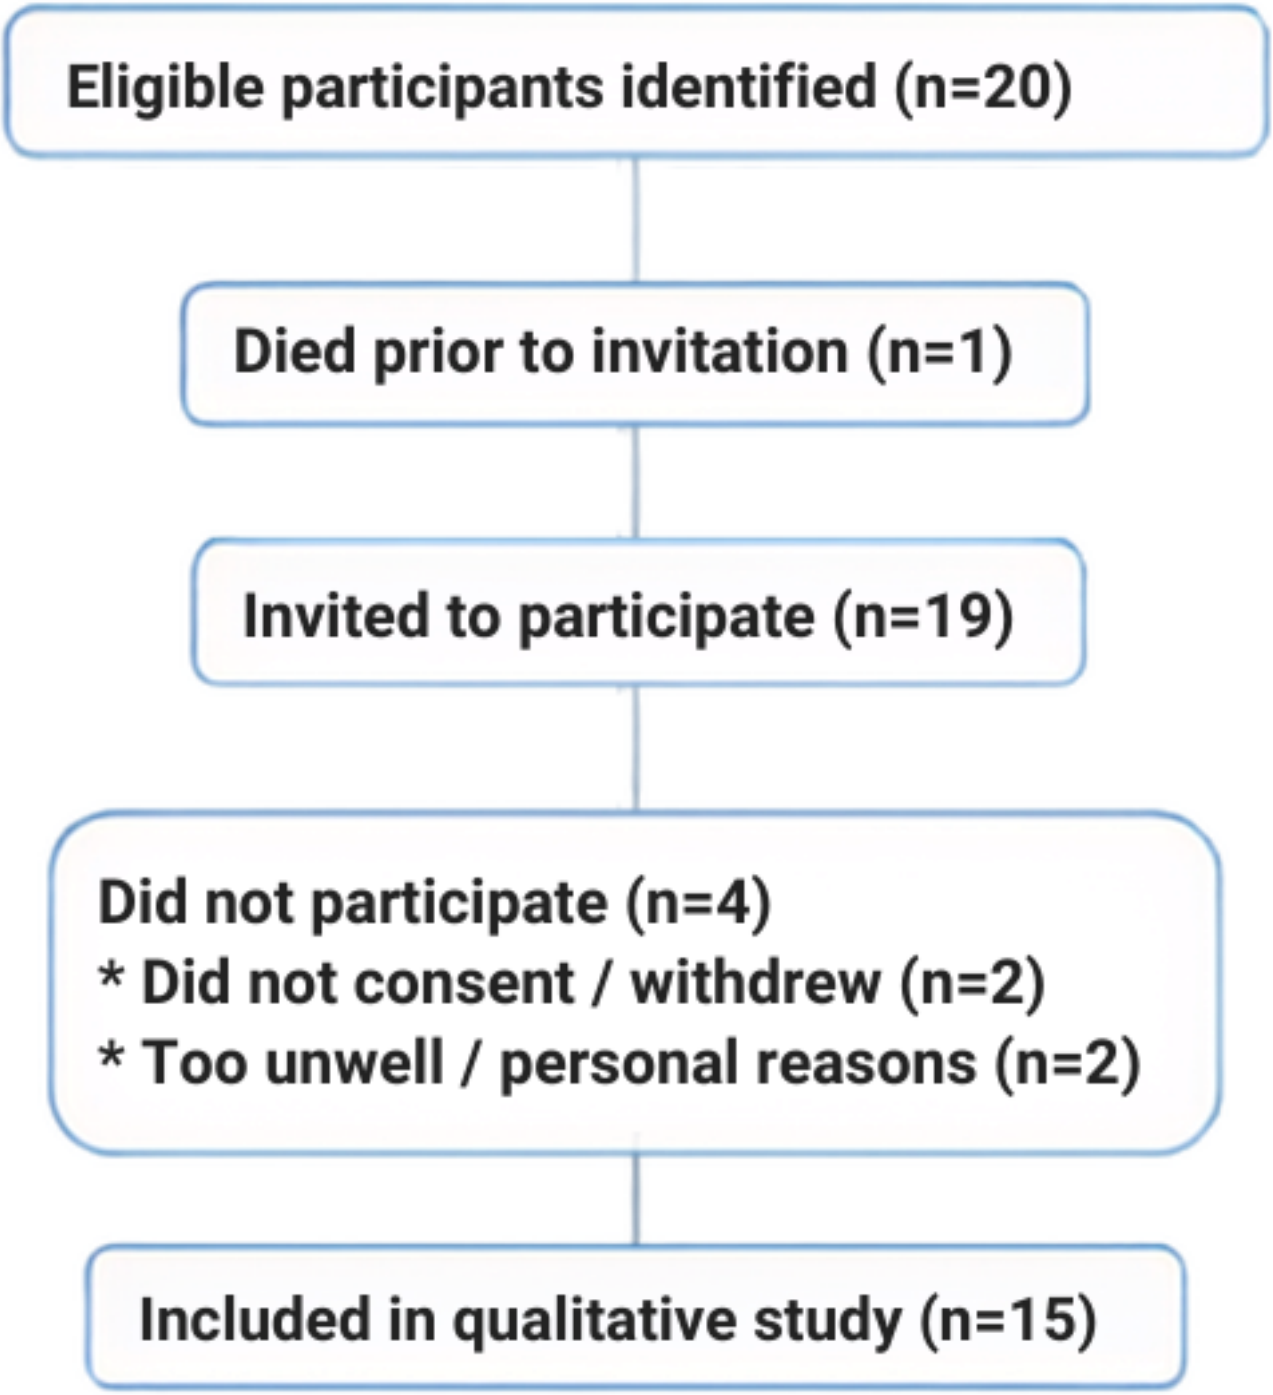
Ethical Considerations

Full ethics approval was granted for this research study by the St. Vincent's University Hospital Research Ethics Committee (reference number: RS23-023). Explicit consent was sought from participants for the collection and processing of their data. Data processing agreements are in place to ensure that personal data are processed as is necessary to achieve the objective of the health research and to ensure that data shall not be processed in such a way that might cause damage or distress to the participants. St. Vincent's University Hospital and University College Dublin are joint data controllers for the study. This study complies with the General Data Protection Regulation. Study results are being presented at medical conferences and disseminated via peer-reviewed journals.

Results

Overview



In total, 15 participants completed the qualitative study (Figure 1).

Demographics of study participants are presented in Table 2. Participants were 80% (12/15) male, 86% (13/15) Caucasian, with a mean age of 62 (SD 16.3) years. This demographic is very similar to the overall PRODIGY-ILD dataset, where participants were 80% (16/20) male, 90% (18/20) Caucasian, with a mean age of 62.5 (SD 14.8) years. Patient-reported outcome measure (PROM) completion was high over the first 12 months (overall adherence >99%). Smartwatch wear time was similarly high, with a median wear time of approximately 96% (IQR 95.9%-99.5%) over 12 months, indicating sustained engagement with the digital monitoring protocol (Multimedia Appendix 4).

Our findings produced 4 main themes with subthemes (Figure 2). NVivo parent and child codes for each theme are available in Multimedia Appendix 3.

Theme 1: Trust and Altruism Override Data Concerns

Reflexive Thematic Concept

In the context of digital surveillance within clinical trials, participants' decisions to share personal health data are not solely determined by individual privacy concerns, but are influenced by confidence in research teams, ethical frameworks, and the belief that their contributions have meaningful impact. This analysis synthesizes 3 core subthemes: trust in safeguards and researchers, altruistic motivation, and low perceived sensitivity of data.

Trust in Safeguards and Researchers

Participants described why they felt comfortable sharing their data, highlighting the importance of transparent communication in building trust. One patient noted:

> *...I wasn't worried, because...I knew from talking to yourself, it's going to be people who require that information…and are going to use it. To see if they can make improvements.* [Patient C]

One patient backed this up by saying:

> *As I say, you know, I mean…there's not enough trust in this world…if you're doing something like this…then you trust the people that are doing it are gonna be…with all the information.* [Patient D]

These sentiments underscore how personal interactions with researchers can directly influence participants' willingness to share sensitive data.

Participants accepted data sharing within the "safe" frame of health research in a University Hospital environment with project approval by the Ethics committee. One patient commented, "...obviously, you know, you've got fairly strong ethics...to consider..." (Patient E). One patient said, "I just thought….It's [name of university], it's a…public body, you got to trust people, don't you?" (Patient F). This participant's willingness to share data was rooted in the institution's reputation.

These findings suggest that clear communication regarding clinical trial governance, such as data security and institutional trustworthiness, may be critical for participant recruitment and retention in clinical trials.

Altruistic Motivation

Participants' belief that their data could help others promoted their willingness to share. Participants expressed a variety of altruistic motivations for sharing their health data (Table 3). The responses suggest that participants viewed their data sharing as a way to directly support others facing similar health challenges, demonstrating a strong sense of empathy and desire to make a positive impact. Participants appeared to see their involvement as an opportunity to advance medical research and improve therapeutic options, reflecting a commitment to the broader scientific community. In addition, participants viewed their data sharing as a way to create a legacy of improved care for others, reflecting a strong sense of social responsibility and a desire to contribute to the well-being of future generations.

XSL•FO
RenderX

Table . Participant altruistic motivations for sharing health data.

Altruistic motivation	Illustrative participant quotations
Helping others directly	• Patient F: "...with the watch..., if it's going to help somebody else [will] wear it.…If it helps collect data, to find,…trends and stuff like that, then that's good, isn't it?" • Patient G: "Oh I have no problem with that, Oh, God, no not a problem at all. If it helps others. If it helps with, you know what I'm going through, and probably will be going through worse, I suppose. If it helps others I have no problem at all. No problem. No. No why, why would it bother me at all? No. As I say, if it helps someone else, it's a great thing." • Patient C: "Didn't bother me…it doesn't, as I say, it's not something that I get excited about. I mean I have a progressive illness.…If I can help, by doing, we'll say, this, then, take as much information as you require. Do you know, that's my attitude…"
Contributing to research and advancing knowledge	• Patient H: "Oh, fine! If it could be of benefit, that's great! I mean….Because I find it convenient, and I like it….And mainly what I like, too, is the idea that you are...you're doing this study." • Patient E: "...and if it'll help you know, to develop, you know, some additional therapies or monitoring with them. That's a very good thing. So no, I have no issue with it at all." • Patient J: "I'm glad that it is being collected,…If we can help, alleviate problems, for other people isn't that…only good. If it contributes to knowledge about this disease. I'm in favour of that. Yes." • Patient I: "I would say that they definitely should consider. Joining it, because really, like, interesting.…Because you could help, like, them to see what's actually going on and make, you know, new medicine or something. To…to help people with the same condition."
Supporting future generations	• Patient D: "Well, no, I mean, it's…if the research…leaves…a better understanding….And things like that. And it could help future generations, like…" • Patient K: "I'd say you're giving information now that in the future, people could use, hopefully. For the betterment of life, I suppose. For other people's health. I'd say, we're here today, and we get all our medicines through other people doing what we're doing. But they did it years ago. And…they've improved our lives. So why shouldn't we pay back and improve? Maybe our grandchildren's life, or whatever. With all this data, all this information, and they correlate it all together. You know well, it's amazing, what you folk can do with it. I haven't a clue, but, you know."

Overall, the range of altruistic motivations expressed by participants, whether helping others directly, advancing research, or supporting future generations, highlights an overarching willingness to share health data for the greater good. These authentic participant voices reinforce the importance of recognizing and honoring these motivations in the design and communication of health research studies.

Low Risk

Participants described the health data collected by digital devices (such as steps or heart rate) as nonsensitive and therefore were not concerned about who might access it. Comparisons to bank details were common: for instance, one participant who felt largely unconcerned about sharing this kind of information explained, "I can't see what…anybody could gain out of it, like, it's not like you're giving them your bank details and things like that." This sentiment was given by another participant, who clarified, "And again, if I mean, it's not information. That's you know. It's not my bank account details." Such comparisons to the sensitivity of banking information emphasize the distinction between health data and sharing perceived high-risk financial details.

For these individuals, the relatively harmless nature of physical activity or biometric data reduced perceived risks; as one participant put it, "It's useless," suggesting that the information collected was not "usable by somebody else." Another participant described their cautious approach to financial data, stating:

> *No....The less people to have access to my bank details, the better. I mean, I'll get some apps that come up, and it says, oh, like, I want you to pay this or pay that, and I just…I just…delete them straight away, like...*

These views illustrate how perceptions of sensitivity are shaped by the type of data in question.

However, one participant admitted some hypothetical unease:

> *I'm not sure…what I would think…if I heard somebody was hacking my devices and taking my*

XSL•FO
RenderX

> *health data. Because…I'm not sure if there's anything personal in what the watch is collecting. Sorry, sorry. When I say personal, I mean usable by somebody else.*

This response highlights the variability in how participants assess the sensitivity of their data and that, for some, concerns about unauthorized access linger even when the data seem relatively harmless.

This response may reflect varying levels of digital literacy or previous experiences with data breaches, suggesting that educational interventions could influence perceived sensitivity. For many, a low perceived sensitivity facilitated trust and willingness to share, while for one, residual concerns persisted. These findings indicate that researchers must remain attentive to the different perceptions of data sensitivity and tailor engagement strategies accordingly.

Taken together, these findings suggest that participant engagement with digital health trials can be supported by building interpersonal trust, transparent ethical safeguards, and clearly framing the perceived value and safety of the data being collected. Researchers should consider how trial communications, onboarding, and technology framing can promote a sense of contribution without harm.

Theme 2: Navigating Digital Tools: Friction and Flexibility

Reflexive Thematic Concept

Participants' experiences with wearable technology and its accompanying app were strongly shaped by individual attitudes, digital literacy, device usability, and workaround strategies. While some approached the technology with confidence and curiosity, "I suppose I tried it because I love gadgets…I was never not going to have a smart watch," others encountered hesitancy and anxiety when facing practical challenges such as charging, syncing, or app lag. The type of smartphone (Android vs Apple) and the need to use unfamiliar or multiple devices created additional friction. One patient shared:

> *I haven't used apple things before, so…to be honest, I had…I can hardly make head or tail of the…iPhone, to be honest with you.* [Patient J]

Technological Literacy

Literacy played a key role in shaping participants' engagement with the digital tools. Individuals who were more comfortable with digital devices generally described the technology as intuitive, unobtrusive, and even enjoyable to use. One patient described the watch as being, "a brilliant piece of technology,…I found it so helpful" (Patient C). For these participants, some cited age (Patient L) as an advantage with fewer barriers. Others described overcoming initial hesitations or lack of interest (Patient I).

In contrast, participants with lower technological confidence described themselves as "technophobes" and often relied on family or informal caregivers for setup and troubleshooting. As one patient described, "my daughter set it up for me…knew what the phone was all about. So, yeah, I got used to it pretty quick" (Patient K). Some participants acknowledged a shift in attitude as the perceived usefulness of the tools became clearer, suggesting that skepticism was not fixed but context-dependent (Patient J).

The varying levels of technological confidence, experiences, and attitudes (Textbox 1) among participants highlight the need for tailored onboarding processes and ongoing support.

Textbox 1. Participant experiences with technology.

Positive experiences

- Patient L: "To be honest, it was fine for me. I suppose maybe my age helped that. If I'd been older, obviously, it would have been more of a struggle."
- Patient E: "I'm perfectly happy with the technology. You know, to me, it's….As technology goes, it's very easy."
- Patient I: "I just never really think about it at all, or had the idea to actually use it. But now, since I started using it, I find it really more interesting. How it can track everything."
- Patient C: "Give it a chance. Use it, because you will find it useful. The technology isn't scary, and it works. And I found it incredibly helpful in my day-to-day activities."

Challenges and scepticism

- Patient F: "I was always a bit of a technophobe. I tended to think they were a bit of a...a bit some of the things a bit gimmicky, some of the stuff."
- Patient K: "It was awkward for me because, as I said, I'm totally illiterate when it comes to computers and whatever."
- Patient M: "I am one of these people that, when I got my mobile phone, I got it for me to use. Not for other people to contact me."
- Patient J: "I'm not a big fan of technology. I'm not really a fan of it at all, like,….Although I'm very used to the Apple Watch now. I'm a bit of a troglodyte."

Usability Friction

Everyday issues such as remembering to wear the device after showering, keeping it charged, app lag, syncing problems, and confusion over duplicate user profiles frequently disrupted initial adherence. One patient noted:

> *The only time I don't wear it is when I take a shower...occasionally I forget to put it back on and again I would defend myself with my age, my issues, and being woolly headed sometimes.* [Patient E]

One patient commented:

XSL•FO
RenderX

> *my biggest problem was charging when I was having a shower and remembering to put it back on…until you got used to it, you'd forget the odd day to put it back on.* [Patient F]

One patient appreciated aspects such as device comfort and battery life:

> *It's very comfy, very usable…the battery lasts for ages. It's good, I was a bit worried about it, but it lasts a day or two.* [Patient F]

Technical issues with the app were also a concern; some struggled with questionnaires and app responsiveness, as one patient described:

> *I do find it a bit laggy at times...you do the first one, and then if you're kind of too quick doing the second one, it doesn't take, and you have to go back in and do it.* [Patient L]

One patient described problems with confusion over user profiles:

> *Obviously, I think some days I've forgotten to do the questionnaires, although there's been a couple of times when that's happened, where I'm nearly convinced that I did answer the questionnaires, and then I'm wondering, did I somehow use the wrong profile.* [Patient E]

Participants expressed the need for more flexibility in device and platform choices to better fit their routines and preferences. One patient described:

> *An Android user, like me, who kept two separate phones, wasn't integrating it into their lives properly.…To use them properly, you have to be able to integrate them into your life, and they become not just a data collector...* [Patient M]

These technical challenges highlight the importance of user-centered, flexible digital health designs.

Workarounds

To overcome initial technological barriers, participants used social support and developed routines. One patient gets family support:

> *I would need some assistance, yes, because I'm not...I'm not too good on this technology....Yes well [my son] goes over things with me there that are on....he comes out every week....He looks over things, and tells me about this or that....He's well up on all of that.* [Patient B]

More confident users like Patient E independently sought solutions:

> *so like I say, it just took me a while to you know, to work around the format of the watch, because again, that was different to the watch I'd had before. But I mean, it's, you know, it's a graphical interface. It's not that difficult to you know, to work through. And you can always Google it if you need to. So yeah, no, I don't think I had too many issues with that.*

One patient described developing routines to efficiently complete required tasks:

> *Because it tends to be just the two questions, the breathing and the coughing. You know, it only takes 30 seconds to do it. So I tend, as soon as I get the message come through, I'll tend to do it straight away. But the, the one where it could be, sort of, 19 questions, or whatever. You know, I tend to sort of sit down for an hour, and then go through them properly, and...try and be as accurate as I can. No, it's fairly straightforward, and, you know, there's nothing complicated about it.* [Patient D]

One patient took a pragmatic approach to device notifications:

> *...when I'm on my bike. It kind of pings the watch. And it says something like. I see you're working out. Or your cycling, or something like that. And, uh, I tend to ignore it.…I just click it back to what it was.…I'm just…wearing it as a watch.* [Patient F]

In terms of charging routines, one patient describes:

> *my biggest problem was charging when I was having a shower and remembering to put it back on,….[Now I]...put it back on straight away. You know, as soon as you come out and dry your hair.* [Patient L]

These varied adaptation strategies demonstrated resilience and resourcefulness, regardless of initial technological proficiency.

Workarounds, whether social (family assistance) or individual (routine-building), illustrate the importance of both personal and environmental resources in successful adoption. Informal caregiver involvement becomes an unplanned implementation mechanism; trials may need to recognize and resource this hidden support network.

Feedback on app reminders was mixed: some found them helpful for adherence, others considered them intrusive (on bank holidays), highlighting the importance of customizable engagement strategies.

Designing trials that acknowledge the desire for more flexibility in device and platform choices highlights the importance of user-centered design. Allowing participants to use their own devices (Bring Your Own Devices [BYOD]) and offering customizable engagement strategies can improve trial inclusivity and reduce the burden on participants.

Theme 3: Participant-Initiated Engagement With Wearable Data

Reflexive Thematic Concept

Although the trial design intended passive data collection, participants frequently engaged actively with their wearable data. For many, the device became embedded into daily routines, supporting self-monitoring, emotional reassurance, and in some cases behavior change, with the majority (14/15) expressing intention to continue using the wearable. Participant-initiated engagement revealed both empowering and distressing impacts, underscoring the personal meanings participants assigned to digital data.

XSL•FO
RenderX

From Passive Monitoring to Personal Engagement

Passive data collection can become active self-monitoring, altering behavior or anxiety levels. The engagement with wearable data spanned a spectrum from enthusiastic daily use to more passive or intermittent interaction, with most (11/15) individuals noting specific health benefits and increased self-efficacy.

For some, the device remained a passive tool, with limited personal interaction, as one patient reflected:

> *I'd just go back to my old watch, so…I'm sorry, yeah, it's not…I should be gushing about it, but I'm not…,* [Patient F]

This illustrates that when data collection is entirely passive and lacks user interaction, engagement may remain minimal.

In contrast, others found significant reassurance and utility in the ability to retrospectively review their health data. One patient shared:

> *...I find it incredibly useful, and it helps me, and it also helps the fact that…the readings are stored on the iPhone. And you can go back and look through them. Plus, it averages out your results over a week, a month, 6 months. And you can start to see if you're…going up, down, or you're remaining stable? So, from that point of view, it's absolutely super.* [Patient C]

This highlights how long-term data tracking and the ability to observe trends can provide participants with a sense of control and reassurance.

For some, the wearable device offered emotional support and comfort. One expressed, "I use it I feel it…it is a comfort to have it," suggesting that the device became more than a data collector—it provided a sense of security (Patient B). One patient went further, describing the device as integral to her sense of self: "If I don't wear it, is it my….It's…it's my…myself is not complete" (Patient N). This sentiment underscores how, for certain individuals, the wearable became an extension of their identity.

Curiosity and discovery also motivated ongoing engagement for some participants. One patient remarked:

> *I find it, like, really interesting, because I never really thought of. How much an apple watch can actually do in the health app? And I just find it really interesting.* [Patient I]

This sense of discovery fostered a positive attitude towards the technology and encouraged regular use.

Others described how the device became embedded in their daily routines, supporting proactive self-monitoring and health management. One patient explained:

> *I would generally look at it in the morning for the oxygen overnight, and then at night, I would check everything, so I would check heart rate for the day. Oxygen saturation, steps walked,…Oh, in the morning, I would check…sleep and oxygen saturation,...then in the evening, everything.* [Patient L]

This routine use demonstrates how wearables can facilitate regular health checks and empower participants to take an active role in managing their condition.

Collectively, these narratives illustrate the diverse ways in which participants engaged with wearable technology—ranging from limited interaction to deep integration into daily life. The emotional and practical significance of these devices varied, but for many, they provided reassurance, comfort, curiosity, and a means to monitor and manage their health more effectively. These insights highlight the importance of considering individual preferences and experiences when designing digital health interventions for people living with chronic conditions.

Responses to Data

Participants described both comfort and anxiety in response to the data. For some, it provided reassurance and control; for others, it increased worry, especially when data confirmed decline. Some participants changed behaviors based on data while others did not.

Participants described how wearable device data influenced their understanding and management of their health. For example, one patient reflected:

> *It's great, because you notice, right, I'm not imagining it. It is there, and it's something, like I was able to say. Like, weirdly enough. Whatever the hell it was. Tuesdays were terrible for AFib. All my episodes have either been on a Monday night, or Tuesday morning.* [Patient C]

This demonstrates how device data enabled validation of symptoms and identification of patterns, enhancing self-understanding.

One patient shared:

> *Yes, it tells me how many hours I slept. Which was a good thing, because then I could justify why I was tired.* [Patient K]

Here, the objective data supported self-justification and explanation of symptoms, reinforcing the device's utility in daily life.

One patient explained:

> *I can sit down and relax and watch it and see if the heart rate starts to go back down. Then I get settled, more settled then you know.* [Patient G]

This illustrates how real-time feedback from the device was used to guide self-regulation and coping strategies.

One patient noted:

> *Yeah. I tried to look at it almost, like, every single day. It's kind of like a routine I like to see if it's, like, normal, high, or low.* [Patient I]

For Patient I and others, daily engagement with wearable metrics became a habitual part of life.

XSL•FO
RenderX

However, not all experiences were reassuring. One patient said:

> *It definitely didn't reassure me, and it made me the opposite, because I could...I knew I was...I knew I was starting to struggle more, and I could see, probably, it was progressing, and I suppose the stats show that, you know, when I, when I checked them, I could see the decline and everything.* [Patient L]

For some, data indicating deterioration contributed to increased anxiety, showing the nuanced emotional impact of continuous tracking.

A patient described:

> *Because I have got used to it now...I'm watching the…you know, steps and that. Like, the Fitbit aspect of it. Again, it's not something I'd be obsessive about, but it's just interesting to see.* [Patient J]

This suggests that integrated tracking features can foster ongoing, non-intrusive engagement without leading to obsession.

Finally, one patient commented:

> *I don't have any little goals or anything, I just...observe what's happening with it, and that's….Okay, no, it's convenient, and….Yes, I realize that it's…that it's there for the statistical records, and that you're interested in the nighttime heart rates and all these things. Of course, I'm interested in it, too. I have a personal interest in it.* [Patient H]

This reflects how some participants engaged with data in a more observational, less goal-oriented manner, highlighting the diversity of usage styles.

The wearable device transitioned from a passive study requirement to a routine aspect of daily life. This integration facilitated regular health checks, promoted new routines, and, for some, prompted behavior change, an unintended consequence. This illustrates how wearables were embedded into morning and evening routines, supporting self-monitoring and proactive health management. Continuous monitoring can have both reassuring and anxiety-inducing effects on participants. Providing clear communication about the purpose and benefits of data collection, along with emotional support resources, can help mitigate negative emotional impacts.

Theme 4: Life-Limiting Illness as a Constraint on Digital Trial Participation

Reflexive Thematic Concept

Participants' engagement with digital tools was shaped by the length of time they have had the diagnosis and ongoing demands of managing chronic and progressive illness. Coping with fatigue, breathlessness, medication routines, and oxygen setup already demands much of patients before introducing additional digital devices.

Disease Duration Might Foster Routine Management or Digital Fatigue

Participants reported a wide range of diagnostic journeys (Multimedia Appendix 5), from recent confirmations to decades-long histories of illness. Some described protracted periods of misdiagnosis or uncertainty, while others experienced abrupt transitions from health to chronic disease management.

Longer disease duration may foster routine management strategies but could also lead to "digital fatigue," a diminished motivation to engage with new technologies due to the cumulative demands of ongoing self-monitoring. Conversely, those with recent diagnoses sometimes reported uncertainty and a steeper learning curve in adopting digital tools. Notably, a dropout from the study who did not consent to be interviewed had been diagnosed a year previously, citing anxiety with using digital tools. In both cases, the context of diagnosis duration shaped the readiness and capacity for digital trial participation.

Symptom Burden May Shape Willingness or Capacity to Use Technology

Participants described how illness-imposed restrictions fundamentally altered their daily routines, social activities, and independence:

> *If I want to do anything, I've got to think oxygen. If I don't, I'll just get caught short. And I'm like a fish out of water, I'm floundering.*

Reliance on supplemental oxygen was a defining feature for many, shaping both physical mobility and daily planning: "I wake up in the morning, and before I go to the toilet or do anything, then the oxygen has to go on...." The logistics of managing oxygen supplies and equipment often required advance planning and adaptation, leaving less flexibility for unscheduled or spontaneous engagement with digital trial tools. One participant had so much to take with them for a trip they didn't bring the study phone:

> *I went up to [the city] Saturday, stayed overnight, came back yesterday evening. I didn't bring my phone with me, you know? So that's the only thing…be inclined to forget…the phone.*

Another spoke about having enough to do when faced with throat cancer to focus on wearing the watch and charging it, "No, I was more concerned about the cancer in my throat. I didn't think of the watch. You know?" This participant's watch wear time completely stopped when faced with cancer.

Cough varied in frequency and severity, with some experiencing persistent symptoms and others only occasional bouts, while for others it seemed irrelevant:

> *…I'm keeping in mind what I've been putting in on the…on the MyCap as well, and I know that. Most of the time, it's been…pretty stable, like….The last two weeks now...my…cough has been getting a little bit worse, because today now, when I'm coughing. It's actually painful in my chest. Now, I don't know whether I have picked up an infection or something. But, as I say, I'll sort of wait and see.*
>
> *All the questionnaires that you've been giving me about coughing, I never understood them….But since about the 2nd of [Month] I am now getting coughing fits....*

XSL•FO
RenderX

> *I get two…questionnaires a week. And one of them is about my cough…I don't really have a cough…doesn't seem that relevant to me*

Fatigue was a prominent and often unpredictable barrier, affecting both physical stamina and cognitive function: "I have a lot of fatigue….I'm sometimes woolly headed," "There's just no energy. I've no energy at all," "I get tired very quickly…it varies from day to day, I mean, some mornings I get up and I feel fine....But then there are other days I wake up, and I've just got nothing in the tank." Fatigue can be a cause of delayed interactions with digital trial tools. The first dropout from the study who declined to be interviewed had been vague in responses to follow-up consistently being late to fill out questionnaires. Perhaps this was due to mental fatigue affecting their focus or articulation. The cognitive effects of fatigue make complex or multistep digital tasks more challenging, underscoring the need for accessible, low-burden digital designs in future trials. These limitations often led to prioritization of essential tasks, with discretionary activities, including digital trial engagement becoming secondary. For some, the cognitive and logistical effort required to interact with apps or devices was an additional burden layered atop daily challenges.

Participants' experiences of life-limiting illness fundamentally shape their engagement with digital technology study tools. Core symptoms—fatigue, breathlessness, cough—and the practical demands of managing comorbidities and oxygen create capacity and motivation challenges. For example, the participant with throat cancer vividly shows how comorbidities directly interrupted study tasks. Understanding this context is essential for designing digital interventions that are feasible, empathetic, and responsive to the lived experiences of people with chronic, life-limiting conditions. To address these challenges, digital interventions should allow flexible participation schedules and low-effort digital interfaces, ensuring that technology adapts to the needs and capacities of participants rather than imposing additional burdens.

Discussion

Principal Findings

Participants described core themes influencing engagement with digital health technologies, including trust, digital literacy, emotional responses to data, and illness-related constraints. This qualitative substudy provides an in-depth examination of how individuals living with fibrotic ILD experience sustained participation in a digitally enabled clinical research program. While digital monitoring is increasingly promoted as a means to enhance data granularity and reduce reliance on clinic-based assessments, our findings demonstrate that engagement with such technologies is not passive or uniform. Instead, participation is actively shaped by trust, digital literacy, emotional responses to data, and the constraints imposed by living with a life-limiting illness.

Continuous digital monitoring has the potential to increase granularity of outcome measurement; however, it may also introduce measurement reactivity, whereby participants alter behavior or reporting in response to being observed [19]. In the context of this study, participants had continuous access to wearable-derived data via the Apple Health app (Apple Inc), enabling interaction with trial data beyond the boundaries of the study protocol. While prior work has focused on feasibility and validation of digital end points, our findings highlight how access to consumer platforms such as Apple Health enables participant-initiated use of trial data, introducing behavioral adaptation and potential cointervention [20-22]. These processes may influence activity patterns, symptom reporting, and disease perception, with implications for the validity and interpretation of trial outcomes. Recognizing and characterizing these mechanisms is essential for the design and interpretation of future digital and hybrid trials [23].

Participants interviewed between 8 and 14 months into the planned 3-year study found digital monitoring acceptable, which aligns with emerging evidence showing high feasibility of home monitoring in ILD and other chronic respiratory diseases [24,25]. High PROM adherence (>99%), alongside high smartwatch wear times (median 96%, IQR 95.9%-99.5) in the first 12 months of PRODIGY-ILD, reinforces the feasibility of sustained digital data collection, an essential requirement for longitudinal outcomes. For clinical trials, this suggests that integrating wearables and regular ePROMs is likely to be acceptable to most participants, supporting their inclusion as trial end points or exploratory biomarkers. However, the context provided by qualitative interviews also highlights that certain factors such as comorbidities can limit willingness or capacity to engage with digital tools over time. For some participants, illness-related challenges led to reduced engagement or prioritization of digital trial activities, underscoring the importance of designing flexible, low-burden interventions that adapt to fluctuating participant capacity and lived experience. This suggests that while overall feasibility is high, successful implementation requires ongoing attention to accessibility, participant support, and the minimization of additional burdens.

The qualitative analysis of participant experiences in the PRODIGY-ILD study reveals a number of implications for the design and conduct of clinical trials that incorporate digital monitoring tools. Our 4 themes: trust and altruism, navigating digital tools, adoption of technology, and the impact of life-limiting illness offer insights into how clinical trials can be refined to improve recruitment, adherence, data quality, and participant well-being.

Participants' willingness to share personal health data was significantly shaped by their trust in research teams, confidence in ethical safeguards, and a strong sense of altruism. Transparent communication about data governance and the institutional reputation of research settings were central to fostering trust. For clinical trials, this highlights the need for clear onboarding processes that articulate data security, privacy protections, and the ethical framework underpinning the study [26,27]. Recognizing and explicitly honoring participants' altruistic motivations, such as helping others, contributing to research, and supporting future generations, can further strengthen engagement and retention [28,29]. Trial communications should frame participation as a meaningful contribution to the advancement of care, while addressing any residual privacy concerns through ongoing dialogue [30,31].

XSL•FO
RenderX

Participant experiences with digital tools varied widely according to technological literacy, device compatibility, and everyday usability. Those less familiar with technology relied on informal support from family or caregivers, consistent with prior findings that digital literacy strongly shapes engagement and retention in remote studies [32]. Usability friction, such as charging, syncing issues, and app lag, caused frustration and has similarly been recognized as a key barrier to sustained adherence in digital health interventions [33-35]. To mitigate these barriers, clinical trials should incorporate stratified onboarding and support mechanisms tailored to different levels of digital literacy [33-35]. Flexible approaches, such as allowing participants to use their own devices and providing customizable engagement strategies, can reduce burden and improve inclusivity [36]. Recognizing the hidden labor of informal caregivers and resourcing this support where possible may be crucial for sustained adherence, especially among older or less tech-savvy populations [32,35].

The study revealed that participants often engaged actively with their wearable data, leading to both empowering and distressing impacts. While many found reassurance and motivation through self-monitoring, others experienced heightened anxiety when confronted with evidence of disease progression. These findings highlight the importance of developing communication strategies that provide support and emotional resources to help participants understand their data. Trials should carefully consider how much real-time data visibility is appropriate, balancing the benefits of participant engagement against the risk of unintended psychological harm. Structured feedback mechanisms and clear explanations of the purpose and limitations of digital end points should be used to safeguard participant well-being and trial integrity [20,25].

The demands of managing progressive illness, fatigue, breathlessness, medication regimens, and comorbidities significantly shaped participants' capacity and motivation to engage with digital trial tools [37-39]. For participants with severe comorbidities, the burden of treatment can mean trial activities are deprioritized [37,39]. To accommodate these realities, clinical trials must design digital interventions that are flexible, low-burden, and adaptive to fluctuating participant capacity [22,26]. Features such as adjustable participation schedules, simple interfaces, and options to pause or modify engagement can make trials more feasible and empathetic. Understanding the lived experience of chronic illness should inform all stages of digital trial development, from feasibility testing to ongoing support [16].

Limitations

There are limitations that should be considered when interpreting the findings of this study. First, the sample size was small (n=15), reflecting the exploratory nature of the work and the intensive, interview-based methodology. While this enabled rich, in-depth accounts, the perspectives captured may not represent the broader population of individuals living with fibrotic ILD. Two participants who dropped out of the study did not consent to being interviewed, which may bias findings toward acceptability of technology use. Participants were also drawn from a single specialist ILD service, which may limit transferability to settings with different patient demographics, service structures, or technology access. Second, several participants relied on informal caregiver support to manage digital trial tasks, such as device setup, troubleshooting, and data entry, which may not be replicable for individuals without such assistance. The role of caregivers, although integral for some participants' engagement, introduces variability that may influence the feasibility and acceptability of digital tools in more socially or digitally isolated groups. Elements of response bias may have been introduced, as participants could have been influenced by their existing relationship with the researcher, potentially leading them to provide responses they perceived as desirable or expected. Finally, the heterogeneous clinical course of fibrotic ILD, many of which are progressive and may be life-limiting, may have influenced participants' engagement with the study. Participants described a strong desire to understand their condition, reflecting the scarcity of effective treatments and the uncertainty surrounding disease trajectory. This sense of urgency and investment may have enhanced adherence to digital tools and PROMs beyond what might be expected in conditions with a more stable or treatable course, limiting generalizability to other patient populations.

Conclusion

Taken together, these findings extend existing literature on the feasibility and acceptability of digital monitoring in ILD by demonstrating that sustained engagement is a dynamic, emotionally mediated process embedded within the broader context of illness, identity, and daily life. While overall adherence in PRODIGY-ILD was high, qualitative insights reveal the effort, adaptation, and negotiation that underpin this success. Embedding qualitative research within digital trials provides critical insight into how technologies are actually used, interpreted, and experienced and is essential for understanding the mechanisms through which digital end points are generated.

In conclusion, successful integration of digital technologies into clinical trials requires more than technical feasibility. It demands a participant-centered approach that builds trust, acknowledges altruistic motivations, accommodates variability in digital literacy, recognizes the role of informal caregivers, and addresses the emotional and practical realities of living with chronic, life-limiting illness. By illuminating these processes, this study contributes to the methodological foundations of digital health–enabled research and offers actionable insights to inform the design, conduct, and interpretation of future digital and hybrid clinical trials.

Acknowledgments

The authors gratefully acknowledge the support of the Health Research Board – Trials Methodology Research Network (HRB-TMRN), Galway, Ireland, and the UCD Clinical Research Centre for their guidance and support throughout this study. We thank Lindsay Brown, advanced nurse practitioner, for her valuable advice on patient-reported outcome measure (PROM)

selection and her ongoing clinical input during the study. We also acknowledge Dylan Keegan for his contribution to the development of the Participant Information Leaflet and Informed Consent Form. We are grateful to the Irish Lung Fibrosis Association Patient and Public Involvement (PPI) contributors, Nicola Cassidy, Paula Jenkins, and Robert Hurley, whose feedback informed the design of the study website. Finally, we thank Patrick McKay of Advantage Point Creative Consultancy for the design and development of the study website.

Funding

Grant support for this research study was provided by the Health Research Board – Trials Methodology Research Network (HRB-TMRN). The funding body had no role in the design of the study protocol and was not involved in the collection, analysis, and interpretation of data or manuscript preparation. UCD Clinical Research Centre provided digital device funding.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the sensitive nature of qualitative interview data and the potential risk of participant reidentification in a rare disease population, but they are available from the corresponding author on reasonable request.

Abstract

Background: Mobile health (mHealth) interventions with virtual coaches offer scalable and potentially cost-effective solutions for health behavior change. However, these interventions commonly present challenges, such as limited personalization and insufficient grounding in evidence-based strategies. Perfect Fit (PF; Perfect Fit consortium), a personalized mHealth intervention with a text-based virtual coach, supports adults in quitting smoking and becoming more physically active. By combining innovative techniques, including sensor technology, end user involvement, and evidence-based strategies, PF aims to address common challenges faced by mHealth interventions, including those with virtual coaches.

Objective: The study primarily investigated the feasibility and acceptability of PF. The secondary aim was to explore associations between sociodemographic, smoking-, and physical activity–related characteristics and the feasibility and acceptability outcomes. The third aim was to evaluate the feasibility of conducting the research study.

Methods: A single-arm, pre-post, mixed methods study was conducted in the Netherlands with 100 adults who smoked. The intervention lasted approximately 16 weeks. Data were collected at baseline, during the intervention, and postintervention (4 months). Quantitative data included usage data and self-report questionnaires on feasibility, acceptability, and baseline characteristics. Qualitative data were gathered through postintervention semistructured interviews. Analyses included descriptive and inferential analyses, as well as the framework approach for the qualitative data.

Results: PF usage varied considerably across participants (n=87). The mean satisfaction rating was 2.79 (SD 0.73; scale range 1 - 4), and perceived usability had a median score of 67.50 (range 12.50 - 87.50; scoring range 0 - 100), indicating OK-to-good usability. The mean virtual coach acceptance rating was –0.27 (SD 1.30; scale range −3 to 3; n=77). Higher PF usage was associated with greater satisfaction, usability, and coach acceptance (all $P \leq .004$). Frequent connection issues with the smartwatch were a disruptive factor. Qualitative findings (n=12) provided in-depth insights into PF's feasibility and acceptability, encompassing both positive and negative experiences. For instance, some participants valued the virtual coach for its anonymity, low-threshold access, and the sense of control it offered, while others preferred a human coach for greater accountability. Suggested improvements included more varied content and enhanced adaptability of the coach to users' input and personal situations. Exploratory analyses suggested that high PF users were older than moderate ($P=.01$) and low PF users ($P=.05$). Importantly, PF was perceived as similarly feasible and acceptable across socioeconomic groups ($P>.05$), aligning with one of the project's goals. Finally, research procedures and recruitment strategies proved feasible.

Conclusions: PF shows potential as an accessible and inclusive strategy for multiple health behavior changes, contributing to public health. Findings highlight areas for improvement and can guide the future development of virtual coach interventions.

Introduction

The development of mobile health (mHealth) interventions has increased noticeably over the past 30 years [1,2], offering promising solutions in terms of reach, accessibility [3], and scalability [2,4]. A systematic review of reviews has shown that mHealth interventions can support individuals in adopting healthier behaviors [5]. This is especially relevant for high-risk behaviors such as smoking and insufficient physical activity (PA), which are major contributors to chronic diseases and premature mortality [6-8] and the primary targets of the intervention evaluated in this study. In 2021, approximately 17% of the global adult population smoked [8], and in 2022, 31% did not meet PA recommendations. Moreover, unhealthy behaviors often co-occur [9,10], especially among individuals with lower literacy or in vulnerable positions. These individuals also tend to experience poorer health outcomes and reduced life expectancy [6,11-14]. Given the high prevalence and health burden of smoking and insufficient PA, these behaviors are key public health concerns [6].

Encouraging smoking cessation and PA promotion simultaneously may be particularly beneficial, as they can reinforce each other [15-17]. PA can help reduce nicotine cravings [15] and alleviate withdrawal symptoms [16], while quitting smoking improves fitness, potentially encouraging more PA [17]. However, sustained behavior change is difficult to achieve without effective support. Studies show that the likelihood of successfully quitting smoking is around 3 times higher with professional support compared to no support [13,18]. Similarly, PA interventions incorporating behavioral support elements (eg, feedback on performance) can effectively promote both the initiation and maintenance of PA [19]. This highlights the need for effective support to facilitate lasting behavior change.

Due to the ongoing health care crisis, professional support is increasingly limited. Health care demand exceeds supply [20], and mHealth interventions could help alleviate this burden by providing scalable [2,21], remote [4], and potentially cost-effective [5] smoking cessation and PA promotion support [5]. They can empower individuals to take greater control of their health, improve health outcomes, and potentially reduce health care use [22]. Additionally, mHealth interventions may lower barriers related to fear of stigmatizing interactions when seeking support, often experienced by people who smoke [21]. Finally, they enable just-in-time adaptive interventions, which adjust delivery based on the time of day and integrate into users' daily lives [4,23]. Hence, mHealth interventions are seen as a promising way to meet growing health care demands.

Although promising, mHealth interventions also have disadvantages. Compared to human support, they are often experienced as less personal and tailored [24] and can evoke a reduced sense of personal accountability [21], which can contribute to low user engagement and adherence [4]. Integrating virtual coaches into mHealth interventions may help overcome these limitations by simulating human support while maintaining digital delivery advantages. Virtual coaches are AI conversational agents that mimic human interactions through text, speech, or both [1,25,26]. They offer interactive, personalized support, which may enhance adherence and engagement compared to more static mHealth interventions [27]. Reviews of virtual coach interventions for smoking cessation [21,25] and PA promotion [1] reported positive outcomes regarding effectiveness, acceptability, and user experience. However, these findings should be interpreted with caution due to study heterogeneity and underpowered studies. While these findings highlight the potential of virtual coaches, further research is needed to address key challenges and knowledge gaps.

The literature on mHealth interventions with virtual coaches identifies key challenges, including a lack of theory-based development; limited and mixed evidence on long-term engagement (eg, due to nonstandardized measurement methods) [1,4,25,28]; and digital inclusion problems [2,20,21,24]. Several strategies have been proposed to address these challenges. First, it is crucial to base interventions on behavior change techniques [29], theories, or models [1,4,14]. Second, personalizing content and timing may increase relevance [27], a sense of autonomy [25], and engagement [4,27,28]. In PA interventions, wearables can further support this personalization by enabling real-time feedback [30]. Third, prioritizing simple and user-friendly content can increase engagement [4,14,31]. Fourth, incorporating relational strategies, such as motivational interviewing [28] or emoji [3] to mimic human-like interactions, can support long-term behavior change [25,32]. Finally, interdisciplinary collaboration [4,21] and early end user involvement in development [14,20,22,31,33] can improve research and intervention quality. Incorporating these strategies is vital, as low engagement hinders the feasibility, acceptability, and, ultimately, effectiveness of interventions [25,27,28].

In addition to these challenges, the literature highlights several knowledge gaps, including limited research on the feasibility and acceptability of virtual coaches [1,5]. While effectiveness is crucial, long-term adoption also depends on factors such as ease of use, trust in the technology, and user satisfaction, making it essential to understand user needs and experiences [24-26,33,34]. To address this knowledge gap, qualitative and mixed methods designs can help to explore facilitators, barriers, and limitations [14,26,33]. Another knowledge gap is the limited

XSL•FO
RenderX

understanding of who benefits most from virtual coaches and under which circumstances [1,25,26]. Such insights could support tailored intervention development [4], improve feasibility and acceptability across diverse populations [26], and help identify target groups [5]. Particular attention is needed for individuals with lower digital skills, eHealth literacy [20,21,24], and socioeconomic positions (SEP) [1,2,14]. Although mHealth interventions have the potential for broad scalability [2], many remain inaccessible to these populations [20,22,31]. To avoid exacerbating health disparities [20-22], virtual coaches should be designed with accessibility in mind [2,14]. This includes early end user involvement [14,20,22,31,33,35] and tailoring interventions to users' digital skills and eHealth literacy [20,22]. It is also key to examine how individual characteristics, such as age, SEP, and eHealth literacy, influence feasibility and acceptability to identify who benefits most [33].

With an interdisciplinary consortium, we developed Perfect Fit (PF; Perfect Fit consortium) [36], a smartphone-based mHealth intervention with a virtual coach that provides real-time, personalized, text-based, and visual feedback to support smoking cessation and PA promotion. PF was specifically designed to leverage the assumed synergy between these behaviors. It also addresses common challenges and knowledge gaps in mHealth interventions, including those with virtual coaches. For instance, it includes behavior change techniques (eg, goal-setting) [29] commonly used in smoking cessation [37] and PA promotion [38], as well as behavioral theories, namely identity theories [39-41] and the Relapse Prevention Model [42]. Additionally, PF incorporates sensor-based personalized feedback using a smartwatch and was developed iteratively with end users [43].

This study presents the results of the real-world evaluation of PF, using a single-arm, pre-post, mixed methods design. The first aim is to investigate the feasibility and acceptability of PF. The second aim is to explore associations between baseline characteristics (ie, sociodemographic-, smoking-, and PA-related characteristics) and the feasibility and acceptability outcomes. This will provide insight into factors influencing intervention success and PF's suitability for different individuals. The third aim is to investigate the feasibility of conducting the study itself. Many mHealth studies face high dropout rates [21] and difficulties in recruiting participants, particularly those with lower SEP [14]. Examining these factors can inform effective recruitment and retention strategies for future research. By using a mixed methods approach, we gain insight into PF's overall potential, participant experiences, and contextual factors. This will help identify strengths and areas for improvement, ultimately informing future development and evaluation.

Methods

Study Design

This paper reports on a larger study conducted in the Netherlands, in which PF was evaluated using a single-arm, pre-post, convergent mixed methods design [43]. This paper focuses on the feasibility and acceptability of PF, as well as the feasibility of conducting the study itself. The data relevant to this paper were collected between August 2023 and June 2024. Findings on short- and long-term preliminary effectiveness will be reported elsewhere. This study is reported in line with the Good Reporting of A Mixed Methods Study (GRAMMS) checklist [44] (Checklist 1).

To assess the feasibility and acceptability of PF and the study itself, data were collected at baseline, during the intervention (ie, user log data and sensor data), and at postintervention (4 months after baseline). The quantitative component included (1) self-report questionnaires on baseline characteristics, feasibility and acceptability of PF, and virtual coach acceptance; (2) app-generated usage data; and (3) data on study procedures documented in a researcher's log. Self-report questionnaires comprised both self-developed and adapted items, as well as validated instruments, including the eHealth Literacy Questionnaire (eHLQ) [45,46], the Fagerström Test for Nicotine Dependence (FTND) [47], the Godin-Shephard Leisure-Time PA questionnaire (GSLTPAQ) [48,49], and the System Usability Scale (SUS) [50]. The qualitative component consisted of semistructured interviews exploring the feasibility and acceptability of (1) PF, (2) the virtual coach, and (3) the study procedures. The study was approved by the scientific committee of the Department of Public Health and Primary Care at Leiden University Medical Center (approval number: WSC-2023 - 24). Full study details are available in the published protocol [43]. Deviations from the protocol are reported below.

Patient and Public Involvement

Patient and public involvement (PPI) activities were conducted during the development of PF and the execution of this study. Multimedia Appendix 1 provides a description of the PPI aims, methods, results, and reflections, reported according to the revised version of the Guidance for Reporting Involvement of Patients and the Public (GRIPP2) short-form checklist [51] to ensure transparency and comprehensiveness. Additional details on PPI activities can be found in the published article on the development of PF [36].

Participants and Recruitment

Participants were recruited using a combination of online and offline strategies. Examples include social media posts and advertisements, newsletters or websites of affiliated organizations (eg, health care insurers), a news item in a local newspaper, and outreach via the networks of the PF research team and advisory panel. Recruitment started mid-August 2023, and the final participant was included on February 5, 2024. Sample size estimation is discussed in the study protocol [43].

Participants were eligible if they (1) were aged ≥18 years, (2) smoked daily, (3) intended to quit smoking within 6 weeks, (4) could walk pain-free, (5) could understand and read Dutch (at least B1 level), and (6) owned a smartphone with Internet access. To examine PF in high-risk individuals, at least 50% of participants were required to be at higher cardiovascular risk according to the Dutch general practice guideline [52]; that is, women aged ≥55 years or men aged ≥50 years. Additionally, at least 75% of participants had to reside in the Leiden region. Exclusion criteria included (1) enrollment in smoking cessation treatment at intervention start at the time of eligibility screening, (2) major lower extremity surgery in the past year, (3) use of

XSL•FO
RenderX

antipsychotics or diagnosis of a serious psychiatric illness (eg, schizophrenia/psychosis or major depression), and (4) pregnancy.

For the qualitative interviews, we aimed to recruit around 10‐15 participants to achieve data saturation [53]. A heterogeneous subsample was sought, with variation primarily in PF usage level, as well as in gender, age, SEP, and success in changing health behavior.

Intervention

PF is an evidence-based, personalized mHealth intervention with a virtual coach that supports individuals in quitting smoking and increasing PA. The intervention was expected to last around 16 weeks but could be adjusted to individual needs. The virtual coach, "Sam," guided users through 3 phases, including a preparation phase, an execution phase, and a closing dialog. Communication consisted of chat messages enriched with emoji, images, and animated informational videos, and users received links to relevant external sources. The coaching system allowed for both system- and user-initiated conversations, with a mix of constrained (preset responses) and unconstrained (free-text) input. A smartwatch (Garmin Forerunner 55; Garmin Ltd) [54] measured PA, enabling the coach to provide personalized PA goals and feedback. Users interacted with the coach via a smartphone app with chat functionality (ie, the NiceDay app; NiceDay Healthcare Nederland BV; [55], originally developed for remote therapy), and users installed 2 additional apps to enable a connection between the smartwatch and the coaching system.

In the preparation phase, users were encouraged to complete activities and dialogs that prepared them for quitting smoking and increasing PA. These dialogs covered topics such as medication and nicotine replacement therapy and self-monitoring of current behavior. Users were also guided in selecting a quit date and formulating a specific, measurable, achievable, relevant, and time-bound (SMART) long-term PA goal through the coach-initiated goal-setting dialog. After this dialog, the coach provided daily short-term PA goals (ie, step goals) based on previous PA measured via the smartwatch, along with feedback on whether the goal was met. The self-selected quit date (within a predefined range) then marked the start of the execution phase, during which the coach provided support through activities facilitating behavior change and weekly reflections on progress. The closing dialog was the final conversation in which the coach encouraged users to review their progress and achievements and develop a relapse prevention plan. PF included 21 coach-initiated core components considered important for supporting behavior change and forming the overall intervention structure. These consisted of 7 preparation phase dialogs or videos, the introduction video for the execution phase, the weekly reflection dialog occurring 12 times, and the closing dialog. In addition, users could initiate optional components at any time, including dialogs (eg, a high-risk situation and relapse dialog for difficult moments) and 25 short activities (eg, positive self-talk healthy eating tips), which could be repeated as often as desired to enhance engagement and personalization. Further details on the development of PF [36], the intervention components and features [43], the technical architecture [56], and the open-source code of the system [57] are described elsewhere.

Procedures

After consent, an onboarding procedure was initiated. Participants received the smartwatch and information materials. Specifically, participants received a video explaining the study and intervention, an installation booklet with instructions on app installation and smartwatch-coach connection, and an information booklet summarizing key instructions and tips for interacting with the coach. The latter also served as a workbook, offering space for notes. After receiving the materials, participants had a meeting with a researcher (via video call or telephone) to verify app installation, coach connection, and smartwatch use. During the intervention, participants could contact the research team via email or phone for technical support. A detailed participant timeline is described in the study protocol [43].

Quantitative Data Collection

Participants received a link to the online baseline questionnaire (T0) during the week of the onboarding meeting and the postintervention questionnaire (T1) 16 weeks later, at the expected end of the intervention. To maximize completion, researchers reminded participants via email and phone calls. Participants could keep the smartwatch if they completed at least 80% of the questionnaires of the larger study.

Qualitative Data Collection

A subsample of participants who had given prior consent to be contacted for an interview was invited at T1. Interviews were conducted online or in person (at Leiden University Medical Center), lasted approximately one hour, and were carried out by 2 medicine master's students trained in interviewing. In order to prevent social desirability bias, the interview schedule consistently focused on both positive and negative aspects of PF in general and its specific components.

Outcomes

Only measures relevant to the present paper are reported below. The interviews conducted at T1 were used to assess both primary and secondary qualitative outcomes (eg, experiences with PF and research participation). Full details are described in the protocol [43].

Baseline Variables

The following variables were assessed at baseline (T0) and were used to describe the sample and explore associations with the primary outcomes.

Participant Characteristics

Background characteristics were assessed using self-developed items and included gender, age, educational level (as a measure for SEP) [58], and the presence of any physical or mental (chronic) conditions.

eHealth Literacy

Assessed using 5 of the 7 scales of the Dutch eHLQ: (1) using technology to process health information (Cronbach α=0.77; McDonald ω=0.81); (2) understanding of health concepts and

XSL•FO
RenderX

language (Cronbach α=0.77; McDonald ω=0.84); (3) ability to actively engage with digital services (Cronbach α=0.83; McDonald ω=0.88); (4) feel safe and in control (Cronbach α=0.83; McDonald ω=0.87); and (5) are motivated to engage with digital services (Cronbach α=0.81; McDonald ω=0.85) [45,46]. The remaining 2 scales were not included, as they were not considered relevant to our study. Each scale consists of 5 items rated on a 4-point scale from 1 (strongly disagree) to 4 (strongly agree).

Intention to Quit Smoking

Assessed using a single item, "Which of the following plans best applies to you? I intend to…" [59]. Answer categories were (1) quit within the next month, (2) quit between 1 and 6 months from now, (3) quit sometime in the future, beyond 6 months, or (4) not planning to quit.

Smoking Behavior and Physical Nicotine Dependence

Assessed using a Dutch translation of the 6-item FTND (eg, "Do you smoke more in the morning than during the rest of the day?") [47,60]. Total scores were calculated according to standard FTND scoring, resulting in a total score ranging from 0 to 10, with higher scores indicating higher nicotine dependence.

Using E-Cigarettes

Participants were asked, using self-developed items, whether they used e-cigarettes. If they responded "yes," they were subsequently asked whether they used e-cigarettes with or without nicotine.

Intention to Become Sufficiently Physically Active

Assessed using a single item, "Which of the following plans best applies to you? I intend to…" [59]. Answer categories were (1) become sufficiently physically active within the next month, (2) become sufficiently physically active between 1 and 6 months from now, (3) become sufficiently physically active sometime in the future, beyond 6 months, or (4) not planning to become sufficiently physically active. Before this question, the definition of PA (ie, exercise, but also physical activities like walking to the supermarket) and the World Health Organization (WHO)–recommended PA guidelines [7] were explained.

Self-Reported Level of PA

Assessed using a Dutch translation of the 3-item GSLTPAQ [48,49]. Participants were asked to report, on average, how many times during a typical week they engaged in more than 15 minutes of (1) strenuous exercise (eg, running and soccer), (2) moderate exercise (eg, brisk walking and badminton), or (3) mild exercise (eg, easy walking yoga). Example activities for each intensity level were provided. Total scores were calculated according to standard GSLTPAQ scoring. A total score of 24 or more was defined as "active," a score between 14 and 23 as "moderately active," and a score below 14 as "insufficiently active" [48].

Feasibility and Acceptability of PF and the Virtual Coach

To investigate the feasibility and acceptability of PF, the following primary outcomes were assessed [43].

PF Usage (During Intervention and T1)

Objective intervention usage data collected through the app throughout the intervention duration included (1) the number of days used (ie, from the first to the last recorded activity in the app), and (2) the number of completed coach-initiated core intervention components (ie, 21 in total). Components were only logged as completed if finished in full, providing a conservative estimate of usage. As part of the T1 questionnaire, participants also self-reported how frequently they interacted with the virtual coach during PF using a self-developed item.

A deviation from the study protocol [43] was that we did not analyze the self-reported intervention completion item. Due to the personalized intervention duration and content, the definition of "completion" was somewhat subjective. Therefore, app usage data, which objectively tracked completed components, was considered more reliable and also correlated significantly with self-reported completion.

Satisfaction With PF (T1)

Assessed using 2 self-developed items that were rated on Likert scales from 1 to 4 (Spearman-Brown r=0.75, indicating sufficient overlap to allow averaging the scores on the 2 items): "How satisfied are you with the amount of support you received?" and "Would you use the Perfect Fit program again, if needed?" Higher average scores reflected greater satisfaction.

Usability of PF (T1)

Assessed using the 10-item SUS [50] (Cronbach α=0.84; McDonald ω=0.90). Responses were given on a 5-point Likert scale from 1 (strongly disagree) to 5 (strongly agree; eg, "I think the Perfect Fit program is unnecessarily complex"). Standard SUS-scoring was used, resulting in total scores ranging from 0 to 100, with higher scores indicating greater usability.

Acceptance of the Virtual Coach (T1)

Assessed with 6 items adapted from Provoost et al [61] covering satisfaction, usability, willingness to continue interaction, relationship, preference for a human coach versus coach Sam, and adherence to advice from coach Sam [62] (Cronbach α=0.81; McDonald ω=0.90). Items were scored on a 7-point Likert scale from −3 to 3 (eg, "How satisfied were you with Coach Sam?"). Item 2 was reverse-scored, so that higher average scores indicated more positive attitudes.

Qualitative Data From Semistructured Interviews (T1)

Qualitative feedback regarding participants' experiences with PF, the virtual coach, and the smartwatch complemented the quantitative data (see protocol for the interview protocol [43]).

Sensor Data Issues (During Intervention)

During the study, we observed frequent issues with the connection between the smartwatch and the virtual coach. These issues caused the coach to communicate inaccurate step counts and goals and triggered repeated notifications from the coach

XSL•FO
RenderX

to the user about connection issues. The extent and nature of the sensor data issues were investigated, as they may have negatively impacted PF's feasibility and acceptability. This was analyzed as an exploratory outcome and was an addition to the original protocol [43].

Study Feasibility

The following secondary outcomes were used to assess the feasibility of conducting the study: (1) recruitment, response, and consent rates, recorded by the researchers in a participant screening and inclusion log throughout the study; (2) recruitment strategies, assessed at T0 via a self-report item asking participants how they were informed about the study (eg, via social media); (3) study adherence, monitored by the researchers from onboarding until T1 (ie, those who withdrew before completing onboarding were categorized as withdrawals rather than dropouts); and (4) qualitative data from semistructured interviews at T1, capturing participants' experiences with research participation (see protocol for the interview protocol [43]).

Data Analysis

Quantitative

Most data preparation and analyses were performed in SPSS (version 29.0; IBM Corp), and RStudio (version 2024.04.2+764; PBC) was used for calculating McDonald omega and for preparing and analyzing PF usage and step count data. Details on data preparation, including age and SEP coding, winsorizing [63] of extreme outlying PA values, dichotomization of variables for exploratory analyses, and sensor data processing are provided in Multimedia Appendix 2.

Descriptive statistics (eg, mean, SD, and frequencies) were used to summarize baseline characteristics of the study sample. Chi-square tests, independent samples *t* tests, and Mann-Whitney *U* tests were used for dropout analyses.

To address the primary and tertiary study aims—investigating the feasibility and acceptability of PF, acceptance of the virtual coach, and feasibility of conducting the study—descriptive analyses were conducted.

To address the secondary aim—exploring associations between baseline characteristics and the feasibility and acceptability outcomes—exploratory one-way ANOVAs, Kruskal-Wallis tests, Mann-Whitney *U* tests, chi-square tests, and Pearson and Spearman correlations were performed. Post hoc pairwise comparisons were conducted with Tukey honestly significant difference (HSD) corrections for ANOVAs and Bonferroni corrections for Kruskal-Wallis tests.

For the exploratory sensor data issue analyses, descriptive statistics were used. Associations between days with step count data and weekday, phone operating system, and PF usage group were explored with a Pearson chi-square test, a Mann-Whitney *U* test, and a Kruskal-Wallis test.

Qualitative

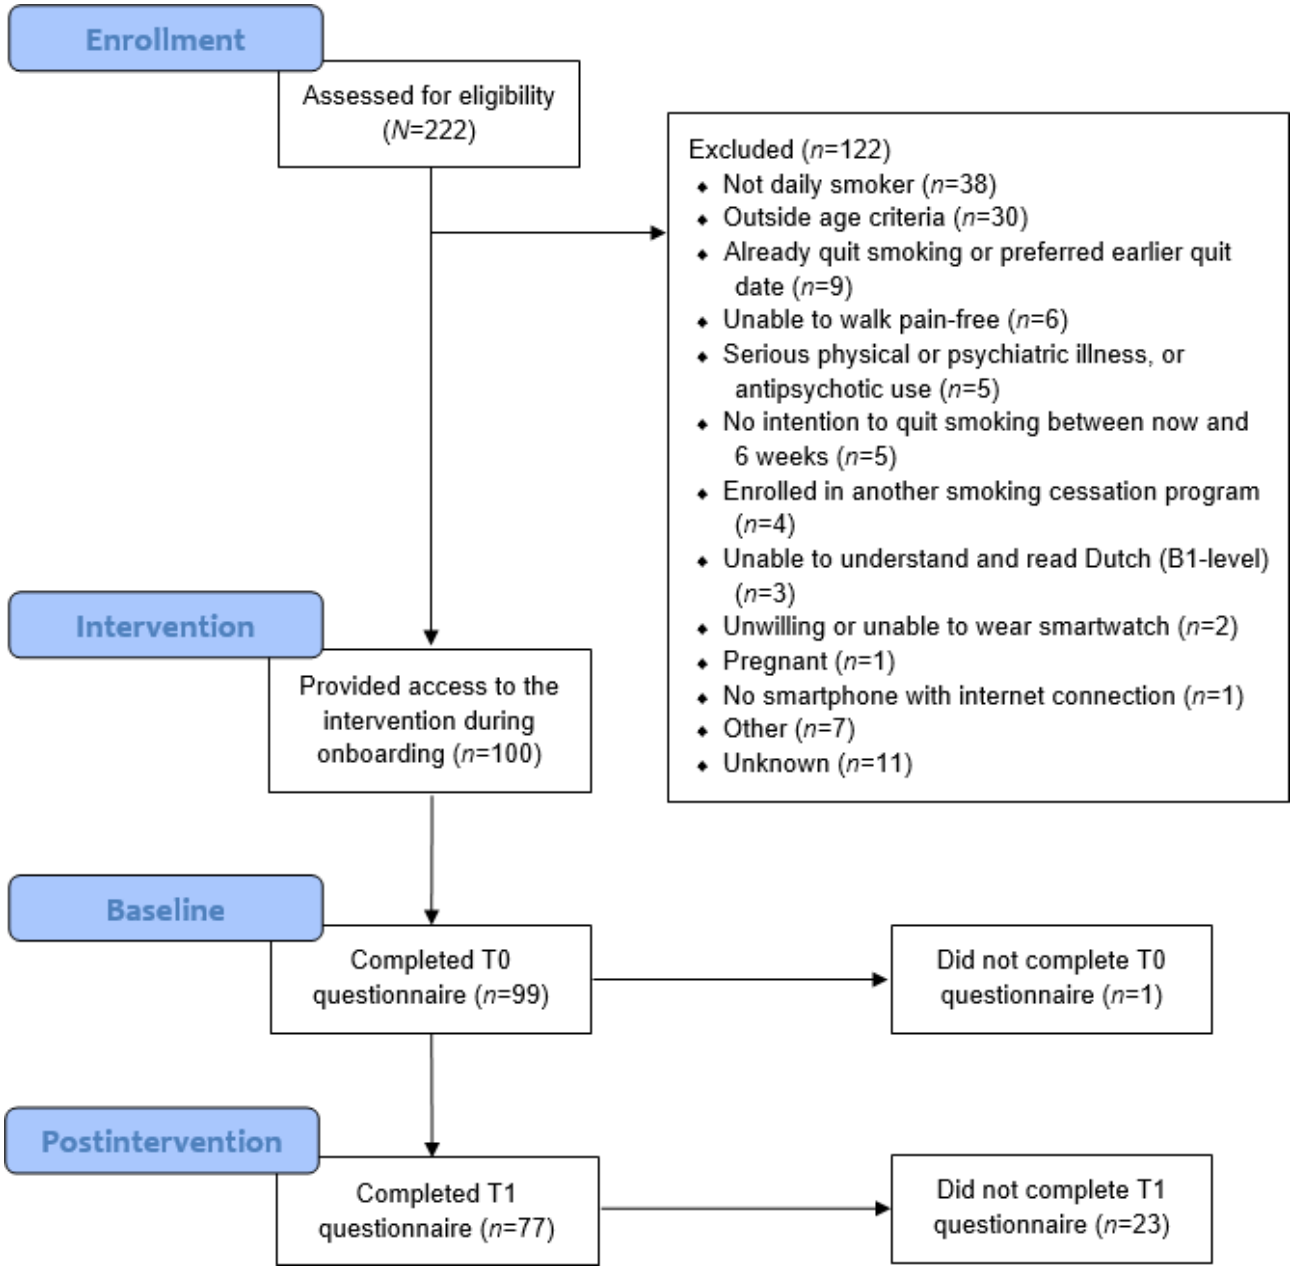
All semistructured interviews were audio-recorded, pseudonymized, and transcribed verbatim. Qualitative data were analyzed using the framework approach [64,65] in ATLAS.ti (version 23.2.3.27778; ATLAS.ti Scientific Software Development GmbH). The first transcript was independently coded by the 2 master's students who had conducted the interviews and by MHMvV, resulting in an initial coding scheme. The students then independently coded and discussed the second and third transcripts, refining the coding scheme when discrepancies arose. The remaining transcripts were each coded by one student, with the coding scheme further adjusted as needed. All revisions were discussed with MHMvV, RAvE, and EM. Data interpretation and theme generation were carried out by MHMvV in collaboration with EM and AV and were guided by the research aims, with consideration of the corresponding quantitative outcomes. Interview quotations were labeled with participant identifiers according to PF usage category (L=low, M=moderate, and H=high) and an individual interview number. Quotations were translated from Dutch to English with care to preserve the original meaning.

Data Triangulation

The analysis followed a convergent mixed methods approach. Quantitative and qualitative data were first analyzed separately using applicable analytical methods. Qualitative codes were derived from the interview data and organized within categories aligned with the study aims and quantitative outcomes. Subsequently, findings from both data sources were compared and integrated for each outcome. Results are therefore presented per outcome, combining quantitative results with qualitative findings to illustrate convergence and divergence and to provide additional context to the interpretation of the data.

Ethical Considerations

This study has been approved by the scientific committee of the Department of Public Health and Primary Care at Leiden University Medical Center (approval number: WSC-2023 - 24). The Medical Research Ethics Committee Leiden, The Hague, and Delft reviewed the study proposal and provided a declaration of no objection, indicating the research does not fall under the Dutch Medical Research with Human Subjects Law (nWMO; approval number: N23.045 METC-LDD). Interested individuals received a digital information letter and a link to the online screening questionnaire (hosted in secure software, Castor electronic data capture) [66]. Eligible participants were included after signing an online informed consent form and were informed that they could withdraw from the study at any time for any reason. Verbal informed consent was obtained and audio-recorded before each interview. Participants received a €25 (based on the conversion rate of 1.0786 between August 2023 and June 2024, this amount is equivalent to approximately US $26.97) gift voucher for the interview.



Results

Sample Characteristics

The participant flow diagram is presented in Figure 1 [67]. One hundred participants were given access to PF during onboarding. One participant dropped out before completing the baseline questionnaire, resulting in 99 participants who started PF and completed the baseline questionnaire.

XSL•FO
RenderX

Figure 1. Adapted CONSORT (Consolidated Standards of Reporting Trials) participant flow diagram (adapted from Hopewell et al [67]).

Baseline sociodemographic, smoking- and PA-related characteristics for the total sample (n=99) and T1 completers (n=77) are presented in Table 1. Of the 99 participants, 58.6% (n=58) were female, and the mean age was 51.96 (SD 14.08) years, ranging from 19 to 86 years. The distribution of SEP was comparable to the general Dutch population [68]. Median scores on the 5 eHealth literacy scales ranged from 2.80 to 3.00 on the 4-point scale. Regarding smoking-related characteristics, the majority of participants (n=77, 77.8%) intended to quit smoking within one month. At baseline, participants smoked an average of 15 cigarettes per day and reported low-to-moderate nicotine dependence [47,69]. Regarding PA-related characteristics, 54.5% (n=54) of the participants intended to be sufficiently physically active within one month. The median GSLTPAQ score suggests that at least half of the participants were already sufficiently active at baseline. However, the GSLTPAQ data were highly skewed and included extreme outliers; therefore, absolute values should be interpreted with caution. Dropout analyses showed that none of the baseline characteristics were significantly associated with study adherence at T1.

A total of 12 participants actively withdrew (via email or phone) from both the intervention and the study (ie, full dropouts), and 7 participants discontinued the intervention but continued completing study questionnaires. Reasons for dropout included: (mental) health problems (n=4), persistent technical issues with the smartwatch and/or app (n=4), dissatisfaction with the smartwatch functionality or intervention content (n=4), personal circumstances (n=1), a preference for human support over virtual coaching (n=1), smoking relapse and stress experienced due to the PA component of the intervention (n=1), having quit smoking and therefore no longer needing the intervention (n=1), and unknown reasons (n=3).

[e]GSLTPAQ: Godin-Shephard Leisure-Time Physical Activity Questionnaire.

Qualitative Interview Sample

Twelve participants took part in the postintervention individual interviews, forming a heterogeneous sample, including 3 low PF users, 5 moderate users, and 4 high users. Seven of the 12 participants were male, the average age was 54.8 (range 35 - 77) years, and SEP levels varied (see Table S1 in Multimedia Appendix 2 for detailed characteristics).

Primary Outcomes

Feasibility and Acceptability PF

Usage of PF

Twelve of the 99 participants had missing PF usage data, likely due to dropping out before entering their participant code in the app or entering it incorrectly, which prevented linkage between their app usage data and questionnaire responses.

Participants with available PF usage data (n=87) completed on average 54.7% of the 21 core intervention components (mean 11.49, SD 5.89). Six participants completed all components. The median PF usage duration was 107 days (range 4 - 202), which closely approximates the expected intervention period of 16 weeks (ie, 112 days). Participants completed a median of 4 optional short PF activities (range 0 - 46, as all 25 available activities could be repeated). Twelve participants completed none. Participants' self-reported frequency of weekly coach interaction is presented in Multimedia Appendix 2. A significant positive correlation was found between the number of completed core components and optional activities (Spearman ρ=0.638; P<.001). For subsequent exploratory analyses, usage was categorized into 3 groups (low, moderate, and high) based on the number of core components completed. See Table S2 in Multimedia Appendix 2 for details on this categorization and the corresponding distribution of optional activities completed within each group.

Exploratory analyses (n=77) revealed significant differences between PF usage groups in the other primary outcomes: satisfaction with PF ($F_{2, 74}$=6.09; P=.004; η^2=0.14), usability of PF (H_2=11.16; P=.004), and acceptance of the virtual coach ($F_{2,74}$=8.59; P<.001; η^2=0.19). Post hoc tests showed that high PF users reported significantly higher scores than moderate users on all 3 outcomes. Additionally, high users reported significantly higher scores on the acceptance of the coach than low users.

Qualitative data provided insight into reasons for lower usage of PF. Some participants reported that, after a while, they found PF or the virtual coach too intense, repetitive, or even irritating, which led to lower usage:

> *In the last few weeks, I used Coach Sam a bit less because I found it quite intense.* [M2, participant who was still smoking and increased PA at T1]

Others expressed a growing desire for autonomy, leading them to reduce their interaction with the coach as they gained confidence in managing their behavior change independently:

> *Over time, I noticed I got used to it […] and started looking at it less. In the beginning, I used it a lot, but gradually I started thinking. 'I'll do this myself now.'* [H2, abstinent and decreased PA at T1.]

Satisfaction With and Usability of PF

At postintervention, the mean satisfaction rating was 2.79 (SD 0.73; n=77) on a scale from 1 to 4. Perceived usability had a median score of 67.50 (range 12.50 - 87.50), indicating OK-to-good usability [70].

Qualitative interview data revealed that participants expressed both positive and negative experiences regarding satisfaction with and usability of PF, which are summarized in Table 2. Some features were experienced differently by participants, such as perceptions of how enjoyable and motivating PF was and the perceived variation in short optional activities. Issues with the connection between the smartwatch and the coach were often mentioned and likely impacted PF's feasibility and usability (see Results, Exploratory analyses section, "Sensor data issues").

XSL•FO
RenderX

Table . Perceived strengths and points for improvement of Perfect Fit, with illustrative quotations from the qualitative interviews, grouped under descriptive labels reflecting recurring topics in participants' responses.

Strength	Point for improvement
General experience	
Useful, comprehensive, and informative • "I really think it's a good product you've created, and I genuinely believe it's useful and effective for people seeking that kind of support. I do hope that […] such a product could become available on the market for smoking cessation and increasing physical activity." (H1[a], abstinent and decreased PA[b] at T1[c])	—[d]
Enjoyable[e] • "When it worked properly [without technical issues], I enjoyed using Perfect Fit." (H3, abstinent and increased PA at T1)	Not sufficiently enjoyable/engaging • "It worked, so I thought it was a good program. But I didn't find it very engaging. I wasn't looking forward to it like, 'Oh great, I get to use the program again soon', or anything." (M5, abstinent and increased PA at T1)
Motivating • "It's a good initiative. I think it stimulates people. […] Those videos were good, also the questions that were asked and the occasional tips you got. […] Like, 'What is this really doing to you?'. It actually says what you already know. We all know it, but we push it aside, and those things were confronting again. Like, 'Oh right, that could indeed be a consequence' – but it was told in a pleasant and friendly way." (H2, abstinent and decreased PA at T1)	Not sufficiently motivating • "In general, I found it very interesting because you're really working on your own development. You really start thinking about it. And you actually do move more and smoke less. Except at the end of the program, because maybe you become a bit more complacent – or maybe coach Sam just didn't provide the right trigger. I thought that was a pity. But I do think it's very personal." (M2, smoking and increased PA at T1) • "It didn't motivate me enough to quit smoking." (L1, smoking and increased PA at T1)
Personalization	
Timing: on-demand support and 24/7 availability • "Of course, you have people around you who support you when you're trying to quit smoking. But Sam was there 24/7. So even late at night or early in the morning, I could reach out to Sam." (M3, abstinent and increased PA at T1)	—
Content: personalized step goals • Interviewer: "Which aspects of the program did you like?" P: "Definitely the step goal. You want to reach it, so that's motivating when you get it. I used it a lot." (H4, abstinent and increased PA at T1)	—
Content: variety in short optional activities • "What I liked about the program was the variety – you didn't keep getting the same thing, but you could choose. I enjoyed doing the relaxation exercises and watching the information videos." (H3, abstinent and increased PA at T1)	Content: insufficient variety in short optional activities • "I found them a bit underwhelming [referring to the PF activities], because they didn't really add anything for me. […] They didn't shift my mindset. […] You know, you've been at it for so long, and you already know everything so well – that smoking is bad for you. You've already tried quitting a thousand times." (M2, smoking and increased PA at T1) • "Maybe expand the activities. […] For example, once you've completed an activity, you could move on to a next step – like, 'you've finished this level, now you can continue to the next level' or something like that." (H1, abstinent and decreased PA at T1)
—	Content: insufficient variety during execution phase • "The week after, I just got exactly the same questions again, and I would have preferred if the tone or the way the questions were asked had been a bit different. So that you'd feel like you were progressing further in the program together with Sam." (M3, abstinent and increased PA at T1)
Technical aspects and usability	

XSL•FO
RenderX

Strength	Point for improvement
Clear and easy to use • "It wasn't disappointing. I mean, I'm obviously not 20 anymore, so I didn't grow up with apps and computers. I don't think I'm completely incapable, but it's not my hobby. So it's always a bit nerve-wracking, but it's quite manageable, even if you're less skilled." (H3, abstinent and increased PA at T1)	Complicated installation and app integration • "The installation was technically challenging. It was difficult that you needed to link the Garmin Connect app with the NiceDay app and also to add Sammy as a chatbot. That was a bit complicated and tricky, and it should be simpler." (L1, smoking and increased PA at T1)
—	Technical issues • "Except when it malfunctioned, I thought: here we go again. 'I haven't heard anything for a while,' Sam said. Then I thought, well, it's not that long, Sam, but yeah, you can't really express that (laughing)." (H3, abstinent and increased PA at T1)
—	Smartwatch connection issues • "I contacted you [the researchers] again at some point because the step counter wasn't working. I couldn't get it to work. And eventually, I sort of gave up – like, 'Never mind, I don't want to be a bother.' If I'd had a mid-program evaluation talk [with a researcher], I might have brought it up again. I would've really appreciated that." (M5, abstinent and increased PA at T1)
Responsive technical support and troubleshooting • "And you [the researchers] were always very accessible, which makes a difference. If something doesn't run smoothly, it's easy to get in touch. […] It's just a quick email and you get an immediate reply, so that makes things less frustrating when something goes wrong." (H1, abstinent and decreased PA at T1) • "A few times, I saw that zero steps were recorded, and I wondered how that could be. Then I checked the booklet [the Perfect Fit paper manual]: 'Oh right, every time something happens or if you put your phone in battery-saving mode, you have to reopen the app.'" (H2, abstinent and decreased PA at T1)	—

[a]Interview ID is based on Perfect Fit usage: low (L), moderate users (M), and high (H) users.

[b]PA: physical activity.

[c]T1: postintervention.

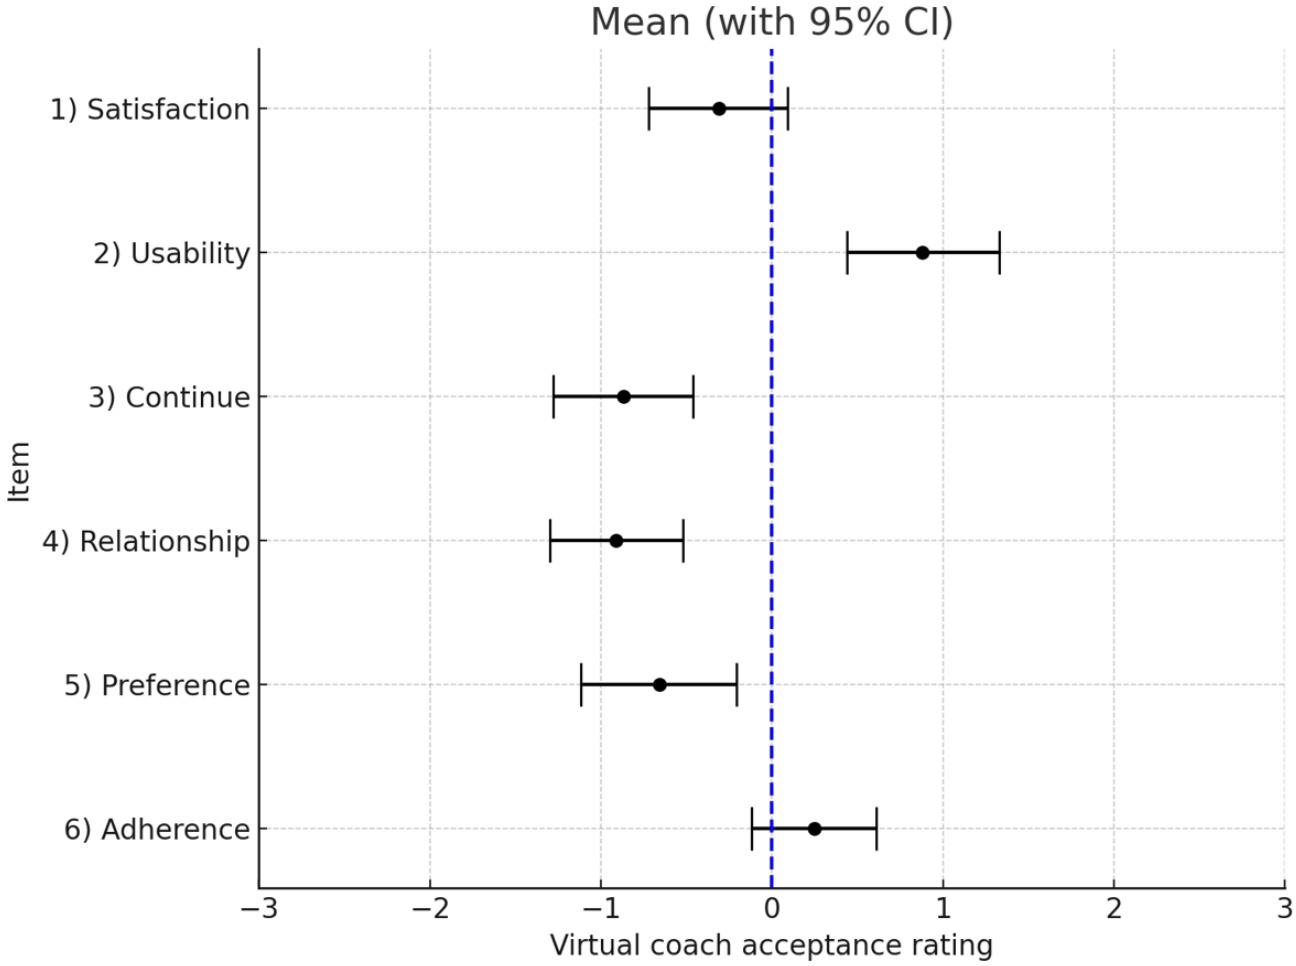
[d]Not applicable.

[e]Quotes placed opposite each other illustrate opposing experiences reported by different participants; not every strength has a corresponding point for improvement, and not every point for improvement corresponds to a strength.

None of the 12 interview participants reported feeling uncomfortable or unsafe when sharing personal information during the intervention. Some noted that the questions were not particularly sensitive and/or attributed their sense of safety to the study's affiliation with Leiden University Medical Center, an academic hospital in the Netherlands:

> *Yes, I felt safe sharing information. Although I'm not exactly sure why – maybe because it was still in the research phase and the data was handled confidentially for a good cause. […] And it wasn't that much personal information anyway.* [L3, smoking and increased PA at T1]

Acceptance of the Virtual Coach



At postintervention, the mean virtual coach's acceptance rating was −0.27 (SD 1.30; n=77) on a scale from −3 to 3. Figure 2 shows the mean scores and 95% CIs for each of the 6 items assessing coach acceptance. The item on usability received the highest rating, whereas the coach-user relationship was rated the lowest.

Qualitative findings provided context and depth to the quantitative results, for instance, regarding the moderately negative appraisal of the virtual coach, "I think the setup [of PF] is really great. […] But the virtual coach – yeah, I actually liked that the least." (L1, smoking and increased PA at T1). Participants frequently described the coach's communication as repetitive and static in style and content. Many expressed a desire for more flexibility, suggesting the coach should be able to adapt to personal situations (eg, being ill and unable to exercise) or user input (eg, by reflecting on user messages or tailoring content accordingly).

> *Probably because he [the virtual coach] didn't learn from my experiences. […] At one point, there was an exercise where you had to note why things were going well or not. I typed it in my notes or the app, but it wasn't read or analyzed. […] So that doesn't help. Maybe it's useful for a bit of self-reflection, but […] that coach didn't learn anything from me.* [L3, smoking and increased PA at T1]

XSL•FO
RenderX

Figure 2. Mean scores (95% CIs) for the 6 virtual coach acceptance items (with varying response labels, eg, difficult-easy), with higher scores indicating more positive attitudes toward the virtual coach.

Still, several participants expressed appreciation for the support provided by the coach and its friendly, nonjudgmental, and empathetic tone:

> *Not judgmental and really encouraging when you'd done something well. Like occasionally checking in: 'How are you feeling?', 'How's it going?', ' Any difficult moments?', 'No?', ' Great job.'* [H1, abstinent and decreased PA at T1]

Participants held differing views on specific features of the coach. For example, the frequency of notifications and the chatbot format were appreciated by some but criticized by others. The fact that Sam was a chatbot, rather than a human coach, was seen as a benefit by some participants, as it offered a sense of anonymity, nonjudgment, and autonomy. In contrast, others perceived it less favorably, noting that it reduced their sense of personal accountability and placed full responsibility on themselves:

> *Of course it's a computer, but I actually liked that. […] Constantly talking to a real person – 'Why did you smoke?' – that can get frustrating. Like: I don't know, just drop it. And with this program, you could choose what you wanted and how you wanted to receive support.* [H3, abstinent and increased PA at T1]

> *You know, a lot of things in the app are quite noncommittal, and I wouldn't mind a stricter Sam. […] Less 'you may', and more 'you must'.* [M1, smoking and increased PA at T1]

These different experiences of participants appeared to influence their perceived bond with coach Sam. While the above-mentioned positive aspects seemed to contribute to a sense of support, several participants felt that Sam being a computer made it difficult—if not impossible—to form a real connection, unlike with a human coach. At the same time, participants noted that developing a human-like bond was not necessary to find Sam's support helpful or to have a positive experience with PF, "What did I think of coach Sam? […] A nice computer, right? (laughs)" (H2, abstinent and decreased PA at T1).

Exploratory Analyses

Sensor Data Issues

Given the unexpectedly frequent issues with the connection between the smartwatch and the virtual coaching system (see Methods, Outcomes section, "Sensor data issues"), the extent and nature of these issues were explored post hoc.

Among the 87 participants with available PF usage data, the median percentage of days with available step count data during the intervention period (ie, from first to last activity in the PF

XSL•FO
RenderX

app) was only 43.1% (range 0.0% - 98.3%), indicating substantial missing data. Several participants mentioned smartwatch connection issues during contact with the research team. These issues occurred despite participants wearing the smartwatch, suggesting that the missing data were primarily due to technical issues. Supporting this, exploratory analyses showed that the missing step count data were not associated with specific days of the week (χ^2_6=5.97; *P*=.43; Cramér *V*=0.03), suggesting that missing data were not due to patterned nonwear (eg, on weekends) but more likely due to technical issues. This is further supported by the significant association between operating system and the percentage of days with step count data (*U*=670.00; *Z*=−2.14; *P*=.03; *r*=−0.23). Specifically, Android users (n=51, 58.6%; median rank=48.86) had significantly more days with data than iPhone users (n=36, 41.4%; median rank=37.11), possibly reflecting connectivity issues specific to the operating system. In addition, there were significant differences between PF usage groups in the percentage of days with step count data (H_2=24.29; *P*<.001). Post hoc comparisons showed that participants in the high-usage group (median 85.6%, range 0.0% - 98.3%) had significantly more days with step count data than those in the moderate-usage (median 26.8%, range 0.0% - 88.8%; *P*<.001) and low-usage groups (median 30.8%, range 0.0% - 97.8%; *P*=.003). These findings could indicate that persistent connection issues might have contributed to lower usage. This interpretation is supported by qualitative data: some participants reported feeling demotivated or even discontinuing their use of PF due to unresolved connection issues between the smartwatch and coach (also see the quotation accompanying the point for improvement "Smartwatch connection issues" in Table 2):

> *I sent several emails about it, but it just kept being difficult that Sam didn't register my steps. And that was actually demotivating – when Sam would say, 'you've walked zero steps today.' Then I'd try again [to fix it], and sometimes it worked, sometimes it didn't. I still can't put my finger on it. But yes, that did demotivate me at times.* [M3, abstinent and increased PA at T1]

Although potential causes of the sensor connection issues were identified, many remained difficult to trace. Troubleshooting strategies had limited and often temporary effects. Technical lessons learned and recommendations for future research are provided in Multimedia Appendix 3.

Associations

To explore associations between baseline characteristics and PF usage, satisfaction, usability, and coach acceptance, we conducted exploratory quantitative analyses, complemented by qualitative data that provided contextual insight. As PF was specifically designed to be suitable for individuals with lower SEP and eHealth literacy, results related to these variables and significant associations with other variables (*P*<.05) are highlighted here. Full details and additional nonsignificant results are provided in Table S3 in Multimedia Appendix 2.

Age differed significantly between PF usage groups. Post hoc comparisons showed that participants in the high-usage group (mean 58.39, SD 12.79) were older than those in the low-usage (mean 50.30, SD 13.95; *P*=.05) and moderate-usage groups (mean 48.47, SD 13.85; *P*=.01). This contrasts with some of the interview data, in which older participants expressed that they expected PF to be easier to use for younger individuals, often linking this to digital skills:

> *When I typed something and Sam replied, it happened very quickly, and every time I had to scroll back to read it. But as soon as he typed something new, it jumped up again. I found that really annoying. […] Younger people probably find that easier, they're also faster than me.* [M4, 61 years]

Digital literacy was also mentioned more generally as influencing ease of use, particularly in dealing with errors, such as the smartwatch connection issues:

> *You had to first open and then close the app again to get a connection. Luckily, I'm quite tech-savvy, so I sorted it out quickly. But I can imagine that being very frustrating if you're not.* [M1, 48 years]

However, a few older participants with lower digital skills noted that they still found PF manageable (see quotation accompanying the strength "Clear and easy to use" in Table 2).

In addition to age, quantitative analyses showed that the eHealth literacy scale 4—"Feel safe and in control"—was weakly, positively correlated with the perceived usability of PF. This suggests that participants who felt more ownership over their data and perceived it as secure reported higher usability of PF.

No significant associations were found in the quantitative analyses between SEP, eHealth literacy subscales (except for scale 4), and any of the primary outcomes. This suggests that PF may have been perceived as similarly feasible and acceptable across these groups. Interestingly, a trend-level difference in satisfaction with PF was observed across SEP groups, with somewhat higher satisfaction among participants with low SEP (mean 3.03, SD 0.67) compared to middle (mean 2.90, SD 0.70) and high SEP participants (mean 2.56, SD 0.71). However, a post hoc power analysis using the largest observed effect size for SEP and eHealth literacy associations (*f*=0.30) indicated only about 61% power with the current sample size. This likely limits the ability to detect significant differences.

Secondary Outcomes

Recruitment, Response, Consent Rates, and Recruitment Strategies

Recruitment took place over approximately 6 months. In total, 361 individuals expressed interest in the study, of whom 222 were screened for eligibility, resulting in a response rate of 0.61. The consent rate among those eligible was 0.83 (see Figure 1). These rates indicate both the feasibility of the recruitment strategies and substantial initial interest in PF. The target sample size of 100 was reached before all eligible individuals could be enrolled, further suggesting promising user interest in a virtual coach-based mHealth intervention for smoking cessation and PA promotion.

XSL•FO
RenderX

Among the 100 participants enrolled, recruitment was most effective through newsletters from 2 health insurance companies (n=37, 37.0%), followed by social media (mainly Facebook advertisements) and recruitment via family, friends, or work contacts (both n=21, 21.0%). More labor-intensive strategies, such as in-person flyer distribution or a local newspaper interview, yielded only a few participants (both n=4; see Table S4 in Multimedia Appendix 2).

Since recruiting participants from lower SEP backgrounds is often reported as challenging [14], we also examined recruitment effectiveness across SEP groups. No significant differences in recruitment strategy were found between SEP groups (χ^2_{18}=20.06; *P*=.33; Cramér *V*=0.33).

Study Adherence

A significant association was found between PF usage (low, moderate, and high) and study adherence at T1 (χ^2_2=9.32; *P*=.009; Cramér *V*=0.31). T1 completers (n=77) were more likely to be in the high-usage group (n=26, 33.8%) than noncompleters (n=7, 9.1%). Conversely, most noncompleters (n=15, 63.6%) were in the low-usage group, compared to 29.9% (n=23) of completers.

Discussion

Principal Findings

This single-arm, pre-post, convergent mixed methods study primarily aimed to investigate the feasibility and acceptability of PF, an mHealth intervention with a virtual coach offering real-time, personalized feedback to support both smoking cessation and PA promotion. Additional aims included exploring associations between baseline characteristics and feasibility and acceptability outcomes, as well as examining the feasibility of conducting the research study. Overall, PF showed adequate feasibility and acceptability, and study procedures proved feasible. Furthermore, the mixed methods design yielded valuable insights into participants' experiences and areas for improving PF and virtual coach interventions in general.

The main findings showed that PF usage varied considerably across participants. Descriptive analyses indicated moderate-to-good satisfaction and usability of PF, but virtual coach acceptance was somewhat negative. High PF users reported greater satisfaction with PF, usability of PF, and coach acceptance. Frequent connection issues between the smartwatch and coach emerged as a disruptive factor, reported more often in the low- and moderate-usage groups than in the high-usage group. Qualitative results provided in-depth insights into PF's feasibility and acceptability, encompassing both positive and negative experiences. Exploratory analyses suggested that high PF users were older than those with moderate and low usage and that the eHealth literacy scale "Feel safe and in control" was weakly positively correlated with usability. Importantly, PF was perceived as similarly feasible and acceptable across SEP groups, aligning with one of the research project's goals. Finally, there was substantial initial interest in PF, and study retention postintervention was 77%, which is relatively high given typical attrition in eHealth studies [21,71].

Understanding Variation in Usage and Experiences

Variation in PF usage and experiences may first be explained by user engagement, conceptualized as (1) the extent of usage and (2) the subjective experience (ie, attention, interest, and affect) [72]. Regarding usage extent, quantitative data showed that weekly coach interaction and intervention duration were generally high; yet, completion of core intervention components varied widely. This may reflect the intervention's personalization but also differences in satisfaction and usability. Subjective engagement, inferred from qualitative data, also varied: some participants found PF motivating and enjoyable, whereas others did not. Increased attention and interest were reported when content prompted reflection or self-reflection, felt personally relevant, or was delivered empathetically. Participants reported the need for evolving goals and content to maintain relevance, challenge, and a sense of progress. This may support perceived competence, potentially leading to high engagement or "flow," consistent with psychological flow theory [73]. This emphasizes the value of personalization, as shown in prior studies [32,74,75]. A second explanation for variation in usage and experiences concerns technical issues. These issues caused frustration and loss of interest for some participants, mirroring findings from a previous review [25]. A particularly disruptive issue was the smartwatch-coach connection, interfering with step tracking and goal personalization. Findings indicated that these issues were associated with lower PF usage and early dropouts, consistent with a review on mHealth interventions for PA promotion [75]. Although many connection issues were difficult to trace, we shared lessons learned (Multimedia Appendix 3) to help mitigate them in future studies. For example, implementing real-time monitoring systems may help detect missing sensor data early and allow researchers to intervene before data loss undermines engagement or intervention delivery. Together, these findings highlight 2 potential factors underlying variability in usage and experiences, offering guidance for future interventions.

Challenges and Opportunities for the Virtual Coach

The virtual coach was the least appreciated component of PF. Qualitative feedback showed participants generally valued its supportive, empathetic, and nonjudgmental style but were critical of its repetitive, static communication and limited adaptability to user input or personal situations. Similar concerns have also been reported in a previous review of virtual coaches for smoking cessation [25]. One potential strategy to improve the coach's communication is the use of natural language processing, which can increase variation and adaptability by training the system to classify and generate responses based on large textual datasets [1,21,25,76]. While recent advances make this a promising approach that might increase the coach's acceptability, such models can produce potentially misleading, inappropriate, or nonfactual outputs [21,77,78]. It remains crucial to balance flexibility (eg, responsiveness to context) with controllability, consistency in content delivery, and safety. As rule-based systems offer greater control [21,76], a hybrid approach combining rule-based and probabilistic techniques may be most suitable for future virtual coach interventions [79].

XSL•FO
RenderX

Accessibility and Inclusivity

We aimed to make PF accessible to individuals often underserved by health behavior change interventions, including those with a lower SEP, limited eHealth literacy, or digital skills [21,25]. Exploratory analyses revealed no significant differences in feasibility and acceptability across SEP groups. Although the study was underpowered to detect small effects, there was a trend toward higher PF satisfaction among participants with a lower SEP. Moreover, participants scoring higher on the "feel safe and in control" eHealth Literacy subscale reported greater usability of PF. Qualitative feedback, especially from older participants with self-reported lower digital skills, indicated that they expected PF to be easier for younger participants or would have appreciated additional support (eg, from a human assistant). However, experiences varied, as some older participants with limited digital skills found PF manageable. Interestingly, participants in the high-usage group were significantly older than those in the low- and moderate-usage groups. These findings suggest that older age does not necessarily limit the ability to use PF, possibly because PF was designed to be suitable for individuals with lower digital skills. Furthermore, older users may have had fewer prior experiences with digital interventions, which can lead to lower expectations and, consequently, a more positive appraisal of the intervention [75]. Finally, dropouts did not differ significantly from completers in SEP, age, or eHealth literacy. These findings are noteworthy given concerns that virtual coaches (for smoking cessation) may exacerbate health disparities [21,25]. Developing accessible and inclusive interventions is therefore essential, and these findings indicate that PF may be a promising step in that direction.

Strengths and Limitations

This study has several strengths. First, PF integrates behavior change techniques commonly used in smoking cessation [37] and PA promotion [38], as well as behavioral theories. Additionally, we incorporated features previously reported as lacking in virtual coaches, such as relational strategies [25], and addressed literature gaps, including transparent intervention reporting [25], which we provided in our published protocol [43]. Moreover, PF was developed by an interdisciplinary team in collaboration with end users [36], likely enhancing feasibility and acceptability. Second, we conducted an in-depth evaluation of PF's feasibility and acceptability. These aspects remain underresearched in virtual coaches [1], despite their importance for long-term adoption [24-26,33,34]. Our convergent mixed methods approach captured both general patterns and nuanced user experiences, helping to identify key strengths and areas for improvement. Third, initial interest in PF was high, and the retention rate was approximately 77% at postintervention (4 months after baseline). This is a positive outcome given the typically high dropout rates in digital interventions [21,71]. Furthermore, recruiting participants from lower socioeconomic backgrounds is often challenging [14] but essential to promote digital inclusion. Therefore, we applied recruitment strategies to reach a broad, diverse audience, resulting in a SEP distribution comparable to the general Dutch population [68].

This study also has some limitations. First, we did not include a dedicated user engagement questionnaire (eg, the short form of the User Engagement Scale [80]), which might have provided a more explicit assessment of engagement. However, there is ongoing debate about the best way to measure engagement in virtual coach interventions, and many studies rely solely on objective usage data, overlooking users' subjective experiences [1,25]. By applying a mixed methods approach, we inferred subjective engagement from qualitative data and identified potential barriers and facilitators. Second, an error in the SEP measurement prevented distinguishing between lower-level (1-2) and middle-level (3-4) vocational education. As a result, all participants with vocational education were classified as middle SEP, likely underestimating the lower SEP group. Third, postintervention completers generally showed higher PF usage, which may have led to an overestimation of feasibility and acceptability. Furthermore, although we aimed to recruit a diverse group for the interviews, participants who were more engaged with PF may have been more likely to participate. To address this, we explicitly invited participants with different levels of PF usage, leading to interviews with 3 low PF users. This may have helped mitigate potential overestimation.

Research and Practical Implications

Several implications emerged for further development of PF and virtual coaches in general. Key areas for improvement included greater content variation, enhanced adaptability of the coach to user input and personal situations, integration of intervention into a single app, and a more reliable smartwatch-coach connection. Although PF incorporated personalization strategies (eg, adaptive step goals), qualitative feedback highlighted the need for additional personalization. For example, adapting the coach to users' preferred coaching style (eg, more directive vs autonomy-supportive) may enhance engagement [81,82]. As engagement can change over time [28], personalization based on dynamic user states (eg, motivation) may also be beneficial [25,83]. Besides enhancing personalization, identifying which populations these interventions best serve is important. Our findings revealed varying preferences; for instance, some participants valued a virtual coach for anonymity, low-threshold access, and a sense of control, while others favored a human coach for greater accountability. These insights can guide future research on aligning population characteristics with different delivery modes of virtual coach interventions. At the same time, broad accessibility should be promoted to avoid exacerbating health disparities, for instance, by exploring different implementation formats. PF was evaluated as a standalone intervention, which may be suitable for those preferring self-guided support or facing barriers to human care. Adding low-level human involvement could further support individuals with lower digital skills (as indicated by our qualitative findings) or lower SEP [14], while considering limited health care resources and ethical allocation. Strategies such as human feedback messages [83] or adaptive designs escalating from low-intensity digital support to human involvement at certain moments [84] may help achieve this balance. Future research should explore how to balance effectiveness, resource use, and equity in virtual coach interventions.

XSL•FO
RenderX

Conclusions

PF shows adequate feasibility and acceptability as a virtual coach-based intervention for smoking cessation and PA promotion. It is accessible to groups often underserved by behavior change interventions, such as those with lower SEP or older age. Usage varied considerably, potentially due to differences in engagement and technical issues (eg, smartwatch-coach connection). Participants valued the coach's empathetic style but noted limitations in its adaptability. This underscores the need for additional personalization, for example, through hybrid approaches combining rule-based systems with natural language processing. Variation in participant experiences highlights the importance of identifying which populations are best served by virtual coaches while promoting broad accessibility to avoid exacerbating health disparities. One strategy is to add low-level human involvement while accounting for limited health care resources.

Overall, PF shows potential as an accessible, inclusive multibehavior change intervention that could benefit public health. This study lays the groundwork for follow-up research evaluating PF's effectiveness and suitable implementation strategies, and provides recommendations for the development of future virtual coach interventions.

Acknowledgments

The authors would like to thank the Perfect Fit advisory board members, members of the Perfect Fit consortium, including collaborating public and private parties, experts who shared their knowledge during expert sessions, and several students for their contributions to the development of the Perfect Fit intervention and this research study.

The members of the Perfect Fit consortium are as follows:

Willem-Paul Brinkman (Department of Intelligent Systems, Delft University of Technology, Delft, The Netherlands), Sven van der Burg (Netherlands eScience Center, Amsterdam, The Netherlands), Winifred A. Gebhardt (Department of Psychology, Unit Health, Medical and Neuropsychology, Leiden University, Leiden, The Netherlands), Joost N. Kok (Faculty of Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, The Netherlands), Mark Neerincx (Department of Intelligent Systems, Delft University of Technology, Delft, The Netherlands), Jasper Reenalda (Biomedical Signals and Systems, University of Twente, Enschede, The Netherlands)

Abstract

Background: Artificial intelligence–based skin cancer screening apps (AISCSAs) offer diagnostic potential but face limited adoption. App store cues, such as ratings, may influence acceptance; yet, little is known about how users cognitively process app store information in high-stakes health contexts. To address this gap, eye-tracking was used to measure visual attention while participants evaluated a mock AISCSA app store listing.

Objective: This study aimed to test whether a single negative rating captures visual attention and whether an extended technology acceptance model (TAM) can predict behavioral intention to use (BI) AISCSAs.

Methods: Participants (N=76) evaluated a mock app store listing for an AISCSA under positive (n=42) or negative (n=34) rating conditions while their eye movements were recorded. Analyses combined fixation durations in defined areas of interest (AOIs) with self-reported measures of perceived usefulness (PU), perceived ease of use (PEOU), trust, BI, willingness to pay, and the self-rated importance of app attributes.

Results: Normalized fixation durations (seconds per square pixel) revealed the highest attention to the description (0.166 s/px^2), followed by the reviews (0.11 s/px^2) and the ratings (0.04 s/px^2), while the price and the data protection received the least attention. Of the 5 self-rated app attributes, only reviews correlated positively with fixation durations on the reviews-AOI (r=0.28; P=.01). Rating valence had no significant effect on gaze patterns, PU, PEOU, trust, BI, or willingness to pay (all Ps>.05). However, PEOU (P=.001), PU (P<.001), and trust (P<.001) were significantly correlated with BI.

Conclusions: Although the expected attentional capture effect of the negative rating was not observed, the weak or nonexistent associations between fixation durations on the AOIs and the self-rated importance of app attributes suggest that eye-tracking captures aspects of information processing that are not directly reflected in self-reported evaluations. These findings indicate that eye-tracking provides a more direct approximation of actual user behavior by revealing implicit attentional processes beyond what is captured by questionnaires. While the technology acceptance model constructs and trust predicted BI, rating valence alone did not affect acceptance or gaze behavior. In high-stakes health contexts, textual information may outweigh rating valence in driving adoption. Future research should explore conditions under which rating valence matters, including more extreme rating contrasts, variations in accompanying review texts, and the influence of individual differences such as preexisting attitudes toward artificial intelligence and levels of artificial intelligence literacy.

Introduction

Background

Skin cancer is a highly prevalent global health concern, with melanoma, the deadliest subtype, posing a significant challenge. Early detection is crucial for improving survival rates, and clinical guidelines recommend full-body skin examinations by trained dermatologists and the use of dermoscopy for assessing skin lesions [1,2]. However, a growing shortage of dermatologists is exacerbating diagnostic delays [3,4]. Even today, more than half of all skin cancers are first noticed by patients themselves rather than detected during professional screenings [5], which has driven the exploration of artificial intelligence (AI) to support skin cancer detection. Empirical studies show that deep learning models can achieve diagnostic performance comparable to human experts in analyzing dermoscopic images for melanoma [6,7]. When integrated into mobile apps, these systems provide immediate risk assessments through automated, deep learning–based image analysis. Despite their potential to support early detection, adoption rates remain

XSL•FO
RenderX

low, as many users continue to prefer conventional dermatological consultations [8-10].

This reluctance reflects a broader adoption gap identified in research on AI in health care—a discrepancy between the high diagnostic performance of AI systems and their limited acceptance in real-world practice [11,12]. While this gap is well-documented, less is known about the specific digital cues that drive such skepticism. Given that users increasingly rely on app store information to evaluate AI-based health apps, understanding how user-generated ratings shape acceptance becomes critical—particularly as these ratings represent a powerful yet understudied influence on decision-making in high-stakes health care scenarios.

Despite extensive research on rating valence in e-commerce, 3 key gaps remain. First, the role of rating valence in high-stakes health contexts, such as AI–based skin cancer screening apps (AISCSAs), remains largely unexplored. Second, prior research has not systematically integrated rating valence into the technology acceptance model (TAM) [13], particularly with regard to its causal effects on perceived usefulness (PU), perceived ease of use (PEOU), trust, and outcomes such as behavioral intention to use (BI) and willingness to pay (WTP). Existing studies predominantly rely on observational, nonexperimental designs, limiting causal inference. In contrast, this study uses an experimental manipulation of rating valence (positive vs negative) to directly examine its causal impact on these constructs. Third, prior work relies almost exclusively on self-reported measures and thus provides limited insight into the underlying cognitive processes, neglecting objective behavioral data such as eye-tracking.

To address these gaps, this study develops an integrative framework that combines the TAM, trust, and rating valence within a dual-process perspective of technology acceptance. By linking experimentally manipulated rating valence with both self-reported measures and eye-tracking data, we provide novel insights into how rating valence causally shapes acceptance beliefs and intentions, how users visually process app store information, and how closely self-reported evaluations align with actual attentional behavior.

Theoretical Foundation and Research Hypotheses

Effects of Rating Valence on Technology Acceptance

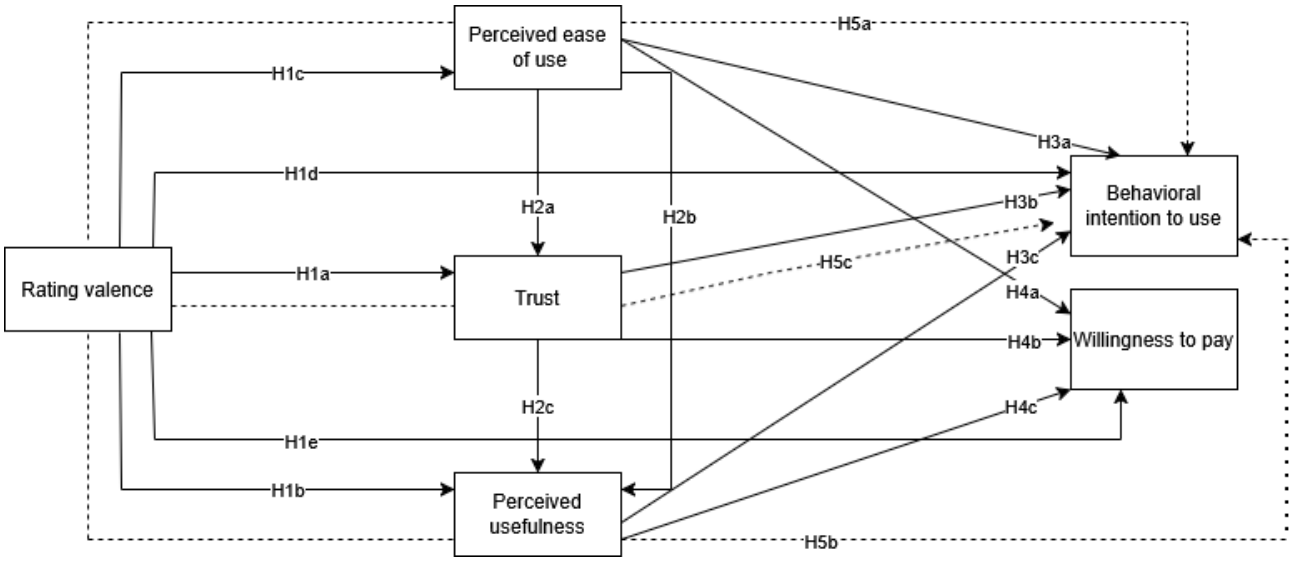
Traditional technology acceptance research, particularly the TAM, assumes that technology evaluation is primarily a deliberate and analytical process. The TAM posits that PU and PEOU are the key determinants of BI [13]. However, dual-process theory suggests that human cognition is governed by 2 interacting systems: type 1 processing, which is fast, intuitive, and heuristic-based, and type 2 processing, which is slower, reflective, and cognitively effortful [14]. Because individuals tend to act as “cognitive misers,” they typically default to type 1 processing and rely on heuristic cues, particularly in uncertain or information-rich environments [14].

In digital marketplaces, such as app stores, these heuristic processes are highly relevant. User-generated star ratings serve as salient cues that shape users’ initial impressions before more deliberate evaluations take place. In this context, ratings and reviews function as key signals of product reliability by conveying aggregated user experiences and recommendations [15-17]. Meta-analytic evidence confirms that review valence exerts a powerful effect on purchase intentions [18]. While positive reviews enhance perceived quality and download likelihood [19-21], negative reviews often exert even stronger effects because they are perceived as more diagnostic and trustworthy [22,23]. This asymmetry is attributed to the negativity bias, where negative information attracts greater attention and has a stronger impact on decisions than positive ones [24-26].

Taken together, this suggests that rating valence may act as an early heuristic signal that shapes subsequent evaluations before more analytical processing occurs. Acceptance beliefs, such as PU, PEOU, trust, BI, and WTP, may already be biased by initial exposure to rating information. Importantly, WTP appears less stable than BI and may be influenced in a more complex and indirect manner, as it reflects distinct evaluative judgments and is shaped by both functional and psychological factors [27-29]. Building on this reasoning, this study introduces an experimental manipulation of rating valence, enabling a direct test of how external heuristic cues causally influence the formation of PU, PEOU, trust, and outcomes such as BI and WTP. Accordingly, we address the following research question: What is the effect of positive versus negative ratings on behavioral intentions? To empirically examine this proposed preprocessing role of rating valence across different outcome variables, the following hypothesis is formulated:

- H1: Rating valence significantly influences user perceptions and intentions, such that a negative rating leads to lower (a) trust, (b) PU, (c) PEOU, (d) BI, and (e) WTP.

Extending the TAM



While the previous hypothesis proposed that rating valence influences initial evaluations, it remains unclear through which mechanisms these effects translate into acceptance decisions. The TAM provides a well-established framework to explain how user beliefs shape behavioral intentions. However, in AI-based health care contexts, the TAM alone may not fully capture user acceptance. A recent review by Lee et al [30] shows that the core TAM constructs are insufficient in complex health care environments, where additional factors, such as trust, organizational support, and education, significantly influence adoption. Due to the complexity, opacity, and perceived unpredictability of intelligent systems, trust emerges as an essential additional construct. Trust reflects the belief that a system performs reliably and safely, thereby reducing perceived risk and supporting decision-making under uncertainty [31,32]. Empirical evidence indicates that trust not only directly affects BI [22,33,34] but also positively influences PU [35-38]. Based on this framework, the following hypotheses are proposed (Figure 1):

- H2: Within the AISCSA context, PEOU is positively associated with (a) trust and (b) PU, and (c) trust is positively associated with PU.
- H3: BI is positively associated with (a) PEOU, (b) trust, and (c) PU.

XSL•FO
RenderX

- H4: WTP is positively associated with (a) PEOU, (b) trust, and (c) PU.

Figure 1. Integrative research model incorporating rating valence and trust into the technology acceptance model to predict behavioral intention to use and willingness to pay. H: hypothesis.

We want to test whether the TAM is able to explain the effects of the experimental manipulation. Prior research extending the TAM in AI-based health care contexts predominantly relies on cross-sectional survey designs to examine relationships between the TAM constructs and additional factors (eg, trust and privacy concerns) without experimentally manipulating external inputs [33,34,39,40]. While these approaches allow for the estimation of theoretically grounded causal pathways, they are based on observational (nonexperimental) data and therefore remain limited in establishing causal effects. Against this background, a key question is whether the TAM can adequately explain how externally manipulated rating information translates into behavioral intentions. Accordingly, we address the following research question: To what extent can the TAM explain the effect of rating valence on behavioral intentions? Building on this reasoning, we propose the following hypotheses:

- H5: The effect of rating valence on BI is mediated by (a) PEOU, (b) PU, and (c) trust.

Visual Attention and the Processing of Heuristic Cues

While heuristic cues such as rating valence are assumed to influence evaluations, this assumption does not account for how users cognitively process such information at the moment of exposure. Traditional technology acceptance research has largely relied on self-reported measures to assess acceptance beliefs, thereby conceptualizing decision-making as a consciously accessible and predominantly rational process [13]. However, such measures are limited, as individuals are often unable to accurately report the processes underlying their decisions due to recall bias and introspective inaccessibility [41-43]. Eye-tracking offers an important window into these processes by capturing objective and continuous measures of visual attention and cognitive engagement. According to the eye-mind hypothesis, individuals process what they fixate on, making visual fixation a reliable indicator of ongoing cognitive processing [44,45]. In this context, fixation duration reflects cognitive effort and information processing depth, with longer fixations indicating more intensive processing [46]. From a dual-process perspective, fixation patterns can be interpreted as indicators of different processing modes: shorter fixations are associated with intuitive, heuristic-based (type 1) processing, whereas longer fixations suggest more deliberate and analytical (type 2) processing [47,48]. Importantly, eye-tracking captures nonconscious attentional processes and thus provides an unobtrusive and behaviorally grounded measure of information processing that complements self-reported evaluations. Here, we use eye-tracking to improve our understanding in 3 ways.

First, we investigate where people look for information in the app store when browsing for health-related apps. In digital environments, attention is inherently selective and shaped by both stimulus characteristics and user goals. Prior eye-tracking research suggests that users tend to focus on visually salient elements such as images [49-53]. However, app store-specific evidence indicates that decision-making often relies more heavily on textual information, particularly descriptions and user reviews [54]. At the same time, existing findings point to substantial variability in attention patterns. Eye-tracking studies show that while some users engage extensively with review content, others allocate more attention to product selection, with differences observed across user groups such as different age cohorts [55]. Conversely, privacy- and security-related information typically receives limited attention, especially when presented in less salient formats [56]. Users may overlook privacy policies despite expressing concerns and rely on heuristic cues when apps are perceived as necessary [57,58]. Taken together, these findings suggest that attention allocation in app store environments is neither uniform nor fully explained by existing theory. In particular, it remains unclear which types of information users prioritize when evaluating high-risk health apps. To address this gap, we descriptively analyze gaze patterns.

Second, we test whether users' consciously reported importance of app attributes corresponds to their actual allocation of visual

XSL•FO
RenderX

attention during decision-making. While self-reports and eye-tracking capture different levels of cognitive processing [59], they are expected to converge on attributes that users deem personally relevant. If an attribute is integrated into an individual's conscious value system, it should actively guide attentional resources toward related information. Accordingly, we address the following research question: To what extent are the self-rated importance of app attributes reflected in users' gaze patterns? Based on this reasoning, the following hypothesis is proposed:

- H6: There is a positive relationship between the self-rated importance of app attributes and actual visual attention (fixation durations) to the corresponding areas of interest (AOIs).

Third, we test the effect of our experimental manipulation on visual attention. Consistent with the negativity bias [24-26], prior eye-tracking research shows that negative information attracts greater visual attention and elicits more intensive cognitive processing [60,61]. Such heightened attention may reflect a shift from intuitive, automatic processing (type 1) to more deliberate and analytical processing (type 2), particularly when users encounter risky or conflicting information [47]. Supporting this view, evidence suggests that negative or misleading stimuli can activate type 2 processing and prompt deeper evaluation compared to consensus-based stimuli [62]. Based on this reasoning, the following hypothesis is proposed:

- H7: A single negative rating increases visual attention to user reviews, as reflected in longer fixation durations on the reviews-AOI.

Moderating Role of Attention and Individual Differences

While rating valence shapes perceptions through the TAM-related mechanisms, its impact is unlikely to be uniform across users and situations. Dual-process theory suggests that the influence of heuristic cues depends on processing depth: information that is processed more extensively exerts a stronger effect on subsequent judgments [63]. Visual attention provides an observable indicator of this processing depth, as information receiving more attention is more likely to be incorporated into decision-making [64]. Beyond mere information acquisition, research indicates that visual attention actively biases decisions through a causal amplification effect. According to this mechanism, fixations are not neutral; rather, they amplify the relative value signal of the attended information. Consequently, longer fixations increase the weighting of a specific cue, such as rating valence, within the value integration process, thereby exerting a disproportionate influence on the final evaluation [65,66]. This implies that rating valence should have a stronger impact on user beliefs and intentions when it receives greater visual attention. In other words, the effect of rating valence is not fixed but depends on how deeply the cue is processed and integrated into the decision-making process. To capture this conditional effect, we propose that visual attention moderates the relationship between rating valence and acceptance-related outcomes:

- H8: The effect of rating valence on (a) PU, (b) PEOU, (c) trust, and (d) BI is moderated by visual attention, such that higher fixation durations on the ratings-AOI strengthen this relationship.

Prior research suggests that individual differences influence how users process and respond to app store information. Factors such as age, sex, education, prior experience with health apps, and self-reported AI knowledge may shape reliance on heuristic cues as well as attention allocation and acceptance judgments [67-69]. Less experienced users, for instance, may rely more strongly on ratings, whereas more knowledgeable users may engage in more analytic processing. However, existing evidence does not support a comprehensive set of directional hypotheses for each characteristic. Therefore, these variables are included as control and exploratory factors to provide additional insights into users' attention, perceptions, and behavioral intentions.

Methods

Participants and Recruitment

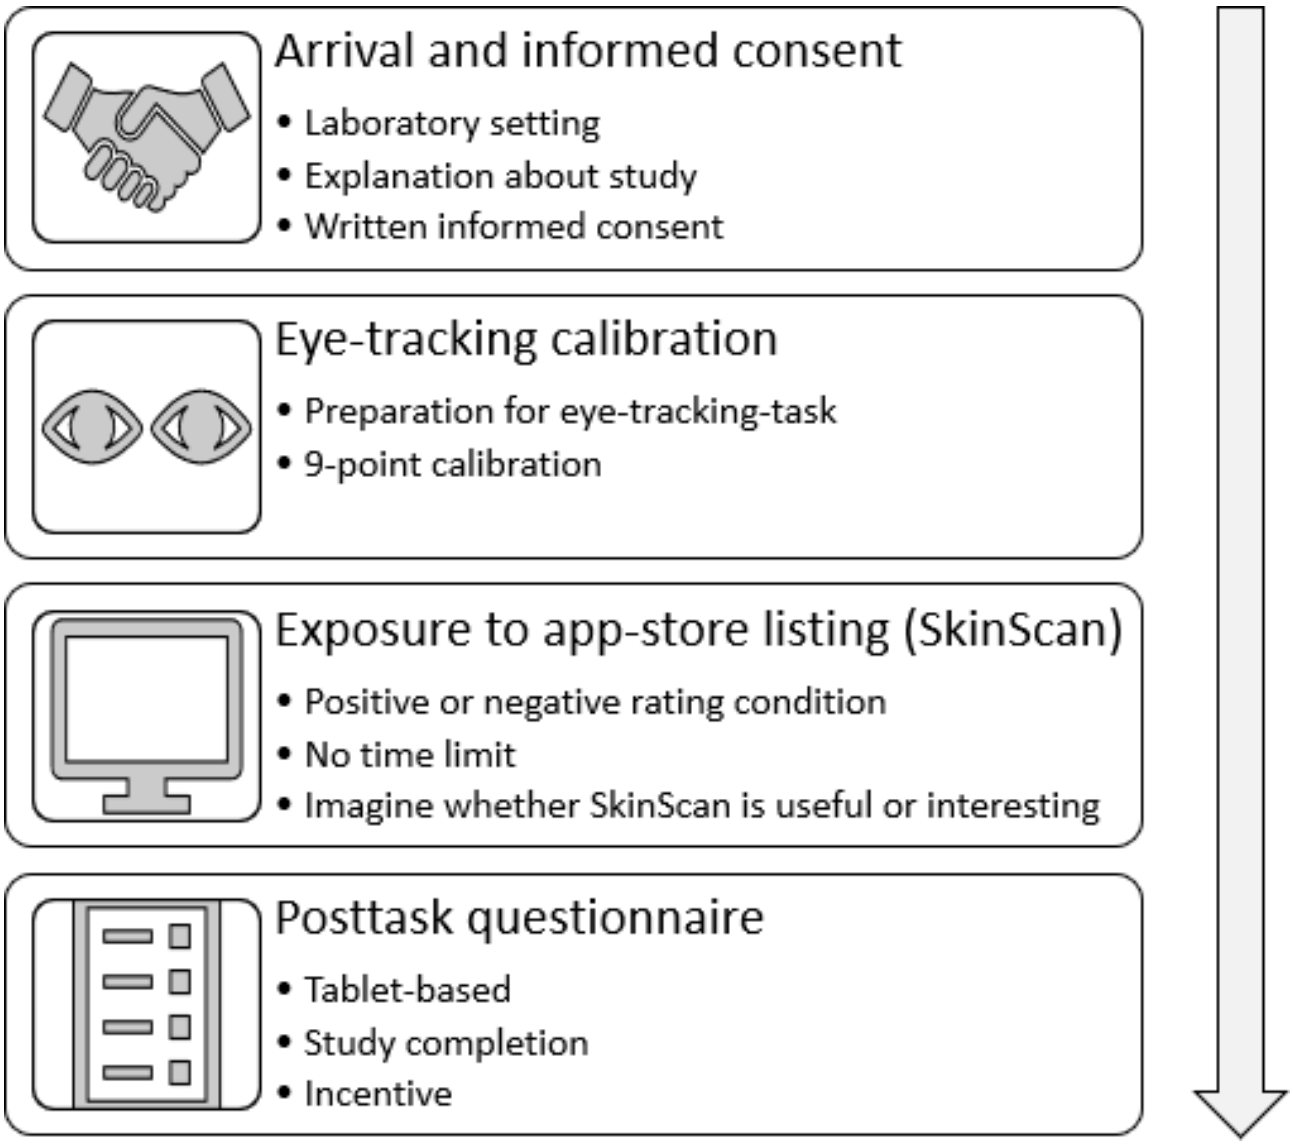
Participants were recruited via university mailing lists, flyers, and student WhatsApp groups. Eligibility criteria included a minimum age of 18 years and fluency in German. Data collection took place between April 28 and May 31, 2025. A total of 95 participants were initially recruited; 19 were excluded due to insufficient eye-tracking accuracy or failed attention checks, resulting in a final sample of 76 participants (positive condition: n=42; negative condition: n=34). An a priori power analysis (G*Power; α=.05; power=0.95; effect size=0.80) indicated a required sample size of at least 35 participants per group, confirming sufficient statistical power. In response to the reviewers' and editor's comments, we have streamlined and refined our hypotheses. Importantly, this revision involved a structural clarification rather than changes to the underlying analyses or hypothesis testing. The updated hypotheses and their correspondence to the original versions are presented in Table S1 in Multimedia Appendix 1.

Eye-Tracking Setup

Gaze data (fixation duration) were recorded using a Tobii Pro Spark eye tracker (60 Hz), mounted below a 22-inch laptop screen (1920×1080 pixels, 60 Hz). Sessions were conducted individually in a controlled laboratory environment, with participants seated approximately 45 - 55 cm from the screen [70]. A standard 9-point calibration was performed prior to the experiment, and only calibrations with a validation accuracy below 0.80° were accepted [71].

Materials

The stimulus for the eye-tracking experiment was a mock-up of an Apple app store listing for a fictitious skin cancer screening app ("SkinScan"), modeled after existing apps. To reduce familiarity bias, app name and content were adapted. Two versions of SkinScan were created, identical in all aspects except for the middle of the 3 user star ratings: the positive rating condition showed two 5-star ratings and one 4-star rating, while the negative rating condition replaced the middle 5-star with a 1-star rating to introduce the experimental manipulation (Multimedia Appendix 2)Multimedia Appendix 2. All other elements, including the overall star rating and review text, were



XSL•FO
RenderX

identical across conditions. Both app versions were integrated into and presented through Tobii Pro Lab.

Procedure

After providing informed consent, participants were seated in front of the eye-tracking system. They were instructed to view the app page as they normally would and to imagine evaluating its usefulness. Subsequently, a 9-point calibration procedure was conducted. Following calibration, the experiment began. No time limit was imposed, and gaze behavior was recorded continuously throughout the task. After stimulus exposure, participants completed a questionnaire on a tablet device and received compensation (see Figure 2 for the procedure of the experiment). A small pretest (n=3) using a think-aloud approach was conducted to ensure clarity and usability of the study design.

Figure 2. Schematic representation of the study workflow.

Posttask Questionnaire

The questionnaire consisted of 29 items. The first section measured PEOU, PU, trust, and BI using validated multi-item scales, with each construct measured by 4 items (see Table S2 in Multimedia Appendix 1 for a complete list of items and scale specifications). The second section assessed the self-rated importance of app attributes (eg, price, reviews, and data protection) on 5-point Likert scales (1=not at all important and 5=very important). The third section included self-rated AI knowledge, WTP, and demographic variables (age, sex, previous experience with health apps, and education). All scales were adapted from prior research. Following established scale development procedures [72,73], content modifications were made to reflect the study's objectives. To ensure linguistic accuracy, all items were translated using a back-translation procedure [74]. An attention-check item was included to ensure data quality. A full list of questionnaire items is provided in Table S2 in Multimedia Appendix 1.

Data Analysis

To assess potential common method bias, the Harman single-factor test was conducted [75]. An exploratory factor analysis including all questionnaire items was performed. Parallel analysis indicated a multifactor structure, and the single-factor solution accounted for only 30% of the total variance. Moreover, the 1-factor model showed poor fit

XSL•FO
RenderX

(χ^2_{135}=4364.2; P<.001). These results suggest that common method bias is unlikely to be a significant concern in this study.

Fixation durations (in seconds) were recorded within predefined AOIs (Multimedia Appendix 3)Multimedia Appendix 3 and processed using Tobii Pro Lab. Fixation duration data were aggregated into composite categories (eg, reviews, ratings, and description) and normalized by AOI size (seconds per square pixel) to account for differences in area. Mean fixation durations per AOI were then calculated at the participant level. Participants with insufficient tracking accuracy or missing data were excluded (n=19), yielding a final sample of 76.

Prior to analysis, scatterplots were examined to assess linearity and identify influential outliers. Pearson correlations were used to test relationships between variables, and independent-samples 2-tailed *t* tests (including Cohen *d*) were conducted to compare experimental conditions. Multiple regression analyses were performed to assess predictors of BI and WTP. Mediation and moderation effects were tested using regression-based approaches with bootstrapped CIs. All analyses were conducted at a significance level of P<.05, with 95% CIs reported.

Ethical Considerations

The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008. An ethics approval was granted by the University of Applied Sciences and Arts Bielefeld (2025_002), and the study was preregistered. Informed consent was required from all participants in this study. Participants received approximately US $5.83 compensation.

Results

Sample Characteristics

The final sample consisted of 76 participants. Of these, 42 of 76 (55%) participants were randomly assigned to view the positive rating condition, while 34 of 76 (45%) participants saw the negative rating condition. As shown in Table 1, participants had a mean age of 22.88 (SD 3.13; range 18-33) years and a median age of 22 (IQR 21-24) years. The majority of participants were female (53/76, 70%). Most reported having a general school leaving certificate (49/76, 64%), while 13 of 76 (17%) held a university degree. The mean level of self-rated AI knowledge was 2.65 (SD 0.91). None of the participants had prior experience with skin cancer screening apps.

Effects of Rating Valence on Technology Acceptance

To address the research question of how a single negative rating affects behavioral intentions, independent-samples comparisons were conducted to examine the effect of rating valence on trust, PU, PEOU, BI, and WTP (Table 2). The results indicated no significant differences between positive and negative rating conditions for any of the examined variables (all Ps>.05). Thus, H1a-e are not supported.

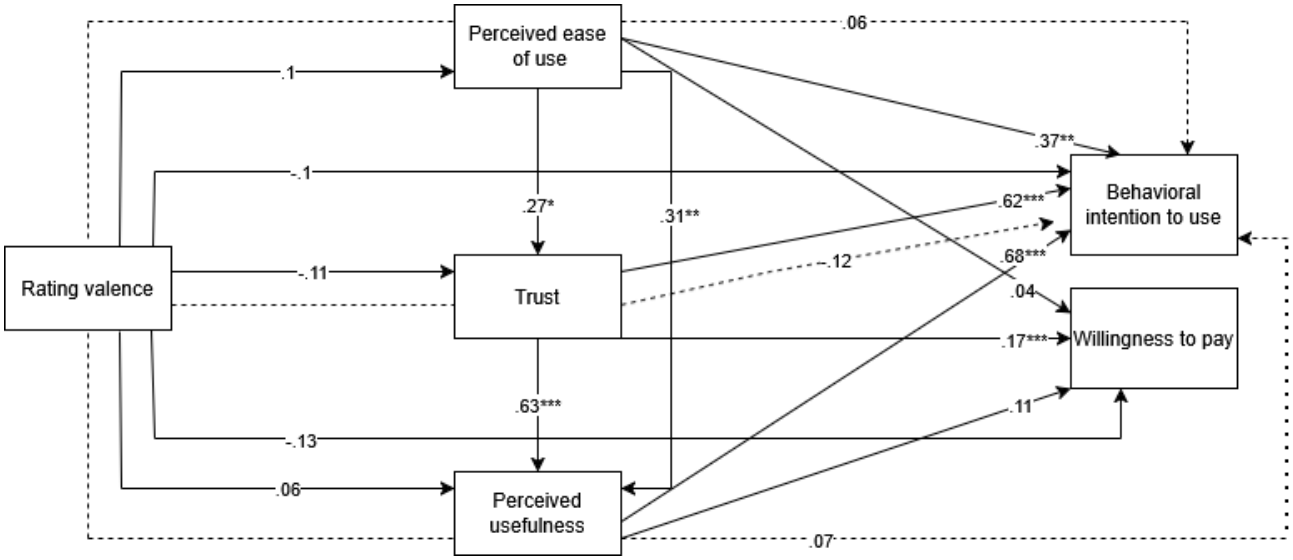
XSL•FO
RenderX

Table . Effects of rating valence on the technology acceptance model constructs.

Hypothesis (H)	Variable	Positive rating (n=42), mean (SD)	Negative rating (n=34), mean (SD)	*P* value, overall	Cohen *d*
H1a	Trust	2.48 (0.61)	2.62 (0.70)	.35	0.22
H1b	PU[a]	3.78 (0.64)	3.71 (0.71)	.64	0.11
H1c	PEOU[b]	4.23 (0.48)	4.12 (0.62)	.41	0.20
H1d	BI[c]	2.96 (0.84)	3.14 (1.01)	.42	−0.19
H1e	WTP[d]	19.5 (76.4)	63.1 (229)	.30	−0.27

[a]PU: perceived usefulness.

[b]PEOU: perceived ease of use.



[c]BI: behavioral intention to use.

[d]WTP: willingness to pay.

Extending the TAM

To investigate the research question concerning the applicability of the TAM framework in connecting rating valence to behavioral intentions, Pearson correlation coefficients were calculated to examine the strength of the relationships between the hypothesized constructs (Figure 3). PEOU was positively correlated with PU (H2b; r=0.31; P=.007) and trust (H2a; r=0.27; P=.02). Trust also showed a strong positive correlation with PU (H2c; r=0.63; P<.001). Regarding BI, all proposed constructs were significantly positively correlated: PEOU (H3a; r=0.37; P=.001), trust (H3b; r=0.62; P<.001), and PU (H3c; r=0.68; P<.001). In addition, Pearson correlation analyses revealed a small but significant positive association between trust and WTP (H4b; r=0.17; P<.001). In contrast, WTP was not significantly correlated to PU (H4c; r=0.11; P=.35) or PEOU (H4a; r=0.04; P=.76).

Figure 3. Summary of the results of the extended technology acceptance model. Dashed lines illustrate mediation analysis. H: hypothesis. *P=.05, **P<.01, ***P<.001.

To further examine the predictors of BI, a multiple linear regression analysis was conducted including rating valence (condition), PU, PEOU, and trust. The overall model was significant ($F_{4,71}$=22.36; P<.001), explaining a substantial proportion of variance in behavioral intention (R^2=0.56; adjusted R^2=0.53). PU emerged as the strongest predictor of BI (β=.65; P<.001). Trust also showed a significant positive effect (β=.37; P=.01), while PEOU had a marginal positive influence (β=.27; P=.06). In contrast, rating valence (condition) did not significantly predict BI (β=−.20; P=.18). Overall, the findings closely resemble the individual correlations, with the exception that the effect of trust weakens once PU is included, pointing toward a potential mediation effect.

To examine whether rating valence and the TAM-related constructs predict WTP, a multiple linear regression analysis was conducted including condition, PU, PEOU, and trust. The overall model was not significant ($F_{4,71}$=0.77; P=.55) and explained only a negligible proportion of variance in WTP (R^2=0.04; adjusted R^2=−0.01). None of the predictors showed a significant effect on WTP, including rating valence (β=−.20; P=.32), PU (β=.02; P=.85), PEOU (β=.00; P=.99), and trust (β=.10; P=.39). Overall, the regression results largely mirror the correlation findings. However, the initially observed association between trust and WTP did not remain significant in the regression model, suggesting that this relationship is weak and not robust when controlling for other variables.

XSL•FO
RenderX

To examine whether the effect of rating valence on BI is mediated by PEOU, PU, and trust (H5a-c), mediation analyses were conducted (see Table 3 and dashed lines in Figure 3). Results revealed no significant indirect effects for any of the mediators, as all CIs included 0. Additionally, no significant total or direct effects of rating valence were observed. Thus, H5 is not supported.

Table . Mediation effects of rating valence on behavioral intention to use via PEOU[a], PU[b], and trust.

Hypothesis (H)	Mediator	Indirect effect (ACME[c]), estimate (95% CI)	Direct effect (ADE[d]), estimate (95% CI)	Total effect, estimate (95% CI)
H5a	PEOU	0.06 (−0.10 to 0.25)	−0.24 (−0.63 to 0.18)	−0.17 (−0.57 to 0.25)
H5b	PU	0.07 (−0.22 to 0.35)	−0.24 (−0.56 to 0.05)	−0.17 (−0.60 to 0.23)
H5c	Trust	−0.12 (−0.40 to 0.14)	−0.05 (−0.38 to 0.30)	−0.17 (−0.55 to 0.28)

[a]PEOU: perceived ease of use.

[b]PU: perceived usefulness.

[c]ACME: average causal mediation effect.

[d]ADE: average direct effect.

Visual Attention and the Processing of Heuristic Cues

To examine the research question of where users look for information when browsing for a skin cancer screening app, we analyzed how participants allocate visual attention across the app store interface. During data preprocessing, individual AOIs were aggregated into composite AOIs. Specifically, all review-related AOIs were combined into a reviews-AOI, all rating-related AOIs into a ratings-AOI, icon and screenshots into a design-AOI, and information and description into a description-AOI. To control for differences in AOI size, fixation durations were normalized and expressed as seconds per pixel² (s/px^2). As shown in Table 4, the description-AOI attracted the longest fixation durations (mean 0.16, SD 0.10 s/px^2), followed by the reviews-AOI (mean 0.11, SD 0.07 s/px^2) and the ratings-AOI (mean 0.04, SD 0.04 s/px^2). In contrast, the price-AOI (mean 0.02, SD 0.03 s/px^2) and the data protection-AOI (mean 0.02, SD 0.02 s/px^2) received the least attention.

Table . Normalized fixation durations by area of interest (AOI).

AOI	Values, n	Mean (SD) (s/px^2)	95% CI
Design	76	0.04 (0.02)	0.04 - 0.05
Description	76	0.16 (0.10)	0.14 - 0.19
Reviews	76	0.11 (0.07)	0.09 - 0.13
Ratings	68	0.04 (0.04)	0.03 - 0.05
Data protection	76	0.02 (0.02)	0.02 - 0.03
Price	76	0.02 (0.03)	0.01 - 0.03

To examine the research question of whether the self-rated importance of app attributes is reflected in users' gaze patterns, Pearson correlations were computed between participants' ratings and normalized fixation durations on the corresponding AOIs (Table 5). Results revealed a significant positive correlation for reviews (r=0.28; P=.01), while all other relationships were nonsignificant (Ps>.05). Thus, only H6b is supported.

XSL•FO
RenderX

Table . Pearson correlations between participants' self-rated importance of app attributes and fixation durations on corresponding areas of interest (AOIs).

Hypothesis (H)	Normalized fixation durations on AOI (s/px^2)	Self-rated importance of app attributes	App attribute, mean (SD)	*r* (95% CI)
H6a	Design	Importance of design	4.03 (0.83)	−0.11 (–0.32 to 0.11)
H6b	Reviews	Importance of reviews	4.21 (0.80)	0.28[a] (0.05 to 0.47)
H6c	Ratings	Importance of reviews	4.21 (0.80)	0.17 (–0.07 to 0.39)
H6d	Price	Importance of price	4.57 (0.63)	≈0 (–0.26 to 0.22)
H6e	Description	Importance of description	4.72 (0.53)	−0.21 (–0.41 to 0.01)
H6f	Data protection	Importance of data protection	3.82 (1.05)	0.08 (–0.14 to 0.30)

[a]*P*<.05.

To address the research question of how rating valence affects gaze patterns, fixation duration on the manipulated review-AOI was compared across rating conditions. Absolute fixation durations were used, as the AOI size was identical across conditions. Results showed no significant difference between the positive (mean 6.17, SD 4.15 seconds) and negative conditions (mean 6.21, SD 3.98 seconds; *P*=.97; *d*=−0.01). Although participants in the negative condition showed a slight tendency toward longer viewing times, this effect was not statistically significant. Thus, H7 is not supported.

Moderating Role of Attention and Individual Differences

To test whether visual attention moderates the relationship between rating valence and key constructs (H8a-d), moderation analyses were conducted using fixation durations on the ratings-AOI (Table S3 in Multimedia Appendix 1). Results indicated no significant interaction effects between rating valence and fixation durations on PU, PEOU, trust, or BI (all *P*s>.05). Thus, H8 is not supported.

Analyses of individual differences revealed no significant effects of demographic or experiential variables on the main outcome measures (trust, PU, PEOU, BI, and WTP; all *P*s>.05). Notably, both age and prior experience showed limited variance within the sample, which restricts the interpretability of their relationships with the outcome variables. In particular, none of the participants reported prior experience with skin cancer screening apps. Furthermore, self-reported AI knowledge was not significantly associated with any of the outcome variables (all *P*s>.05). Similarly, no significant differences were observed across sex or education levels (all *P*s>.05)

Exploratory Analysis

Furthermore, we explored potential sex differences in self-rated app attribute importance and gaze patterns. Overall, female and male participants evaluated most app attributes similarly. No significant sex differences were observed for the importance of price, data protection, or evidence (all *P*s>.05). However, female participants rated the importance of reviews (*d*=0.63; *P*=.01) and design (*d*=0.69; *P*=.02) significantly higher than male participants (Table 6).

XSL•FO
RenderX

Table . Sex differences in self-rated importance of app attributes and normalized area of interest (AOI) fixation durations.

Measure and attribute or AOI	Female (n=53), mean (SD)	Male (n=23), mean (SD)	*P* value, overall	Cohen *d*
Self-rated importance				
Price	4.66 (0.52)	4.39 (0.84)	.17	0.43
Data protection	3.83 (1.03)	3.83 (1.11)	.99	<.001
Evidence	4.70 (0.57)	4.78 (0.42)	.48	−0.16
Reviews	2.36 (0.79)	3.87 (0.76)	.01[a]	0.63
Design	4.21 (0.72)	3.65 (0.98)	.02[a]	0.69
Normalized fixation durations on AOI (s/px^2)				
Price	0.02 (0.03)	0.02 (0.03)	.81	−0.05
Data protection	0.03 (0.03)	0.02 (0.02)	.26	0.24
Ratings	0.05 (0.05)	0.03 (0.02)	.03[a]	0.47
Reviews	0.12 (0.07)	0.09 (0.05)	.12	0.34
Design	0.05 (0.03)	0.04 (0.01)	.08	0.36
Description	0.17 (0.11)	0.16 (0.07)	.46	0.15

[a]*P*<.05.

With regard to gaze patterns, female participants demonstrated longer fixation durations than male participants across all AOIs; however, this difference reached statistical significance only for ratings (d=0.47; P=.03). No significant sex differences were observed for fixation durations on data protection, description, reviews, design, or price (all Ps>.05; Table 6).

Discussion

Principal Findings

This study investigated the acceptance of AISCSAs by integrating the TAM with eye-tracking and the experimental manipulation of rating valence. Importantly, by systematically varying rating valence as an external heuristic cue, the study enabled a direct test of how such cues causally influence the formation of PU, PEOU, and trust, as well as BI and WTP. Our findings reveal a hierarchy of visual attention dominated by textual descriptions and social proof while also identifying a significant gap between self-reported attribute importance and actual gaze behavior. Although the core TAM constructs (PU, PEOU, and trust) emerged as robust predictors of BI, the experimental manipulation of rating valence did not significantly alter acceptance beliefs or attention patterns in this specific laboratory context.

Effects of Rating Valence on Acceptance and Attention

Contrary to our expectations, rating valence did not significantly influence trust, PU, PEOU, BI, or WTP. Likewise, the negative rating condition did not increase visual attention to the review section. Thus, neither H1 nor H7 was supported. At first glance, these findings appear inconsistent with research on negativity bias and online review effects, which often show that negative information attracts more attention and exerts a disproportionately strong influence on judgments [24,60]. However, our findings are more plausibly interpreted as evidence of a boundary condition than as evidence against the relevance of rating valence per se.

A first explanation concerns the subtlety of the manipulation. In this study, rating valence was altered only minimally, replacing 1 of 3 visible ratings with a single 1-star evaluation, while all other cues remained favorable. Such a minor discrepancy may have been insufficient to shift appraisals of a high-stakes health app. This is consistent with meta-analytic evidence by Purnawirawan et al [76], which demonstrates that valence effects are not uniform; rather, they are highly dependent on the degree of extremity and the evaluative context, such as product type and brand familiarity. In high-stakes environments, a single negative cue may lack the weight necessary to override a predominantly positive information environment. In addition, in high-stakes contexts, users may engage in more motivated and systematic processing, thereby reducing the relative impact of simple heuristic cues such as rating valence.

A second explanation is that app store ratings may have limited informational value in digital health contexts. Several studies show that consumer ratings are poor proxies for clinically relevant attributes such as quality, safety, and privacy. For example, Hyzy et al [77] found that ratings and downloads do not reliably reflect professional assessments, while de Chantal et al [78] reported a clear gap between user ratings and expert evaluations. Similarly, Levine et al [79] demonstrated that star ratings correlate only weakly with critical dimensions such as privacy, security, and interoperability, with even highly rated apps often performing poorly in these areas. This suggests that rating information may not provide users with meaningful signals for evaluating clinically relevant aspects of health apps. As a result, ratings may play a limited role in shaping acceptance beliefs.

XSL•FO
RenderX

From a dual-process perspective, the results indicate that the manipulated rating did not cross the threshold required to redirect processing from a default heuristic impression (type 1) to more effortful elaboration (type 2). While negative information can trigger deeper scrutiny [62], this is most likely when it is salient, coherent, and clearly diagnostic. Here, the cue may have been noticeable but not sufficiently consequential to reorganize attention or alter technology beliefs. This interpretation also fits the absence of any moderation by fixation durations on the ratings-AOI (H8): without a sufficiently strong evaluative signal, there was little for visual attention to amplify. Importantly, the null findings for H1 and H7 should not be interpreted as evidence that rating valence is irrelevant in digital health. Rather, they indicate that isolated, weakly negative rating cues are insufficient to meaningfully influence acceptance beliefs or increase visual attention in a high-risk medical AI context.

TAM Validity and the Role of Trust in AI Health Apps

Despite the absence of direct effects of rating valence, the internal structure of the extended TAM was strongly supported. The positive relationships between PEOU, PU, and trust (H2a-c), as well as their associations with BI (H3a-c), are consistent with prior research, demonstrating the robustness of the TAM in digital health contexts [37,40,80]. The regression results further refine this picture by highlighting a differentiated role of the constructs: PU emerged as the strongest predictor of BI, followed by trust, while PEOU showed only a marginal effect. This pattern suggests that usefulness constitutes the primary decision criterion, whereas ease of use operates mainly indirectly via PU.

The clear hierarchy of predictors reveals a specific decision-making logic in high-stakes AI health contexts. The dominance of PU suggests that for potentially life-impacting technologies such as AISCSAs, users follow a strongly instrumental evaluation logic, prioritizing diagnostic utility over interface convenience. In such contexts, perceived functional value appears capable of compensating for usability barriers, indicating that effectiveness outweighs ease of use. This finding is consistent with prior research in health care contexts, showing that PU is typically the strongest predictor of behavioral intention [34,40].

At the same time, our findings highlight the important role of trust in AI-based health care. While PU emerged as the strongest predictor of BI, trust remains as an independent predictor and is particularly relevant in contexts characterized by uncertainty and limited user expertise. In such settings, users rely on systems whose diagnostic processes are not easily interpretable, making trust a necessary condition for acting on PU. In this sense, trust may function as an enabling mechanism or boundary condition that determines whether PU translates into behavioral intention. This interpretation aligns with trust theory, which emphasizes its importance under conditions of uncertainty and risk [81,82], and with prior extensions of the TAM that position trust as a core belief construct [34,83-86].

Interestingly, the marginal effect of PEOU challenges the traditional emphasis on usability as a key driver of technology acceptance [13] and aligns with prior research, showing that PU is typically the dominant predictor, particularly in high-stakes contexts [34,37]. In this study, PEOU appears to play a secondary role once a system is perceived as useful and trustworthy. Users may be willing to tolerate complexity if it is associated with higher perceived competence or clinical rigor. This suggests that simplicity is not the primary objective in AI-based health care apps, with reliability and effectiveness outweighing usability considerations.

In contrast, WTP was not explained by the included variables. As WTP was measured using an open-ended response format, the variable was not normally distributed. To account for this, additional nonparametric correlation analyses (Spearman ρ) were conducted, yielding the same pattern of results. WTP was not significantly associated with PU or PEOU, and its relationship with trust remained weak (H4a and H6c not supported). This indicates that WTP represents a distinct and less stable evaluative judgment that cannot be fully explained by the traditional TAM constructs [23,28]. Instead, monetary evaluations appear to be driven more strongly by psychological and normative factors, such as perceived risk, fairness, and emotional or social considerations [27]. Accordingly, while the TAM provides a robust framework for explaining acceptance intentions, it appears less suitable for capturing economic decision-making without incorporating additional constructs.

The lack of significant mediation (H5) and moderation (H8) effects is directly tied to the nonsignificant main effect of rating valence. Without an initial “push” from the experimental condition, the “amplification effect” of visual attention, where fixations serve to increase the weighting of attended information [65,66], had no baseline signal to amplify. These findings underscore the robustness of the TAM framework while highlighting that single-cue manipulations may be insufficient to shift these deeply interrelated constructs.

Visual Attention Allocation and Information Processing

The eye-tracking results reveal a clear attentional hierarchy: users primarily focused on the app description, followed by reviews and ratings, while price and data protection received little attention. This pattern suggests that, in high-stakes contexts such as AI-based health apps, users prioritize information that helps them understand the app’s functionality and potential clinical value, indicating more deliberate and analytical processing (type 2). This finding is consistent with prior research showing that textual information plays a central role in app evaluation, despite developers often emphasizing visual design [54,87].

At the same time, the secondary attention given to reviews and ratings highlights that social proof remains relevant, particularly under uncertainty. These cues are easily interpretable and visually salient, making them effective heuristics for initial evaluation and risk reduction [19,21,60]. However, the fact that they received comparatively less attention than the description suggests that social proof complements rather than dominates decision-making in this context. Overall, the findings indicate that users integrate both analytical and heuristic processing, with greater weight placed on substantive, information-rich content.

XSL•FO
RenderX

In contrast, the data protection-AOI and the price-AOI received minimal attention. The limited focus on these elements is consistent with prior eye-tracking research, showing that users often overlook pricing information and security indicators in digital environments [58,88,89]. Several factors may explain this pattern. First, many health apps follow freemium models, where pricing information is either absent or only becomes relevant after installation. Second, although users frequently report privacy as a major concern [90,91], the complexity and legalistic nature of privacy policies may discourage active engagement. In addition, users may rely on implicit trust in platform-level regulation or assume a baseline level of data protection for health-related apps [92]. Finally, the low visual salience of these sections likely contributes to their neglect, as prior research shows that subtle privacy indicators are easily overlooked, whereas more prominent cues attract attention [56]. Taken together, these findings provide behavioral evidence for the well-documented "privacy paradox": despite expressing concerns about data protection, users allocate little attention to related information during decision-making.

The Discrepancy Between Self-Reports and Gaze Patterns

A central finding of this study is the limited alignment between self-reported importance and actual visual attention, with the exception of reviews (H6b). While participants who rated reviews as important also allocated more attention to them, no such relationship was observed for design, price, evidence, or data protection (H6a and H6c-f). This discrepancy suggests that self-reports and gaze data capture different aspects of the decision-making process. In line with prior research, eye-tracking reflects implicit attentional processes that are not accessible through retrospective self-reports [41].

From a dual-process perspective, this divergence can be interpreted as a misalignment between type 1 and type 2 processing [14]. Self-reported importance ratings primarily reflect deliberative, reflective evaluations (type 2), often shaped by normative expectations or socially desirable responses, particularly in sensitive contexts such as health care. In contrast, eye-tracking captures spontaneous, heuristic-driven allocation of attention during actual interaction (type 1). This gap is particularly pronounced for data protection. Although participants rated privacy as highly important, it received little visual attention during the task. This pattern is consistent with prior findings on the "privacy paradox," where expressed concerns do not translate into corresponding behavior [57,58]. Taken together, these findings highlight that technology acceptance cannot be understood as a purely rational process, as suggested by traditional TAM frameworks. Instead, it reflects an interplay between reflective evaluations and implicit attentional processes. By capturing these behaviorally grounded mechanisms, eye-tracking provides a valuable complement to self-report measures and offers a more nuanced understanding of how users evaluate health-related AI systems.

Individual Differences in AI App Evaluation

Our exploratory data suggest sex-specific patterns in app evaluation, with female participants assigning greater importance to reviews and design and showing longer fixation durations on ratings. This aligns with prior research, indicating that female participants tend to engage in more comprehensive information processing and pay closer attention to user-generated content when evaluating digital products [60,67,93]. Beyond sex, recent studies highlight the broader relevance of sociodemographic factors in shaping AI acceptance in health. For instance, Aras et al [68] show that younger individuals, female participants, and those with higher income levels are more likely to adopt AI in health care. Similarly, Méndez-Suárez et al [69] find that positive attitudes toward AI-based products are more prevalent among younger individuals and those with higher socioeconomic status. Complementing these findings, Kauttonen et al [94] demonstrate that individuals with moderate knowledge exhibit the highest acceptance of AI apps in health, whereas both low and high knowledge levels are associated with more cautious evaluations.

The absence of significant effects for AI knowledge and prior experience in this study likely reflects the relative homogeneity of the student sample, which limits variability in key characteristics. This highlights an important boundary condition of the findings. Future research should therefore examine more diverse populations, particularly older users and individuals with varying socioeconomic backgrounds and levels of digital literacy, to better capture how individual differences shape trust and acceptance in AI-based health care contexts.

Limitations

This study, while offering valuable insights, is subject to several limitations that should be acknowledged. First, although the stimulus used in the eye-tracking experiment ensured a high degree of ecological validity by closely resembling an actual app store page, the experimental environment and the task itself remained artificial and hypothetical; for instance, participants did not autonomously decide to search for an AISCSA. This setting may not fully capture the complexity and dynamics of real-world app evaluation and decision-making. Moreover, the absence of real consequences, such as actually downloading or using the app, could have influenced participants' engagement, attention patterns, and responses. Second, all participants were young university students with a narrow age range and no prior experience with skin cancer screening apps. This homogeneity limits the generalizability of the findings to other populations, especially older users or individuals with specific health concerns, who may differ in their levels of trust, digital literacy, and motivation. Therefore, the findings should be interpreted with caution, particularly when generalizing to more diverse or clinically relevant populations. Third, the internal consistency of some constructs, such as PU, PEOU, and trust, was relatively low, with Cronbach α values falling slightly below the conventional 0.70 threshold. While these levels are often considered acceptable in exploratory research within emerging fields, they suggest a moderate reliability, which should be taken into account when interpreting the strength of the observed relationships. Future research could benefit from further refining these scales to enhance their psychometric robustness in the context of AI-based health apps.

Conclusions

Addressing a key gap in prior research, this study extends the TAM by experimentally manipulating rating valence as an external variable and examining its effects on trust and core acceptance constructs. While prior research has largely relied on observational data, this approach enables a direct test of how external information influences the TAM-related belief structures.

The findings confirm that PU, PEOU, and trust remain significant predictors of behavioral intention in the context of AISCSAs. However, rating valence showed no direct effect on user acceptance or visual attention. This suggests that in high-stakes health contexts, users are less influenced by simple social-proof cues and instead prioritize substantive, information-rich content.

The primary implication for developers and marketers of health-related AI tools is that relying solely on positive ratings to drive adoption may be an insufficient strategy. Instead, efforts should be directed toward providing transparent, evidence-based information, as the description-AOI received the longest fixation duration. Building acceptance through verifiable information appears to be more critical than leveraging simple social proof in this domain. Moreover, designing a more appealing data protection section may increase user attention, rendering them better-informed consumers. Importantly, the weak or nonexistent associations between fixation durations on specific AOIs and the self-rated importance of app attributes indicate that eye-tracking captures aspects of information processing that are not directly reflected in self-reported questionnaires. These findings demonstrate that combining self-report measures with behavior-based methods, such as eye-tracking, provides a more comprehensive understanding of user acceptance processes in health-related AI systems. This dual approach captures both reflective, self-reported evaluations (type 2) and implicit, attention-driven processes (type 1), which are not accessible through questionnaires alone.

Funding

This research was conducted within the framework of the project “SAIL: SustAInable Lifecycle of Intelligent Socio-Technical Systems,” funded by the Ministry of Culture and Science of the State of North Rhine-Westphalia (grant NW21-059B).

Abstract

Background: There are around 20,000 mental health apps available in app stores. The Organisation for the Review of Care and Health Apps (ORCHA), a United Kingdom digital health compliance company, has assessed a number of digital mental health apps with regard to their quality, professional and clinical assurance, data privacy, and user experience. This study analyzes the data that were collected by ORCHA when they assessed mental health apps.

Objective: This study aimed to examine the characteristics of mental health apps regarding their quality, target users, features, underpinning evidence, and data privacy.

Methods: A dataset comprising ORCHA Baseline Review assessments of over 2000 digital health apps, including 436 mental health apps, was used. This study uses exploratory data analysis to gain insight into the quality and characteristics of mental health apps. Methods such as descriptive and inferential statistics, k-modes clustering, and association rule mining were used to explore the quality of mental health apps as well as reveal insights into the different cost types, target users, app features, data types, and evidence of app content.

Results: Information provision, data capture, and data sharing were the most common features within the 436 mental health apps. The examined apps primarily targeted the following groups: adults (n=229, 52.5%), everyone (n=184, 42.2%), and teens (n=135, 31%). The cost of apps has not been linked to the quality of mental health apps, although paid apps or apps with in-app purchases may include additional services. Indicated user acceptance or benefit is the most common type of evidence provided by these mental health apps. A total of 241 (55.3%) apps included a qualified professional in app development, and 251 (57.6%) apps provided evidence within the app that the developer validated any guidance with relevant reliable information sources or references. Usage data and email were the most commonly collected data types. Association rule mining showed that email, IP address, name, and usage data are often co-collected by the same apps. K-modes cluster analysis showed that mental health apps can be categorized into 2 clusters, where one cluster of apps (n=182, 41.7%) collected more data than apps in the other cluster.

Conclusions: Mental health apps are commonly targeted for everyone to use, but many apps are targeted toward teens or adults. Our study suggests that many publicly available mental health apps did not take the precautions (such as the involvement of appropriate health professionals, literature references, or conducting tests) to ensure that their content is valid and research based. Greater effort on behalf of mental health app developers is needed to ensure that the public is provided with high-quality apps. Moreover, our study indicates that the mental health apps that collect more data tend to score better on the ORCHA Baseline Review assessment.

digital mental health; mental health apps; machine learning; health informatics; data privacy; mobile health

Introduction

According to a World Health Organization report [1], there are nearly 1 billion people living with a diagnosed mental health condition, and most do not have access to effective care. Moreover, during the COVID-19 pandemic, mental health issues became more predominant and prevalent [2-4] and have remained prevalent as of 2024 [1]. Mental health conditions affect many people's lives; for example, a study from 2020 [5] showed that social stigma is a contributing factor to unemployment in people living with mental health issues. With

XSL•FO
RenderX

the decline in mental health, it is important to mitigate a global mental health crisis.

While apps might be useful, it is important to understand their quality. For example, a study from 2020 has shown that college counseling centers in the United States often recommend unsafe and not up-to-date mental health apps to students [6]. Another paper from 2016 [7] has shown that suicide prevention apps may also provide potentially harmful content. Moreover, Sander et al [8] indicated that the public can have difficulty identifying high-quality apps for posttraumatic stress disorder. Beyond apps, other digital tools also require further investigation; for example, social media has been linked to an increase in mental health issues [9,10].

Arguably, the most accessible tools for mental health care in the public are mental health apps or websites [11]. Estimates show that there are around 20,000 mental health apps available in app stores [11,12]. However, it is important to identify mental health apps based on their quality before health care professionals recommend them to patients or clients.

The Organisation for the Review of Care and Health Apps (ORCHA) [13] is a United Kingdom–based digital health compliance company that specializes in the quality assessment of digital health apps. ORCHA is currently working with 70% of National Health Service organizations within England and provides digital health app libraries, hosted by various health care organizations, that contain information about digital health apps and their quality. The ORCHA Baseline Review (OBR) is a proxy for digital health apps' compliance with best practice standards. Specifically, the OBR assessment results provide information (including an assessment score between 0 and 100) regarding a digital health app's compliance with best practices in the domains of professional and clinical assurance (PCA), data privacy (DP), and user experience (UX), allowing end users and clinical professionals to make informed decisions on whether to use or recommend these digital health apps. National Institute for Health and Care Excellence (NICE) [14] provides guidance on digital health app research. ORCHA uses Evidence Standard Framework (ESF) [15], developed by NICE, to categorize digital health apps, and the ESF has been influential in the development of the OBR assessment tool.

It has been suggested that mental health apps can enhance but not replace existing mental health services [16]. Similarly to a 2023 study [16], a meta-analysis from 2021 [17] studied the treatment of depression using apps and found that there was no difference in the outcomes between human-guided digital interventions and face-to-face psychotherapy. For apps to do more good than harm, it is important to recommend only mental health apps of sufficient quality for public use. A meta-review of meta-analyses from 2020 stated that more studies related to the quality of mental health apps are needed [18]. Previous studies have assessed the UX, engagement, and popularity of mental health apps [19,20]. This paper also extends the work conducted in 2023 [21], which examined the quality of digital health apps across different health care domains or categories.

Expanding on these studies, the objective of this study was to examine the characteristics of mental health apps, specifically regarding their quality, the level of underpinning evidence, and aspects related to DP. ORCHA has provided a dataset of OBR results and documentation from their assessment of 436 digital mental health apps. While there are studies regarding the use of conversational agents for mental health [22,23], these were not included in this study. To achieve our objective, the following research questions were examined:

1. How do mental health apps score on the OBR assessment tool (as indicated by ORCHA, PCA, UX, and DP scores)?
2. Is there a difference in ORCHA, PCA, UX, or DP scores among mental health apps that are free and those that are paid or contain in-app purchases?
3. Who are the target users of mental health apps?
4. What features are included in mental health apps, and which are linked to the ORCHA score?
5. What evidence is presented to validate the content of mental health apps?
6. What are mental health apps' use and development characteristics?
7. What data are collected by mental health apps?

By answering the abovementioned questions, we believe we will be able to broadly report on the characteristics of digital mental health apps. This will allow us to identify areas of concern where improvements can and should be made regarding digital health app quality.

Methods

The Dataset and Tools

ORCHA provided an assessment dataset of 2127 digital health apps. All the apps were assessed using the OBR tool, Version 6 (OBR V6). The assessment and app categorization of all the digital health apps were conducted by 2 ORCHA reviewers. A third reviewer was included only if there was any dispute between the original 2 reviewers during an assessment. It takes around 6 months for an ORCHA reviewer to be trained on how to use the OBR tool and to be considered ready to carry out live reviews using the tool. The training involves teaching the new reviewer about each area (UX, PCA, and DP) of the OBR. Training is carried out either in person or via online meetings. The dataset used included digital health app assessments that were published between January 18, 2021, and January 6, 2022.

From the 2127 digital health apps, a subset of 436 mental health apps was created and used for this study. The only selection criterion was that an app had been categorized as a "mental health app." Multimedia Appendix 1 states more specific categories (mutually inclusive) of mental health apps that were included.

The OBR V6 tool is the latest version of the ORCHA assessment tool, which consists of approximately 300 objective (mostly dichotomous yes/no) assessment questions in 3 domain areas: PCA, DP, and UX. Each of the areas is scored individually on a scale from 0 to 100 and combined into an overall ORCHA score. Moreover, the collected data of OBR assessments of mental health apps included information such as target users, features, and associated cost types (free, paid, and in-app purchases). Information relating to app development was also collected, such as whether there is a suitably qualified

XSL•FO
RenderX

professional involved in the development team of the app. All the collected data allowed us to examine what sort of evidence is being provided regarding the content of mental health apps.

NICE, a UK-based organization, provides guidance relating to health technologies, including health apps. NICE has produced an ESF that can be used to classify digital health apps using A, B, and C tiers based on their functionality, risk, and regulatory status. All the assessed mental health apps were assigned a NICE ESF tier. Tier A indicates that the digital health apps provide health and social care services with no measurable user outcome. Tier B denotes that the digital health apps can provide a 2-way communication between users and health care professionals and provide health care information or a health diary. Tier C indicates that digital health apps provide preventative behavioral change aimed at health issues; they may allow users to self-manage a specific condition, indicate that the digital health apps provide or guide treatment for a condition, record and transmit data about this condition to a professional, caregiver, or third party without a user's input, contain a calculator that impacts treatment, provide diagnostics for a specific condition, or guide a diagnosis. Since the NICE tiers are dependent upon functionality, risk, and regulatory status, it would be inappropriate to, for example, use OBR on a tier C digital health app using OBR tier B score weighting. See Checklist 1 for included topics and items in this paper.

Data Analysis

Descriptive statistics were used to study the data. In this study, box plots, line plots, and heatmaps were used for the exploratory visualization of data. Descriptive statistics were used when conducting analysis of OBR scores, cost types, target users, features, presented evidence, use and development characteristics, and collected data types. Quantiles were used to represent the spread of domain (OBR) scores from 0% to 100% in increments of 25%. Median and IQR were calculated for some of the data.

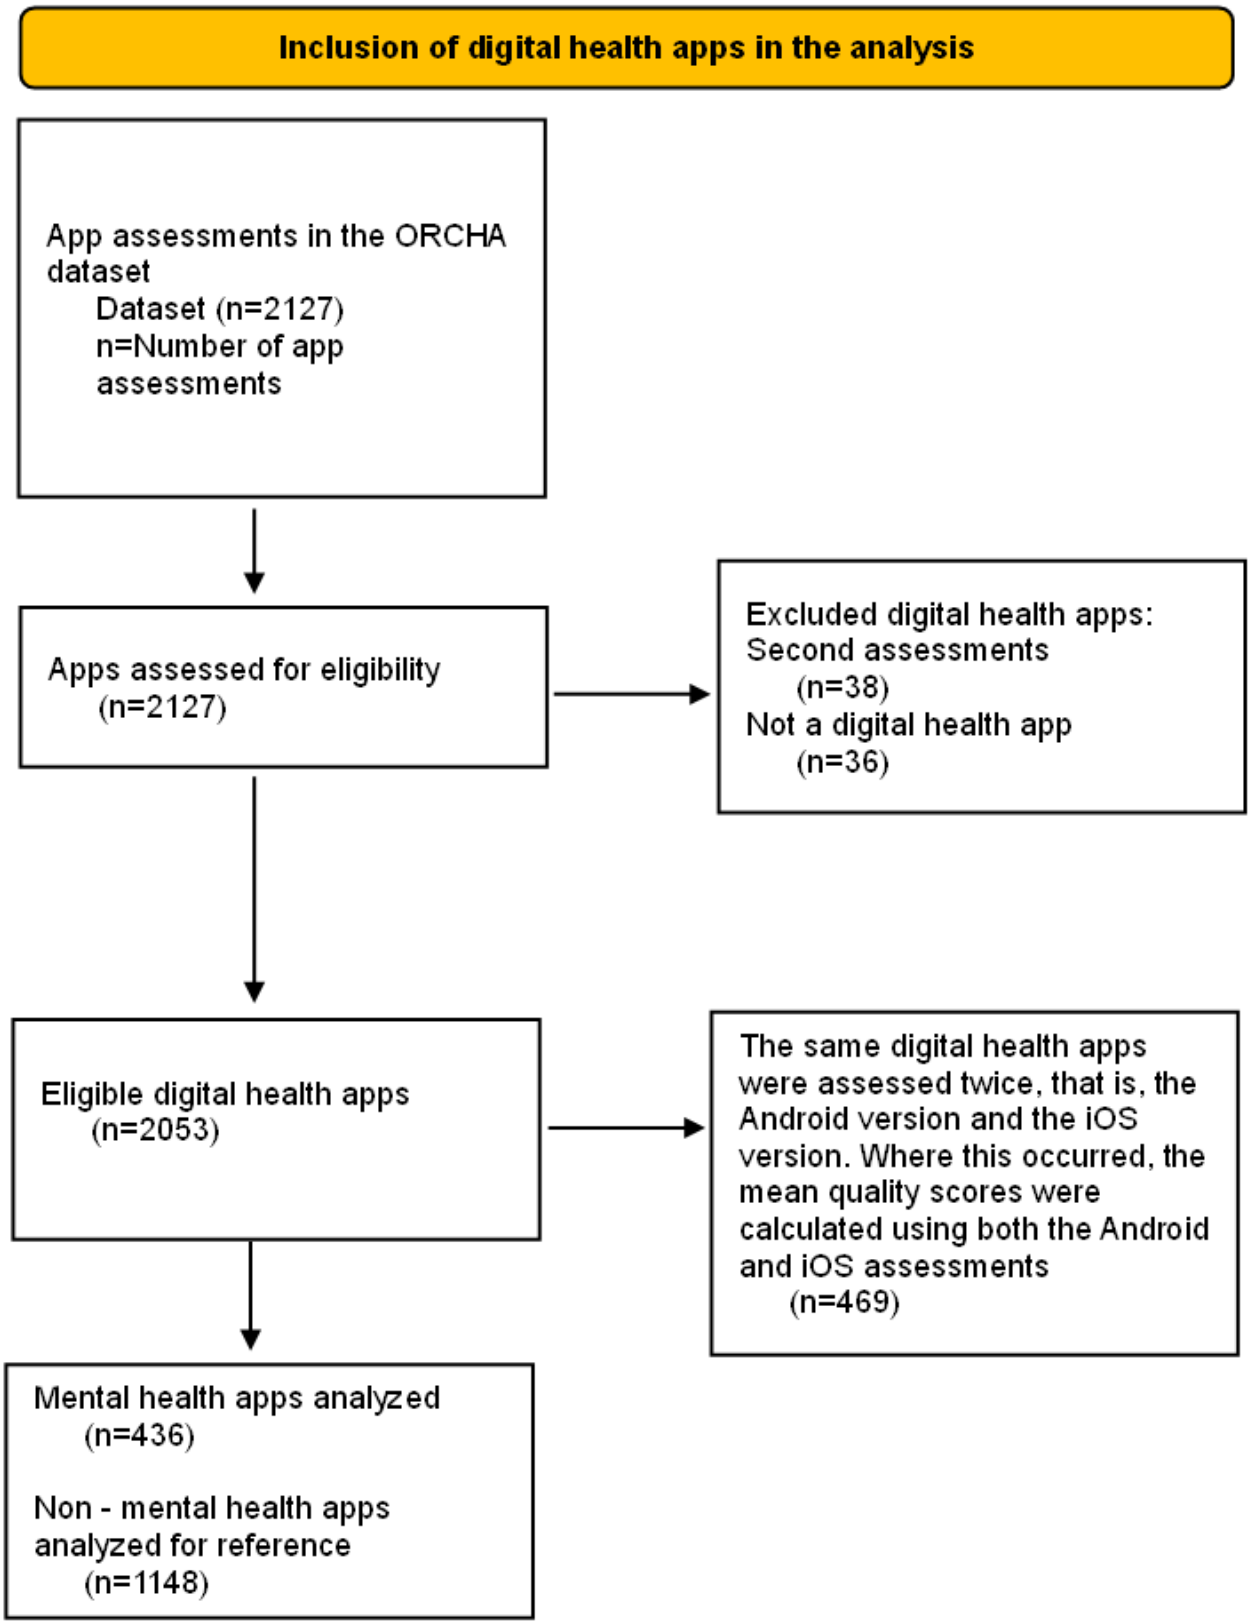
The Wilcoxon rank sum test was used to compare 2 samples of data to determine any statistically significant differences between them. A *P* value less than or equal to .05 was considered statistically significant. A Bonferroni-corrected α value was calculated when multiple hypothesis testing was conducted. This was used when comparing ORCHA scores between apps that had a specific feature and those that did not.

A random forest algorithm was used to determine feature importance, with mean square error (increase in mean squared error) and node purity (increase in node purity) calculations, when predicting the overall ORCHA score when using app features as predictors (eg, goal setting, gamification).

Association rule mining (a priori algorithm) was used to identify commonly co-occurring types of data collected by mental health apps. K-modes cluster analysis was performed on the data types. K-modes was chosen as a clustering method because the data were recorded in binary format. An optimal number of clusters was determined using the NbClust package in R [24]. The package uses 30 indices to determine the best number of clusters for a dataset.

Ethical Considerations

This secondary data analysis study gained ethical approval from Ulster University (Ethics Filter Committee, Faculty of Computing, Engineering and the Built Environment, project number: CEBE_RE-22 - 002). The process undertaken by ORCHA ensures that digital health app developers are aware of their score and are given time to contest findings of the assessment, which may be amended if developers provide additional relevant information. All reviews, unless explicitly requested to be removed by the developer, are covered as suitable for research in ORCHA's privacy policy [25]. Informed consent was obtained by ORCHA to use the data from the assessments for the purposes of research, provided that the assessed apps are anonymized in publications.



Results

App Selection

Figure 1 shows the process of selecting mental health apps from the ORCHA dataset.

How Do Mental Health Apps Score on the OBR Assessment Tool (as Indicated by ORCHA, PCA, UX, and DP Scores)?

Table 1 shows domain scores per NICE ESF tier. Color coding was applied as follows: red for values greater than 75, green for values from 65 to 75, and blue for values less than 65. Since there were only 2 mental health apps assigned to tier A, they were not included in Table 1.

As can be seen in Table 1, the median ORCHA score for 436 mental health apps was 60 (Tier B: 62 and Tier C: 55). ORCHA, together with the National Health Service, determined that an ORCHA threshold score of 65 indicates adequate compliance with the assessment criteria to be recommended for use by the public. Most mental health apps do not meet that threshold. This finding demonstrates that greater effort is needed on behalf of developers to produce higher-quality mental health apps.

Figure 2 visualizes NICE ESF tiers per domain score with box plots. When separated into NICE ESF tiers, the sample sizes were as follows: tier A, 2; tier B, 332; and tier C, 102.

Table . Mental health apps' ORCHA scores per tier.

Tier and scores	Values, median (IQR; range)
All apps (n=436)	
ORCHA[a]	60 (51-73; 25.0-96.0)
UX[b]	75.2 (69.8-79.6; 27.4-92.7)
PCA[c]	46.1 (30.3-75.3; 7.57-98.5)
DP[d]	65.6 (52.5-73.1; 4.28-99.3)
Tier B (n=332)	
ORCHA	62 (52-73; 28.0-90.5)
UX	75.2 (70.2-79.6; 32.6-88.3)
PCA	47.7 (30.3-75.3; 11.4-95.3)
DP	65 (52.5-73.1; 16.5-95.3)
Tier C (n=102)	
ORCHA	55 (46.3-71; 25.0-96.0)
UX	72.5 (68.6-77.8; 27.4-92.7)
PCA	39.5 (31.1-68; 7.57-98.5)
DP	67.3 (51.7-75.3; 4.28-94.9)

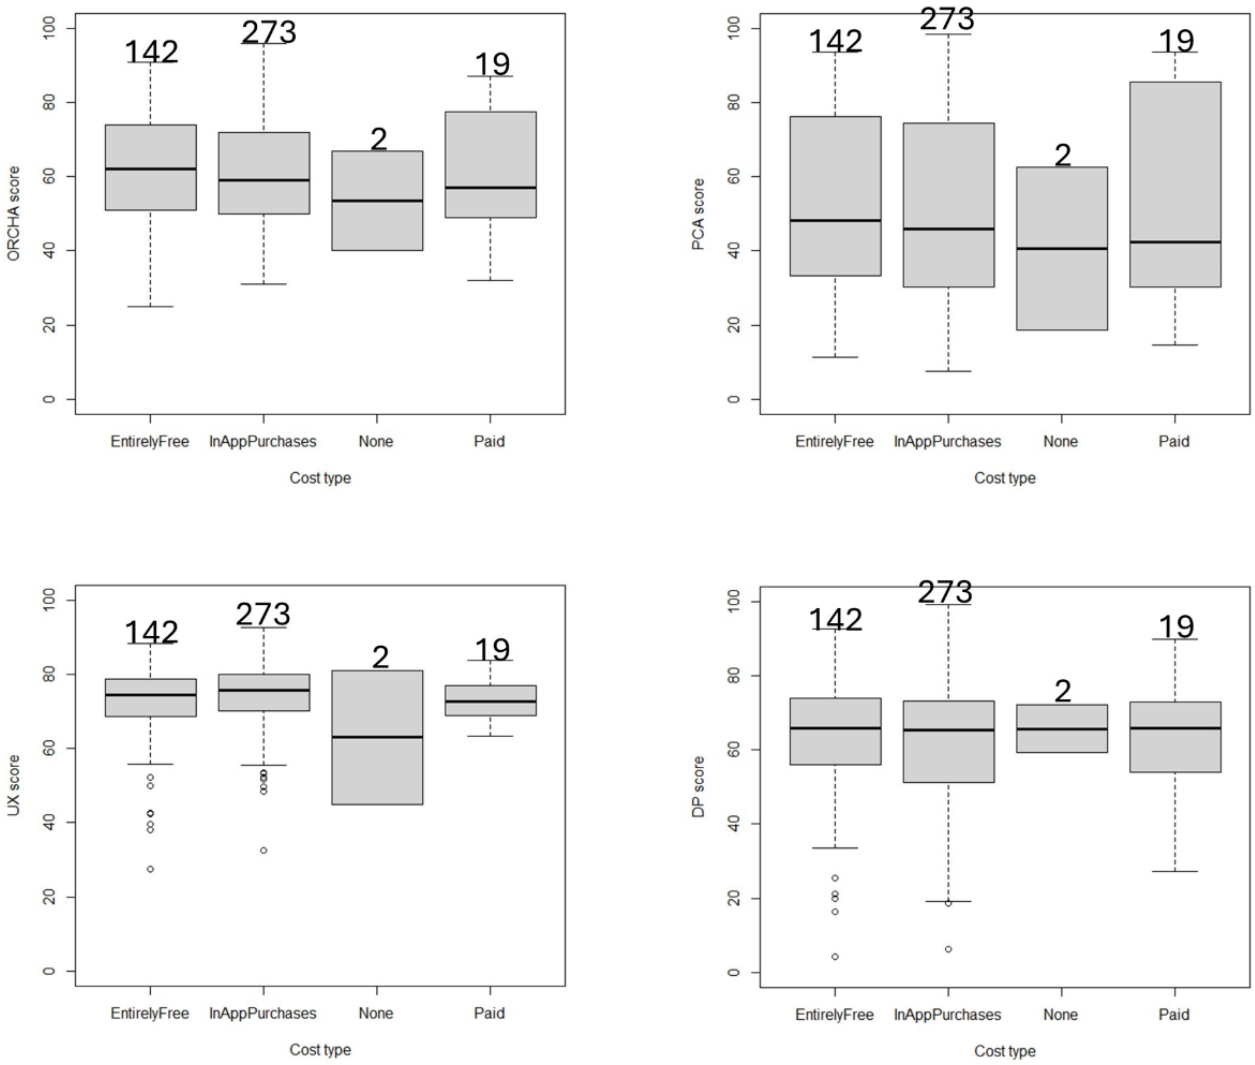
Figure 2. Quality scores per assessment domain (user experience [UX], data privacy, and professional clinical assurance) and per National Institute for Health and Care Excellence (NICE) Evidence Standard Framework (ESF) Tier (Tier A, B, and C). DP: data privacy; ORCHA: Organisation for the Review of Care and Health Apps; PCA: professional and clinical assurance.



Is There a Difference in ORCHA Score, PCA, UX, or DP Among Mental Health Apps That Are Free and Those That Are Paid or Contain In-App Purchases?

Figure 3 shows domain scores against cost type. As can be seen from the box plots, the quality of a mental health app does not appear to be influenced by cost. This is further confirmed by the Wilcoxon rank sum test, where none of the cost types achieved a statistically significant ($P \leq .05$) difference when compared for each of the domain scores. When separated by cost types, the sample sizes were as follows: none: 2, paid: 19, entirely free: 142, and in-app purchases: 273.

This study has shown that there appears to be no difference in OBR scores in relation to cost. Figure 3 shows that the distributions of OBR scores (ORCHA, PCA, UX, and DP) for mental health apps that are free, paid, and those with in-app purchases are similar, with a nonstatistically significant ($P \leq .05$) difference when using the Wilcoxon 2-sample rank sum test. Nevertheless, it is possible that paid apps or those with in-app purchases may include features not offered by those apps that are available for free. Further study is needed to determine whether paid apps or those with in-app purchases offer features or services that are unavailable in free digital mental health apps.

Who Are the Target Users of Mental Health Apps?

Table 2 shows the target users of the 436 mental health apps that were included in this study. Target users are presented in descending order of frequency. The table shows that most mental health apps appear to be targeted at adults, followed by everyone and teens.

Table . Mental health apps' target users (N=436).

Target users	Frequency, n (%)
Adults	229 (52.5)
Everyone	184 (42.2)
Teenagers	135 (31)
Older adults	51 (11.7)
Children	27 (6.19)
Preteens	20 (4.59)
Clinicians	5 (1.15)
Patients	2 (0.459)
Infants	2 (0.459)
Health care administrators	1 (0.229)
Caregivers	1 (0.229)

What Features Are Included in Mental Health Apps and Which Are Linked to ORCHA Score?

In this section, we aim to identify features that may improve the use and quality of digital mental health apps. Table 3 shows the features that were recorded for the 436 mental health apps included in this study and their frequency. Features are presented in descending order of frequency. The table indicates that the most common features are information provision, followed by data capture and data sharing.

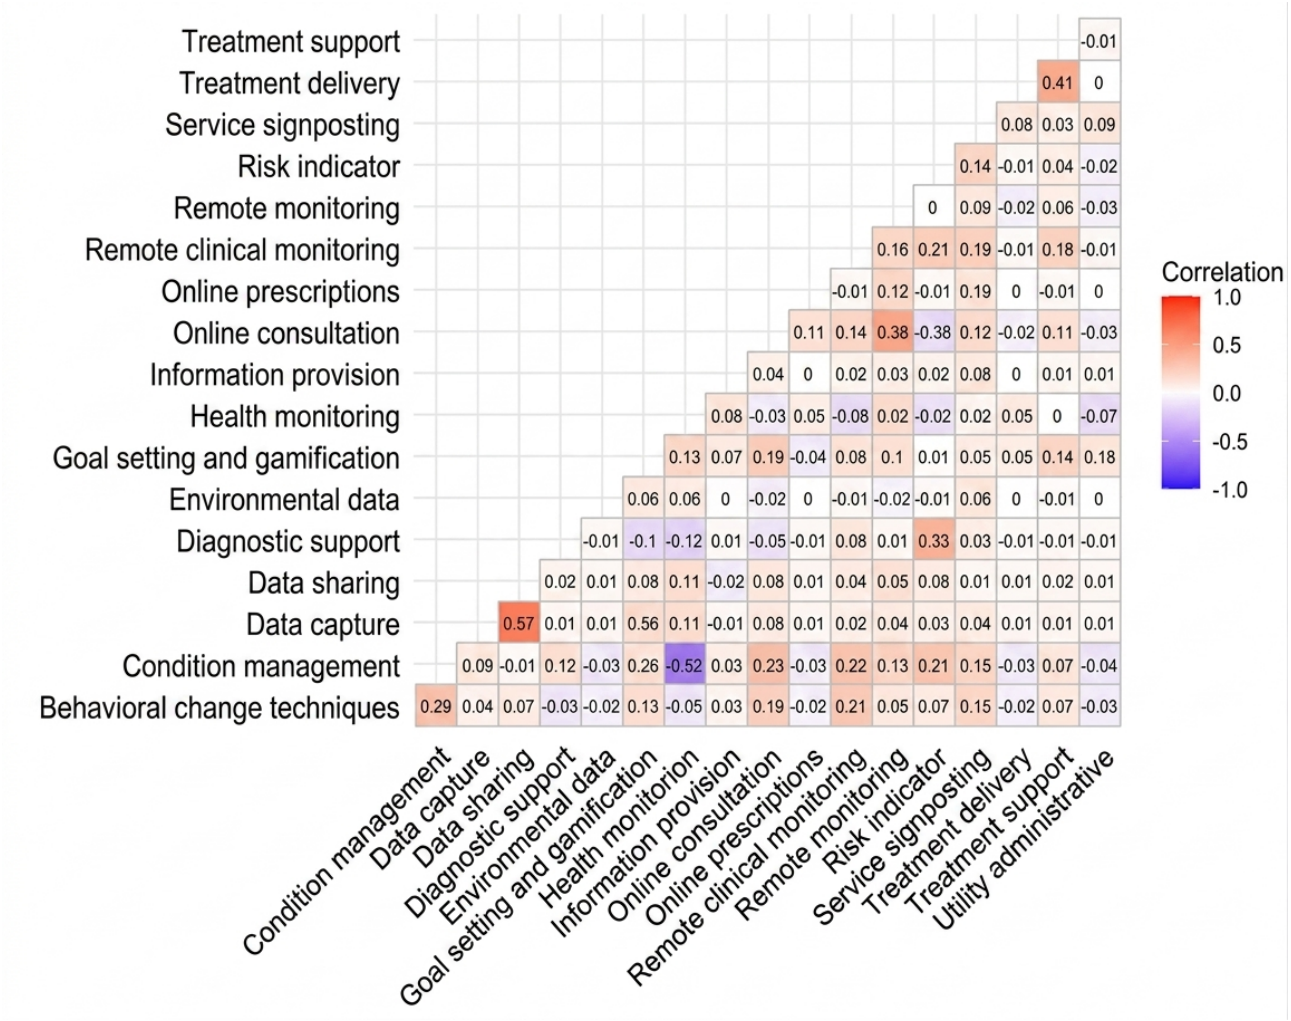

Figure 4 depicts pairwise Spearman correlations among the features. The highest being between data capture and data sharing, with a Spearman correlation of 0.57. Figure 5 depicts the importance of features (increase in mean squared error and increase in node purity), with ORCHA scores as the independent variable and features as the dependent variables. Multimedia Appendix 2 depicts feature importance and correlation for each tier.

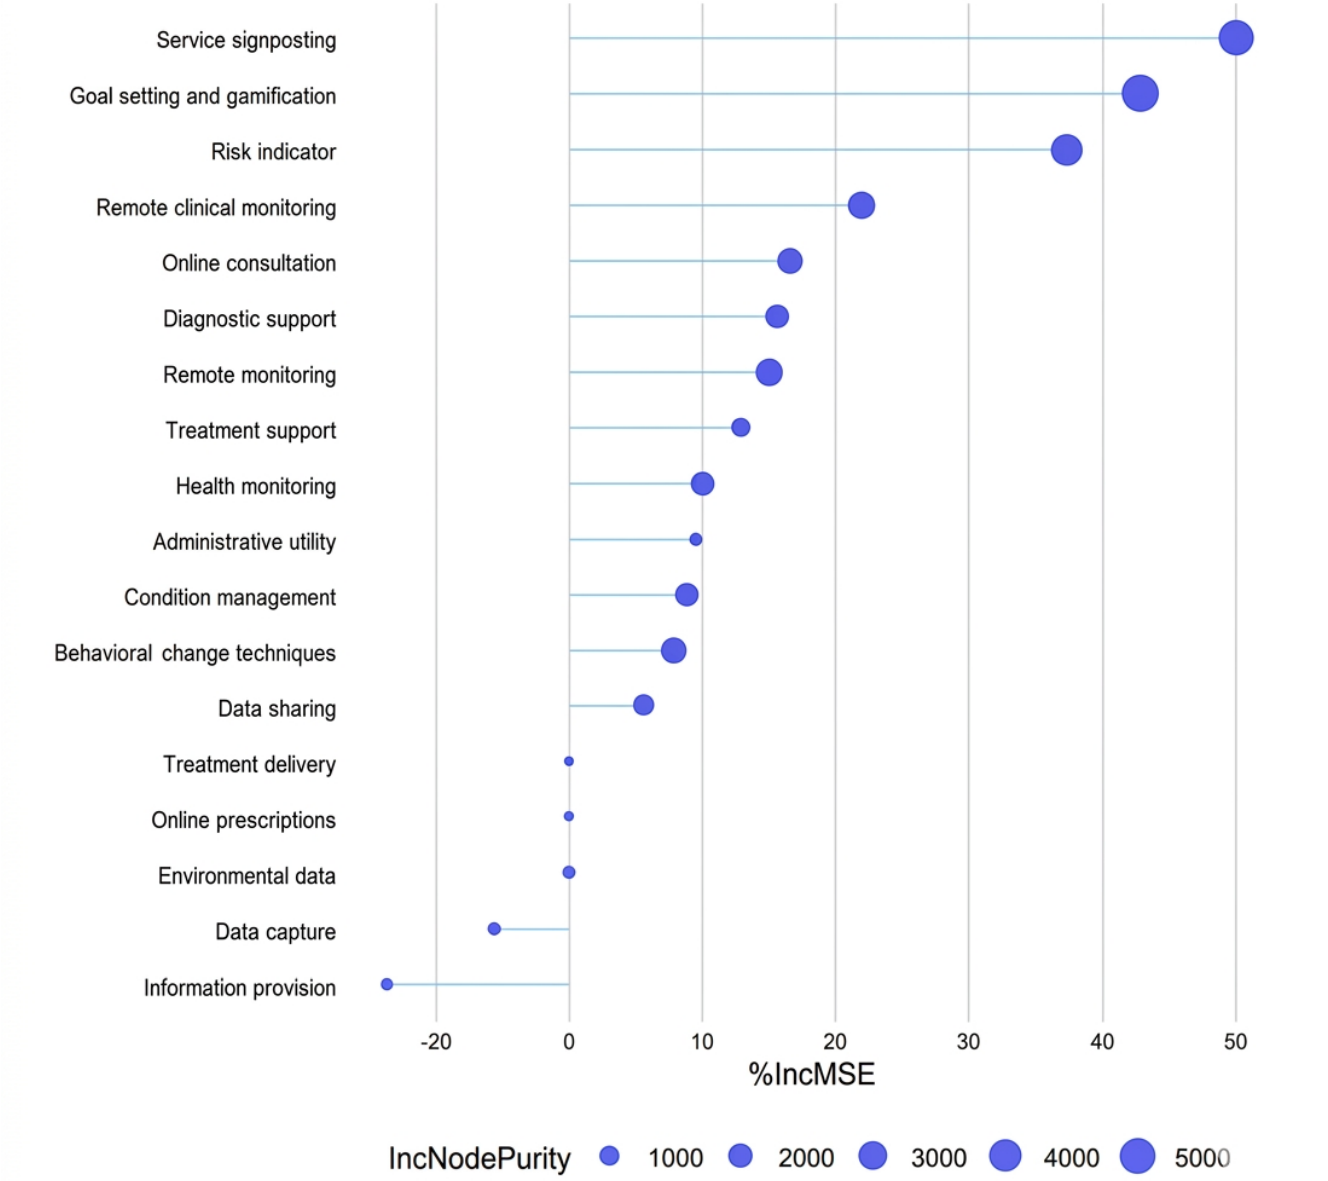
Table . Feature frequency (N=436).

Features	Frequency, n (%)
Information provision	433 (99.3)
Data capture	431 (98.9)
Data sharing	421 (96.6)
Health monitoring	215 (49.3)
Goal setting and gamification	184 (42.2)
Service signposting	159 (36.5)
Condition management	107 (24.5)
Online consultation	69 (15.8)
Remote monitoring	62 (14.2)
Behavioral change techniques	56 (12.8)
Risk indicator	34 (7.80)
Remote clinical monitoring	17 (3.90)
Treatment support	6 (1.38)
Diagnostic support	6 (1.38)
Utility/administrative	2 (0.459)
Treatment delivery	1 (0.229)
Online prescriptions	1 (0.229)
Environmental data	1 (0.229)



XSL•FO
RenderX

Figure 4. Spearman correlations among features.

XSL•FO
RenderX

Figure 5. Feature importance with random forest for the Organisation for the Review of Care and Health Apps (ORCHA) score. incMSE: increase in mean squared error; incNodePurity: increase in node purity.

Random forest feature importance was used to identify which features are linked to the ORCHA score (Figure 5). Service signposting and goal setting and gamification were identified as the 2 most important features that are positively associated with the ORCHA score, whereas the risk indicator was negatively associated with the ORCHA score.

Table 4 depicts the top 3 features for mental health apps altogether and when partitioned by NICE ESF tier (tier B and tier C). It also states the number of apps with and without the feature, with their ORCHA scores' median and IQR. The Wilcoxon rank sum test with a Bonferroni-corrected α value was calculated to check for statistically significant differences between the 2 distributions of apps regarding the ORCHA score among apps with and without the feature. See Multimedia Appendices 2 and 3 for more information regarding features for each tier and data visualizations.

XSL•FO
RenderX

Table . Top 3 features for each tier. Bonferroni corrected α value is .05/9 ≈ .006.

Tier and feature	Apps with feature, n	Apps with feature ORCHA[a] score, median (IQR)	Apps without feature, n	Apps without feature ORCHA score, median (IQR)	Wilcoxon test (*P* value)	Effect size (Cohen W)
All apps						
Service signposting	159	66 (55.0-76.5)	277	56 (48.0-71.0)	<.001	0.271
Goal setting and gamification	184	67.5 (54.0-78.0)	252	57 (48.0-68.0)	<.001	0.156
Risk indicator	34	49.5 (45.3 -57.0)	402	61 (51.0-74.0)	<.001	0.844
Tier B						
Service signposting	105	70 (59.0-77.0)	227	57 (49.0-70.0)	<.001	0.368
Goal setting and gamification	127	68 (54.5-78.0)	205	60 (49.0-70.0)	<.001	0.235
Online consultation	38	67 (60.5-74.0)	294	61 (51.0-73.0)	.01	0.771
Tier C						
Goal setting and gamification	57	62 (52.0-76.0)	45	51 (46.0-57.0)	<.001	0.118
Risk indicator	33	48 (45.0-57.0)	69	57 (51.0-76.0)	<.001	0.353
Behavioral change techniques	32	72 (55.0-82.0)	70	53 (46.0-59.5)	<.001	0.373

[a]ORCHA: Organisation for the Review of Care and Health Apps.

What Evidence Is Presented to Validate the Content of Mental Health Apps?

Table 5 depicts the types of evidence that were presented in the OBR assessment of mental health apps, separated by NICE ESF tier, and by their medical device status in Table 6. Some mental health apps can be classified as medical devices if they conduct diagnoses or provide treatments. The data indicate that indicated user acceptance (295/436, 67.7%) and observational studies (59/436, 13.5%) are the most commonly presented evidence types for the content of digital mental health apps. However, 118 of 436 (27.1%) digital mental health apps provided no evidence.

Tables 5 and 6 show that the most common evidence presented by mental health apps during the assessment is indicative of user acceptance or benefit (295/436, 67.7%). The rarest type of evidence presented was meta-analysis or systematic review (10/436, 2.29%). More evidence from academic and clinical sources may improve the quality of mental health apps. Relying mainly on user acceptance or benefit does not verify that the content of those apps is of clinical standard and value. Moreover, 118 out of 436 (27.1%) apps did not present any evidence. In the time of a mental health crisis and the accessibility of mental health apps, it should be a requirement for all mental health apps to include a qualified professional in the app development lifecycle, as well as validate any guidance provided by an app with relevant information sources and references to mitigate any risk associated with its use.

Table 7 depicts the characteristics of evidence that were provided. The table presents which methods were used to validate mental health apps' evidence, separated by NICE ESF tiers. The key takeaway from the table appears to be that most mental health apps did not involve a qualified professional, and most of the presented evidence did not involve any calculation

XSL•FO
RenderX

of the *P* value, as it was deemed not applicable (NA). Table 7 shows that many of the mental health apps in this study did not provide information on the characteristics of the evidence, such as details on the sample size used, use of a comparator, or *P* values, indicating that even when evidence is presented for mental health apps, important related information is missing.

Table . Evidence characteristics across tiers.

Characteristics	Tier A (apps: n=2), n (%)	Tier B (apps: n=332), n (%)	Tier C (apps: n=102), n (%)
Is there a suitably qualified professional involved in the development team of the app?	Yes: 1 (50); No: 1 (50)	Yes: 169 (50.9); No: 163 (49.1)	Yes: 71 (69.6); No: 31 (30.4)
Is the sample size appropriate?	Yes: 1 (50); No: 0 (0%); N/A[a]: 1 (50)	Yes: 35 (10.5); No: 11 (3.31); N/A: 286 (86.1)	Yes: 23 (22.5); No: 7 (6.86); N/A: 72 (70.6)
Does the evidence found provide a *P* value?	Yes: 1 (50); No: 0 (0); N/A: 1 (50)	Yes: 36 (10.8); No: 10 (3.01); N/A: 286 (86.1)	Yes: 28 (27.5); No: 2 (1.96); N/A: 72 (70.6)
Does the *P* value demonstrate significance ($P<.05$)?	Yes: 1 (50); No: 0 (0); N/A: 1 (50)	Yes: 35 (10.5); No: 1 (0.301); N/A: 296 (89.2)	Yes: 27 (26.5); No: 1 (0.980); N/A: 74 (72.5)
Does the *P* value demonstrate near significance ($P<.2$)?	Yes: 0 (0); No: 0 (0); N/A: 2 (100)	Yes: 1 (0.301); No: 3 (0.904); N/A: 328 (98.8)	Yes: 1 (0.980); No: 1 (0.980); N/A: 100 (98)
Is there a comparator?	Yes: 1 (50); No: 0 (0); N/A: 1 (50)	Yes: 28 (8.43); No: 18 (5.42); N/A: 286 (86.1)	Yes: 26 (25.5); No: 4 (3.92); N/A: 72 (70.6)
Is the comparator validated?	Yes: 0 (0); No: 1 (50); N/A: 1 (50)	Yes: 9 (2.71); No: 21 (6.33); N/A: 302 (91.0)	Yes: 9 (8.82); No: 17 (16.7); N/A: 76 (74.5)

What Are Mental Health Apps' Use and Development Characteristics

Table 8 depicts the characteristics of mental health apps regarding their use and development. This table states what key information is available to users of digital mental health apps and whether key professionals were involved. This study shows that 241 out of 436 (55.3%) apps included a qualified professional in app development. A total of 251 out of 436 (57.6%) apps provided evidence within the app that the developer validated any guidance with relevant reliable information sources or references.

XSL•FO
RenderX

Table . Mental health apps characteristics regarding their use and development.

Question	MH[a] apps that answered the question, n	Yes, n (%)	No, n (%)
Is there a suitably qualified professional involved in the development team of the app?	436	241 (55.3)	195 (44.7)
Does the organization behind the app have relevant credentials?	436	26 (5.96)	410 (94)
Is there evidence of an endorsement by a relevant body?	436	78 (17.9)	358 (82.1)
Are organizations using the app?	436	110 (25.2)	326 (74.8)
Is there a statement that it has been positively evaluated or validated by a relevant health care professional?	436	76 (17.4)	360 (82.6)
Is there evidence within the app that the developer has validated any guidance with relevant reliable information sources or references?	436	251 (57.6)	185 (42.4)
Is there a statement or any evidence showing that appropriate safeguarding measures are in place around peer-support and other communication functions within the platform?	171	141 (82.5)	30 (17.5)
Does the developer make clear risks associated with using the app?	436	27 (6.19)	409 (93.8)
Is there a privacy policy clearly available via the app/web app/website?	374	364 (97.3)	10 (2.67)
Does the developer fully inform the user of how they will collect data about them?	407	376 (92.4)	31 (7.62)
Is there a statement that confirms the app's compliance to GDPR[b] 2016 (or Data Protection Act 2018)?	371	160 (43.1)	211 (56.9)
Are users informed of their rights with regard to their data? Are users clearly informed of the individual privacy rights they are entitled to expect under GDPR?	365	270 (74)	95 (26)

[a]MH: mental health.

[b]GDPR: General Data Protection Regulation.

What Data Is Typically Collected by Mental Health Apps?

Table 9 depicts the types of data that mental health apps collect. Non–mental health apps have been included as a comparator. The table is sorted in descending order of digital mental health app frequency. The most common data type is usage data (357/436, 81.9%), followed by email (322/436, 73.9%). Percentage delta indicates the difference between mental health apps and non–mental health apps. The Fisher exact test (with Bonferroni-corrected α) was used to check for statistical significance between mental health apps and non–mental health apps. Many mental health apps collected data that may not be necessary to provide a mental health service. These were cookies or web beacons (233/436, 53.4%), location data (212/436, 48.6%), and full address or postcode (125/436, 28.7%). However, non–mental health apps also collected these data with a similar proportion; see Table 9 for a list of what types of data were collected. Figure 6 depicts occurrences of data types that were collected by the same apps. Multimedia Appendix 4 depicts the top 10 rules resulting from an association rule mining analysis, showing that email, IP address, name, and usage data are often co-collected by the same apps.

Figure 6 depicts occurrences of data types that were collected together by digital mental health apps. The most common occurrences appear in the top left.

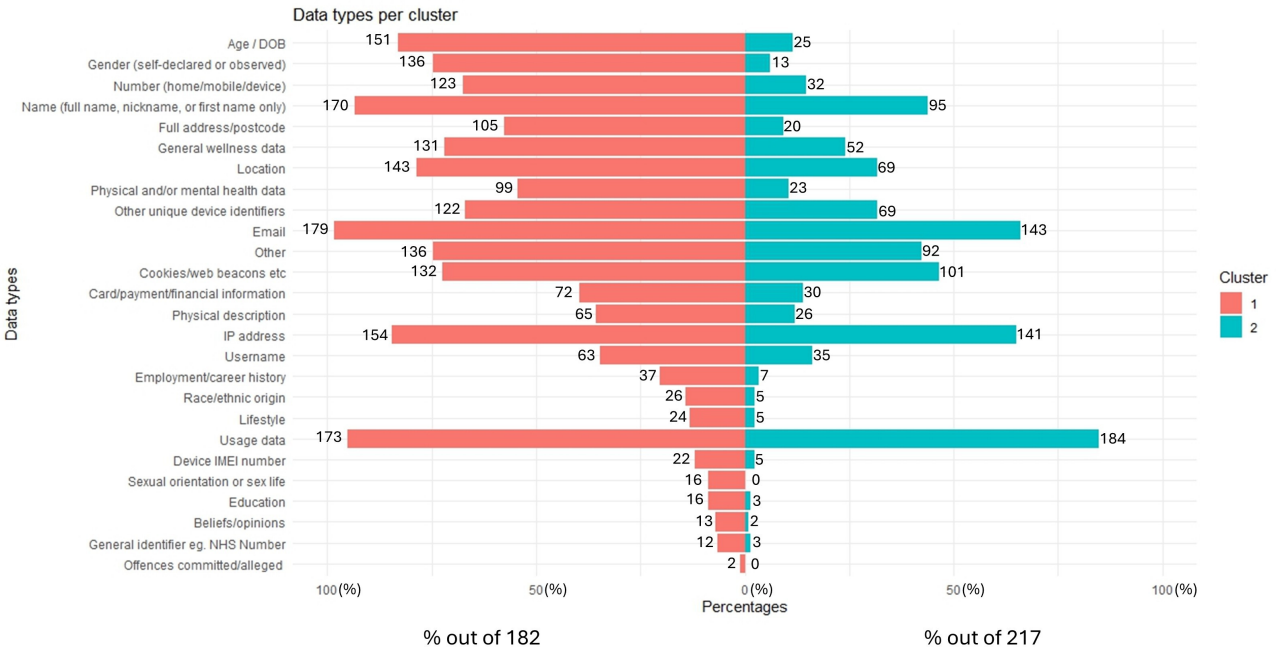
[a]MH: mental health.

[b]DOB: date of birth.

[c]IMEI: International Mobile Equipment Identity.



[d]NHS: National Health Service.

Figure 6. Heatmap of occurrences of collected data. Apps with "No information on data collection provided" and "None (data is stored on the device)." A total of 399 mental health apps are represented in the figure. DOB: date of birth; IMEI: International Mobile Equipment Identity.

The results show that mental health apps can be split into 2 clusters. This is visualized in Figure 7, where mental health apps in cluster 1 collected more data than cluster 2. Moreover, on average (median), mental health apps in cluster 1 present a higher ORCHA score than apps in cluster 2. This indicates that mental health apps that collected more data, on average (median), outperformed those that collected less. Previous work analyzed the top 27 ranked Google Play Store mental health apps regarding their DP [26]. It found that many of the apps had DP-related issues such as unnecessary permissions, insecure cryptography implementations, leaks of personal data, credentials in logs, web requests, as well as risk of user profiling. Further analysis is needed to confirm whether it is data collection that contributed to the apps achieving higher ORCHA scores in this study, as indicated by cluster analysis.

Figure 7. Bar plots showing frequency of data types per cluster, ordered in descending order of percentage delta (% difference) between clusters. DOB: date of birth; IMEI: International Mobile Equipment Identity; NHS: National Health Service.

XSL•FO
RenderX

K-modes cluster analysis was conducted on 399 of 436 mental health apps (apps with data types "No information on data collection provided" and "None" were excluded). Figure 7 depicts bar plots for each of the data types per cluster. The x-axis represents percentages (corresponding to the size of each cluster) of frequency for each of the data types per cluster. Multimedia Appendix 5 depicts the results of K-modes clustering conducted on the 399 mental health apps.

Multimedia Appendices 4 and 5 depict the results of association rule mining and K-modes clustering conducted on data types, respectively.

Discussion

Principal Findings

The objective of this study was to examine the characteristics of mental health apps. A total of 436 digital mental health apps were assessed in this study. This study found that most mental health apps do not meet the necessary threshold for quality of ORCHA score of 65. Many apps do not follow precautions such as involvement of professionals in the app development process, and organizations behind the apps often do not have the necessary credentials. This study analyzed the distribution of OBR scores across domains (PCA, UX, and DP) and across NICE ESF tiers. The study also analyzed the relationship between quality and cost and the importance of app features in relation to their quality, as indicated by the ORCHA score. Moreover, this study states the types of evidence that underpin mental health apps and the characteristics of app development, use, and DP.

The findings of this study demonstrate that many publicly available mental health apps may not take precautions (such as involvement of appropriate health professionals, literature references, or conducting tests) to ensure that their content is valid and research based. Moreover, as shown by previous research [6-8,18,19], there is a place for improvement regarding the quality of mental health apps. The inclusion of an appropriate health professional in the development of a mental health app could potentially improve the quality of an app, as they would be able to advise on the content of an app and any necessary features.

A study analyzing the mental health app marketplace found that, for mental health apps, user ratings and downloads are not linked with app features, function, or evidence [27]. Similarly, a study that analyzed digital health apps across 26 categories found that user ratings and downloads are not linked to quality [28]. Since user ratings and downloads are not reliable indicators, this study of mental health app characteristics and quality is necessary to further their improvement. Moreover, this indicates that users may be unable to judge whether a mental health app is of appropriate quality and may require expert recommendations. Previous work has been done trying to help in the selection of mental health apps by proposing a digital health app database [29] of apps that were assessed using the American Psychiatric Association app evaluation model [30]. Similarly, the ORCHA database could be used [31], allowing for better selection of digital health apps, which may improve their adoption. A study focused on opportunities and tensions surrounding the use of technology-enabled mental health services found that clinicians saw potential in using technology-enabled mental health care services [32]. In the context of mental health apps, this study could be helpful in making technology-enabled mental health care services improve in quality.

A study on implementation strategies for mental health apps in health care settings [33] explored strategies such as "Exploration Phase Strategies." This strategy considers the use of evidence-based services based on the needs of those in a setting. This study on the characteristics of mental health apps may influence future strategies, as it provides insight into the quality of mental health apps, the types of evidence that are collected, and the data types that are collected. This study may be useful in determining what is needed for a mental health app to be considered useful and reliable.

Limitations

The OBR evolved from earlier versions during the height of the COVID-19 pandemic. Originally, it was created as a more stringent version so that ORCHA could recommend the most compliant digital health apps to members of the UK population with confidence. ORCHA tested a new version of the OBR on a selection of highly compliant digital health apps (as determined by prior versions of the OBR). This set of 30 digital health apps served as the pilot group, with the subsequent 2097 (original dataset used in this study, Figure 1) digital health apps being assessed with ORCHA's typical assessment approach of categorizing digital health apps into categories ordered by number of downloads and assessing the most downloaded digital health app in each category, followed by the second, and so forth.

This study is limited to the characteristics that were included in the OBR assessment, meaning that features not included in the OBR may have a strong influence on quality but were not considered in this study. For example, target users such as gender or mental health symptoms were not included. Future studies could focus on additional characteristics. This study was exploratory; a more in-depth study in terms of target users and features could be conducted, for example, by analyzing feature importance for different categories of mental health apps.

This study was conducted using 436 mental health apps; a study with a larger sample size could lead to better results. Using different assessment tools (other than the OBR) could provide different results, as different characteristics and questions may be included, and a study comparing these findings with findings from other tools could lead to more insights.

Conclusion

The objective of this study was to examine the characteristics of mental health apps regarding their quality, target users, features, underpinning evidence, and DP. To achieve this objective, 7 exploratory research questions were proposed and answered. In this study, common features and data types were examined regarding their link to quality, as indicated by the ORCHA score. The key findings of the study indicate that the quality of mental health apps could be improved, as the median

XSL•FO
RenderX

ORCHA score for mental health apps is 60, which is below the ORCHA threshold score of 65. The findings of this study demonstrate that many publicly available mental health apps did not take precautions (such as involving appropriate health professionals, literature references, or conducting tests) to ensure that their content is valid and research based. Greater effort on behalf of mental health app developers is needed to ensure that the public is provided with high-quality apps.

Participant Engagement With a Digital Behavioral Health App for Chronic Pain: Descriptive Secondary Analysis of a Feasibility Randomized Controlled Trial

Abstract

Background: Chronic pain is a widespread condition that impairs quality of life and is often managed primarily with medications. National guidelines now recommend nonpharmacologic, mind-and-body, and behavioral approaches as first-line or complementary treatments. However, access to these evidence-based options remains limited. Digital health technologies offer a scalable way to deliver integrative, self-care interventions that empower patients to live well with pain.

Objective: This study examined engagement with and perceived usefulness of a patient- and health care professional–informed mobile app designed to deliver behavioral and educational content to support pain self-management.

Methods: Adult primary care patients with chronic pain were enrolled in a 12-week feasibility trial. The app included lessons addressing the physical, emotional, and social aspects of pain; tracking and personalized insights; self-screenings; and optional in-app coaching. Participants completed baseline and 3-month surveys assessing usability and satisfaction. Engagement was evaluated through app analytics and milestone completion.

Results: Of 49 patients assigned to the app, 40 (81.6%) activated it. Participants used the app for an average of 27.3 (SD 25.2) unique days and completed an average of 25.5 (SD 22.5) core lessons. Engagement highlights included 42.5% (17/40) completion of the valued living module, 25.0% (10/40) completion of all lessons, and 50.0% (20/40) use of daily check-ins. Usability ratings were high, with 86.7% (26/30) reporting that the app helped them better understand or manage their pain and 90.0% (27/30) recommending it to others.

Conclusions: Adults with chronic pain engaged with the program and reported high satisfaction with this evidence-informed digital mind-and-body intervention. Findings from this feasibility study suggest the potential for digital tools to support access to nonpharmacologic, integrative pain self-care and complement traditional clinical approaches.

KEYWORDS

chronic pain; self-management; digital health; behavioral health; acceptance and commitment therapy

Introduction

Chronic pain is one of the most common reasons why adults seek medical care [1]. It affects over 50 million adults in the United States—more than 20% of the population—with approximately 8.5% experiencing pain that limits daily functioning, including participation in work and social activities [2]. The burden is not equally distributed; rates are higher among individuals with lower income and educational levels and those with public health insurance [3]. Chronic pain is associated with long-term opioid use, emotional distress, and disability [4,5] and is estimated to cost the US economy between US $560 and US $635 billion annually in direct health care expenditures and lost productivity [6].

In response to the opioid epidemic, national guidelines recommend behavioral interventions as first-line or complementary treatments for chronic pain [7,8]. Evidence supports cognitive behavioral therapy, acceptance and commitment therapy, and mindfulness-based interventions [9-11], yet these treatments are underused in routine care. Primary care providers, often the first point of contact for patients [12], face barriers to implementing these strategies,

XSL•FO
RenderX

including limited training in behavioral approaches for pain; time constraints; and system-level barriers such as insufficient insurance coverage, access challenges, and limited availability of trained professionals [12-14]. Because most behavioral pain treatments are delivered in specialty settings, scalability and accessibility are limited [13-15]. The National Academy of Medicine has called for the development of innovative strategies to reduce these barriers and support more equitable and effective pain care [12].

Digital health technologies, including mobile apps, can extend the reach of evidence-based behavioral interventions by delivering support asynchronously outside traditional clinical settings and being integrated into broader care models. They align with needs to diversify service delivery and equip medical professionals, including those in primary care, with accessible tools for pain management [13,16-18]. However, reviews show that many consumer apps lack credible content or health care professional input, have limited functionality, and fail to engage users [19,20]. This highlights the need for engaging, evidence-based, patient- and health care professional–informed apps that address the full biopsychosocial experience of pain and can be used in clinical practice.

We conducted a feasibility study of a self-directed mobile app designed to deliver evidence-based educational content and behavioral strategies to adults with chronic pain. This study evaluated participant engagement, including patterns of use, frequency of use, and feature use. Insights into user interaction with digital behavioral tools are essential for refining intervention design, informing clinical integration, and guiding future research and scale-up.

Methods

Study Design

We analyzed engagement data collected during a feasibility randomized control trial of a mobile behavioral health app designed to help patients treated in primary care for chronic pain management. The feasibility trial was a 2-arm randomized controlled trial designed to assess the feasibility of trial implementation (recruitment, randomization, treatment, and retention) and explore preliminary impacts on pain, pain interference, and mental health. This paper presents a descriptive analysis of user experience and app use data among participants in the intervention arm, who had access to the mobile behavioral health app during the study period. Participants were randomized using a stratified approach based on health care system and age to ensure balanced allocation across health systems and approximate the national age distribution of adults living with chronic pain.

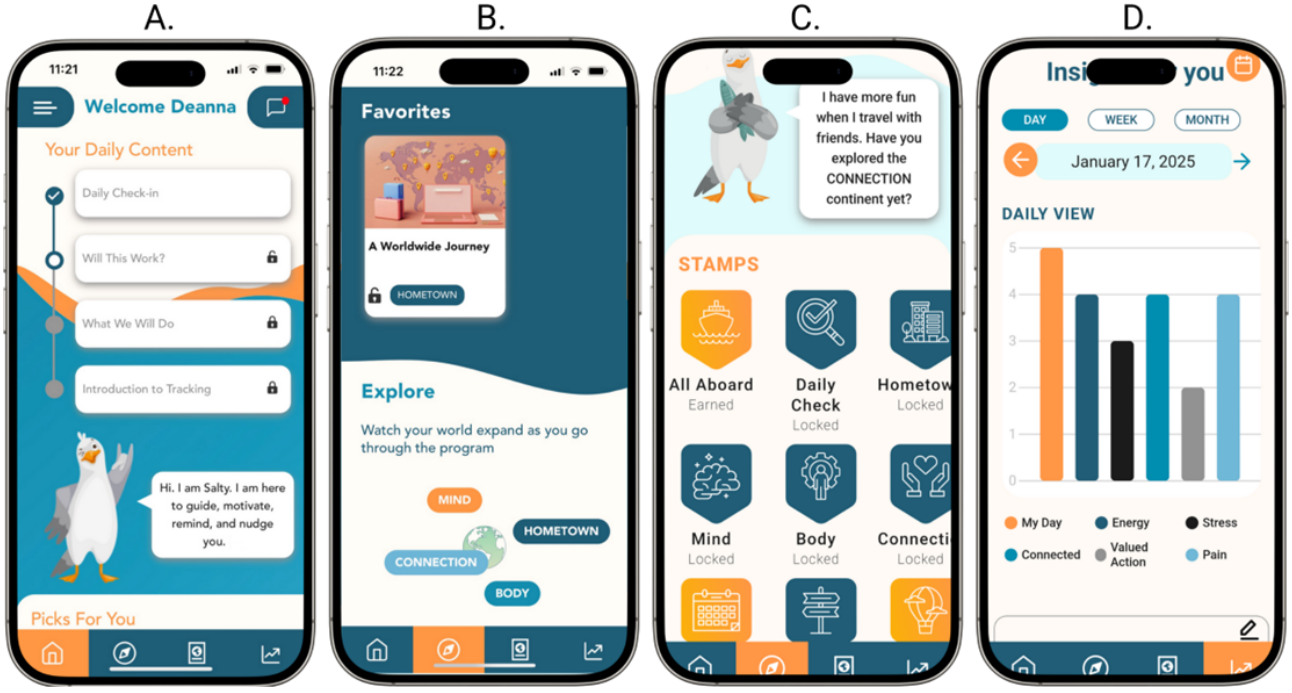
Ethical Considerations

This study was conducted as part of a National Institutes of Health Small Business Innovation Research–funded collaboration, with 2Morrow Inc serving as the grant recipient and developer of the intervention and the University of Washington serving as the academic research partner.

All study procedures, including recruitment, consent, data collection, and follow-up, were reviewed and approved by the University of Washington Institutional Review Board (STUDY00016340) and were conducted in accordance with the approved study protocols and applicable federal regulations. All patients provided informed consent prior to participation. Patient privacy and confidentiality were protected through multiple safeguards. Data were stored on secure, access-controlled systems, and all analytic datasets were deidentified prior to analysis. No directly identifying information was included in analytic files. App use data were captured automatically through the intervention platform and linked to study data using unique participant identifiers. Data handling procedures complied with applicable privacy and confidentiality requirements. Patients assigned to the Salty program were provided with 2Morrow's privacy policy at the time of program activation, which outlines how user data are collected, used, and protected.

Patients received a US $50 electronic gift card for each completed survey (up to US $200 total).

Recruitment and Eligibility



Primary care patients with chronic pain were identified through electronic health records at 4 health systems (60 clinics) in Washington and Idaho, sent an email invitation to participate in the study, and directed to complete a screening survey to determine eligibility. Eligible participants had at least one documented chronic pain condition identified through electronic health records. Types of pain represented in the study population included back pain, neck pain, noninflammatory joint pain, abdominal or bowel pain, fibromyalgia, and headache disorders. Patients were selected to participate if they were actively receiving care for their chronic pain (≥2 primary care visits in the previous year), currently endorsed struggling with chronic pain for 3 months or longer, endorsed having pain interference in their lives (≥55 on the Patient-Reported Outcomes Measurement Information System Pain Interference scale [21,22]), could use an app in English, and had a smartphone compatible with the behavioral health app.

Patients randomized to the intervention group received access to the Salty for Chronic Pain app, a novel digital behavioral health intervention developed by 2Morrow Inc (Figure 1). To be included in this study and analysis, patients had to successfully activate the app, which included downloading it and completing their in-app personal profile.

Patients were invited to participate via email and directed to an online interest survey. The survey provided 3 options: proceed to eligibility screening, request a call from a study coordinator for additional information, or opt out of the study. Patients who completed the eligibility screening were informed of their eligibility status at the end of the survey. Those who were eligible were directed to an electronic consent form, which allowed them to confirm participation, request further discussion with a study coordinator, or decline participation. Patients who confirmed participation provided informed consent electronically prior to enrollment.

Program Design and Features

Salty for Chronic Pain (pain app) is a 12-week self-directed program designed to educate and support patients managing the emotional, social, and behavioral aspects of living with chronic pain with the goal of reducing pain interference and improving function and quality of life. The program was created with input from patients, health care professionals, and pain behavioral health specialists during phase 1 of the Small Business Innovation Research trial; health care professionals indicated that they wanted additional options for their patients with pain that were evidence based but did not require much of their time [23].

The program used the metaphor of guiding patients on a personal journey to explore the physical, emotional, and social aspects of pain to learn how to live life despite having pain. The program included a total of 58 core lessons divided into 4 sections and additional bonus content. The first core section, known as "Hometown," included 22 lessons related to the concept of valued living and living with pain based on principles from acceptance and commitment therapy. The other sections covered the physical (16 lessons), emotional (13 lessons), and social (7 lessons) aspects of pain.

The program included tools for gaining personal insights into pain and daily functioning. The "Daily Check-in" allowed patients to rate their overall day ("awesome" to "awful"), as well as energy, activity, stress, social connection, valued activities, and pain (all on 5-point scales), with results displayed graphically across daily, weekly, or monthly views. A journal feature was provided for recording additional reflections, and patients could optionally connect a Fitbit (provided at no cost) to track activity, sleep, and heart rate. Self-screenings were available in the "Self-Discovery" section, including the Depression, Anxiety, and Stress Scale-21 (DASS-21 [24]); Valued Living Questionnaire (VLQ; [25]); Drug Use Disorders Identification Test (DUDIT [26]); and Alcohol Use Disorders Identification Test (AUDIT [27]). Although the program was intended to be self-guided, participants could message with a coach on the app about lessons, personal discoveries, and progress. These features and others on the app are described in Textbox 1.

XSL•FO
RenderX

Textbox 1. Summary of core features and functionality on the app.

Profile

- Description: pain-related questions that patients complete to set up their account
- Purpose: benchmark data and personalization

Core lessons

- Description: 58 short lessons related to 4 domains (valued living—acceptance and commitment therapy concept, physical aspects of pain, emotional aspects of pain, and social aspects of pain)
- Purpose: pain information, education, and coping skills

Bonus lessons

- Description: additional content that patients could access
- Purpose: additional education, tips, and patient stories

Daily check-in

- Description: a brief daily questionnaire for patients to rate various aspects of living with pain
- Purpose: a personal pain tracking tool

Journal

- Description: patients could record their pain experience in their own words
- Purpose: a flexible and personal pain tracking and insight tool

Personalized messaging

- Description: brief in-app messages
- Purpose: provided to direct, motivate, or reinforce concepts

Sensor integration

- Description: participants could link a Fitbit device to the app to track additional insights
- Purpose: objective tracking of sleep, activity, and heart rate

Self-screening questionnaires

- Description: 4 standard questionnaires for patients to explore alcohol and drug use, mental health, and valued living
- Purpose: to explore and better understand their substance use, mental health, and what is most important to them

Insight dashboard

- Description: a visualization tool to explore pain insights
- Purpose: ability to view the interconnection among self-reported pain, energy, activity, stress, social connection, and other metrics

Milestone achievement

- Description: participants could receive up to 12 stamps on their passport page
- Purpose: summarize and reward progress on the app

Monthly check-in

- Description: a brief monthly questionnaire
- Purpose: in-app survey to measure pain, interference, mental health, quality of life, and satisfaction each month after a patient enrolls in and uses the program

Message a coach

- Description: asynchronous chat tool with a coach
- Purpose: meant to provide additional support and encouragement for patients who wanted to connect with a coach; patients could share insights and achievements as well

XSL•FO
RenderX

Navigation and pacing features

- Patients were instructed to complete a certain number of lessons along with a daily check-in each day that they visited the app
- The app required completion of all Hometown lessons before moving on to another section
- Patients needed to complete each core section before selecting another one to complete
- Patients could complete the self-screening tools only once per month
- Save a favorite: a feature on the app to save content that participants found helpful

How the Intervention Worked

Each time patients opened the app, they were prompted to complete a "Daily Check-in" and up to 3 scheduled lessons and could view optional bonus content. They were encouraged to engage with the app 2 to 3 times per week over 12 weeks, with lesson access paced to discourage rapid completion and promote sustained use. All participants began with valued living content in the "Hometown" section before advancing to the "Social," "Physical," or "Emotional" modules. Completion of all lessons within a category was required before moving on as content was designed to build sequentially. Participants could bookmark favorite lessons and retained access to app content and features for 100 days.

App Milestone Completion

Patients earned up to 12 milestone stamps (Table 1) as a gamified feature to promote engagement and track progress. Stamps were displayed on the "Passport" tab and awarded for completing the profile, core content (values, body, mind, connection, and bonus), at least 10 "Daily Check-ins," and a monthly check-in, as well as for connecting a Fitbit, messaging a coach, completing self-screenings, and visiting all recommended sections.

Table . Passport stamps for the 12 milestones completed on the app (N=40).

Milestone	Stamp name	Participants receiving the stamp, n (%)
Completion of profile	All Aboard	40 (100.0)
Completion of daily check-in 10 times	Daily Check	20 (50.0)
User visited the "Self-Discovery," "Passport" (stamp location), "Explore" navigator tool, and "Insights" pages	Traveler	19 (47.5)
One self-screening (alcohol or substance use, depression and anxiety screening, or valued living questionnaire) completed	Discover	17 (42.5)
Hometown core content completed (22 lessons)	Hometown	17 (42.5)
Mind core content completed (13 lessons)	Mind	11 (27.5)
Body core content completed (16 lessons)	Body	13 (32.5)
Connection core content completed (7 lessons)	Connection	11 (27.5)
15 bonus lessons completed	Extras	14 (35.0)
First monthly check-in completed	Monthly Check	14 (35.0)
One engagement with a coach	Coach	13 (32.5)
Synchronizing the Fitbit	Sync Up	5 (12.5)

Data Collection

Demographics (age, gender, race and ethnicity, educational level, and employment status) and pain history (type and duration) were collected at screening or baseline. Use metrics were captured from the app data system. App metrics included app use milestones achieved (eg, earned passport stamps) and use metrics, including unique days of use, duration (days between first and last use), core lessons completed, feature use (tracking and self-screenings), and in-app actions.

User experience was measured at 3 months via the mHealth App Usability Questionnaire (MAUQ [28]) and a custom perceived usefulness survey developed by 2Morrow, Inc. Acceptability and usefulness were derived from the MAUQ Ease of Use and Satisfaction Domain (Q1-8). The custom survey asked patients to rate the helpfulness of the app overall and of specific features, value, and the likelihood that they would recommend the app to others.

Recruitment, screening, and survey administration were managed by the University of Washington. Patients had 2 weeks to complete each survey.

Analyses

Descriptive statistics (frequencies, means, ranges, and percentages) were calculated for demographics and engagement, describing the types of app content, features, and tools accessed.

Results

Study Population

Of the 49 patients randomized to the pain app intervention arm, 40 (81.6%) met the inclusion criteria for this study (ie, successfully activated the program by downloading the app and completing their profile). Participants reported living with chronic pain for 3 or more years; were aged 47.3 (SD 17.3) years on average (the most common age group was 30-44 years); and identified as women for the most part followed by men, with a smaller proportion (3/40, 7.5%) identifying as nonbinary. Nearly half (19/40, 47.5%) of the participants identified as White individuals, with the remainder (21/40, 52.5%) identifying as Asian, Pacific Islander, or Hawaiian; Black; multiracial; or other. Educational attainment ranged from high school to postgraduate education, with most participants (32/39, 82.1%) reporting at least some college education. At baseline, a substantial proportion of the participants reported a history of mental health conditions, reflecting the clinical complexity of the study population. Employment status varied, including part-time work, full-time employment, and disability status. Counts and percentages are reported in Table 2.

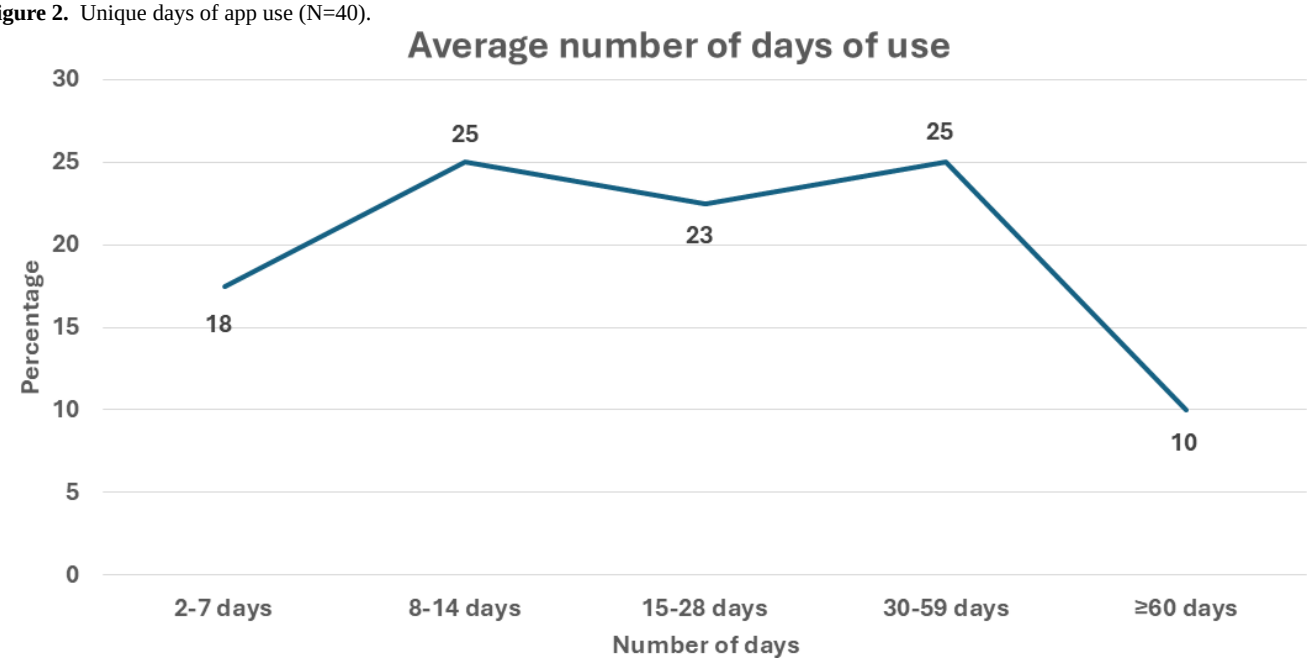
Outcome Measures

App Use

Passport Stamps Earned

All participants earned at least one passport stamp, with a mean of 4.9 (SD 3.8; range 1 - 12) stamps per user, indicating broad engagement with the app. The most frequently earned stamps reflected onboarding and routine use, including completing the profile (40/40, 100.0%), completing at least 10 daily check-ins (20/40, 50.0%), and exploring multiple app sections (19/40, 47.5%). A total of 42.5% (17/40) completed at least one core content module, with all of these participants completing the valued living ("Hometown") module; in this subgroup, 58.8% (10/17) completed all 4 content modules, and 82.4% (14/17) accessed bonus content. Overall, 25.0% (10/40) of the



XSL•FO
RenderX

participants earned 9 or more stamps, suggesting a subset engaged deeply with multiple features, whereas others demonstrated more selective use.

Lesson Completion and Days of Use

Participants completed a mean of 25.5 (SD 22.5, range 2 - 58) core lessons. A total of 42.5% (17/40) completed the valued living module, and 25.0% (10/40) completed all 58 core lessons across the 4 content areas. Participants engaged with the app on an average of 27.3 (SD 25.2, range 2 - 118) unique days over the 12-week period; 57.5% (23/40) used the app on 15 or more days, and 75.0% (30/40) interacted with the app across a span of 30 to 100 calendar days (Figure 2).

Figure 2. Unique days of app use (N=40).

Additional Engagement Indicators

Use of tracking and optional features varied. In total, 82.5% (33/40) completed at least one milestone related to pain insight activities (daily check-ins, self-screenings, or monthly check-ins), with over 40% (17/40, 42.5%) completing at least one mental health or substance use self-screening. Completion rates for each self-screening ranged from 22% to 30%: DUDIT (9/40, 22.5%), VLQ (10/40, 25%); AUDIT (10/40, 25.0%), and DASS-21 (12/40, 30.0%). A smaller proportion engaged with coaching features (13/40, 32.5%) or synchronized a Fitbit device (5/40, 12.5%). Across all users, mean in-app activity totaled 2123 (SD 2579.8, range 48 - 10,332) actions, reflecting substantial variability in depth of interaction.

User Survey Results

Overview

The response rate to the follow-up survey at 3 months was 85.0% (34/40) for the MAUQ ease of use and satisfaction domain questions (Table 3). Due to an error in the survey build, the custom perceived usefulness survey response rate was somewhat lower (30/40, 75.0%), and missing responses were mostly due to random missingness (Table 4).

MAUQ Ease of Use and Satisfaction Domains

Overall usability and satisfaction ratings were favorable (Table 3). Most participants reported that the app was easy to learn (29/34, 85.3%) and use (28/34, 82.4%). More than 70% (25/34, 73.5%) agreed that the app was well organized and the time commitment was appropriate, were satisfied overall, and would use it again.

Custom Perceived Usefulness Survey

Core features—including daily check-ins; structured lessons; and content addressing the physical, emotional, and social aspects of pain—were rated as helpful by 76.7% (23/30) to 90.0% (27/30) of the participants. While features such as receiving passport stamps, Fitbit integration, and coach messaging received somewhat lower ratings, more than two-thirds (20/30, 66.7%) still found them useful. Overall, 90% (27/30) of respondents reported that they would recommend the app to others. Additionally, 23.3% (7/30) rated the daily check-ins and emotional content as extremely helpful, with comparable ratings across other content areas (Table 4).

Discussion

Principal Findings

This study evaluated the Salty for Chronic Pain app, a behavioral digital health program designed to support adults living with chronic pain. Unlike most studies on digital health programs for pain that report only frequency or duration of use, our evaluation incorporated milestone completion, lesson progression, self-tracking, and perceptions of usefulness, offering a more comprehensive view of engagement and potential value as a complement to clinical care. Patients demonstrated sustained engagement for nearly a month, advanced through structured lessons, and reported high usability and satisfaction, suggesting that the program appeared feasible and was generally well received. These findings add to a growing body of research showing that digital platforms can deliver behavioral pain self-management strategies in ways that are usable, acceptable, and aligned with evidence-based approaches [10,16,23,29].

Although direct comparisons to other studies are limited due to differences in design, content, and metrics, our findings are broadly consistent with those of prior digital pain intervention research [30,31]. Activation rates were high, suggesting that patients could begin using the app with minimal support, which may help reduce burden on clinical staff. Most participants met recommended frequency targets, indicating that the app design supported regular use without intensive reminders. These results are comparable to those of Thomson et al [32], who reported that 77% of participants achieved minimum engagement during a 6-week intervention.

On average, patients completed more than 25 core lessons, and engagement extended beyond the introductory module, with a subset completing all lessons and others using bonus content. This level of engagement is noteworthy given that lessons were sequenced, requiring completion of one section before progressing, and the valued living module (“Hometown”) was mandatory before others could be accessed. In addition, no automated reminders were delivered due to a technical issue. Hence, engagement occurred without automated reminders, suggesting that participants were self-motivated. It is possible that greater use would have been achieved with automated reminders or more flexible sequencing. At the same time, these findings raise important questions about how much content exposure is necessary to achieve meaningful improvements in pain, acceptance, and functioning. Some patients may benefit from a targeted subset of lessons, whereas others may require more extensive exposure. Clinical outcomes will be reported separately. Future refinements, such as adding flexible sequencing or automated prompts, may increase completion rates and help identify the “dose” of content most strongly associated with clinical benefit or perceived value.

These findings highlight the potential of digital behavioral health tools to support access to evidence-based pain self-management strategies. Participants engaged with structured lessons and interactive features that promoted reflection, self-monitoring, and awareness of valued living—processes associated with acceptance, coping, and resilience in chronic pain populations [33,34]. The results suggest that such strategies can be delivered in digital form with high usability and satisfaction; however, engagement metrics reflect exposure to content rather than therapeutic dose or clinical effect.

Several limitations should be considered when interpreting these findings. The relatively small sample size reflects the feasibility nature of the trial and limits generalizability to all adults with chronic pain. The eligibility criteria and study context further shape interpretation: participants were required to have smartphone access, English-language proficiency, and clinically significant pain interference, and most reported long-standing pain. Accordingly, the sample may overrepresent individuals who were digitally ready or motivated to engage with a self-directed program. The engagement patterns observed in this study may not generalize to all adults with chronic pain,

XSL•FO
RenderX

particularly those with limited digital access or differing readiness to engage in behavioral interventions.

Taken together, these findings suggest that this type of digital behavioral health program may be particularly well suited for individuals who are motivated to engage in self-directed care and interested in nonpharmacologic or complementary approaches to chronic pain management. The observed engagement without automated reminders further suggests potential fit for users who prefer flexible, low-burden support delivered outside traditional clinical settings.

Engagement and satisfaction ratings may have also been influenced by study participation, incentives associated with survey completion, novelty effects, or app design constraints such as fixed lesson sequencing.

Despite these limitations, this study provides early evidence that an evidence-informed, user-centered mobile program can be feasibly delivered and meaningfully engaged with by adults receiving care for chronic pain. These findings can inform intervention refinement and support the design of larger studies to evaluate engagement patterns; predictors of sustained use; and effects on pain interference, functioning, and quality of life [17,18].

Conclusions

Patients successfully activated the program without support, most met recommended use targets, and many engaged deeply with the available content and insight tools. These findings are promising for the use of self-directed evidence-based digital behavioral health apps in clinical pain management. While patients rated the features favorably, additional research is needed to determine how much exposure is necessary to achieve clinical benefit. Future studies should evaluate the impact of these tools on pain interference and functioning, identify engagement patterns linked to improved outcomes, and test refinements such as flexible sequencing or automated reminders. Addressing these questions can help digital behavioral health programs expand access; supplement usual care; and support more equitable, scalable approaches to chronic pain management.

Abstract

Background: Smart home emergency response systems (SHERS) leverage existing smart home infrastructure to detect critical events and alert emergency services without manual activation. Unlike personal emergency response systems, which require users to trigger alarms, SHERS initiate alerts autonomously. Although technically feasible, user acceptance has received limited empirical attention.

Objective: This study examined factors influencing the intention to adopt SHERS in private households, identifying key facilitators and barriers to acceptance.

Methods: A mixed methods study followed the Double Diamond framework. In the discover/define phases, expert interviews (n=3) and secondary data analysis informed persona and scenario development. In the "develop" phase, brainwriting workshops (6-3-5 method, n=12) generated design requirements translated into a low-fidelity prototype. In the "deliver" phase, an online survey (n=85) assessed acceptance using the Technology Usage Inventory. Structural equation modeling tested hypothesized relationships, and methodological triangulation integrated qualitative and quantitative findings.

Results: Perceived accessibility was the strongest positive predictor of intention to use (β=0.33, *P*=.02), while skepticism showed a marginally negative effect (β=−0.34, *P*=.06). The model explained 66% of variance in behavioral intention (R^2=0.66). Triangulation confirmed that concerns about complexity, false alarms, and data privacy underlie these effects. Experts emphasized that technology should support rather than replace human decision-making; workshop participants stressed intuitive setup and user control over alarm cancellation.

Conclusions: SHERS acceptance is primarily associated with perceived accessibility, while skepticism may act as a barrier. Developers should prioritize seamless integration with existing ecosystems, clear feedback mechanisms to prevent false alarms, and strong data protection.

KEYWORDS

smart home emergency response systems; SHERS; user acceptance; emergency response; mixed methods research; Double Diamond; structural equation modeling

Introduction

Background

Emergency response systems usually assume that affected individuals can seek help by calling emergency services, activating alarm buttons, or evacuating dangerous areas [1]. However, physical limitations, cognitive impairments, or environmental factors often stop timely self-rescue. This is especially true for older adults living alone and people facing sudden medical issues [2]. In Germany, almost 6 million people aged 65 years and older live in single-person households [3], which puts a significant number at risk of delays in emergency response.

Smart home technologies provide a technical basis for addressing these gaps [4]. Recent developments in ambient assisted living and health monitoring show that these systems can spot anomalies, track daily activities, and detect potential emergencies through patterns of inactivity or changes in the environment [5,6]. Building on these abilities, smart home emergency response systems (SHERS) represent a new type of safety-critical application that can automatically identify emergency situations and send alerts to emergency services, caregivers, or nearby responders without requiring users to take action [7].

Such systems may draw on heterogeneous sensor configurations already present in smart home environments, including motion

XSL•FO
RenderX

and presence sensors, environmental detectors for smoke or carbon monoxide, pressure-based bed and chair sensors that track prolonged inactivity, and wearable devices capable of detecting falls or abnormal vital signs [5,6]. By combining data from multiple sources, SHERS can distinguish routine patterns from potential emergencies and initiate alerts accordingly.

Unlike traditional personal emergency response systems that rely on manual activation, such as wearable alarm buttons [1], SHERS change the approach from user-initiated to system-initiated emergency management. When individuals cannot act, automated detection can close the delay between event and response and may help reduce mortality [8].

Related Work

Research on smart home applications for health and safety has grown considerably, with ambient assisted living and telecare studies showing that sensor-based monitoring can support older adults [1,9-11]. Intelligent fire-detection systems have shown improved accuracy over standalone smoke detectors [12,13]. However, most current implementations operate as closed-loop systems that alert residents locally but still rely on human action to contact emergency services.

Behavioral research shows that people may fail to hear alarms, underestimate risks, or attempt to resolve emergencies independently [14-18]. These behavioral bottlenecks show that systems must be able to act autonomously when human response is delayed or absent.

At the infrastructure level, frameworks such as the Internet of Emergency Services [19] and smart emergency response systems [20] focus primarily on professional responders rather than end-user integration.

Technology acceptance research identifies usefulness, ease of use, trust, and privacy as key determinants of smart home adoption [21]. Similar patterns have been observed specifically for health-related smart home applications, where concerns about data security and loss of autonomy can inhibit adoption even when functional benefits are recognized [22]. However, safety-critical automation that acts on behalf of users in emergencies remains underexplored.

Research Gap

Despite the technical feasibility of SHERS, empirical evidence on how users perceive *automated* emergency notification remains limited [23]. Three specific gaps emerge from the literature:

First, acceptance research rarely addresses safety-critical automation, where concerns about false alarms and privacy may differ from convenience-oriented applications [1,9,24].

Second, most studies examine acceptance factors in isolation rather than modeling their joint influence on behavioral intention. Understanding how psychological dispositions such as technology anxiety and curiosity, functional factors such as physical independence, and social factors such as prosocial orientation interact to shape adoption intentions requires multivariate approaches.

Third, the perspective of emergency professionals is rarely integrated into the design process.

Objectives

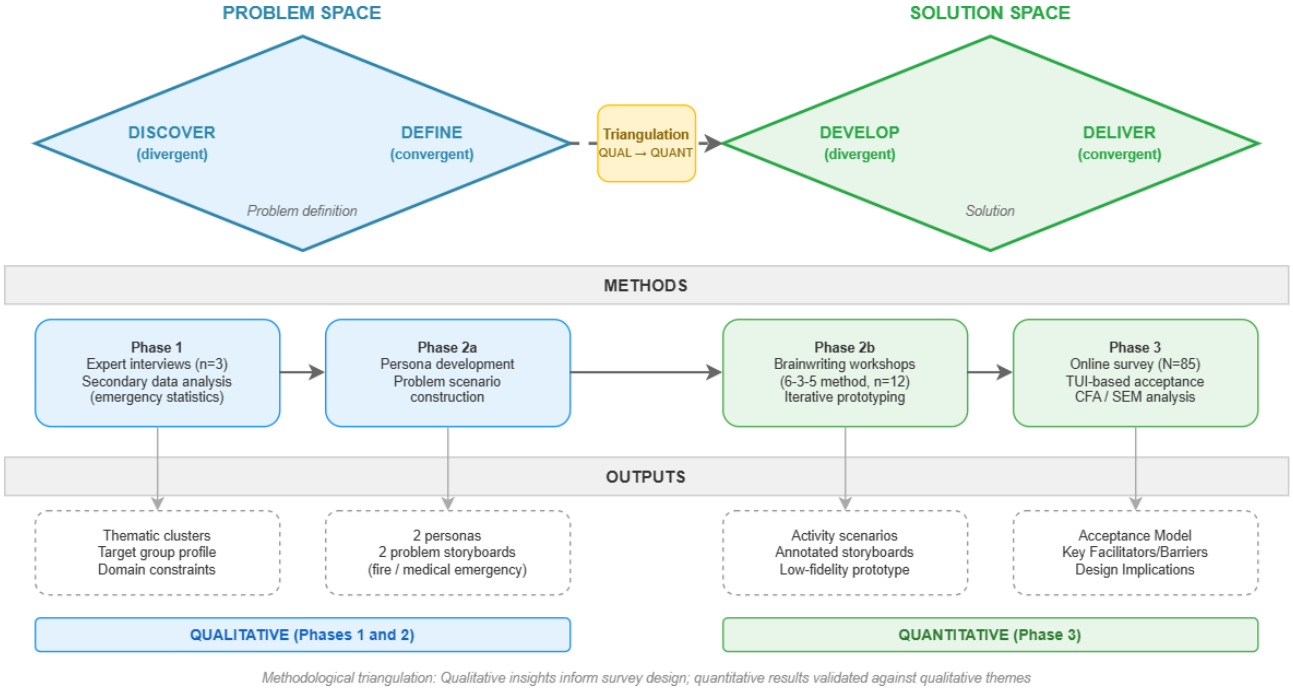
This study addresses these gaps by investigating the adoption and intention to use SHERS in private households. Guided by a user-centered design approach, it pursues three objectives:

1. *Discover and define* the operational context, user needs, and design requirements for SHERS through expert interviews with emergency professionals and scenario-based design workshops.
2. *Develop and evaluate* a system concept that integrates qualitative insights into concrete design artifacts (personas, scenarios, and low-fidelity prototypes).
3. *Assess the determinants* of user acceptance through a quantitative survey examining how psychological, functional, and social factors influence intention to use.

By triangulating qualitative and quantitative findings within a structured design framework, this study seeks to provide both conceptual guidance for SHERS development and empirical evidence on the factors shaping public acceptance of automated emergency technologies.

Methods

Research Approach



This study adopted a user-centered design approach [25] operationalized through the Double Diamond framework [26], which structures innovation processes into 4 iterative phases: discover, define, develop, and deliver. This framework involves different user groups to ensure solutions reflect actual needs [27,28].

The study combined qualitative and quantitative methods across the 4 phases in a sequential exploratory design [29]. The reporting of this mixed methods approach is informed by the Mixed Methods Article Reporting Standards (JARS-MMARS) [30], which provide guidance on transparently documenting how qualitative and quantitative components are integrated. By synthesizing insights from expert interviews, participatory design workshops, and a structured acceptance survey, findings from each phase informed and validated subsequent stages.

Figure 1 illustrates the research design, mapping each phase to its corresponding methods, outputs, and how findings were iteratively integrated.

Ethical Considerations

The ethics committee of Witten/Herdecke University approved the research project on September 7, 2022 (protocol code: S-152/2022). All participants provided informed consent prior to participation. For the online survey, consent was obtained electronically on the first page of the questionnaire. All data were collected anonymously; no personally identifiable information was stored. No financial or material incentives were offered for participation in any phase of this study.

Phase 1: Discover—Domain Analysis and Problem Identification

The "discover" phase aimed to understand the operational context of emergency response and identify user groups who would benefit most from smart home-based emergency notification. This phase combined qualitative contextual inquiry with secondary data analysis.

Expert Interviews

We conducted 3 semistructured interviews with key stakeholders across the emergency response chain: a paramedic, a fire department unit leader, and a control center dispatcher. All 3 experts were affiliated with the Dortmund Fire Department, which served as the operational partner in the ADLeR (Automatisiertes Detektions-, Melde- und Leitsystem für Rettungskräfte [Automated Detection, Notification, and Guidance System for Emergency Responders]) project. Participants were purposively selected to represent the 3 core operational perspectives along the emergency response process: emergency dispatch and coordination, tactical incident management, and frontline medical care. This maximum-variation approach prioritized structural coverage over the number of interviews. As the interviews served primarily exploratory purposes within the "discover" phase, the resulting themes were subsequently validated and expanded through 2 participatory workshops with 12 additional participants (phase 2).

Following a problem-centered approach [31], interviews explored challenges in alerting, communication, and decision-making under uncertainty. Sessions were conducted using a virtual whiteboard, enabling participants to cocreate digital mind maps that captured workflows, pain points, and preliminary solution ideas. This participatory method aligns with principles of contextual design [32].

Interview data were thematically clustered by 2 researchers (OK and MP) to identify cross-cutting needs and constraints. Each researcher independently reviewed the mind map outputs and assigned thematic labels. Discrepancies were resolved through discussion until consensus was reached. As this step served primarily exploratory purposes, detailed COREQ (Consolidated Criteria for Reporting Qualitative Research) [33] reporting was not applied; however, the interview guide and mind map outputs are provided in Multimedia Appendix 1.

Secondary Data Analysis

To complement the qualitative findings, descriptive analysis was conducted using publicly available demographic data and anonymized emergency call statistics. The emergency data were provided by the Fire and Rescue Service of the City of Dortmund (Germany) and comprised all medically induced emergency calls recorded in 2021 (n=19,200). The dataset included age group classifications but contained no personally identifiable information. We analyzed age-stratified distributions to identify high-incidence population segments and inform target group selection for subsequent design activities.

Phase 1 Output

The combined findings provided a domain-grounded foundation for phase 2, including identified user needs, operational constraints, and a validated target group profile.

XSL•FO
RenderX

Phase 2: Define and Develop—Scenario-Based Design and Prototyping

Building on insights from phase 1, phase 2 used scenario-based design techniques [34] to translate empirical findings into concrete design artifacts. This phase corresponds to both the "define" stage (problem framing through personas and scenarios) and the "develop" stage (solution ideation through participatory workshops) of the Double Diamond model.

Persona and Scenario Construction

Based on the thematic clusters from expert interviews and demographic indicators from the statistical analysis, we developed 2 representative user personas, capturing attributes such as age, living situation, health status, and technology familiarity. These personas guided the creation of 2 problem scenarios, a residential fire and a fall-related medical emergency, representing prototypical high-risk situations. Each scenario was visualized through low-fidelity storyboards depicting the current emergency response process without technological intervention, highlighting behavioral bottlenecks and communication gaps.

Participatory Design Workshops

We conducted 2 brainwriting workshops to validate and expand the initial scenarios. Brainwriting is a structured written ideation technique distinct from verbal brainstorming. Participants independently generate ideas in writing before passing them to others for elaboration, which reduces dominance effects and encourages balanced contributions [35]. We applied the 6-3-5 variant, in which 6 participants each write 3 ideas within 5 minutes, then rotate sheets for iterative refinement.

Workshop 1 involved 6 emergency professionals (first responders and dispatch personnel) who reviewed the problem scenarios and contributed design ideas using the 6-3-5 method. The session focused on identifying pain points, desired system behaviors, and integration requirements.

Workshop 2 involved 6 domain experts from academic and applied research institutions with expertise in aging societies, human-machine interaction, and sociotechnical systems. This session addressed system-level considerations, including usability, information interpretability, and edge-case behavior.

Based on workshop outputs, the problem scenarios were iteratively transformed into activity scenarios incorporating envisioned system functionalities. These were synthesized into a low-fidelity prototype combining key system elements into a coherent, user-facing concept.

Data Analysis

We conducted workshop sessions online using digital whiteboards. Exported materials served as the primary qualitative data source. Two researchers (AR and MP) independently analyzed the content following qualitative content analysis principles, inductively coding idea clusters to identify recurring patterns and design requirements. Discrepancies were resolved through iterative discussion until consensus was reached. Reporting follows the COREQ guideline [33]; details are provided in Multimedia Appendix 2.

Phase 2 Output

Validated activity scenarios, annotated storyboards, and a low-fidelity prototype serving as stimulus material for the acceptance evaluation.

Phase 3: Deliver—Acceptance Evaluation

The "deliver" phase evaluated user acceptance of the proposed system concept through a quantitative online survey, completing the Double Diamond cycle by testing the developed solution with end users.

Survey Design and Constructs

Survey constructs were based on the Technology Usage Inventory (TUI) [36], which extends traditional acceptance models by incorporating individual traits including curiosity (NEU), anxiety (ANG), interest (INT), perceived usefulness (NÜT), user-friendliness (BEN), skepticism (SKE), and accessibility (ZUG). Abbreviations reflect the original German instrument. In the TUI framework, accessibility refers to the perceived availability of and ease of access to the technology, including how readily it can be obtained, set up, and integrated into daily routines. This construct does not refer to disability-related accessibility in the sense of barrier-free design. Two additional validated measures were included: the social compatibility (SOC) scale [37] for prosocial attitudes and the activities of daily living (ADL) scale [38] for functional independence.

The survey used a pre-post design: participants first completed demographic questions, smart home experience items, and baseline constructs (NEU, ANG, ADL, and SOC). They were then exposed to visual storyboards illustrating the emergency scenarios with integrated smart home functions (developed in phase 2). Post-exposure, participants rated the remaining TUI constructs and intention to use (ITU). This design enabled measurement of both general dispositions and concept-specific evaluations.

A pilot test (n=5) ensured item clarity and technical robustness. Survey implementation followed CHERRIES (Checklist for Reporting Results of Internet E-Surveys) reporting standards [39]; details are provided in Multimedia Appendix 3.

Participants

The survey was implemented as an open online questionnaire using LimeSurvey, hosted on a secure university server. It was distributed between October 2022 and June 2023 through multiple channels: housing cooperatives and senior advisory councils served as the primary recruitment partners, and the Dortmund Fire Department shared the survey link via social media (X, Facebook, and LinkedIn). Participants were also able to share the link independently. No financial or material incentives were offered. The only inclusion criterion was the ability to complete the German-language questionnaire; no further restrictions regarding age, health status, or technology experience were applied. A total of 128 individuals accessed the survey, of whom 85 completed all 4 sections (completion rate: 66%). Cookies were used to prevent repeated participation from the same device. The final sample included adults aged 20 to 89 years.

XSL•FO
RenderX

Statistical Analysis

We performed analyses in R (version 4.3.3) using lavaan (version 0.6 - 20). We evaluated internal consistency using Cronbach α, with values ≥0.70 considered acceptable [40]. A 2-stage modeling strategy combined confirmatory factor analysis (CFA) and structural equation modeling (SEM). Given ordered-categorical measurement and the number of indicators per construct, a diagonally weighted least squares (DWLS) estimator with robust corrections was used. We evaluated model fit using scaled indices (chi-square, comparative fit index [CFI], Tucker-Lewis index [TLI], root mean square error of approximation [RMSEA], and standardized root mean square residual [SRMR]), with CFI/TLI >0.90 and RMSEA <0.08 interpreted as acceptable.

While no universally accepted minimum sample size exists for DWLS estimation, simulation research suggests that DWLS with robust corrections can yield adequate parameter estimates and fit indices at sample sizes below 200, particularly when indicators are ordinal and factor loadings are moderate to strong [41,42]. Nevertheless, with 85 participants and 9 latent predictors, the ratio of sample size to model complexity is limited, which may reduce statistical power for detecting moderate effects and increase the uncertainty of individual path estimates. The results should therefore be interpreted with appropriate caution regarding the precision of nonsignificant coefficients.

Phase 3 Output

Validated acceptance model identifying key facilitators and barriers to adoption intention.

Methodological Integration and Triangulation

Findings from each phase directly informed subsequent stages. Specifically, the thematic clusters from expert interviews identified key concerns (such as false alarms, data privacy, and complexity of setup) that shaped the selection of acceptance constructs for the survey. The design requirements and activity scenarios generated in the workshops were translated into annotated storyboards that served as the stimulus material for the quantitative evaluation, ensuring that participants rated a concept grounded in domain-specific insights rather than an abstract technology description.

Methodological triangulation combined qualitative methods (interviews and workshops) with quantitative methods (survey and SEM), enabling cross-validation of findings. Table 1 summarizes the mapping of methods to phases and outputs.

Table . Mapping of Double Diamond phases to methods and outputs.

Phase	Double Diamond stage	Methods	Key outputs
1	Discover	Expert interviews (n=3) and secondary data analysis	Thematic clusters and target group identification
2a	Define	Persona development and problem scenario construction	2 personas and 2 problem storyboards
2b	Develop	Brainwriting workshops (12 participants) and iterative prototyping	Activity scenarios and low-fidelity prototype
3	Deliver	Online survey (n=85) and CFA[a]/SEM[b] analysis	Acceptance model and design implications

[a]CFA: confirmatory factor analysis.

[b]SEM: structural equation modeling.

Following JARS-MMARS recommendations, the qualitative components (phases 1 and 2) adhere to COREQ reporting standards [33], while the quantitative component (phase 3) follows CHERRIES guidelines [39]. The integration of both strands occurred at multiple points: qualitative findings shaped the survey stimulus materials, and quantitative results were interpreted in the context of qualitative themes identified earlier. This sequential design meant that the acceptance evaluation was built on domain-specific insights instead of abstract constructs.

Results

Phase 1: Domain Analysis and Target Group Identification

Thematic Clustering From Expert Interviews

Across the 3 interviews conducted, a total of 82 individual idea nodes were cocreated using digital whiteboarding tools, resulting in 3 structured mind maps (Multimedia Appendix 1). Thematic clustering revealed recurring barriers and requirements along 3 operational layers: dispatch coordination, responder navigation, and lay responder integration.

A central theme concerned the limited situational awareness available to dispatchers at the time of call intake. Interviewees described frequent uncertainty due to missing contextual data, such as the caller's precise location, environmental hazards, or patient-specific health risks.

First responders, in turn, reported considerable time losses caused by restricted access to buildings and unclear apartment layouts. Navigating unfamiliar environments, particularly under time pressure, was cited as a major operational burden. Participants noted that prior knowledge about access points, apartment configurations, or mobility limitations could significantly streamline response efforts.

Finally, the role of lay responders proved both promising and problematic. While early arrival can be beneficial, the lack of standardized guidance and limited integration into formal rescue

XSL•FO
RenderX

coordination restricts their effectiveness. Suggestions included structured onboarding, risk-adapted task delegation, and access to context-specific information prior to arrival.

Demographic Analysis and Emergency Statistics

Descriptive analysis of age-stratified emergency statistics confirmed the relevance of older adults as a disproportionately affected population segment. Although individuals aged 60 years and above represent less than one-third of the general population, they accounted for 64% (12,232/19,200) of all medically induced emergency calls in 2021 (Table 2). This disproportionality indicates that age is not merely a proxy for population size but a significant factor in emergency system usage. Thus, older adults were selected as the primary target group for subsequent design phases.

Table . Age distribution of medical emergencies in domestic settings reported in Dortmund (Germany), a subset of total emergency calls in 2021 (N=19,200).

Age group (years)	Emergencies, n (%)
0 - 9	666 (3.47)
10 - 19	438 (2.28)
20 - 29	1291 (6.72)
30 - 39	1310 (6.82)
40 - 49	1258 (6.55)
50 - 59	2005 (10.44)
60 - 69	2611 (13.60)
70 - 79	3479 (18.12)
80 - 89	4644 (24.19)
90 - 99	1457 (7.59)
100 - 110	41 (0.21)

These findings emphasize the need for improved information availability, environmental transparency, and support mechanisms for nonprofessional actors, which directly informed the scenario development in phase 2.

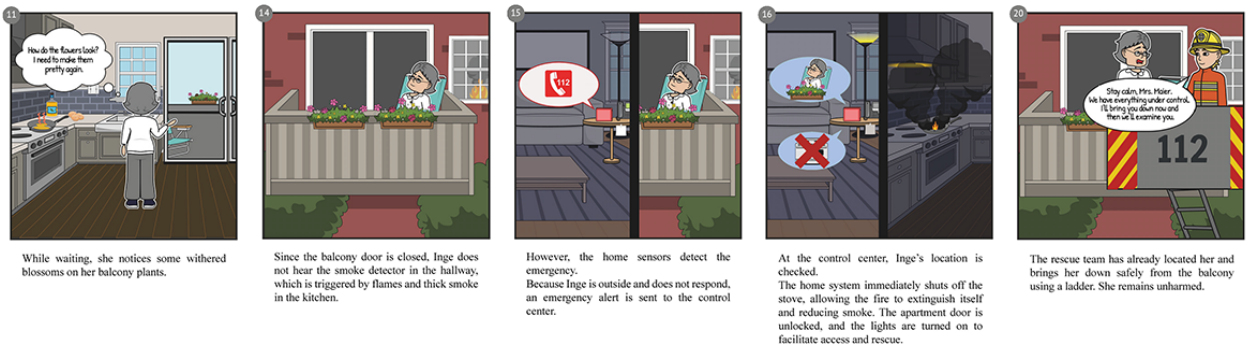
Phase 2: Scenario Development and Requirements Engineering

Findings From Scenario-Based Brainwriting

The structured idea generation yielded a diverse set of system-relevant concepts, which were subsequently clustered into key design implications. Participants emphasized the importance of real-time contextual awareness enabled by ambient and body-worn sensor data, precise geolocation, and adaptive alarm routing tailored to user roles and incident types. Suggestions also included infrastructure-level support for building access and orientation, such as dynamic lighting, illuminated door signage, and smart locking mechanisms.

Several contributions addressed systemic integration challenges, highlighting the need for interoperability across heterogeneous devices and platforms. The envisioned system was expected to balance automation with user override options and to provide differentiated access to sensitive data, depending on responder qualification and proximity. Participants also raised concerns regarding privacy, false-positive prevention, and reliability under edge-case conditions.

Scenario Iteration and Consolidation



Based on these inputs, we revised the initial scenarios into detailed activity scenarios incorporating technical functionalities and user interactions, visualized through annotated low-fidelity storyboards.

A subsequent workshop evaluated these scenarios, focusing on usability, privacy, and error tolerance. Feedback was synthesized into a low-fidelity prototype illustrating key components and user touchpoints.

Figure 2 illustrates selected panels from the fire emergency scenario, depicting the sequence from unnoticed hazard through autonomous detection, system-initiated intervention, and successful responder arrival (see Multimedia Appendix 2 for complete storyboards).

XSL•FO
RenderX

Figure 2. Selected panels from the fire emergency scenario illustrating autonomous system intervention.

The resulting artifacts, including 29 design requirements and annotated storyboards (Multimedia Appendix 2), served as the conceptual foundation for the acceptance study conducted in phase 3.

Phase 3: Evaluation and Statistical Analysis

Descriptive Analysis

A total of 85 participants completed all 4 sections of the survey. The sample included individuals aged 20 to 89 years, with the most represented groups being those aged 30 - 39 years (n=23, 27%) and 20 - 29 years (n=16, 19%). A majority of participants identified as male (n=55, 65%), and most lived either in one-person (n=28, 33%) or two-person households (n=36, 42%). Regarding education, 44% (n=37) reported a college degree, while 29% (n=25) held a secondary school qualification.

Current smart home usage was reported by 61% (52/85) of participants, with 33% (28/85) indicating an intention to adopt such technologies within the next 12 months. Adoption intentions varied slightly by age, gender, and living arrangement (see Table 3).

Table . Demographic distribution of participants and their smart home technology usage patterns, including current usage and future intentions.

	Count (n=85), n (%)	Current smart home usage, n (%)	Planned smart home adoption, n (%)
Total		52 (61)	28 (33)
Sex			
Female	30 (35)	15 (50)	5 (17)
Male	55 (65)	37 (67)	23 (42)
Age (years)			
20 - 29	16 (19)	9 (56)	6 (38)
30 - 39	23 (27)	14 (61)	9 (39)
40 - 49	13 (15)	9 (69)	4 (31)
50 - 59	12 (14)	8 (67)	5 (42)
60 - 69	9 (11)	7 (78)	3 (33)
70 - 79	8 (9)	4 (50)	1 (12)
80 - 89	4 (5)	1 (25)	0 (0)
Education			
Intermediate school	25 (29)	12 (48)	4 (16)
High school	15 (18)	11 (73)	7 (47)
College	37 (44)	24 (65)	13 (35)
Doctorate/PhD	8 (9)	5 (62)	4 (50)
Living situation			
Single-person household	28 (33)	18 (64)	6 (21)
Two persons	36 (42)	23 (64)	13 (36)
Three or more persons	21 (25)	11 (52)	9 (43)

Descriptive statistics for all psychometric constructs and individual items are summarized in Table 4. Participants reported high levels of functional independence, with mean scores above 4.6 across all ADL items (eg, ADL1: mean 4.81, SD 0.72). Social compatibility showed moderate to high values (SOC1-SOC5: mean>4.2), though lower agreement was

XSL•FO
RenderX

observed for items reflecting burdensome social responsibility (SOC6-SOC9: mean≈3‐4).

XSL•FO
RenderX

Table . Descriptive statistics of item responses.

Item	Mean (SD)
ADL (activities of daily living)	
ADL1	4.81 (0.72)
ADL2	4.68 (0.88)

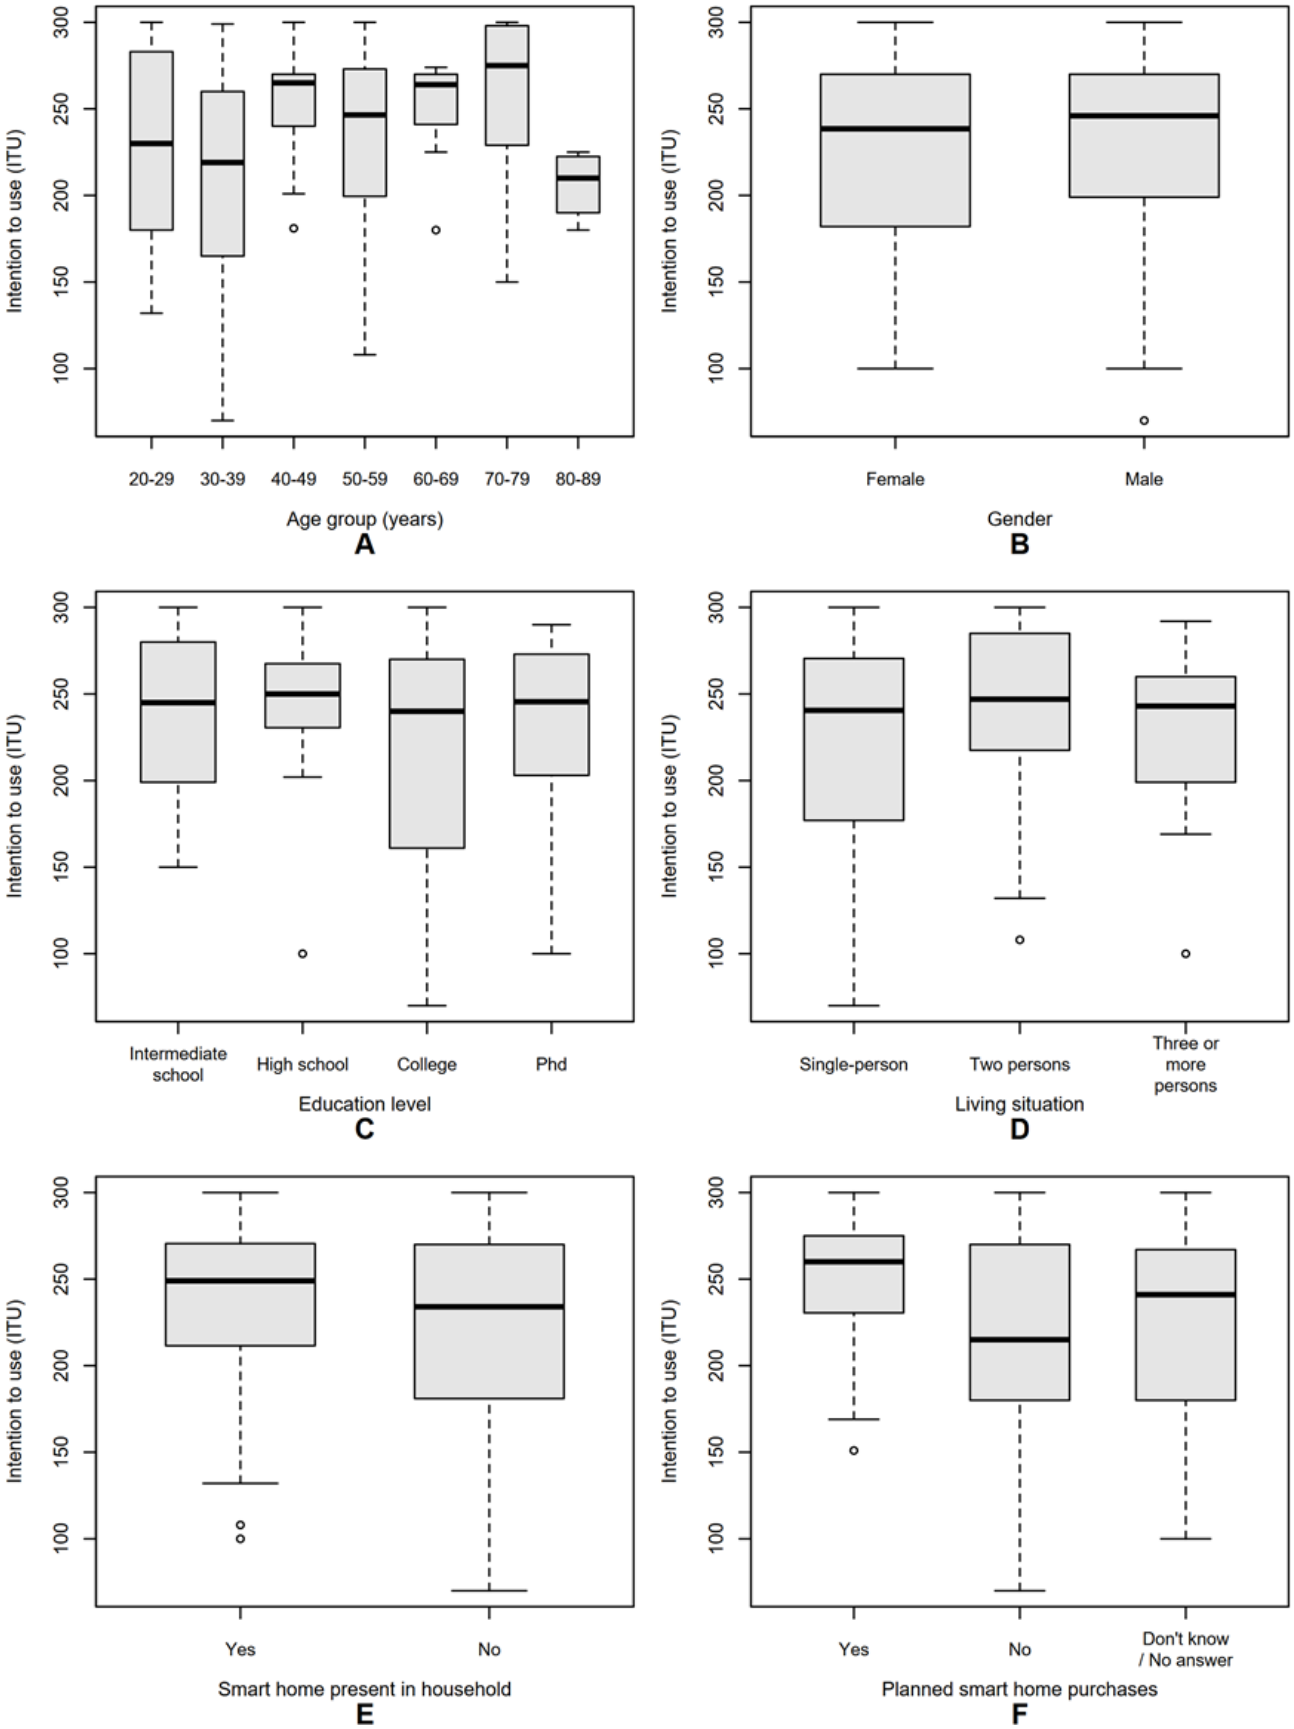
XSL•FO
RenderX

Item	Mean (SD)
BEN1	5.20 (1.35)
BEN2	5.21 (1.22)
BEN3	5.09 (1.44)
ZUG (accessibility)	
ZUG1	3.60 (1.49)
ZUG2	4.41 (1.48)
ZUG3	4.38 (1.46)
ITU (intention to use)	
ITU1	78.15 (20.53)
ITU2	70.34 (23.98)
ITU3	81.59 (17.95)

Pre-exposure assessments revealed high curiosity (NEU1: mean 6.04, SD 1.19) and low technology-related anxiety (ANG1: mean 2.38, SD 1.58). Following the storyboard intervention, participants rated the proposed system as generally useful (NÜT1: mean 5.99, SD 1.11) and user-friendly (BEN1: mean 5.20, SD 1.35), with only moderate skepticism. Accessibility received more varied evaluations (ZUG1: mean 3.60, SD 1.49).



We measured the ITU via a 0‐100 visual analog scale. Participants reported moderately high usage intentions, with item means ranging from 70.34 (SD 23.98) to 81.59 (SD 17.95) across the three ITU items.

Sociodemographic Variation in Intention to Use

Before conducting the latent-variable analyses, we performed exploratory comparisons to examine whether ITU differed across sociodemographic and contextual subgroups. Figure 3 displays the distribution of ITU scores by age group, education level, gender, living situation, and smart-home–related characteristics (ie, presence of smart-home devices in the household and planned future purchases).

XSL•FO
RenderX

Figure 3. Distribution of intention to use (ITU) scores across sociodemographic and contextual subgroups. Panels show median, IQR, and outliers for (A) age group, (B) education level, (C) gender, (D) living situation, (E) planned smart-home purchases, and (F) smart-home presence in the household.

Across age categories (Figure 3A), median ITU scores appeared largely comparable, with slightly higher intentions in the youngest (20 - 29 years) and older (70 - 79 years) participants, but no consistent age-related trend. Regarding smart-home–related factors, participants who already had smart-home devices in their household (Figure 3E) tended to

XSL•FO
RenderX

report slightly higher ITU scores than those without such devices, although the spread of values was wide and overlapping. Similarly, those who planned to purchase smart-home technologies in the near future (Figure 3F) reported somewhat elevated intentions relative to those without purchase plans, but again without clear statistical separation. Given the absence of significant mean-level differences in ITU across sociodemographic subgroups, these variables were not included as exogenous predictors in the SEM.

Overall, these analyses indicated no meaningful sociodemographic bias in ITU across the examined groups. This supports the focus on psychological and attitudinal constructs as the main determinants in the subsequent latent-variable modeling.

Preliminary Reliability and Correlational Analyses

Before estimating the latent variable model, we examined reliability and zero-order associations among the observed constructs. All multi-item scales demonstrated good internal consistency, with Cronbach α values ranging from 0.72 (BEN) to 0.93 (ADL) (see Table 5).

Table . Internal consistency and bivariate associations of study constructs with intention to use.

Construct	Cronbach α	Correlation with ITU[a]	β coefficient	*P* value
ADL (activities of daily living)	0.930	−0.064	−1.265	.56
SOC (social compatibility)	0.838	0.369	2.512	.001
NEU (curiosity)	0.813	0.366	4.158	.001
ANG (anxiety)	0.828	−0.112	−1.341	.31
INT (interest)	0.869	0.236	2.515	.03
NÜT (usefulness)	0.784	0.600	7.230	<.001
SKE (skepticism)	0.762	−0.539	−6.824	<.001
BEN (user-friendliness)	0.720	0.238	6.204	.03
ZUG (accessibility)	0.780	0.441	6.661	<.001

[a]ITU: intention to use.

Bivariate correlations showed that NÜT (r=0.60, P<.001), ZUG (r=0.44, P<.001), SOC (r=0.37, P=.001), NEU (r=0.37, P=.001), INT (r=0.24, P=.03), and BEN (r=0.24, P=.03) each correlated positively with ITU. In contrast, SKE correlated negatively (r=–0.54, P<.001), while ANG (r=–0.11, P=.31) and ADL (r=–0.06, P=.56) showed small, nonsignificant associations.

Simple linear regressions mirrored these bivariate patterns: positive effects on ITU emerged for NÜT, ZUG, SOC, NEU, INT, and BEN (all P≤.03), whereas SKE exerted a significant negative effect (β=–6.82, P<.001). Neither ANG nor ADL reached statistical significance (P>.30).

Together, these findings supported the proposed directionality of the theoretical model and justified proceeding to latent-variable analyses.

Confirmatory Factor and Structural Equation Modeling

We applied a comprehensive confirmatory factor and SEM approach using a DWLS estimator with robust corrections, appropriate for ordered-categorical indicators and the comparatively high number of observed variables per construct. The 9-factor measurement model, plus a 3-indicator factor for ITU, demonstrated an acceptable overall model fit on scaled indices (χ^2_{815}=1052.21, P<.001; CFI=0.928; TLI=0.920; RMSEA=0.059, 90% CI 0.048 - 0.069; SRMR=0.107; Bentler-SRMR=0.0923) (Table 6).

XSL•FO
RenderX

Table . Scaled global model fit (DWLS[a], robust) for the confirmatory factor and structural model (n=85).

Index	Value	Interpretation
Chi-square (*df*=815)	1052.21 (*P*<.001)	N/A[b]
CFI[c]	0.928	Acceptable
TLI[d]	0.920	Acceptable
RMSEA[e]	0.059 (90% CI 0.048 - 0.069)	Good
SRMR[f]	0.107	Moderate
Bentler-SRMR	0.092	Acceptable given categorical indicators

[a]DWLS: diagonally weighted least squares.

[b]N/A: not applicable.

[c]CFI: comparative fit index.

[d]TLI: Tucker-Lewis index.

[e]RMSEA: root mean square error of approximation.

[f]SRMR: standardized root mean square residual.

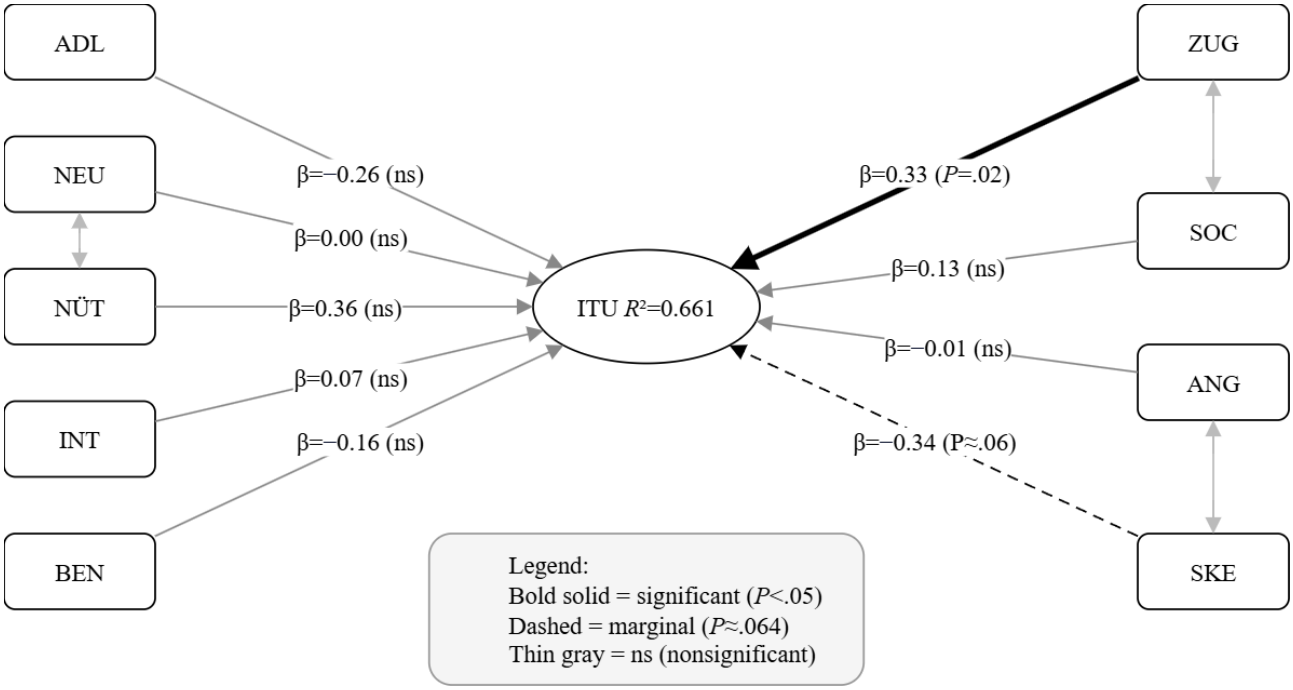
Although both SRMR indices were slightly above conventional thresholds [43], simulation research indicates that SRMR tends to be inflated when using categorical estimators such as DWLS, particularly in complex models with many indicators [44]. The combination of CFI and TLI values close to 0.93 and an RMSEA below 0.06, given the categorical measurement level and the model's complexity, supports an adequate and stable representation of the empirical covariance structure. All standardized factor loadings were positive, substantial, and statistically significant (*P*<.001), ranging from 0.46 to 0.99, with most exceeding 0.70. No cross-loadings or Heywood cases were detected, and the factor solution remained stable across estimation runs, confirming the stability of the measurement specification.

The SEM maintained an acceptable overall fit that closely mirrored the CFA solution and accounted for 66.1% of the variance in ITU (R^2=0.661). Among the latent predictors, ZUG was the strongest positive determinant (β=0.325, *P*=.02). In contrast, SKE showed a negative association with ITU that approached but did not reach conventional significance levels (β=−0.336, *P*=.06). NÜT (β=0.357, *P*=.15) and SOC (β=0.129, *P*=.25) showed positive but nonsignificant trends, while BEN, INT, NEU, ANG, and ADL displayed no meaningful associations (|β|≤0.26, all *P*>.10; Table 7). A comparison between the full model (with all 9 predictors) and a reduced model (retaining only significant predictors) revealed minimal differences in fit indices (ΔCFI=−0.003; ΔRMSEA=0.004; ΔSRMR=0.004). Although a nested model test indicated a statistically significant decrement in fit (*P*=.001), the negligible changes in practical fit indices suggest that retaining theoretically motivated but statistically nonsignificant constructs did not materially distort the overall model.

Table . Standardized path coefficients predicting intention to use (scaled SEM[a] and DWLS[b]).

Predictor → ITU (intention to use)	β (std)	SE	*z* score	*P* value	Significance
ZUG (accessibility)	0.325	0.239	2.33	.02	Significant
SKE (skepticism)	−0.336	0.312	−1.85	.06	Marginal
NÜT (usefulness)	0.357	0.431	1.42	.15	—[c]
SOC (social compatibility)	0.129	0.191	1.16	.25	—
BEN (user-friendliness)	−0.164	0.321	−0.87	.38	—
INT (interest)	0.070	0.323	0.37	.71	—
NEU (curiosity)	0.002	0.373	0.01	.99	—
ANG (anxiety)	−0.005	0.416	−0.02	.98	—
ADL (activities of daily living)	−0.255	0.324	−1.35	.18	—

[a]SEM: structural equation modeling.



[b]DWLS: diagonally weighted least squares.

[c]Not applicable.

XSL•FO
RenderX

The final structural equation model is depicted in Figure 4, illustrating the pattern of relationships among the 9 latent predictors and ITU. All exogenous latent constructs were allowed to covary, controlling for shared variance among psychological, functional, and social factors. These correlations are depicted as curved double-headed arrows in the structural model but were not interpreted further, as they were not part of the primary hypotheses.

Figure 4. Structural equation model predicting intention to use (ITU) from psychological, functional, and social determinants. ADL: activities of daily living; ANG: anxiety; BEN: user-friendliness; INT: interest; ITU: intention to use; NEU: curiosity; NÜT: usefulness; SKE: skepticism; SOC: social compatibility; ZUG: accessibility.

To assess the robustness of the structural findings, we conducted several complementary diagnostics. To ensure that the constructs included in the latent-variable model were empirically distinct and not affected by multicollinearity, we performed additional post hoc diagnostics. The latent factor correlations extracted from the CFA model indicated satisfactory discriminant validity, as none of the interfactor correlations approached unity and all remained well below critical thresholds ($|r|<0.85$). This supports the conceptual distinctness of the modeled constructs.

Variance inflation factors (VIF) confirmed the absence of problematic multicollinearity, with values ranging from 1.24 to 1.81 (all VIF<5), indicating that the predictors were sufficiently independent. Alternative model specifications (eg, method factors, item parceling) provided no meaningful improvement and were not retained.

The findings provide a coherent picture of the psychological and contextual factors underlying intention to use. The next section discusses their theoretical and practical implications.

Discussion

Principal Findings

This mixed methods study identified key drivers and barriers of SHERS adoption by combining domain analysis, scenario-based design, and SEM.

The structural model explained two-thirds of the variance in behavioral intention (R^2=0.66), underscoring the strong explanatory power of psychological and usability-related factors. Among all predictors, ZUG had the strongest positive effect on intention to use, emphasizing that participants' perception of how easily the technology can be set up and integrated matters most for adoption. Conversely, SKE showed a negative association with intention that approached statistical significance (P=.06), suggesting that residual doubt about reliability, privacy, or false alarms may reduce willingness to adopt. Other theoretically relevant constructs such as NÜT and SOC displayed positive but nonsignificant trends, indicating that their effects may be more indirect or context dependent.

These findings suggest that beyond functional utility, the perceived ease of obtaining and setting up the technology may be more relevant to adoption intentions than its perceived benefits alone.

It is important to note that only ZUG reached conventional statistical significance as a predictor of intention to use. The negative trend for SKE (P=.06) is suggestive but does not meet the conventional threshold. All remaining constructs were nonsignificant in the multivariate model, despite several showing meaningful bivariate associations with intention to use. This pattern is consistent with the limited statistical power of the sample (n=85) to detect moderate effects among multiple correlated predictors and may also partly reflect the storyboard-based evaluation format, which limits experiential assessment of constructs such as BEN. Accordingly, interpretations involving nonsignificant predictors should be considered exploratory.

XSL•FO
RenderX

Integration of Qualitative and Quantitative Findings

Methodological triangulation allowed cross-validation of qualitative and quantitative findings.

The quantitative analysis identified ZUG as the strongest predictor of intention to use. This finding directly mirrors qualitative themes: Expert 3 (unit leader) noted that "technical setup is complex and costly," stressing that incentives or mandates would be necessary. Experts also stressed integration with existing infrastructure, proposing connections between "smart-watches, home emergency systems, and fire alarm systems" [Expert 3]. These convergent insights suggest accessibility represents a reliable determinant of adoption.

SKE was a negative predictor (P=.06), reflecting concerns about reliability, false alarms, and data privacy. Expert 1 (paramedic) proposed a "filter function to distinguish false alarms from actual emergencies" and mechanisms to "allow user intervention to cancel the alarm." Expert 2 (dispatcher) emphasized that cameras should only be activated "after explicit request and consent." These findings suggest skepticism is rooted in concrete operational and privacy concerns.

NÜT showed a positive but nonsignificant effect despite strong bivariate correlations. Experts recognized value for "vulnerable groups" [Expert 3], yet emphasized that determining whether "it is truly an emergency" should remain a "decision to be made by the incident commander" [Expert 3], and that "situational assessment by people on site is necessary" [Expert 2]. This tension may explain the attenuated effect. However, this interpretation remains exploratory, as the nonsignificant path coefficient may also reflect insufficient statistical power to detect a moderate effect at n=85, or measurement limitations arising from the storyboard-based evaluation format.

An overarching theme concerns the balance between automation and human control. Experts consistently emphasized that "human decision-making competence cannot be replaced" [Expert 1] and that "technology should initially only propose a classification" [Expert 1]. Expert 3 cautioned that "weighing up 'deploy or not' under the influence of data or a second opinion is highly critical." These insights explain why both accessibility and low skepticism are central to acceptance.

Triangulation strengthens confidence in results while revealing contextual nuances.

Comparison With Prior Work

The identified role of accessibility is consistent with findings from previous acceptance studies in digital health and smart-home contexts, where usability barriers frequently outweighed perceived benefits in determining behavioral intention [45,46].

The negative association between skepticism and intention mirrors earlier observations in related domains such as telemonitoring and artificial intelligence–assisted care [1,9]. Concerns about data privacy, false alarms, and perceived loss of control are well-documented inhibitors of trust in automated systems. The present results suggest that skepticism may reduce adoption intentions, although the association did not reach conventional significance (P=.06). This pattern is consistent with prior findings and points to trust calibration as a relevant design consideration.

Unlike some prior studies that found strong demographic effects, such as age-related declines in technology acceptance or gender-specific differences in curiosity and anxiety [47-49], the current analysis revealed no significant sociodemographic bias in intention to use. This suggests that, when users are adequately informed and exposed to a concrete system concept, psychological and design-related factors may play a larger role than demographic predispositions in shaping adoption intentions. This aligns with recent evidence indicating that participatory exposure and scenario-based demonstrations can reduce pre-existing reservations toward unfamiliar technologies [50].

Practical Implications

From a design perspective, the findings highlight the importance of making accessibility tangible through intuitive setup, clear user guidance, and compatibility with existing smart home ecosystems. Developers should focus on reducing friction points such as complex configuration, opaque data handling, or unclear error feedback.

Addressing skepticism requires trust-building measures that communicate reliability and data protection standards. Clear alert protocols, privacy assurances, and demonstrated reliability under real conditions can increase confidence in automated emergency technologies. For policymakers and emergency service providers, these findings support the case for public communication and certification frameworks focused on safety and interoperability.

The consistency between expert and user perspectives observed in this study supports co-design approaches that bring emergency professionals and end users together early in the development process. Such collaboration can connect technical, psychological, and organizational perspectives and support the wider adoption of SHERS.

Limitations

Several limitations should be considered. First, the quantitative evaluation relied on a conceptual rather than interactive prototype presented through annotated storyboards. Although this format is suitable for early-phase acceptance testing [34], it may have limited participants' ability to evaluate usability and reliability. Constructs that depend on direct interaction experience, particularly BEN, may be underestimated or imprecisely captured when assessed on the basis of visual scenarios alone. This could partly explain the nonsignificant effect of BEN in the structural model, as participants lacked the hands-on experience needed to form differentiated usability judgments. Conversely, constructs reflecting general attitudes, such as curiosity or skepticism, are less likely to be affected by prototype fidelity. Future studies should use functional or simulated prototypes to validate these findings under more realistic conditions.

Second, although DWLS estimation is robust to smaller samples with ordinal data, the sample size (n=85) limits generalizability and the ability to test subgroup interactions. The recruitment strategy relied on housing cooperatives and senior advisory

XSL•FO
RenderX

councils, which may have introduced selective bias by overrepresenting individuals with existing institutional ties and underrepresenting isolated, low-income, or digitally disengaged populations. These groups may stand to benefit most from SHERS but are typically harder to reach through organizational channels. The sample was also skewed toward higher educated (44% college degree) and male (65%) participants, which may affect the transferability of findings. Individuals with limited digital literacy or those living in underresourced housing conditions may hold different attitudes toward automated emergency systems. Larger and more diverse samples, including targeted recruitment of digitally excluded and lower-income populations, are needed to confirm the stability and generalizability of the observed effects.

The limited sample size also increases the risk of type II errors, particularly for predictors with moderate effect sizes. Several constructs with meaningful bivariate associations with intention to use, such as NÜT (r=0.60), did not reach significance in the multivariate model. While this pattern may partly reflect shared variance among correlated predictors, insufficient power to detect moderate effects in the presence of 9 simultaneous paths cannot be ruled out.

Third, self-reported data may have introduced social desirability bias. Behavioral or longitudinal observations could strengthen future analyses.

Finally, contextual variables (cost, connectivity, and interoperability) were not included and should be addressed in future research.

Future Research

Future research should examine long-term acceptance trajectories and how trust develops during actual system use.

Cross-stakeholder studies should examine how acceptance differs between end users, emergency professionals, and service operators.

Evaluating artificial intelligence–driven emergency systems under field conditions will be necessary for safe deployment.

Conclusions

This study examined the psychological and functional determinants of SHERS acceptance. Accessibility was the strongest statistically significant predictor of intention to use, while skepticism showed a negative trend that suggests it may function as a barrier to adoption. These results indicate that technological development alone is insufficient without user-centered design, open communication, and strategies that address adoption concerns early.

The mixed methods approach allowed us to connect design-level insights with statistical evidence on acceptance factors. Taken together, the findings offer practical orientation for developing emergency technologies that are trusted, usable, and compatible with the living environments of vulnerable populations.

Acknowledgments

The authors thank all participating experts and survey respondents for their valuable contributions to this research.

Funding

This research is part of the project ADLeR, funded by the German Federal Ministry of Research, Technology and Space (BMFTR) under grant 13N16805.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MP conceptualized the study, designed the mixed methods framework, conducted data analysis, and prepared the manuscript. OK conducted the expert interviews in phase 1 and assisted in the preparation of the demographic and contextual data. AR cofacilitated the scenario-based design workshops and contributed to qualitative data analysis and manuscript revision. CD contributed to data analysis and proofreading of the manuscript. SM supervised the study and provided critical feedback on methodological design and interpretation of results. All authors reviewed and approved the final version of the manuscript.

Abstract

Background: Asthma-related deaths in the United Kingdom are the highest in Europe, and only 30% of patients access basic care. There is a need for alternative approaches to reaching people with asthma to provide health education, self-management support, and better bridges to care.

Objective: This study aimed to examine patients' interest in using a chatbot for asthma and to identify factors that influence engagement. Automated conversational agents (specifically, mobile chatbots) present opportunities for providing alternative and individually tailored access to health education, self-management support, and risk self-assessment. But would patients engage with a chatbot, and what factors influence engagement?

Methods: We present results from a patient survey (N=1257) developed by a team of asthma clinicians, patients, and technology developers, conducted to identify optimal factors for efficacy, value, and engagement with an asthma chatbot.

Results: Results indicate that most adults with asthma (53%) are interested in using a chatbot. The patients most likely to do so are those who believe their asthma is more serious and are less confident in their self-management. Results also indicate enthusiasm for 24/7 access, personalization, and for WhatsApp (Meta) as the preferred access method (compared to app, voice assistant, SMS text messaging, or website).

Conclusions: Obstacles to uptake include security and privacy concerns and skepticism of technological capabilities. We present detailed findings and consolidate these into 7 recommendations for developers to optimize the efficacy of chatbot-based health support.

Introduction

Background

Eight million people (12% of the population) in the United Kingdom are estimated to have a diagnosis of asthma [1]. Despite effective treatments and extensive efforts, the UK death rate from asthma is the highest in Europe. Moreover, 65% of people with asthma in the United Kingdom do not receive the professional care they are entitled to (eg, a yearly review, feedback on how to use their inhaler correctly, or an asthma action plan) [2]. In the latest Asthma + Lung UK survey [3], it was reported that only 30% of patients with asthma received basic care in 2021, the lowest proportion since 2015. Moreover, according to the same report, almost half (44%) of the patients who are admitted to the hospital did not receive follow-up care, with younger adults 18-29 years receiving the lowest level of basic asthma care [4].

One of the reasons for this is believed to be poor self-assessment of risk by those with asthma. For instance, according to Asthma + Lung UK, the illness is often not taken seriously enough, as reports show that 1 in 6 people in the United Kingdom do not know, or are not sure, if asthma can be fatal [5]. Moreover,

XSL•FO
RenderX

health education and self-management behaviors play a critical role.

In the United Kingdom, asthma-associated care costs are at least £1.1 billion per year [6], and the bulk of the burden centers on differences in asthma control rather than severity. People with severe uncontrolled asthma are prone to more symptoms, night-time awakenings, rescue medication use, and worse self-reported outcomes [7] and are estimated to represent 3 times the cost to the health care system compared with patients with severe but controlled disease [7]. Studies have shown that informed self-management that is accompanied by professional reviews improves asthma control, reduces exacerbations, and improves overall quality of life [8].

These statistics demonstrate an urgent need for alternative approaches to reaching people with asthma to (1) improve risk self-assessment, (2) improve health literacy and self-management, and (3) encourage them to seek traditional care as needed. One way to support people with asthma could be through a specialized conversational agent (CA). A CA can be any type of dialogue system that has natural language processing capabilities and can respond to input using human language. Moreover, the input and output are not restricted to text but could also happen via voice. Although CAs can be embodied avatars or physical robots, for this study, we refer only to CAs that are nonembodied chatbots used via apps such as WhatsApp (Meta).

New generative chatbot technologies, such as ChatGPT (OpenAI), are rapidly becoming pervasive, and people are likely to continue to consult them for health care advice despite safety risks [9-11]. Conversational interfaces based on large language models can be intuitive, engaging, and provide a level of personalization in their responses based on user input. However, these technologies rely on probabilistic models trained on information from across the internet to generate answers that have never been vetted. These systems are known to fabricate information and present it confidently, sometimes adding artificial citations to sources. Such “hallucinations” could be dangerous or even life-threatening when the system is responding to medical questions. As such, misinformation remains a significant problem for publicly available generative artificial intelligence (AI) services, rendering them unsafe for health applications. The development of a trustworthy conversational system must involve health experts, including patients and clinicians, and must exclusively provide health information that has been verified as safe and accurate for the specific context.

There is existing evidence that mobile technology can be used effectively for health interventions to help people learn about their illness, complete self-assessments, track symptoms, and be directed to appropriate care options. Several bespoke apps for asthma [12-15] and a smaller number of studies on CAs designed for children and adolescents have been reported in the literature [16,17]. However, research is missing that might guide an effective mobile CA for adults with asthma. While the technology itself holds promise, successful outcomes are entirely contingent on human acceptance and use, and research is lacking on what adult patients’ concerns, expectations, preferences, and motivations would make such a conversation-based health intervention valuable to them. Furthermore, how these needs might vary for the groups that most stand to benefit from alternative interventions (eg, patients with poor asthma control, with lower health literacy, or who do not access traditional health services) is not clear.

There are many open questions related to the potential for meaningful patient engagement with a conversation-based asthma intervention. For example, what would patients be looking for from conversational health support? What would be necessary for them to value and trust a technology enough to use it? How does existing technology use play a part? While CAs have a lot of potential to help people with asthma, they are a relatively new type of technology in the public sphere and, in addition to common concerns about privacy, people may mistrust a CA’s ability to help. Also, there is not enough understanding of what motivates or hinders patients’ use of CAs in general, or how socioeconomic variables may relate to lack of trust in, or engagement with, CAs.

The study aimed to provide answers to these questions and contribute to a better understanding of the features required to make a successful CA for asthma based on the expectations, needs, and motivations of adult patients with asthma. Additionally, attention is given to different groups of patients and how developers might most effectively meet the needs of those who stand to benefit the most from such digital services.

Related Work

This section describes previous work in the 3 intersecting areas relevant to this project: mobile technologies for health broadly and asthma specifically; conversational mobile technologies for health broadly and asthma specifically; and the use of WhatsApp as a platform for conversational mobile digital health.

Mobile Technologies for Asthma

Mobile technologies focusing on health care support have been proven to be cost-effective across health domains [2]. Specifically, there is evidence that mobile technology can be used effectively to help patients learn about their illness, complete self-assessments, track symptoms, and be directed to appropriate care options. According to a systematic review, 87% of studies reported improved adherence and 53% reported improved health outcomes for users [14]. Moreover, they are a cost-effective way to reach patients in a personalized and time-efficient manner, for example, by reminding patients to engage in self-management tasks (eg, medication adherence, electronically accessible action plans, and so on) [2]. With respect to asthma specifically, bespoke apps are the most common approach to mobile interventions for asthma. For example, several bespoke apps for young people [13,14] have demonstrated positive outcomes for improving self-management. For adults, the ASTHMAXcel mobile app was designed to improve asthma knowledge and outcomes [18]. The app was tested in multiple studies and revealed an increase in asthma knowledge [18,19] as well as a decrease in clinical outcomes such as emergency department visits, hospitalizations, and prednisone usage [20] among patients.

XSL•FO
RenderX

CAs for Health

Previous studies have shown that CAs can help patients with a range of health care tasks, such as delivering clinical and health risk information, providing elements of basic care, and supporting behavior change [21] through personalized dialogue. The use of CAs for health has been extensively reviewed [22-24].

With respect to asthma specifically, 3 studies explored the use of CAs for young people. Rhee et al [25] described an automated mobile phone–based asthma self-management aid for adolescents that is able to interpret conversational English SMS text messaging describing asthma symptoms. The system was tested over 2 weeks by 15 adolescent-parent dyads, and response rates for daily messages were 81% - 97% for the adolescents. Following the intervention, participants' awareness of both symptoms and triggers, their sense of control, and treatment adherence were higher, with benefits to the partnership between parents and adolescents.

Kadariya et al [16] tested kBot, a chatbot capable of interacting via both text and voice in the form of an Android app, designed to support pediatric patients with asthma (aged 8 - 15 years). Overall, kBot received good technology acceptance and system usability scores from clinicians (n=8) and researchers (n=8), but no patient testing was reported.

A study by Kowatsch et al [26] tested MAX, a CA that was designed to increase knowledge of asthma and behavioral skills, such as inhalation technique, among 10- to 15-year-olds with asthma. MAX incorporated different modes of communicating with the CA; for example, care professionals could communicate with it via email, patients via a mobile app, and family members via SMS text messaging. The results showed not only high acceptability of the CA by all stakeholders but also improved cognitive and behavioral skills. These studies with children and adolescents suggest promise for conversation-based digital health care. However, they are limited to tests with small groups of pediatric patients. Since late-onset asthma often remains undiagnosed [27] and these patients regularly experience more severe forms of asthma compared with people with early-onset asthma [27-29], it is important to assess the needs of adults and understand how they differ from those of pediatric patients, particularly with regard to health literacy and the self-management of symptoms.

Messaging platforms are widely used across age groups in the United Kingdom and elsewhere. According to Statista [30], 80% of people aged 16 - 64 years in the United Kingdom use WhatsApp, and 59.5% use Facebook Messenger (Meta). As such, the potential for conversation-based support for adults could be equally promising, but a better understanding of adult users and what might drive them to engage with conversational tools in real-world settings is needed, including how this may vary between different groups with respect to asthma severity, control, and other factors.

WhatsApp and Digital Health

Although CAs are often delivered as part of custom apps, they can also leverage existing and familiar chat-based tools such as SMS text messaging, WhatsApp, or web-based messaging systems. Indeed, we began our project with the intention of creating a bespoke app, but early engagement with patients and patient advocates led us to change this plan and shift to the widespread platform, WhatsApp. As mentioned in the "CAs for Health" section, most of the UK adult population already uses WhatsApp, which is probably why it was favored by our patient participants. Using a familiar and widespread platform also meant that we could remove the additional friction and technical barriers associated with bandwidth, storage capacity, usability, learnability, and concerns about trustworthiness that can come with downloading and using a new app for the first time.

Previous research has demonstrated positive results for the use of WhatsApp in health care settings. For example, an online questionnaire assessing patient satisfaction with WhatsApp for sharing health information, collected from 14 WhatsApp asthma and allergy groups, concluded that WhatsApp is an effective social media program for improving patient knowledge and behavior [31]. Furthermore, a study by Asthma UK offered young adults access to an asthma nurse who would assist them in managing their asthma via WhatsApp [32]. The service was well received, with 67.1% of participants reporting improved confidence in asthma management post usage.

Similarly, a study conducted across 5 Latin American countries confirmed an interest in WhatsApp as a tool to receive information about asthma. Irrespective of age (mean age of 43 years), 61.5% of patients in the study reported the highest interest in WhatsApp (as compared to SMS text messaging, Facebook, Twitter [X Corp], and email) as a tool for communication [33]. It is noteworthy that patients reported SMS text messaging as the most used service (69.9%) while still indicating that WhatsApp would be the most preferred tool for asthma communication. WhatsApp has several advantages over SMS text messaging, which may help explain its penetration. It is often more cost-effective than SMS text messaging because SMS text messaging is charged differently by mobile network providers than web-based messaging platforms such as WhatsApp; unlike SMS text messaging, the geographic reach of WhatsApp is global (ie, not limited to the mobile service region); and it provides better support for group communication, audio, video, and the option to retain an account even when one's phone number changes.

Despite the above evidence for the potential benefits of using WhatsApp, it is not as widely used as websites or custom apps. One reason (which applies to all messaging platforms) is that text- and voice-based conversations do not provide as many affordances (ie, visual displays and menu interfaces) as other media. Another reason, more specific to WhatsApp, involves privacy concerns. For example, to receive research ethics approval for a follow-up study, the research team carried out thorough discussions with both the ethics committee and the university's data protection office over the use of WhatsApp. Some of the concerns raised and how we recommend addressing them are listed below:

- Sensitive data: a health app could include sensitive data. Given these concerns, we recommend not asking users for

XSL•FO
RenderX

any sensitive information and asking only for the minimum data required to provide functionality.
- Data use by Meta: because WhatsApp is owned by Meta (formerly Facebook), there is no way of knowing how they will use data from chatbot conversations. To address these concerns, we recommend including an explanatory section specific to WhatsApp in the participant information sheet. It is also important to note that, as of September 2023, WhatsApp uses end-to-end encryption, meaning the conversation is readable only by the 2 communicating parties, in this case, the patient and our servers. This means that not even WhatsApp can read the messages. As such, the onus is on the entity hosting the chatbot servers to manage data securely and ethically rather than on Meta.
- Local storage vulnerabilities: local backups of conversations stored on a user's phone could be compromised if the phone is lost. To address these concerns, we recommend instructing users on how to turn off the backup if they wish.
- Management of identifiable data: to further address privacy concerns, we propose that it is not necessary to request any identifiable information and that only the WhatsApp phone number be used to identify a user within the system. Conversely, the user can be invited to give a nickname rather than their real name. For data analysis, data can be anonymized further (eg, phone numbers and nicknames can be removed).

Summary

The studies described in the "Introduction" section, including the asthma chatbot studies with children and adolescents, the survey studies exploring the potential use of WhatsApp in health care, and significant evidence for the efficacy of mobile interventions more broadly within health care, all provide promising evidence for a new conversation-based digital health care approach to complement primary and secondary care. These are summarized in Table 1 to clarify visually how existing work is distributed with respect to the technology used and whether it refers to health broadly or asthma specifically.

Table . Overview of categories under which the related work studies fall.

Category	For health (broadly)	For asthma (specifically)
Mobile technology (broadly; eg, apps, bespoke, and so on)	Ramsey et al [14] and Whittamore [2]	MAX (Kowatsch et al [26]) and ASTHMAXcel (Hsia et al [18,20])
WhatsApp (Meta; specific chat technology)	Saeed Tayeb [31]	Calderón et al [33] and Cumella et al [32]
Conversational agents (automated chatbots that can be used through chat technologies)	Singh et al [21]	kBot (Kadariya et al [16]) and Rhee et al [25]

What remains to be explored is a nuanced understanding of what adult users themselves would use and value, what might drive them to engage with conversational health tools in the real world, and how this might differ for diverse groups (eg, based on differences in disease severity, symptom control, confidence with technology, or trust in the health care system). For this study, we specifically sought this improved understanding for the population of adults with asthma within the United Kingdom, and we did so with a view to improving asthma risk self-assessment, asthma health literacy, and access to care. As such, our study aimed to answer the following research questions: (1) To what extent do different adults with asthma in the UK trust the health care system, and does this level of trust correlate with interest in using a chatbot for asthma? (2) Are those people who are more interested in using an asthma care chatbot more or less likely to already be accessing basic health care services (ie, general practitioner [GP])? (3) In what ways would adults with asthma prefer to access an asthma care chatbot? (4) What features, characteristics, and style preferences for a chatbot would maximize the likelihood of adults with asthma engaging meaningfully with it? (5) To what extent does a person's confidence using technology affect their willingness to use a chatbot for asthma? (6) Is there a relationship between an individual's interest in using an asthma care chatbot and their self-assessment of the seriousness of their asthma?

Methods

Overview

The survey study described herein is part of a larger overarching project funded by the UK Engineering and Physical Sciences Research Council (EPSRC) and conducted in partnership with Asthma + Lung UK, an asthma charity organization. A description of the overarching project is available in the protocol paper by Calvo et al [34].

Recruitment

Participants were recruited through YouGov [35]. To fulfill our recruitment criteria, we recruited only participants with self-reported asthma from the YouGov database. Although no medical proof of their asthma was requested, 1117 participants stated that they had received a diagnosis for their asthma. Participants were paid based on YouGov rates.

Survey

A survey comprising 38 closed- and 12 open-ended questions was conducted with adults living with asthma to gain a better understanding of how design and demographic features might influence interest in, and preferences for, a chatbot to support asthma management. A full list of the survey questions is provided in the Multimedia Appendix 1.

Analysis

The quantitative results were analyzed using SPSS (version 28; IBM Corp) [36] to run all statistical analyses of the quantitative

XSL•FO
RenderX

survey results. Firstly, descriptive statistics were analyzed to gain a better understanding of the sample and participants' general preferences for an asthma chatbot. Following the descriptive statistics, further analyses were conducted with a focus on users' trust in the health care system and to highlight differences between participants who were and were not interested in the chatbot. For all analyses, the significance level was set at α=.05.

Qualitative analysis of the open-ended free-text responses in the survey was conducted via a process of inductive thematic analysis following the steps outlined in Braun and Clarke [37] and using NVIVO (version 11 for Mac; QSR International) [38]. The aim was two-fold: (1) to identify more detailed insights underlying quantitative answers to the closed-ended questions and (2) to highlight patterns of responses or themes salient across participants' free-text contributions. In other words, text responses were coded iteratively, and themes generated were based on repeated patterns of ideas shared across participants. Resulting themes highlight some of the more common motivations and rationales for the quantitative results.

Ethical Considerations

The survey questions were approved by the Imperial College London ethics committee (reference no #21|C7403).

Results

Quantitative Results Overview

A total of 1257 people with self-reported asthma completed the survey (43% male, 57% female, and 4% left the gender question blank). In total, 1117 (88.9%) participants reported that they had received an asthma diagnosis. Of these, 47.8% of participants reported that their asthma was diagnosed younger than the age of 16 years, while 51.7% of participants reported that their asthma was diagnosed older than the age of 16 years, and 0.5% of participants preferred not to provide this information. Overall, 98.9% of participants received their diagnosis more than 6 months ago, 0.8% of participants preferred not to say when their diagnosis happened, and 0.3% of participants were diagnosed with asthma within the last 6 months at the time of participation in the study.

Most participants were older than 40 years; specifically, 44% were older than 55 years, 30% between 41 and 55 years, 19% were between 31 and 40 years, and 7% were between 18 and 30 years. Most participants had either completed a university degree (48%) or trade/technical/vocational training (19%), while 33% indicated that secondary school was their highest education level. For 0.4% of participants, the highest education level was completion of primary school. Fifty-six percent of participants spent most of their lives in a medium to small town, 23% in a rural area, and 21% in a large city.

Sixty-seven (5.3%) participants from our sample identified as being part of a minority ethnic group, while 1178 (93.7%) participants did not, and 12 (1%) participants preferred not to disclose. The number of participants who identified as part of a minority ethnic group was too small to allow for comparisons between participants who do and do not identify as such; however, some correlations with minority group identification and other variables are reported.

A summary of all key results per section is provided in Table 2. Table 3 summarizes the results that distinguish between the preferences of participants interested in an asthma chatbot and the preferences of participants who are not interested in an asthma chatbot for their asthma management.

XSL•FO
RenderX

Table . Summary of key results from each section.

Section	Results
Trust in health care system	• The majority of participants trust the health care system (83%). • People who are interested in the asthma chatbot have more trust in the health care system than those who are not interested. • Around 79.5% of participants seek support from a GP[a]. • Participants with an interest in the asthma chatbot seek more support from a GP than those who were not interested. • The more education participants have, the more likely they are to trust the health care system. • Participants who are more confident in their ability to use technology have a higher trust in the health care system. • Older participants trust the health care system more than younger participants. • Participants who are already confident in dealing with their own asthma trust the health care system more.
Communication preferences	• Around 59.7% of participants were interested in the voice feature. • Participants with a general interest in the asthma chatbot were also more interested in the voice feature of the asthma chatbot. • Around 85.5% of participants would prefer to talk to a human about their asthma. • Participants who were not interested in the asthma chatbot have a stronger preference for in-person conversations about their asthma.
Conversational style	• Most respondents preferred a “reassuring” and “friendly” conversational style and an asthma chatbot that felt “like talking to a nurse.” • However, a significant number of participants selected other preferences, for example, a “direct” approach or an experience that was more “like talking to a doctor.” • Overall, it can be concluded that different styles suit different people.
Technology experience	• The large majority of participants were confident in their use of technology (95%). • Participants who were less confident in their use of technology were less interested in trying a chatbot for asthma. • Participants who were confident in their use of technology, as well as participants who were interested in using an asthma chatbot, used WhatsApp (Meta) and other messenger apps significantly more often compared with participants who were less confident in their use of technology and those who were not interested in an asthma chatbot. • The majority of participants had used a virtual assistant in the past (89.3%). • Participants who had used a virtual assistant in the past were more likely to be interested in using a chatbot for their asthma.
Confidence in self-management	• Most participants felt either very confident (51.5%) or somewhat confident (45.6%) about managing their asthma, with only 2.9% of participants who did not feel confident. • Participants who were not interested in the asthma chatbot reported being more confident in managing their asthma. • The seriousness of their asthma was rated by participants, with 6.2% reporting it asvery serious, 31.1% reporting it as somewhat serious, and 62.7% reporting it as not serious. • Participants who were not interested in the asthma chatbot rated their asthma as less serious.

[a]GP: general practitioner.

XSL•FO
RenderX

Table . Summary of results that distinguish participants interested vs not Interested in an asthma chatbot.

Interested in an asthma chatbot	Not interested in an asthma chatbot
• More trust in the health care system • More likely to ask for support from a general practitioner (GP) than those • More likely to also be interested in a feature that detects asthma from the sound of the voice • Tend to rate their asthma as more serious	• Stronger preference for in-person conversations about their asthma • More confident in managing their asthma

Descriptive Results

YouGov shares some data they collect from all registered users. Existing YouGov data on WhatsApp use was available for 1011 participants and showed that 85% used WhatsApp. According to our own questions, 74% of participants used smartphone messaging apps daily, and 60% specifically used WhatsApp daily.

In contrast, 92.5% of participants indicated that they had never used a mobile app to help with their asthma (eg, to track their symptoms). Instead, participants were more likely to turn to existing familiar technologies (ie, internet search) or to trusted people (eg, nurses, doctors, or family members) for asthma information. The graph in Multimedia Appendix 2 shows which platform and/or source of information participants currently use to obtain information about asthma (multiple answer options; N=1257).

Participants were asked about which platform they would prefer to use to chat with an asthma chatbot, and they were allowed to select more than one. The majority indicated a preference for WhatsApp (refer to Multimedia Appendix 3), closely followed by a website.

Overall, the majority of participants (53%) indicated that they would indeed be interested in using an asthma chatbot via a messaging service such as WhatsApp (17% very interested and 36% somewhat interested).

An even higher number of participants (59%; 22% very interested and 37% somewhat interested) indicated interest in an asthma chatbot that could detect asthma severity from the sound of their voice, a technological feature currently in development by our research team. For this question, we asked participants: “Imagine AsthmaBot could detect your asthma severity by listening to the sound of your voice. You would speak into your phone to provide a short voice recording, and AsthmaBot would analyze this recording for signals (that only a computer can detect) to determine your asthma severity. How interested would you be in trying this voice feature?”

Trust in the Health Care System

To analyze participants’ trust toward the health care system, Spearman rank-order correlations were conducted. There was a significant negative correlation between participants’ education level and their trust in the health care system (coded as 1: participant trusts the system; and 2: participant does not trust the system; $r_s(1255)=-0.07$ and $P=.014$). That is, the higher a participant’s educational attainment, the more likely they were to trust the health care system.

Participants’ confidence in technology significantly positively correlated with their trust in the health care system ($r_s(1255)=0.190$ and $P<.001$). In other words, participants who were more confident in their ability to use technology also had higher trust in the health care system.

Participants’ trust in the health care system just fell short of a significant negative correlation with their identification as a minority ethnic group (or not; $r_s(1255)=-0.054$ and $P=.056$). Therefore, we can only report that there is a tendency for participants who do not identify as part of a minority ethnic group to trust the health care system more than people who do identify as an ethnic minority. This would be an important question to explore in a future study with a larger sample and would support previous research on experiences of discrimination and distrust in the health care system [39].

Age correlated significantly and negatively with trust in the health care system ($r_s(1255)=-0.07$ and $P=.009$), indicating that older participants were more likely to trust the health care system than younger ones.

Participants’ confidence in dealing with their asthma significantly correlated with participants’ trust in the health care system, $r_s(1255)=0.101$ and $P<.001$, showing that participants who were confident in managing their asthma trusted the health care system more. This may suggest that positive experiences with the health care system led to better management and, therefore, confidence in the ability to manage their asthma. However, there are many possible explanations for such a result: for example, people who trust the system less may not access health care and therefore may not get what they need to manage their asthma well; people who have had negative experiences with the system may not have gotten what they need to manage their asthma well despite accessing it; or people with asthma that is more difficult to treat and manage may more clearly see the limitations of the health care system.

Comparing Participants Interested vs Not Interested in an Asthma Chatbot

To allow a straightforward interpretation of the data, some of the variable answers were grouped. The example below (for the variable “How interested would you be in using AsthmaBot?”) shows how the Likert-scale answers were grouped into a binary format (Textbox 1).

XSL•FO
RenderX

Textbox 1. Categorical variable split between participants interested in the asthma chatbot and not interested in the asthma chatbot.

Interested

- Very interested
- Somewhat interested

Not interested

- Neutral
- Not particularly interested
- Not at all interested

There was no significant correlation between participants' interest in using an asthma chatbot and either their age, education level, or identification as a minority. This suggests that neither age, education level, nor identification with a minority ethnic group is likely to be a barrier to engagement.

To account for multiple comparisons, we applied the Bonferroni correction across all tests, which focus on analyzing factors that influence participants' interest in the asthma chatbot. This includes the 8 main chi-square comparisons as well as 1 Mann-Whitney *U* test. The adjusted significance level threshold for these tests is $P<.0056$. All tests answering different research questions were not included in this correction. The Spearman correlations were treated as exploratory analyses and are not included in this correction.

Health Care Usage Predicts Interest

We conducted a chi-square test for association to measure the relationship between participants' trust in the health care system and their interest in an asthma chatbot. The relationship is significant ($\chi^2_1=9.75$; $P=.002$; $\phi=.088$). Overall, the majority of participants trusted the health care system (83%), while 17% did not. Out of the participants who were not interested in an asthma chatbot, 20.1% indicated they did not trust the health care system, while 79.9% did. Of the participants who were interested in using an asthma chatbot, a higher percentage trusted the health care system (86.5%), and a lower percentage of participants did not trust the health care system (13.5%). This indicates that people who are interested in an asthma chatbot were more likely to trust the health care system than those who are not interested.

To check for a difference between participants' interest in an asthma chatbot and their current support from a GP, we conducted another chi-square test for association. The relationship is significant ($\chi^2_1=12.72$; $P<.001$; $\phi=.101$). Overall, 20.5% of participants do not seek support from a GP, while 79.5% do. Of the participants who were interested in the chatbot, 16.7% did not already receive support from a GP, while 83.3% did. For participants who were not interested in the chatbot, 24.8% did not get support from a GP, while 75.2% did. This suggests that overall, participants with an interest in the asthma chatbot were also more likely to be seeking support from a GP. This aligns with our results showing that people who see their asthma as more serious are more likely to be interested in a chatbot. Moreover, participants' perception of the seriousness of their asthma positively and significantly correlated with the Asthma Control Questionnaire items: difficulty sleeping due to asthma ($r_s(1255)=0.313$, $P<.001$); asthma symptoms during the day ($r_s(1255)=0.279$, $P<.001$); asthma affecting usual activities ($r_s(1255)=0.361$, $P<.001$); and asthma caused an accident and emergency (A&E) visit in the last 2 years ($r_s(1255)=0.275$, $P<.001$). Taken together, these findings suggest that at least some participants who were not interested in a chatbot lack interest because they did not feel their asthma was serious enough to motivate use. Qualitative results provide additional evidence for this conclusion (refer to section Reasons for Lack of Interest and Reservations).

Communication Preferences: Participants Would Value Asthma Voice Recognition but Still Favor Human Support

Regarding participants' interest in a feature that detects asthma severity through the sound of one's voice, voice recording could be more appealing (eg, novelty and perceived accuracy) or less appealing (eg, privacy concerns) than the standard text-based chatbot. Therefore, we analyzed the relationship between interest in such a feature and general interest in an asthma chatbot with a chi-square test for association. Again, both variables were coded as interested vs not interested. The relationship is significant ($\chi^2_1=347.100$; $P<.001$; $\phi=0.525$). Overall, 59.7% of participants were interested in the voice feature, while 40.3% were not. Out of the interested participants, 84.1% were interested in the voice feature, while 15.9% were not. Out of participants who were not interested in an asthma chatbot, only 32.4% were interested in the voice feature, and 67.6% were not. These differences show that most participants with a general interest in an asthma chatbot were also interested in a voice feature to detect severity, and that a subgroup of participants not interested in an asthma chatbot was, however, interested in voice-based severity detection for asthma.

A chi-square test for association was conducted to test the relationship between participants' preference for talking to a human about their asthma and their interest in an asthma chatbot. The relationship is significant ($\chi^2_1=17.05$; $P<.001$; $\phi=.116$). Overall, 85.5% of participants reported that they would prefer to talk to a human about their asthma. Of the participants interested in an asthma chatbot, 81.7% would prefer to talk to a human, while 18.3% would not. Of the participants who were not interested in an asthma chatbot, an even higher percentage preferred talking to a human (89.9%), while only 10.1% did not. The findings demonstrate that participants who were not

XSL•FO
RenderX

interested in using a chatbot for asthma, unsurprisingly, have a stronger preference for in-person conversations about their asthma. It is also worth noting that while the large majority would prefer to speak to a human about their asthma, a similar majority had sought asthma information via the internet. This suggests that although human interaction is preferred, when it is not available or easily accessible, most people turn to nonhuman options for support.

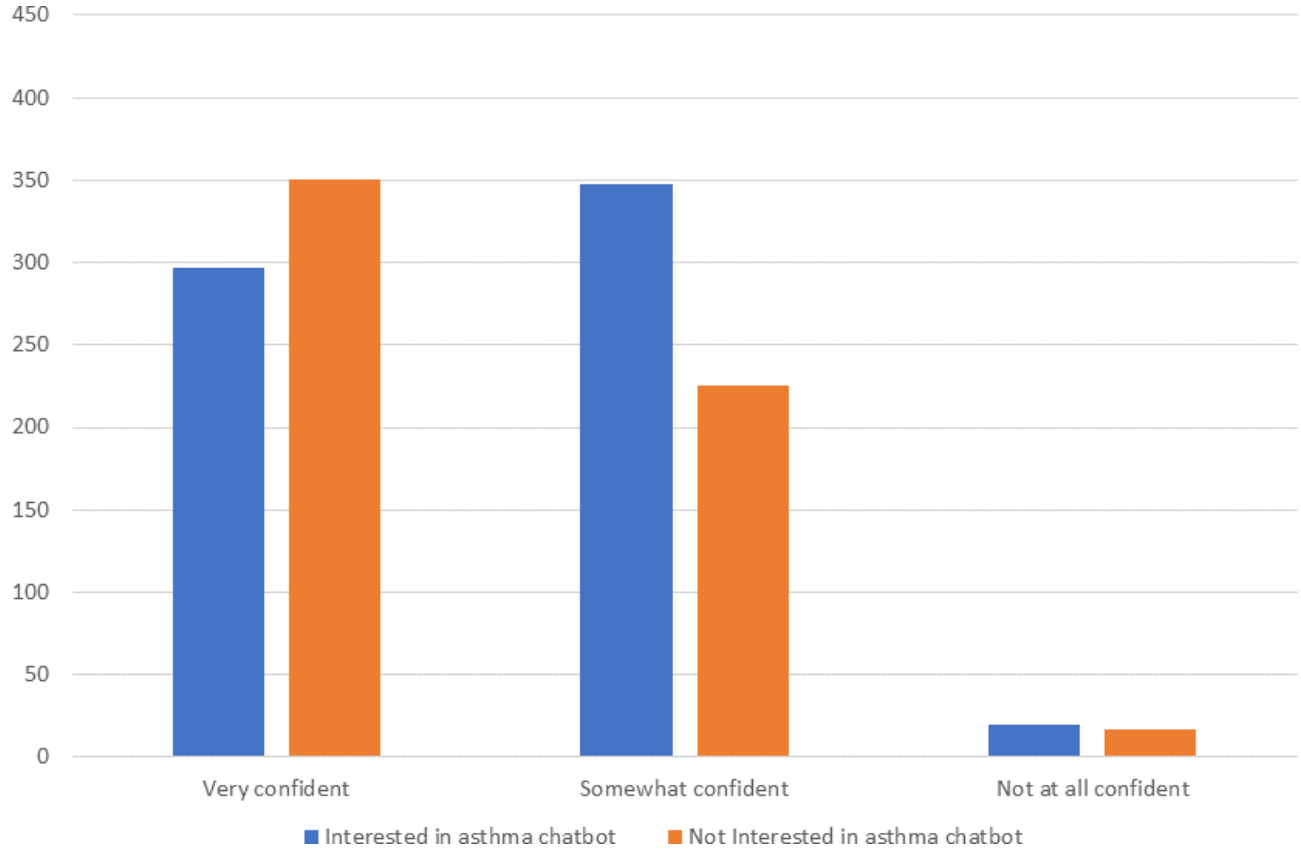
Conversational Style: Most Prefer a Chatbot That Is Friendly, Reassuring, and Like a Nurse

Research suggests that defining personality dimensions and a clear conversational style to guide the dialogue of a chatbot provides a more consistent and effective user experience [40]. Chatbot conversational style can vary across different personality dimensions; for example, it might be more or less formal or informal, authoritative, submissive, or convey warmth through word choice. To determine the kind of conversational style that most people with asthma would feel comfortable interacting with in a chatbot, the survey provided a list of personality descriptors and asked participants to select those they believe to be most appropriate for an asthma chatbot. Among participants interested in an asthma chatbot, the most frequently selected personality descriptors were “reassuring” (n=343), “like talking to a nurse” (n=335), “friendly” (n=316), “caring” (n=261), “good listener” (n=198), “like talking to a doctor” (n=196), “direct” (n=164), and “informal” (n=147). It is notable, however, that a significant number of participants selected other preferences, for example, favoring a “direct” approach or an experience more “like talking to a doctor,” suggesting different styles suit different people.

Technology Experience Predicts Interest

To assess the relationship between participants’ confidence in using technology and their interest in an asthma chatbot, we conducted a chi-square test for association. The relationship is significant (χ^2_1=13.73; P<.001; ϕ=0.105). Overall, the large majority of participants were confident in their use of technology (95%). Of the participants who were not interested in an asthma chatbot, 92.6% were confident in using technology, while 7.4% were not. Of the interested participants, a higher percentage were confident in technology (97.1%), while only 2.9% were not. In other words, and perhaps unsurprisingly, people who reported less confidence with technology use in general were also less interested in trying a chatbot for asthma.

Moreover, 2 Mann-Whitney U tests showed that participants who reported more confidence in their ability to use technology used WhatsApp and other messenger apps significantly more frequently in comparison to people who felt less confident with technology use (U=23652.50; Z=−5.636; P<.001) and that participants who were interested in using an asthma chatbot also used both WhatsApp and other messenger apps significantly more frequently in comparison to participants who were not interested in using a chatbot (U=175969.50; Z=−3.688; P<.001).



We also conducted a chi-square test for association to measure the relationship between participants’ previous use of a virtual assistant and participants’ interest in an asthma chatbot. The relationship is significant (χ^2_1=10.11; P=.001; ϕ=0.090). Overall, the majority of participants reported having used a virtual assistant in the past (89.3%). Of the participants who were not interested in an asthma chatbot, 86.3% had used a virtual assistant before, while 13.7% had not. Of participants who were interested, a higher percentage had used a virtual assistant previously (91.9%), while only 8.1% had not. As such, people who had used a virtual assistant in the past were more likely to be interested in using a chatbot for their asthma.

Lower Confidence in Disease Self-Management Predicts Interest

A chi-square test for association was conducted to assess the relationship between participants’ confidence in the self-management of their asthma and their interest in an asthma chatbot. The relationship is significant (χ^2_2=26.84; P<.001; ϕ=0.146). The majority of participants felt either very confident (51.5%) or somewhat confident (45.6%) about managing their asthma, with only 2.9% of participants reporting that they did not feel confident. Of those interested in the asthma chatbot, 44.7% were very confident, 52.3% were somewhat confident, and 3% were not confident at all. In comparison, out of the participants who were not interested in an asthma chatbot, a higher percentage indicated being very confident in managing their asthma (59.1%), 38% were somewhat confident, and only 2.9% were not confident. Therefore, participants who are less confident about their own ability to manage their asthma were more likely to be interested in an asthma chatbot. For an overview, refer to Figure 1. This provides support for the utility of a chatbot in improving management skills and confidence among those who feel they lack them.

XSL•FO
RenderX

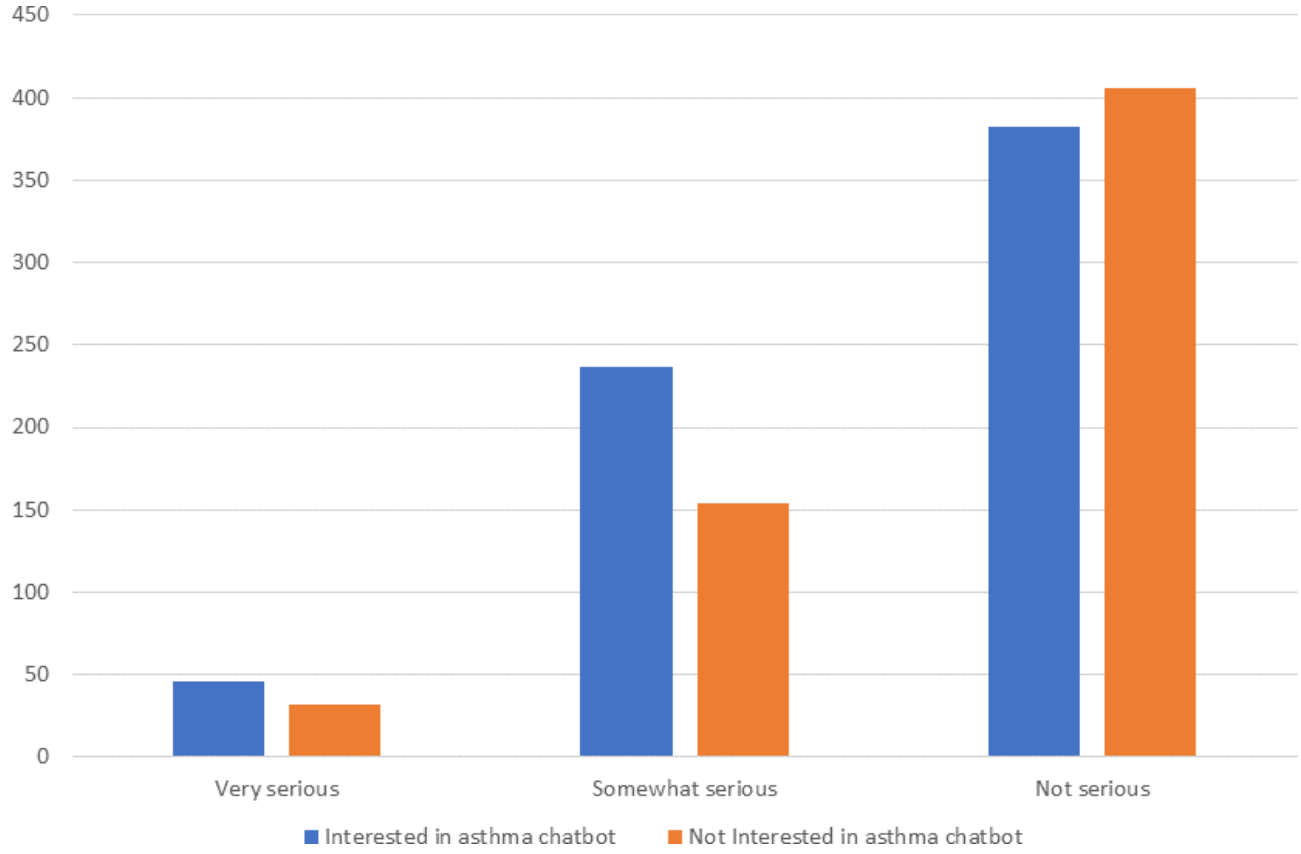


Figure 1. Bar chart showing the confidence level of participants dealing with their asthma, who are either Interested or not Interested in the asthma chatbot.

To assess the relationship between participants' own perception of the severity of their asthma and their interest in using an asthma chatbot, a chi-square test for association was conducted. The relationship is significant (χ^2_2=16.68; P<.001; ϕ=0.115). Asthma seriousness was rated by participants, with 6.2% rating their asthma as very serious, 31.1% as somewhat serious, and 62.7% as not serious. Of the participants who were interested in the asthma chatbot, 6.9% rated their asthma as very serious, 35.6% as somewhat serious, and 57.4% as not serious. Participants who were not interested rated their asthma as less serious overall, with 5.4% indicating that their asthma is very serious, 26% stating that their asthma is somewhat serious, and 68.6% rating their asthma as not serious. Overall, participants who were not interested in an asthma chatbot rated their asthma as less serious. For an overview, refer to Figure 2.

XSL•FO
RenderX

Figure 2. Bar chart showing the level of severity at which participants rate their asthma, who are either interested or not interested in the asthma chatbot.

Qualitative Results Overview

All of the 1257 survey respondents provided at least 1 free-text response to an open question. While quantitative analysis of closed survey questions reveals characteristics correlated with those most interested in an asthma chatbot, open-text results provide explicit insights into the reasons some participants are interested while others are not. In alignment with this "interest vs no interest" focus applied to the quantitative analysis, the qualitative analysis of open-question text was also primarily organized around these 2 categories, including reasons given for these and associated characteristics.

Open-text responses also provided additional information on specific technologies and information sources in relation to survey questions about where participants seek asthma information and what technologies they already use to support self-management.

Reasons for Lack of Interest and Reservations

Data were organized into a set of 4 recurring themes based on the types of reasons and reservations expressed in relation to lower interest in an asthma chatbot. These are provided in Table 4, along with example quotations from respondent comments.

XSL•FO
RenderX

Table . Summary of reasons for not being interested in an asthma chatbot.

Theme	Example quotations from the open comments
Theme 1: technology skepticism	• "I'm unsure it would get details correct and misdiagnose." [P21] • "They're not real, just programs. So they make mistakes and are not to be taken seriously." [P351] • "I dislike AI[a]." [P9] • "I would rather talk to my doctor or asthma nurse." [P109]
Theme 2: personalization skepticism	• "I'm not sure I would use it; these things tend to give general advice and if you need advice specifically for you then I'm not sure it could do that for everyone." [P231] • "I worry that it would tell me basic things that I already know or give generic advice. If it was very tailored to me that might help." [P163] • "My concern is these virtual assistants are programmed to answer specific questions whilst I may want to ask something that they are not equipped to answer!" [P455]
Theme 3: low asthma severity	• "I don't feel that my asthma is severe enough to need anything more than my annual check at the moment." [P367] • "If my asthma was worse than it is, I would find it more useful." [P855]
Theme 4: security and privacy concerns	• "The system gets hacked, and my data is used nefariously." [P35] • "I'd be uncomfortable with the idea of my medical details being stolen either by a hack or 'man in the middle' style attack." [P633]

[a]AI: artificial intelligence.

The first theme, "technology skepticism," captures expressions of doubt in the accuracy and trustworthiness of chatbot technology. For example, a number of participants expressed skepticism about the capacity of current technology to provide information that is accurate and safe (referring to the possibility of misdiagnoses and mistakes). Some participants expressed a general dislike for technological solutions ("I dislike AI" [P9]) or referenced the technology's nonhuman nature as an inherent problem ("They're not real…and are not to be taken seriously" [P352]), or relatedly, the simple preference for human solutions ("I would rather talk to my doctor or asthma nurse" [P109]).

The second recurring theme, "personalization skepticism," refers to responses expressing doubt in a technology's ability to respond in a personally relevant and specific way. For example, participant 163 stated, "I worry that it would tell me basic things that I already know or give generic advice. If it was very tailored to me that might help."

The third recurring reason for lack of interest in a chatbot was perceived low asthma severity, resulting in a perceived lack of need for technological support (eg, "I don't feel that my asthma is severe enough to need anything more than my annual check at the moment" [P367]).

Finally, a fourth reason for hesitancy in using an asthma chatbot was concern about system security and data privacy, including misuse by a malicious third party (eg, "The system gets hacked, and my data is used nefariously" [P35]). For more examples, refer to Table 4.

In addition to expressions of doubt, concern, or reservation with respect to using an asthma chatbot, many participants expressed optimism and interest in the potential for a chatbot to provide benefits. The recurring themes around these responses are summarized in Table 5. They include the capacity for a chatbot to provide education and self-management support, for example, by providing users with health information, warning of future asthma attacks, and helping manage symptoms; and in doing these things, providing an alternative to traditional health services (eg, "Support for my symptoms without risking a trip to the doctors" [P125] and "I have mild asthma and am concerned it may get worse, an asthma bot may help me control it because the National Health Service (NHS) website is next to useless" [P480]).

RenderX

Table . Summary of reasons for interest in an asthma chatbot.

Theme	Example quotations from the open comments
Theme 1: health education and self-management support	• "Help control my asthma." [P120] • "Support for my symptoms without risking a trip to the doctors." [P125] • "To try and predict potential future asthma attacks in case I'm more at risk." [P240] • "It sounds easy and convenient and help manage my asthma worries easily." [P259] • "Learn new things about controlling asthma." [P337] • "It seems like a fun way to learn about the condition." [P453] • "I have mild asthma and am concerned it may get worse, an asthma chatbot may help me control it because the NHS[a] website is next to useless." [P480]
Theme 2: ease of access	• "It already knows the range of symptoms and can come up with something concrete very quickly, instead of me wasting someone's actual time." [P371] • "I need help now but cannot see my GP[b] for seven weeks." [P428] • "It is easier than getting appointment with nurse." [P449] • "I would use it rather than visit A&E[c] out of hours." [P485] • "An easy to access service." [P53] • "If it was free." [P107] • "Free to use and could be helpful before going to see a doctor." [P152] • "It seems like a good tool. It being free would be best." [P226]
Theme 3: trusted endorsement	• "That it is run by the NHS in conjunction with asthma UK not a commercial computer program." [P356] • "Endorsement by my GP practice." [P370]

[a]NHS: National Health Service.

[b]GP: general practitioner.

[c]A&E: accident and emergency.

Another set of responses captured various ways a chatbot provides ease of access to support, as compared to traditional health services ("I need help now but cannot see my GP for seven weeks" [P428]), with an emphasis by some participants on the importance of such a service being available for free ("If it was free" [P107] and "It being free would be best" [P226]).

Finally, some participants highlighted the importance of trusted endorsement by a trustworthy organization, such as their GP or the NHS, rather than a commercial company, as being important to their interest in using the technology (eg, "That it is run by the NHS in conjunction with Asthma UK, not a commercial computer program" [P356]).

Sources of Asthma Support: Sources and Apps

Finally, participants used open-text responses to provide the names of information sources and asthma technologies used. Specifically, 74 participants listed specific technologies they already use, or have used in the past, to get support for their asthma. Those best represented in the text responses included the NHS app (listed by 17 participants), Asthma UK (listed by 9), and Peak Flow (listed by 6).

Discussion

Key Findings and Recommendations

This study is the first to assess and contribute detailed insights on the motivational factors, features, and characteristics necessary for ensuring an asthma chatbot is of value to adults with asthma and that would maximize the likelihood of meaningful engagement. These findings are based on the closed and free-text responses of adults with asthma sharing views about their expectations, needs, and preferences, which were then correlated with differences in background, technology confidence, asthma history, and asthma self-management confidence. The goal is to contribute toward meaningful engagement with an easy-access asthma support technology to help address the care gap. Key findings that can most readily guide the design and development of future asthma chatbots are summarized herein.

Recommendation 1: Prioritize Ease of Access and Consider Existing Technologies Rather Than a Custom App

Overall, our results suggest that a significant percentage of UK adults with asthma (53% of our survey participants) would be interested in using a chatbot to support their asthma, and that an even higher number would be interested in using a voice-based risk detection feature (59% of our survey participants). Moreover, our findings provide a strong rationale for delivering the chatbot via WhatsApp instead of through a custom asthma app, since the large majority of our participants had already installed WhatsApp on their phone (85% of 1011 participants) and reported it to be their most common method of sending messages. Finally, WhatsApp was the number one

XSL•FO
RenderX

platform of preference for interacting with an asthma chatbot. Alternatively, a website was rated the second most popular channel for accessing an asthma chatbot. Although apps have distinct advantages that will sometimes warrant the extra friction, few participants had used an app for asthma, and their 2 top preferences for access leveraged familiar and easily accessible technology.

This aligns with qualitative findings in which participants highlighted ease of access as a major motivator for using an asthma chatbot. Ease of access had three main facets, including (1) that it is available 24/7, including when appointments are not available, (2) that it can (and should) be made available for free to ensure access, and (3) that it is easier to access than health care professionals. How we assessed ease of access aligns with 2 out of 4 key factors of the Unified Theory of Acceptance and Use of Technology model (UTAUT) [41], namely effort expectancy (the level of convenience and usability when using an information system) and facilitating conditions (the belief that the technical infrastructure to support the use of the system exists), which have been shown to positively influence behavioral intention and use behavior of information systems.

Recommendation 2: Center the Needs of People With More Serious Asthma Who Feel They Need Additional Support

Our findings indicate that an asthma chatbot is of particular interest to those who believe their asthma to be more serious. As such, a CA could be most beneficial for those patients who need additional support, either because their asthma is indeed more serious or because they experience more anxiety around it and less confidence in self-management. This is supported by the further results showing that participants who feel less confident in managing their asthma are also more likely to be interested in a chatbot than those who are already confident. Qualitative data confirms this and suggests that at least some people may also feel they do not always get adequate or timely access to traditional care (refer to Table 5). For example, participant open responses included “could be helpful before going to see a doctor” and “I need help now but cannot see my GP for seven weeks.” Thus, collectively, our results suggest there is a strong opportunity to integrate CAs as a supplementary, easily accessible, 24/7 service for patients who are in need of additional support.

Relatedly, participants who would be interested in using an asthma chatbot were also more likely to seek support from a GP in comparison to those who were not. This is consistent with the finding that participants interested in a chatbot have a greater need for support, as they rate their asthma as more serious.

In summary, our results show that an asthma chatbot is likely to be of greatest benefit to (1) patients who believe their asthma to be serious, (2) patients who feel less confident about managing their asthma, and (3) patients who are looking for immediate support while they wait for an appointment with a health care professional.

Recommendation 3: Include Conversational Content for Asthma Education, Risk Assessment, and Customized Self-Management Advice

Across both quantitative and qualitative responses, results demonstrate that participants would value easy access to educational information about asthma, support in assessing and preventing asthma attacks, and support for self-management—particularly tailored support that goes beyond the generic advice broadly available. The clinicians involved in this study add that there is great potential for a chatbot to have conversations about topics that are important to positive health outcomes but that there often is not enough time to cover during medical appointments. These topics include full explanations of what asthma is, what the medicine is for, how and why it works, proper technique, and conversations to support identifying and avoiding triggers. Previous studies have demonstrated that patient self-management not only allows patients to better manage long-term health conditions but also decreases visits to both GP offices and emergency departments [42,43]. A CA can improve health literacy, and this would not only fill in gaps but also provide repeated access to information over time, thus augmenting clinical practice.

Recommendation 4: Craft a Conversational Design That Is Reassuring and Like Talking to a Nurse

Our survey results with respect to people’s preferences for the conversational style (personality) of a chatbot revealed a set of majority preferences, with additional groups of alternate preferences. Most respondents preferred an asthma chatbot that was “reassuring,” “friendly,” and “like talking to a nurse.” It is notable, however, that a significant alternative group favored a “direct” approach or an experience that was more “like talking to a doctor.” Designers and developers could approach this diversity in a number of ways, including by (1) opting for the majority preference, (2) targeting a specific audience, or (3) allowing users to select personalities from a set of options. From a Self-Determination Theory perspective [44], providing options for personalization would support users’ need for autonomy. Fulfillment of all 3 basic psychological needs during technology interaction (autonomy, competence, and relatedness) predicts positive user experience and well-being [45-47], as well as higher intention to use a system [48,49].

Recommendation 5: Address Security and Privacy Concerns

The group of participants who reported more interest in an asthma chatbot also showed more overall trust in the health care system compared with participants who were not interested. This finding suggests that participants who are not interested in the chatbot might be less inclined overall to seek external support for their asthma. Future studies could investigate whether this is simply due to less serious asthma and effective self-management, or a more general lack of trust in external support (eg, negative experience, language barriers). The qualitative analysis provided some evidence for both explanations, indicating a combination of reasons is likely. Specifically, on the one hand, we identified a group of participants who were not interested in the chatbot and believed their asthma to be less severe (refer to theme 3 in Table 4). On

XSL•FO
RenderX

the other hand, we also identified a group who were skeptical of AI solutions and their accuracy in general.

Qualitative results revealed a number of themes that provide richer explanations for the quantitative findings. Specifically, that there were at least four categories of reasons given for lack of interest in an asthma chatbot: (1) technology skepticism (doubt in the technology's ability to be accurate or useful), (2) personalization skepticism (doubt in the technology's ability to provide anything other than very basic and generic advice, or to provide specific advice tailored to specific needs), (3) low asthma severity (perception that their asthma is not severe enough to warrant the use of technological support), and (4) security and privacy concerns (concerns over data misuse or hacking).

A successful chatbot would have to address these concerns to reach ambivalent users. These patient concerns demonstrate the importance of providing clear information and transparency around data security and the technology owner. Our results align with previous studies demonstrating that technology skepticism [50,51], as well as privacy concerns [52-54], can hinder the successful integration of new technologies in health care settings. Moreover, as the results show that previous exposure to a virtual assistant had a positive impact on patients' interest in the CA, these issues may improve over time as exposure increases [55-58].

Addressing security and privacy concerns would, at minimum, require very transparent disclosure of how data would be used and kept private (ie, not shared beyond the system), communicated in easy-to-understand ways. Granular consent options could be provided if providers wanted to use data for other purposes, such as research, and these would need to be opt-in. Sharing data with health care providers or systems (eg, NHS) could be made voluntary and fully under user control. Granular controls could also allow users to share only certain types of information and to withdraw consent [59]. To mitigate risks around data security, newer methods such as federated learning (decentralized model training without the distribution of raw patient data) or blockchain-based federated learning (an additional security layer for data sharing) present alternatives to traditional machine learning approaches and combine technological advances with adherence to legislative requirements (eg, HIPAA [Health Insurance Portability and Accountability Act] or GDPR [General Data Protection Regulation]) [60-62].

Recommendation 6: Address Technology Skepticism

While security and privacy concerns have to do with threats to personal autonomy, technology skepticism was evidenced by participant responses to nonbelief in the technology's capabilities, accuracy, and fitness to purpose. Some participants expressed aversion to using technology in favor of human interaction or general aversion to "AI." Others were doubtful that a chatbot system could provide advice that was tailored enough to the individual to be useful. Aiming to address these doubts, both technologically (making the doubts unfounded) and/or through messaging (communicating the genuine benefits and limitations) is likely to increase the audience for an asthma chatbot.

However, trust in these systems is likely to be a moving target. Given the rapid growth of generative AI chatbots such as ChatGPT (OpenAI), future studies could explore whether increased exposure to these types of chatbots impacts either positively or negatively on trust in related technologies. Although an asthma chatbot should only provide advice vetted by clinicians, generic generative AI chatbots such as ChatGPT and Claude (Anthropic) generate advice that is not safety-checked by a human and may therefore respond erroneously with so-called "hallucinations" or fabrications, which, in a health context, could be highly dangerous. As such, educating patients about the limitations and distinctions among various conversational technologies may become critical going forward. It is crucial to establish AI literacy among patients and health care providers to ensure the effective, ethical, and safe integration of emerging technologies [63,64]. In other words, communicating that there is a clear distinction between (1) general-purpose systems, (2) unproven apps that claim to be for health, and (3) specialized health systems with reliable third-party credentials will be part of the effort. However, there are no easy answers here, as trust must be deserved. To tackle these challenges, a multistakeholder approach should be implemented [53,65]. This involves a difficult, ongoing, and system-wide effort being addressed by academics, health care professionals, and technologists simultaneously as we attempt to find ways to balance the potential of new technologies with the clear risks of harm and challenges for regulation in the face of relentless technological change.

Recommendation 7: Consider a Trusted Endorsement

A final point on trust came from participants who highlighted the importance that a chatbot be endorsed by trusted authorities, such as their GP, an asthma charity, and not a commercial enterprise. For health care systems, trust is being repeatedly named as one of the key factors driving technology adoption even in comparison to the typical Unified Theory of Acceptance and Use of Technology (UTAUT) predictors: effort expectancy, performance expectancy, social influence, and ease of use [66-68]. This may be attributable to the fact that health care is a more sensitive and private topic. Consequently, it is imperative to engage trusted authorities in the development of digital health care solutions. Transparency about the inclusion of trusted authorities will provide users with the necessary trust to engage with novel CAs and other digital health care solutions.

By understanding people's doubts and the reservations that form obstacles to technology adoption, developers can target these concerns through technological improvements, interaction design, and education.

Limitations and Future Work

A limitation to the generalizability of the findings within this study is that it was conducted within the United Kingdom, and with the UK health care system in mind. Results with respect to access to primary care, trust in the health care system, or access to technologies, for example, are likely to vary across other countries. Another important consideration is that the survey was conducted online through an online survey service. Confidence in technology use was reported as very high within

XSL•FO
RenderX

our sample, but results could be different, for example, if a paper-based survey were conducted via community centers.

It is also relevant to highlight that our data rely on participants' self-reports of having asthma (rather than medical proof). To mitigate the risk of inaccurate self-reporting, we asked participants to specify when they were diagnosed by a doctor and to answer questions on symptoms and asthma control. We believe the added detail in questions, combined with the high number of participants who took part in the study, mitigates the potential effects of inaccurate self-reporting.

Another limitation involves our small sample of participants who identify with a minority ethnic group. We did not recruit enough participants from ethnic minority groups through the YouGov database to be able to explore research questions that could contribute to helping these groups specifically get their needs met. Our results are therefore not generalizable across ethnic groups, and additional research is needed to address the specific needs of ethnic minorities. We believe that this is an important research area for future studies, since there are health disparities demonstrated for minority ethnic communities, and easily accessible technologies, such as CAs, might contribute to addressing some of these. We would recommend using alternative methods of recruitment to reach participants from minority ethnic groups.

Relatedly, the majority of participants in our sample get support from a GP for their asthma, and trust in the health care system was high. Follow-up studies could focus specifically on patient groups who do not fall within either of these categories to gain a better understanding of how these groups (who are not accessing traditional care) might be better supported and how a chatbot might play a role.

Finally, in this study, participants did not have the chance to test an actual asthma chatbot. Instead, they were asked to make hypothetical judgments about their interests and preferences, so their responses were speculative and based on their previous experiences. Ideally, a longitudinal study should be conducted to test the long-term effects of, and adherence to, a fully built CA for asthma support. In a next follow-up study, we will test the feasibility of a prototype designed in alignment with the findings of this study. The follow-up study will provide insights into real-world patterns of use, perception of benefit, and final evaluations.

Conclusion

Overall, this study provides evidence for demographically broad interest in an asthma chatbot among adults with asthma in the United Kingdom. It is the first study to explore the potential of a CA to support adults with asthma, since previous research in this area focused on pediatric asthma instead. We were able to identify key factors that correlate with greater interest (ie, easy access, a fast alternative to GP or nurse, lower confidence in asthma self-management, and perception of asthma as serious) and less interest (lack of trust in AI, security concerns, preference for in-person contact, and higher confidence in self-management). These findings offer important insights for the design and development of a CA for asthma management and demonstrate the demand and opportunity in the United Kingdom for providing alternative support for asthma management. The results indicate that CAs can help to improve risk self-assessment, asthma control, and provide easy access to basic care outside of appointments with a health care professional.

Acknowledgments

We are grateful to Asthma + Lung UK and our patient advisory board participants for their constant support.

Abstract

Background: Loneliness among older adults has become a major public health concern associated with cognitive decline, depression, and increased health care use. The advancement of digital health technologies such as wearable devices, smart home systems, and mobile health apps provides new opportunities to monitor and mitigate loneliness through continuous physiological and behavioral assessment. However, the effectiveness of such technologies largely depends on user interface design, ensuring that older adults can understand, trust, and comfortably engage with the technology. Existing research on interactive platforms and user interfaces for psychological and emotional monitoring has mainly focused on usability testing and technology feasibility, with limited attention to structured design frameworks that integrate psychological, emotional, and accessibility dimensions for older adults. Furthermore, most studies rely on qualitative assessments and lack quantitative prioritization of design indicators.

Objective: This study aimed to build on the DELONELINESS (Design for Healthy Ageing: a Smart System to Decrease Loneliness for Older People) system to develop a user-centered hierarchical framework of interface design indicators for older adults.

Methods: A mixed methods design was applied, integrating literature search, qualitative focus group analysis, and expert consultation to build an initial indicator pool. A hierarchical indicator structure with 7 first-level and 26 second-level indicators was developed. The analytic hierarchy process was used to assign indicator weights through surveys of 20 experts with academic or professional experience in human-computer interaction, digital health, gerontology, and health informatics. Based on the weighted results, 3 interface design solutions were developed and comparatively evaluated using the Technique for Order Preference by Similarity to Ideal Solution.

Results: All expert judgment matrices satisfied the analytic hierarchy process consistency requirement (consistency ratio <0.1). The Kendall coefficient of concordance indicated good agreement among experts for both first-level indicators (W=0.313; *P*<.001) and second-level indicators (W=0.156; *P*<.001). Among the 7 first-level indicators, trust and safety (weight=0.206), ease of use (weight=0.187), and accessibility (weight=0.167) received the highest weights, indicating their importance in enhancing user confidence and engagement. Technique for Order Preference by Similarity to Ideal Solution evaluation results showed that design solution 2 achieved the highest overall performance score (relative closeness coefficient C=0.877), emphasizing clear interaction pathways, visual clarity, and guided feedback as key factors for optimal usability.

Conclusions: This study developed a user-centered framework for interface design in loneliness monitoring among older adults by integrating user insights, literature-derived indicators, and expert consensus, and providing a structured data-driven approach to prioritizing design requirements. The proposed framework bridges subjective user experience with objective evaluation, offering practical guidance for developing empathetic, inclusive, and trustworthy digital mental health technologies for older adults.

Introduction

With the rapid growth of the global aging population, loneliness has become a major public health concern in aging societies. It is estimated that up to 1 in 4 older adults worldwide currently experience social isolation [1-3]. Research has demonstrated that older adults are particularly vulnerable to loneliness and social isolation. As people age, they may experience loneliness and social isolation due to reduced social interactions caused by various factors, including physical and cognitive changes and losses, living alone, or the loss of family or friends [4-6]. Prolonged loneliness or social isolation has been linked to a higher risk of depression, dementia, physical decline, chronic illness, and even premature mortality [7,8]. Furthermore, loneliness increases the demand for health care and long-term support services, placing substantial strain on health care systems [5]. Therefore, there is an urgent need for cost-effective and accessible interventions to alleviate loneliness among older adults.

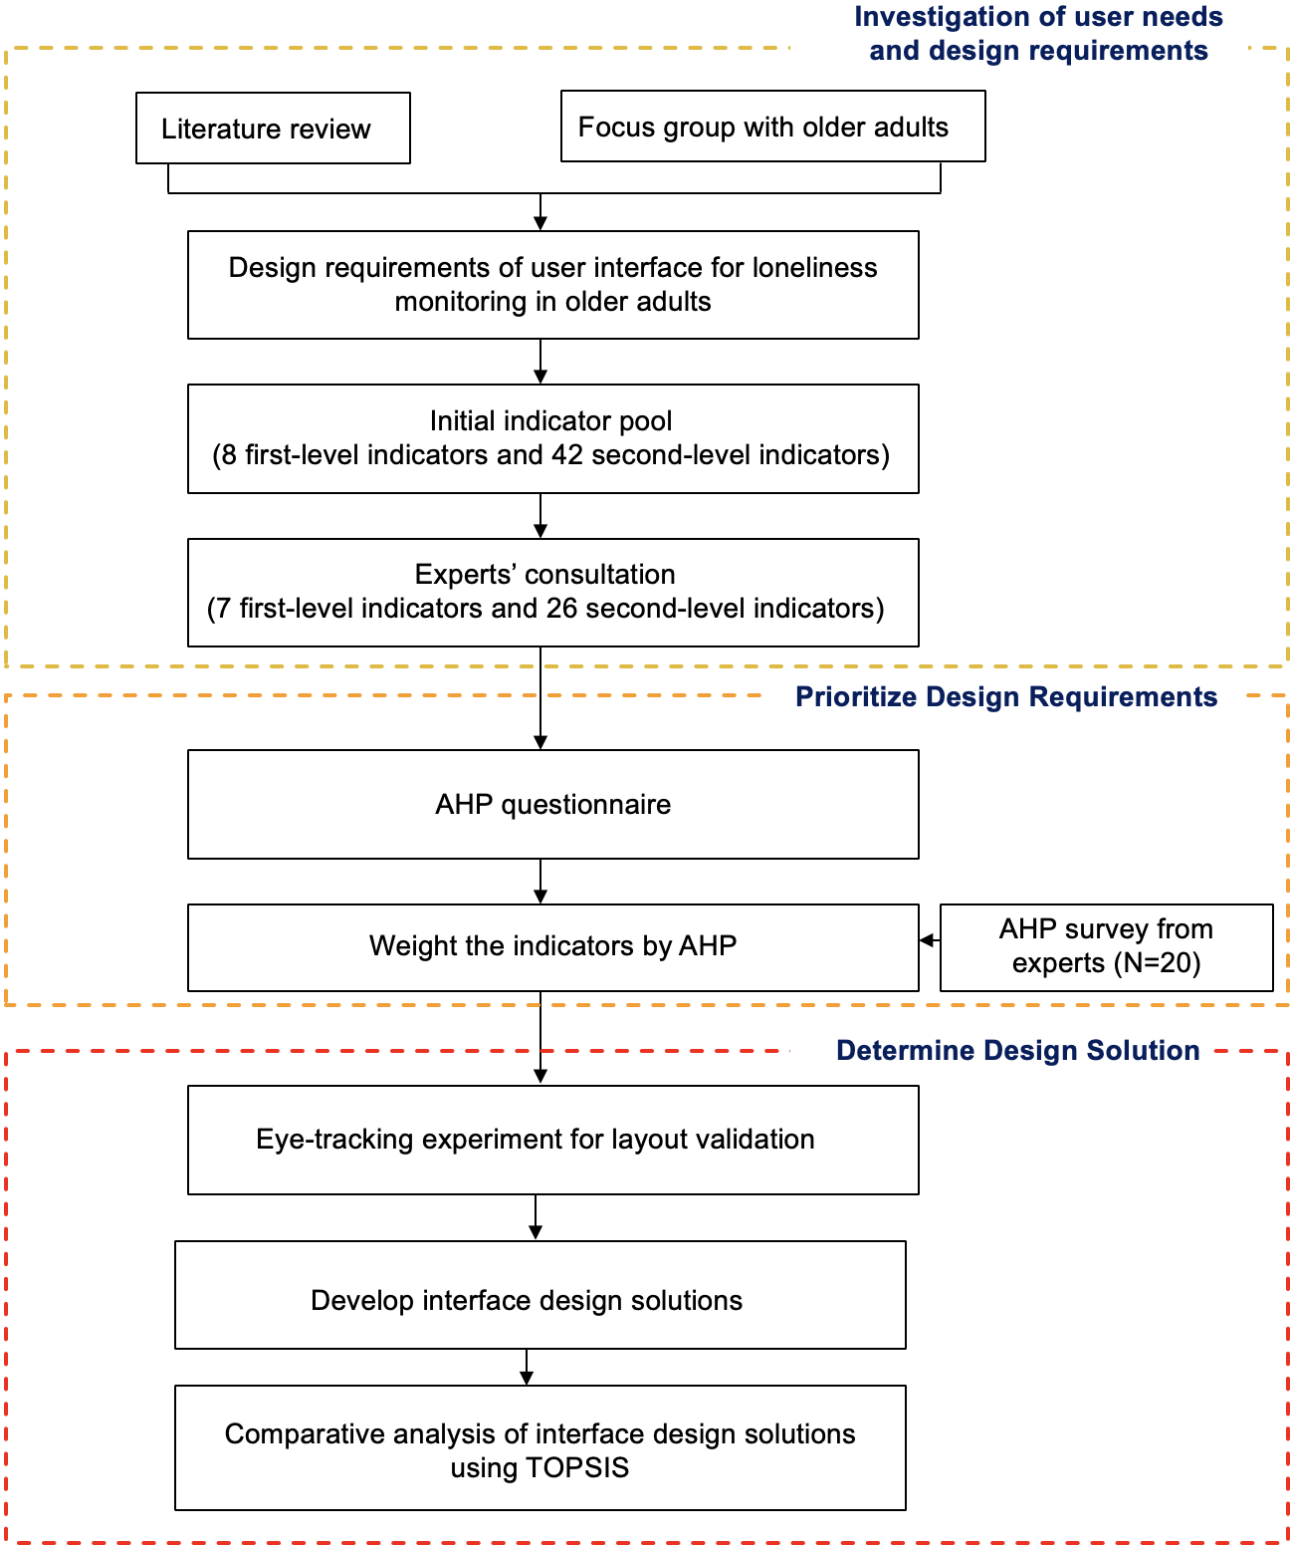
In recent years, the development of digital health technologies such as wearable devices, smart home systems, and mobile health apps has created new opportunities to monitor and mitigate loneliness through continuous physiological and behavioral assessment. For example, smartwatches and sensor-based wearables can monitor posture as well as physiological parameters linked to loneliness, such as heart rate, respiration, and blood oxygen levels [9-12]. Microphone or camera-based smart furniture and environmental monitoring devices can detect activity patterns, and artificial intelligence (AI)-driven interactive platforms are increasingly being used to provide emotional support and facilitate social interaction among older adults [13-15]. Advances in flexible electronics and smart textiles have further enabled the seamless integration of monitoring technologies into garments or furniture, creating unobtrusive and continuous passive monitoring solutions [10,16,17]. These systems can capture multimodal signals such as heart rate, respiration, and movement to infer emotional and social states and deliver personalized interventions. However, despite significant progress in data collection and AI-based analytical technologies, the effectiveness of these systems largely depends on the design of their user interfaces [18,19]. The design of user interfaces, particularly those for older adults, should ensure that users can understand, trust, and comfortably interact with the system, while also promoting inclusivity and long-term engagement to support psychological well-being [20].

Older adults may face greater challenges when interacting with digital technologies and user interfaces due to limited digital literacy, cognitive and sensory changes, and age-related physical decline [21]. For instance, the loss of fine motor skills can make it difficult to interact with small virtual buttons [22]. In addition, visual impairments can hinder the perception of detail, color, and contrast, and hearing loss can reduce responsiveness to auditory feedback cues [23]. Therefore, the design of interactive platforms and user interfaces should consider these age-related changes to ensure inclusivity and usability. Beyond these physiological and cognitive considerations, emotional comfort and psychological acceptance are essential in determining older adults' engagement with digital systems. Many older adults may experience stigma associated with mental health or hold generational beliefs that discourage emotional disclosure [24,25]. As a result, they may be reluctant to use mental health-related technologies, perceiving them as intrusive or impersonal. Increasing evidence suggests that systems lacking empathy, warmth, and reassurance may unintentionally reinforce feelings of loneliness rather than alleviate them [26,27].

Although digital mental health interventions have gained increasing attention, research specifically focusing on the design of interactive platforms and user interfaces for psychological and emotional monitoring among older adults remains limited [20]. Most current studies have mainly focused on usability testing or technical feasibility, such as investigating conversational agents, social platforms, and mobile apps for emotional well-being in older adults [28-31]. And these studies mainly adopted in-depth qualitative evaluation or user testing, providing valuable insights into user experiences and contextual needs. However, they generally do not extend to systematic or quantitatively prioritized design frameworks that integrate technological, emotional, and psychological factors. To address this gap, this study developed a user-centered framework for interface design in loneliness monitoring technologies for older adults. By integrating qualitative focus group analysis, systematic literature search, and expert consultation, this study established a comprehensive design indicator framework based on the analytic hierarchy process (AHP) [32]. Interface design solutions were then developed according to these indicators and evaluated using the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) [33]. Building on the DELONELINESS (Design for Healthy Ageing: a Smart System to Decrease Loneliness for Older People) smart textile loneliness monitoring system we previously developed [34], we aimed to construct a hierarchical design indicator model reflecting the cognitive, emotional, and functional needs of older adults. Expert consensus was used to assign weights to these indicators, followed by the development and evaluation of interface design solutions. Through this process, the study generates a quantified prioritization of interface design requirements for loneliness monitoring in older adults and provides an evidence-based decision model that can be adapted to other age-friendly digital mental health interfaces. This integrated approach bridges user-centered design principles with data-driven decision analysis, providing a solid foundation for the future development of digital mental health technologies and interactive platforms for older adults.

Methods

Study Design



This study applied a mixed method to prioritize interface design indicators and to develop interface solutions for the DELONELINESS system for older adults. The DELONELINESS system is a smart garment and furniture-based platform designed to monitor loneliness in older adults [34]. Through its associated user interfaces, the system provides older users with real-time feedback on various physiological and behavioral parameters such as heart rate, respiration rate, and daily activity levels, while also visualizing the current loneliness

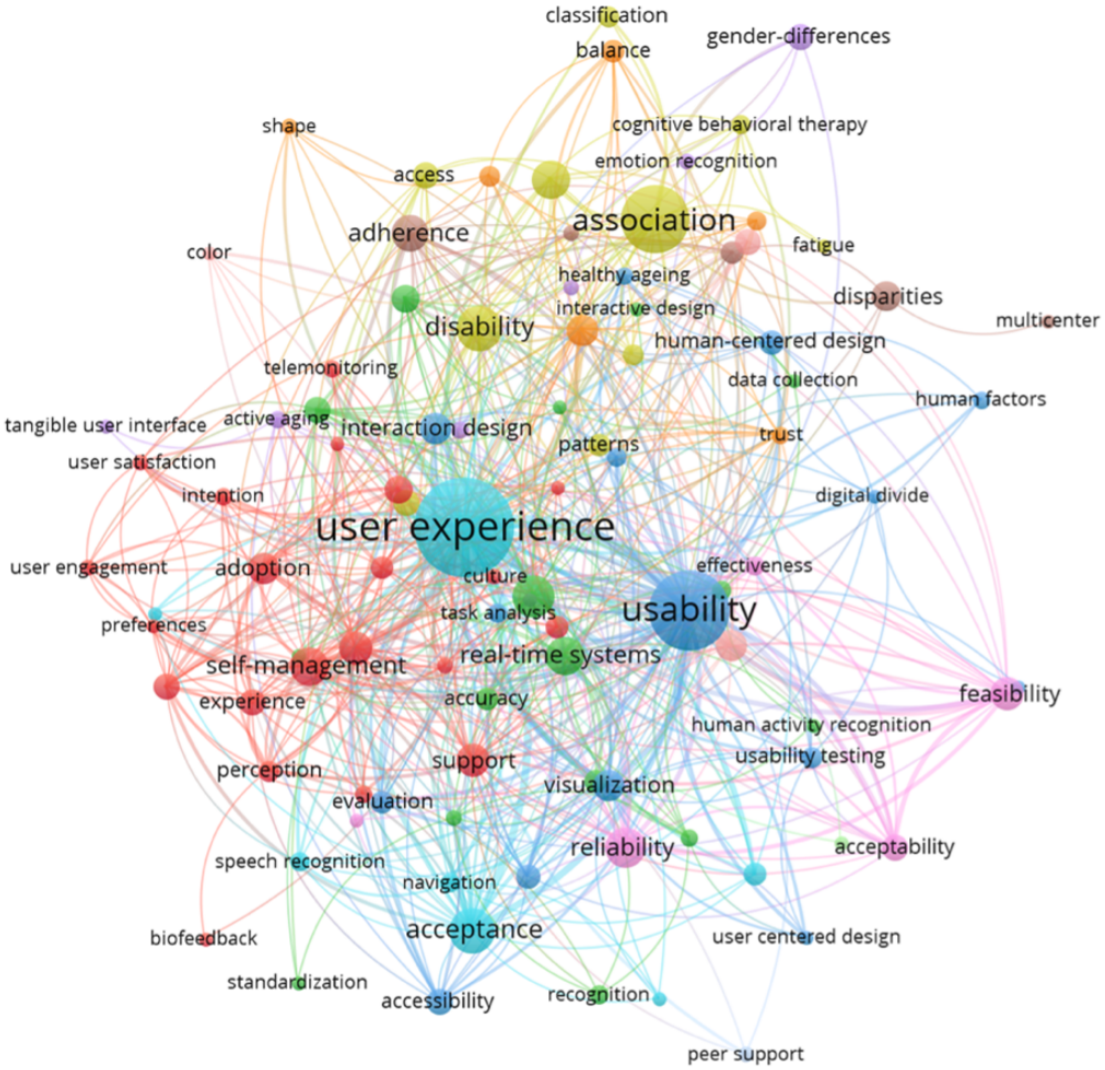
XSL•FO
RenderX

status and offering recommendations for health-promoting activities.

An initial pool of design indicators was constructed based on a literature review and qualitative analysis of previous focus groups with older adults [34]. Following screening by experts of human-computer interaction (HCI), an AHP survey was conducted to determine the relative weights and priorities of the indicators. To further verify the applicability of the design indicators derived from the AHP analysis in actual interface structures, an eye-tracking experiment was conducted to compare different interface layouts in terms of information accessibility and cognitive clarity. Then, the findings of the eye-tracking experiment and user requirements with higher weight values derived from AHP were integrated to produce three interface design solutions for comparative analysis. Finally, the design solutions were evaluated using the TOPSIS to validate their overall feasibility. The research process is presented in Figure 1.

Figure 1. The research process. AHP: analytic hierarchy process; TOPSIS: Technique for Order Preference by Similarity to Ideal Solution.

XSL•FO
RenderX



Construction of Initial Indicator Pool

The initial indicator pool was constructed based on a comprehensive literature search and qualitative analysis of focus groups with older adults. The literature search was conducted across 4 major databases including IEEE Xplore, ACM Digital Library, Scopus, and Web of Science to identify studies related to older adults, health technology platforms, and interface design. The search string was defined as:

("older adults" OR "aging people" OR "aging" OR "senior citizens" OR "elderly") AND ("interface design" OR "user interface" OR "interaction design" OR "human computer interaction" OR "user experience") AND ("loneliness monitoring" OR "mental health" OR "psychological wellbeing" OR "digital health")

From the search results, 3522 highly relevant papers with more than 10 citations were selected for further analysis. First, nondescriptive and generic terms (such as "health" and "technology"), as well as duplicates were removed. Additionally, high-frequency terms were extracted using term frequency–inverse document frequency analysis and visualized [35]. As shown in Figure 2, the node size and color represent word frequency, with larger nodes indicating higher frequency, while node color represents keyword clustering. From this analysis, high-frequency terms were synthesized into preliminary interface-related indicators such as usability, feasibility, accessibility, and reliability.

Figure 2. Co-occurrence analysis of high-frequency terms in research of digital health and interface design for older adults.

Additionally, qualitative thematic analysis was conducted on the results of our previous focus groups with older adults [34]. These focus groups explored older users' lived experiences of loneliness, expectations, and concerns regarding digital health and monitoring technologies for loneliness across diverse living contexts. The transcripts were coded using open coding. Two researchers independently coded data and resolved discrepancies through discussion to ensure consistency. Statements and discussion related to comprehensibility, trust and safety, emotional comfort, and personalization of user interfaces were coded (Multimedia Appendix 1). These findings provided a user-centered perspective and complemented the design requirements identified through the literature search.

By integrating results from both the literature and focus group analysis, an initial indicator pool comprising 8 first-level and 42 second-level indicators was established to demonstrate different aspects of user interface design for loneliness

XSL•FO
RenderX

monitoring in older adults. Then, consultation was undertaken with 8 experts in HCI design. These experts were not involved in the AHP survey. They reviewed the combined results of the literature review and focus group analysis, deleted redundant or overlapping items, and suggested additional indicators where appropriate. Finally, a refined hierarchical indicator structure containing 7 first-level indicators and 26 second-level indicators was determined.

Inclusion Criteria of Experts

To evaluate and prioritize the interface design indicators, experts were recruited to participate in the AHP survey. To ensure the validity and reliability of the weighting results, the inclusion criteria for experts were as follows: (1) professional background: experts were required to have academic or professional expertise in HCI, digital health, gerontology, or health informatics; (2) experience: at least 5 years of professional experience in the relevant fields; (3) academic or professional rank: an intermediate level or higher professional title; and (4) voluntary participation: willingness to participate in the survey and agreement of informed consent for the use of their responses in the research.

A total of 23 experts meeting the above criteria were invited to participate. 20 out of 23 (86.96%) experts completed the questionnaire. All these experts held a master's degree or higher and were mainly composed of university lecturers, postdoctoral researchers, clinical experts, and industry professionals with work experience in HCI design and digital health. The demographic characteristics of the experts are summarized in Table 1.

Weight Assignment of Indicators

Based on the refined indicator pool, we developed an AHP questionnaire (Multimedia Appendix 2) comprising 7 first-level indicators and 26 second-level indicators. The questionnaire was structured as a pairwise comparison matrix, requiring experts to judge the relative importance of each indicator in relation to the others. To guide the evaluation, we adopted the Saaty 1 to 9 scale, which is widely applied in multicriteria decision analysis [32]. On this scale, a score of "1" represents equal importance, while larger odd numbers indicate greater importance, such as "3" (moderate importance), "5" (strong importance), "7" (very strong importance), and "9" (absolute importance). Even numbers (2, 4, 6, and 8) were used to allow for more nuanced judgments between categories. This structured approach ensured that expert evaluations could be translated into quantitative weights for each indicator [36,37]. The survey was distributed via email to 23 eligible experts, and 20 experts completed the questionnaire.

XSL•FO
RenderX

The collected data were first entered into Microsoft Excel and then imported into SPSS software (version 29.0.2.0; IBM Corp) to calculate the weights of both first-level and second-level indicators. For each judgment matrix, the largest eigenvalue and its corresponding eigenvector were calculated to determine the relative weights of indicators. The consistency ratio (CR) was used to verify the logical consistency of expert judgments, with CR <0.1 indicating acceptable consistency. To further assess the degree of agreement among experts, the Kendall coefficient of concordance (Kendall W) was applied, with values ranging from 0 to 1, where higher values represent greater agreement [38]. Results were considered statistically significant when $P<.05$. Finally, the resulting pairwise comparison matrix from all experts was integrated to obtain the final weight of each indicator. The weighted values were normalized so that the sum of all indicator weights equaled 1. These results provided a prioritized structure of interface design requirements, informing the design of following user interface solutions.

Development of Design Solutions

After the weight assignment of design indicators through AHP, we examined the applicability of the prioritized indicators to interface layouts. At this early prototyping stage, an eye-tracking experiment was conducted to inform layout selection and structural design decisions rather than to evaluate end-user experience. The eye-tracking study was designed to assess how different layout types (list-detail, grid, and feed layouts) influenced information localization and visual-cognitive efficiency within the DELONELINESS application. A Tobii Fusion eye tracker (60 Hz) was used to record gaze behavior. The participants were the same 20 experts who had taken part in the previous AHP evaluation. Each expert completed information search tasks in various layout types through locating specific interface elements and triggering screen transitions by clicking on the target area. The system automatically recorded each participant's gaze trajectory and task completion time.

We analyzed 2 primary performance metrics, including gaze path distribution and task completion time (TCT). Based on the results, 3 user interface design solutions were developed. These design solutions varied in layout and user experience but were all aligned with the prioritized requirements identified in the weight assignment stage.

Evaluation of Design Solutions

To evaluate the feasibility of these 3 design solutions, the same group of experts from the AHP phase was invited to participate in a structured assessment. Experts rated each design solution against the indicators obtained from the previous AHP analysis. Ratings were collected using a 9-point Likert scale, ranging from 1 ("Strongly Disagree") to 9 ("Strongly Agree") to quantify the performance of each design solution across the 7 first-level and 26 second-level indicators. After collecting the ratings, the highest and lowest values were excluded, and the mean of the remaining scores was calculated as the composite score for each solution.

To evaluate the reliability of expert ratings, the intraclass correlation coefficient (ICC) was computed. A 2-way random mixed model with absolute agreement was applied. ICC values greater than 0.60 were considered indicative of good consistency, while values above 0.75 indicated excellent consistency. Additionally, we applied the TOPSIS to calculate the evaluation score for each design solution. This method constructs an ideal solution (the best performance across all indicators) and a negative ideal solution (the worst performance across all indicators) and measures the relative distance of each design alternative to these 2 reference points [33]. By calculating the closeness coefficient, these 3 solutions were ranked and the most suitable interface design for the DELONELINESS system was identified.

Ethical Considerations

This research received ethical approval from the Research Ethics Committee of King's College London (reference: LRS/DP-24/25 - 34602). Prior to participation, all participants received a participant information sheet and a consent form via email, which outlined the study objectives, participants' rights, and the voluntary nature of participation. Electronic informed consent was obtained before data collection. Files containing participants' names and contact details were stored separately from research data in password-protected documents, accessible only to the core research team. No compensation was provided for participation.

Results

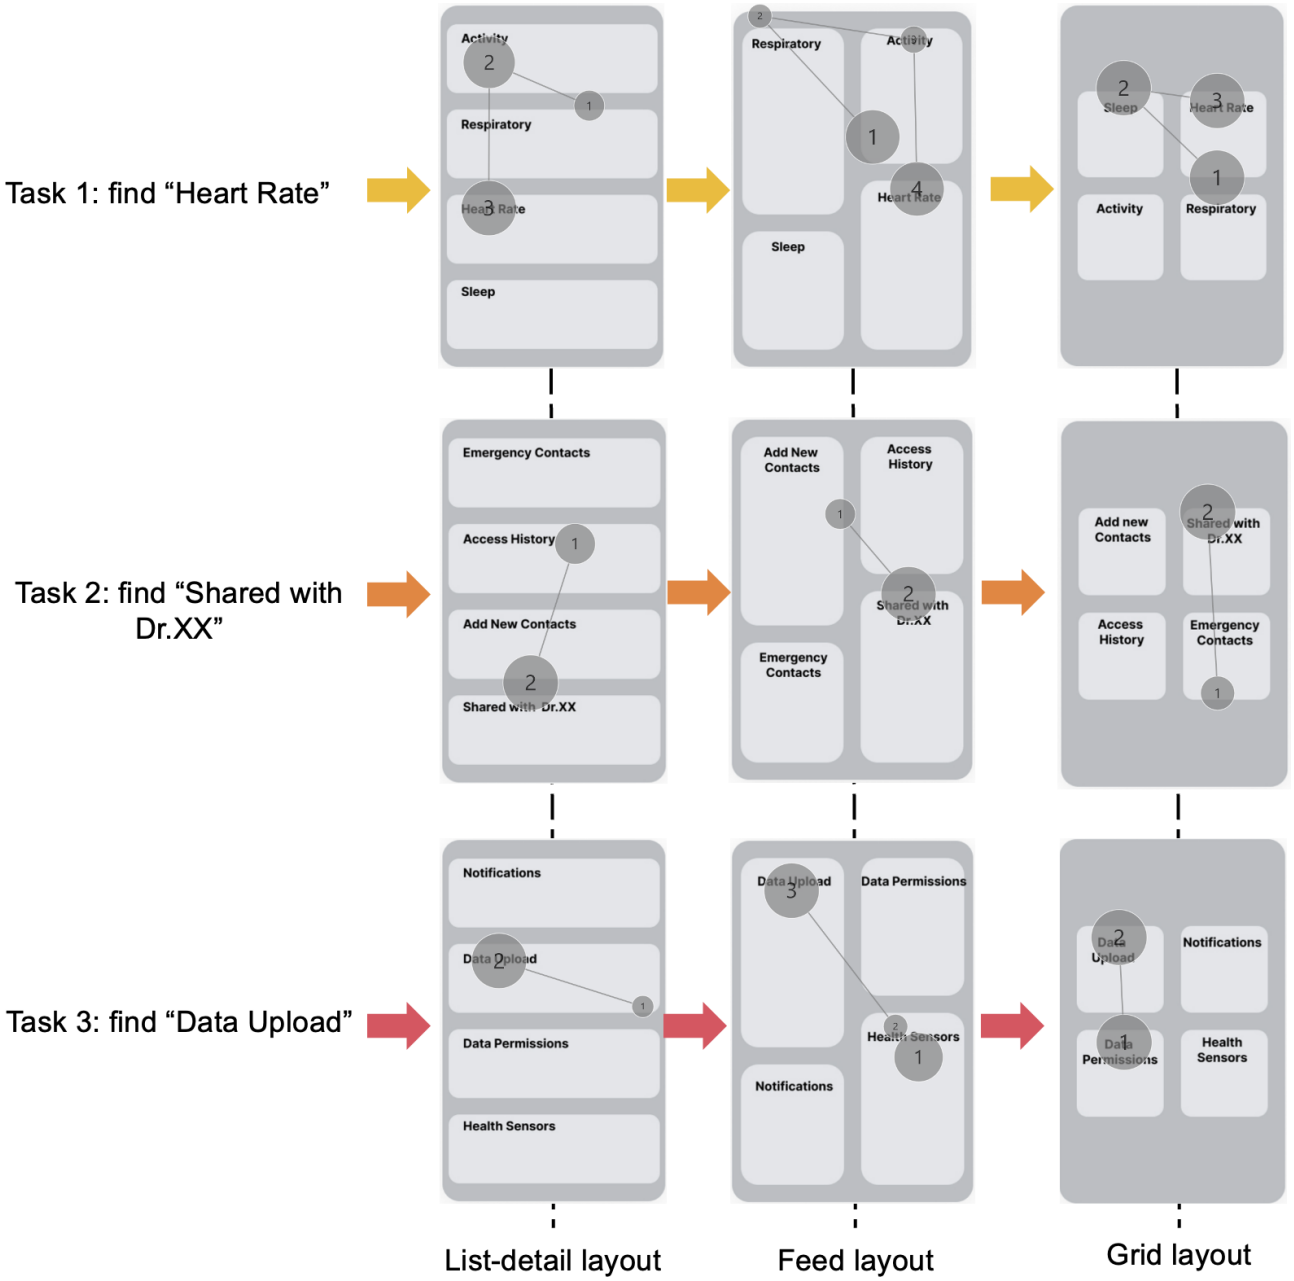
Weight Assignment of Indicators

To evaluate the reliability of expert judgments, a consistency test was performed on each expert's pairwise comparison matrix. The CR of all matrices was less than 0.1, indicating that all expert judgments met the consistency requirement. In addition, to assess the overall agreement among experts in judging the importance of indicators at each hierarchical level, the Kendall W was calculated for both first and second-level indicators. The Kendall's W value was 0.313 for the first-level indicators ($\chi^2=37.606$, $P<.001$) and 0.156 for the second-level indicators ($\chi^2_1=59.286$, $P<.001$). These results demonstrate a satisfactory level of logical consistency among experts, supporting the validity of further weight calculation and coordination analysis.

After the consistency test, the AHP was applied to calculate the normalized weights and combination weights of each indicator. The detailed weighting results are presented in Multimedia Appendix 3. Among the first-level indicators, trust and safety (0.206) had the highest overall weight, followed by ease of use (0.187) and accessibility (0.167), indicating that these dimensions were considered the most critical factors in the interface design of the DELONELINESS system. In contrast, emotional comfort (0.080) and personalization (0.092) had relatively lower weights. At the second level, the highest-weighted indicators included user ability to modify permissions (0.084), clear interaction pathways (0.667), and transparent data collection (0.566), showing that user autonomy and system transparency were regarded as key determinants of older user trust and engagement. Other highly ranked indicators, such as offline usability under poor network conditions (0.550) and clear interaction areas (0.521), highlight the importance of system robustness and interface clarity for older adult users.

XSL•FO
RenderX

Overall, these findings indicate that experts prioritized factors that enhance trust, safety, and operational simplicity over purely aesthetic or emotional aspects. The resulting hierarchical weighting structure provided a quantitative foundation for the further design and evaluation of user interface solutions.



Development of Design Solutions

In the interface design of the DELONELINESS system, we first examined how different layout structures influenced visual-cognitive efficiency and interaction performance. A one-way ANOVA was conducted to analyze the eye-tracking data across different interface layout types. The results revealed significant differences in TCT (P<.05), indicating that interface structure had a significant impact on visual localization efficiency and interaction performance.

Among the 3 layouts, the list–detail layout performed best on TCT (mean 1.33, SD 0.33), lower than the grid layout (mean 1.37, SD 0.33) and the feed layout (mean 1.76, SD 0.65). These findings suggest that the list-detail layout more effectively guided visual attention, reduced information retrieval load, and improved task execution efficiency.

As shown in Figure 3, the list-detail layout showed a more focused and linear visual scanning path, with fixation points concentrated in core information areas. In contrast, the grid layout produced multiple scattered fixation hotspots, whereas the feed layout presented more diffuse but continuous scanning patterns. Overall, the list-detail layout demonstrated outstanding visual and operational efficiency, providing evidence for the following interface prototype design.

Figure 3. Gaze paths across 3 interface layout types in different tasks.

Based on these findings, the hierarchical weighting structure derived from the AHP was integrated into the interface design process. Among all design indicators, trust and safety, ease of use, and accessibility were identified as the most important

XSL•FO
RenderX

dimensions. Therefore, 3 interface design solutions were developed (Figure 4). Each design followed the same hierarchical weighting framework and maintained a consistent functional architecture, including the home, data, activities, sharing, and privacy modules. However, they differed in the expression and emphasis of high-priority dimensions.

Figure 4. User interface design solutions for DELONELINESS (Design for Healthy Ageing: a Smart System to Decrease Loneliness for Older People) system: (A) design solution 1, (B) design solution 2, and (C) design solution 3.

As shown in Figure 4, design solution 1 prioritizes trust and safety and comprehensibility by providing users with transparent control over their data and privacy settings. The homepage displays a simplified loneliness status section, using soft colors and positively framed language to convey feedback. Below, the section titled "What's Happening With Your Data?" allows users to quickly access information about ongoing data collection and its purposes. The "Share and Contacts" page visualizes access permissions and emergency contacts and enables users to view their data-sharing history, which enhances both their sense of security and control. Within the "Privacy Center," users can manage notifications and data permissions and pause data uploads at any time.

Design solution 2 (Figure 4) focuses on ease of use and comprehensibility, addressing users' needs for clarity and intuitive interaction. The homepage features a large central status indicator, accompanied by a simplified health score and encouraging feedback. Navigation follows a linear guided structure to reduce users' cognitive load. Users can access "Quick Controls" for notifications and data uploads, while the "Privacy" section integrates all permission settings in an intuitive toggle-based layout. Additional cues such as tooltips and contextual guidance can help older adults navigate unfamiliar interactions. This design emphasizes clear interaction pathways and immediate guidance, enhancing operational ease and user confidence during daily use.

Design solution 3 (Figure 4) emphasizes accessibility and ensures usability under unstable network conditions. The interface adapts seamlessly across smartphones and tablets and supports a low-bandwidth mode to enable offline access. Key health and loneliness indicators can remain available locally and synchronize automatically once connectivity is restored. The "Accessibility" section offers high-contrast modes, enlarged fonts, and voice-assist features, improving inclusivity and reliability. This design ensures that the system remains usable for older adults with sensory limitations or those living in poor network environments.

Evaluation of Design Solutions

To evaluate the feasibility of these three design solutions, the TOPSIS was applied to compare their performance and identify the optimal interface design for the DELONELINESS system. First, experts rated each design solution across 7 first-level and 26 second-level indicators using a 9-point Likert scale. To assess the reliability of expert ratings, the ICC was calculated. The ICC values for design solution 1, design solution 2, and design solution 3 were 0.761, 0.653, and 0.747, respectively. All ICC values exceeded 0.6, indicating moderate to good consistency among experts. The mean scores of each design solution are shown in Table 2. At the first indicator level, design solution 2 achieved the highest mean scores across most dimensions, particularly in comprehensibility (6.39), ease of use (6.50), and feedback and support (5.67), demonstrating its guided and

XSL•FO
RenderX

user-friendly interaction design. Design solution 1 emphasized trust and data transparency and achieved the highest score in trust and safety (6.17). Design solution 3 focused on accessibility and obtained the relatively higher scores in accessibility (5.23) and comprehensibility (6.22). At the second indicator level, design solution 2 achieved higher average scores in clarity of visual elements (6.61), consistency of interface layout (6.33), and clear interaction areas (6.28), suggesting experts' preference for its clear visual hierarchy and intuitive structure. Design solution 3 performed well in cross-device access (5.43), multisystem compatibility (5.33), and accessibility support functions (4.61), indicating good robustness in supporting diverse usage contexts. Although design solution 1 received slightly lower overall scores, it performed best in transparent data collection (6.17) and user authorization of functions (6.06), demonstrating perceptions of trust and control.

Table . Mean expert ratings of the 3 interface design solutions.

	Design solution 1	Design solution 2	Design solution 3
First-level indicators, mean (SD)			
Comprehensibility	5.28 (0.82)	6.39 (1.14)	6.22 (1.07)
Ease of use	5.26 (1.05)	6.50 (0.64)	6.06 (1.02)
Trust and safety	6.17 (0.98)	5.61 (1.32)	6.11 (1.00)
Feedback and support	5.06 (1.00)	5.67 (1.27)	5.39 (0.82)
Emotional comfort	4.22 (0.72)	5.33 (1.17)	5.22 (1.05)
Personalization	4.22 (1.02)	5.11 (1.15)	5.06 (0.92)
Accessibility	4.44 (0.70)	4.78 (1.23)	5.23 (1.09)
Second-level indicators, mean (SD)			
1.1 Consistency of interface layout	5.17 (1.19)	6.33 (1.45)	6.22 (0.91)
1.2 Clarity of visual elements	5.11 (1.06)	6.61 (1.67)	6.28 (1.08)
1.3 Simplicity of information content	4.94 (1.14)	6.22 (1.38)	6.39 (0.97)
2.1 Clear interaction areas	5.06 (1.08)	6.28 (1.76)	6.06 (1.15)
2.2 Support for multimodal interaction	5.28 (1.16)	6.33 (1.62)	5.83 (0.87)
2.3 Easy correction of errors	5.28 (0.98)	6.22 (1.72)	6.28 (1.02)
2.4 Clear interaction pathways	5.17 (1.14)	6.00 (1.34)	6.06 (1.19)
3.1 Transparent data collection	6.17 (0.94)	6.11 (0.91)	5.72 (1.29)
3.2 User authorization of functions	6.06 (1.15)	6.00 (1.02)	5.96 (1.22)
3.3 User ability to modify permissions	5.39 (0.92)	5.72 (1.21)	5.67 (1.03)
4.1 Real-time health status feedback	4.78 (1.16)	5.50 (1.28)	5.56 (1.19)
4.2 Immediate guidance	4.56 (1.14)	5.22 (1.54)	5.61 (1.33)
4.3 Online assistance	4.50 (1.32)	5.33 (1.44)	5.39 (0.94)
5.1 Emotionally supportive language	4.11 (0.97)	5.06 (1.46)	5.11 (1.04)
5.2 Emotionally supportive images	4.39 (0.94)	5.28 (1.52)	5.28 (1.12)
5.3 Integration with daily life scenarios	4.50 (1.06)	5.28 (1.27)	5.00 (1.21)
6.1 Customizable fonts	4.06 (1.23)	4.89 (1.41)	4.94 (1.10)
6.2 Customizable language	4.39 (1.05)	4.72 (1.59)	4.89 (1.02)
6.3 Customizable notifications	4.00 (1.05)	4.78 (1.35)	4.83 (1.27)
6.4 Customizable mode	4.39 (0.98)	5.00 (1.52)	5.06 (1.34)
6.5 Customizable mood input	4.28 (1.17)	4.89 (1.63)	4.83 (1.06)
7.1 Cross-device access	4.33 (0.91)	4.61 (1.38)	5.43 (1.04)
7.2 Multisystem compatibility	4.28 (0.89)	4.72 (1.59)	5.33 (1.15)
7.3 Accessibility support functions	4.17 (0.76)	4.44 (1.41)	4.61 (1.29)
7.4 Offline usability under poor network conditions	4.22 (0.78)	4.78 (1.61)	4.98 (1.38)

XSL•FO
RenderX

Based on the expert ratings and the AHP indicator weights, the TOPSIS method was used to evaluate the performance of the 3 design solutions. The distances to the positive and negative ideal solutions and the overall closeness coefficients are presented in Table 3. The results showed that design solution 2 had the highest overall score, followed by design solution 3 and design solution 1. These findings indicate that design solution 2 was closest to the ideal interface configuration, which can offer the best balance of trust, usability, and accessibility.

Table . Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) evaluation of design solutions.

	Distance to positive ideal solution (D^+)	Distance to negative ideal solution (D^-)	Relative closeness (C)	Ranking
Design solution 1	0.999	0.002	0.002	3
Design solution 2	0.132	0.942	0.877	1
Design solution 3	0.318	0.855	0.728	2

Discussion

Principal Findings

This study aimed to construct a user-interface design indicator model for the DELONELINESS system, a smart textile system for monitoring loneliness among older adults. To comprehensively integrate design requirements for health technology platforms targeting older users, we applied a mixed methods approach, combining a systematic literature search, qualitative focus group analysis, and expert consultation. These processes led to the construction of a design indicator framework, consisting of 7 first-level indicators and 26 second-level indicators. The AHP was then applied to assign relative weights to each indicator. Based on the derived weights, 3 interface design solutions were developed and evaluated by experts using the TOPSIS to identify the optimal configuration. The findings indicate that trust and safety, ease of use, and accessibility were prioritized over other design dimensions, highlighting the central role of transparency, cognitive simplicity, and inclusive access in interface design for monitoring loneliness among older adults.

The AHP results constructed a hierarchical weighting structure. Among the 7 first-level indicators, trust and safety (0.206), ease of use (0.187), and accessibility (0.167) were identified as the most important dimensions, indicating that data transparency, simplified user operations, and accessibility under different physical and technological conditions are essential for enhancing older adults' confidence and engagement with digital systems. At the second level, user ability to modify permissions (0.084), clear interaction pathways (0.067), and transparent data collection (0.057) received the highest weights, demonstrating the key role of user autonomy and system transparency in fostering trust and usability.

Based on these priorities, three interface design solutions were developed. Each solution followed the same hierarchical framework but emphasized different high-priority dimensions. Specifically, design solution 1 focused on trust and safety, design solution 2 prioritized ease of use and comprehensibility, and design solution 3 emphasized accessibility. Expert evaluation using the TOPSIS method revealed that design solution 2 achieved the highest overall score (C=0.877), followed by design solution 3 (C=0.728) and design solution 1 (C=0.002). These findings suggest that interfaces emphasizing clear interaction pathways, visual clarity, and immediate feedback achieve the most effective balance among trust, usability, and accessibility for older users.

Implications for Practice and Research

In recent years, digital health technologies have played an increasingly important role in addressing loneliness and improving psychological well-being among older adults. Loneliness monitoring platforms, telehealth systems, and mobile mental health apps mainly applied wearable sensors, mobile devices, and AI-driven analytics to provide continuous monitoring and personalized interventions. These systems have shown great potential in detecting early psychosocial risks and promoting engagement in remote health care, particularly for older adults who have limited social support. However, the effectiveness of these technologies largely depends on the design of user interfaces. Therefore, ensuring older users can understand, trust, and comfortably interact with these systems is essential. Furthermore, empathic interface design that resonates with the emotional and relational dimensions of loneliness is important for fostering long-term engagement and psychological support [39]. Such designs not only convey a sense of care but also help bridge the digital divide between older adults and technology, mitigating digital loneliness through inclusive design.

Current research on loneliness and emotional well-being monitoring systems for older adults has primarily focused on usability and acceptability. For example, Choi et al [40] developed a mobile loneliness intervention app, highlighting usability, feedback clarity, and emotional support as key determinants of user acceptance. Rodríguez-Martínez et al [41] proposed a conversational chatbot designed to alleviate loneliness in older adults, emphasizing the importance of privacy and autonomy in interaction design. Xing et al [42] investigated a community engagement platform that supported older adults during the COVID-19 pandemic and underscored the role of data transparency and user control in data sharing. Additionally, Bhattacharya et al [43] demonstrated that multimodal interface design integrating voice, tactile, and visual feedback enhanced the older adults' engagement and comprehension in telehealth applications. While these studies have identified recurring design dimensions such as usability, confidentiality, and accessibility, most relied on qualitative methods or usability testing. To address this gap, this study introduces a user-centered quantifiable hierarchical framework, shifting from single-factor

XSL•FO
RenderX

evaluations to a systematic and multidimensional method for assessing interactive factors.

Theoretically, we introduced a knowledge-driven design pathway grounded in both literature insights and user requirements. Through visualized analysis and keyword co-occurrence mapping of relevant publications, we constructed a research landscape of interface design for mental health technologies in older adults. The qualitative findings were further integrated from focus group discussions, leading to the construction of an initial indicator pool. This process ensured that the theoretical foundation of the framework was both systematic and progressive, enabling the model to reflect not only the expert experience and user needs but also the academic field's evolving focus and research trends. Methodologically, the study integrated the AHP and the TOPSIS to construct a quantifiable hierarchical framework. The AHP was applied to determine experts' judgments on the relative importance of design dimensions, while TOPSIS was used to comprehensively evaluate and prioritize different design solutions based on these weightings, achieving a 3-level validation process spanning theory, structure, and empirical evaluation. This approach transforms interface evaluation from subjective experience into a quantifiable decision-making process, offering a novel means of representing complex psychological and emotional factors in user interface design.

To translate the quantitative results into actionable principles for digital mental health design, we highlighted some major dimensions that received high weighting in the AHP hierarchy. First, trust and safety are the most highly weighted dimensions identified through the AHP, showing that the credibility and transparency of digital platforms are essential for sustained engagement among older adults. Furthermore, significant progress has been made in strategies for health data protection and security, such as encryption technologies, anonymization protocols, and blockchain-based solutions which can improve data privacy and integrity [44-46]. These studies have shown that clear privacy principles and controllability can reduce technology-related anxiety and increase adherence to digital health systems. In the context of loneliness monitoring, fostering user autonomy not only mitigates distrust but also transforms the interaction from passive monitoring to active self-management, thereby promoting psychological empowerment among older adults [47].

Additionally, both experts and older users expressed a strong need for clarity and cognitive simplicity when interacting with digital platforms. The design solution 2 incorporated structured task flows, step-by-step prompts, and consistent layout design, which improved expert ratings for comprehensibility, feedback and support, and ease of use. These findings suggest that guided interaction models, which provide immediate feedback, linear navigation, and supportive cues, can effectively reduce cognitive load and enhance older adults' confidence in digital self-management.

Accessibility was also identified as a key factor in age-friendly interface design. The design indicators such as offline usability under poor network conditions and accessibility support functions received high expert ratings in evaluations. However, the wireless communication technologies commonly used in smart garments and furniture such as Bluetooth and Wi-Fi still face significant challenges, particularly in terms of data quality, sampling rate, and transmission range. Data loss or latency can lead to inaccurate or incomplete monitoring, potentially resulting in misinterpretation of users' health conditions [48]. The restricted range of Bluetooth and Wi-Fi may inadvertently reduce older adults' mobility, especially in spacious living environments or outside the home, when precise data collection is required.

Finally, although personalization and emotional comfort received relatively lower weights in the AHP hierarchy, empathetic and adaptive design remains essential in the context of loneliness monitoring for older adults. This result can be interpreted considering the expert decision-making process. Emotional comfort may be implicitly contingent on more foundational interaction requirements, such as trust, safety, usability, and accessibility. This interpretation aligns with motivational models such as the Maslow hierarchy of needs, in which affective and self-related needs tend to be addressed only after the basic functional and safety needs are satisfied [49]. In the context of digital health interfaces, experts may therefore prioritize dimensions that reduce risk, uncertainty, and cognitive burden before considering emotional engagement. Loneliness is a subjective and context-dependent experience, influenced by emotional states, daily routines, and social relationships [50]. Therefore, interface personalization such as allowing users to adjust the tone of feedback, the frequency of reminders, or the interface mode plays a vital role in enabling the system to respond to diverse psychological and emotional needs. Moreover, emotionally supportive and adaptive design can increase older adults' openness to using digital mental health platforms and foster a sense of emotional stability [51]. For example, emotionally supportive language can be translated into the use of positively framed feedback messages such as "You are doing well today" rather than deficit-oriented alerts [52]. In addition, concerns about psychological acceptance and perceived intrusiveness informed design decisions that minimized the salience of continuous monitoring, such as presenting sensing functions in the background and allowing users to pause data collection or customize notifications [53]. Therefore, emotional support and adaptability should not be regarded as aesthetic additions but as ethical foundations of inclusive digital health design. The goal of digital mental health technologies is not just functional usability, but to foster psychological stability and emotional connectivity through empathic interaction mechanisms tailored to the lived experiences of older adults.

The widespread adoption of digital technologies has developed new opportunities for promoting mental health among older adults while simultaneously revealing persistent digital inequalities in contemporary society. Older populations remain at a disadvantage in terms of accessing, understanding, and trusting digital systems [54,55]. This "digital divide" stems not only from differences in individual capability but also from a broader lack of inclusivity and emotional awareness in technology design. Building on 7 key dimensions, including trust and safety, comprehensibility, accessibility, and emotional

XSL•FO
RenderX

comfort, this study proposes a multifactor hierarchical framework that reconceptualizes "usability" from an individual challenge to a societal design responsibility. This shift suggests that digital health systems should move beyond the narrow focus on "user experience" toward the broader pursuit of citizen well-being. As the interface serves as a mediator between people, society, and technology, it carries the social function of emotional connection and psychological support. Accordingly, the quantitative framework established in this study not only enhances the precision of digital product evaluation but also provides a theoretical pathway for achieving ethical inclusivity and social equity in digital health. Future research should further explore the application of this framework in policy evaluation, geriatric care service systems, and cross-cultural digital health contexts, promoting its integration into real-world practices that advance both technological innovation and social justice.

Strengths and Limitations

The innovation aspect of this study lies in the development of a user-centered quantifiable prioritization framework for interface design in loneliness monitoring among older adults. We integrated qualitative focus group analysis, literature search, and expert consultation to ensure that the final indicator system was both evidence-based and grounded in user needs. Furthermore, we applied the AHP and TOPSIS to achieve the prioritization and empirical validation of interface design solutions, providing a systematic approach for future research in digital health and HCI. In addition, within the context of loneliness monitoring for older adults, psychological and emotional dimensions were integrated into the study. These dimensions are critical for engagement, empathy, and sustained interaction of older adults, but often underrepresented in existing digital health design frameworks. By combining user-centered design principles with data-driven decision analysis, this research contributes to the emerging field of digital mental health for older populations.

However, several limitations should be acknowledged. First, although the number of experts was sufficient for AHP analysis, the limited representation from gerontology and health informatics may have constrained the diversity of perspectives from psychology, data security, and clinical care. This imbalance may have influenced the weighting outcomes by placing greater emphasis on interaction efficiency and technical feasibility, while potentially underrepresenting clinically oriented considerations such as long-term care workflows, symptom interpretation, and psychosocial support needs in later life. Moreover, emotional comfort is inherently subjective and more difficult to operationalize into discrete interface features, which may lead experts to deprioritize it relative to more tangible and measurable design dimensions within a hierarchical decision-making process. Future research should expand the expert pool to enhance representativeness and better capture affective and experiential priorities. Second, the evaluation of design solutions in this study mainly relied on expert judgment and expert-based eye-tracking assessment rather than real-world usability testing with older adults. While the use of experts was appropriate for early-stage evaluation of information architecture, expert participants may not fully represent the emotional characteristics of older adults. Future studies can validate these findings through user trials and incorporate user feedback into the iterative design process. As the user interface developed in this study was built upon our smart textile loneliness monitoring system (the DELONELINESS system), further research is required to examine the usability, accessibility, and user acceptability of the integrated system through follow-up usability testing and in-situ evaluation with older adults to verify whether expert-informed design priorities align with real-world user experiences. Finally, future work may explore the integration of this framework within broader health policy contexts, such as the United Kingdom's National Health Service digital care strategies or other international systems, to adapt the model to evolving user needs and technological ecosystems.

Conclusions

This study developed a user-centered quantifiable prioritization framework for interface design in loneliness monitoring among older adults. By integrating qualitative insights from focus groups, literature-derived indicators, and expert consultation, the study established a comprehensive design indicator system based on the AHP and evaluated design solutions using the TOPSIS. Using user-centered design principles with data-driven decision analysis, this research not only provides a systematic design framework for future research in HCI, but also bridges subjective user experience with objective design evaluation, offering practical insights for developing empathic and inclusive digital mental health technologies for older adults. Beyond the DELONELINESS system, the proposed framework can be adapted to inform the design and evaluation of other digital mental health platforms and age-friendly interactive systems by supporting structured prioritization of usability, trust, accessibility, and emotional considerations across diverse contexts.

Abstract

Background: Digital self-monitoring applications could provide individuals with macular disease with a convenient, quantitative method for tracking metamorphopsia at home; yet the usability of such tools remains to be fully established.

Objective: This study evaluated the usability of a macular quantitative square grid self-examination application, a semiquantitative, touch-based self-monitoring application for macular function.

Methods: This study used a convergent mixed methods design. The application quantifies (1) distortion severity, (2) distortion area, and (3) temporal trends through a 3-step touch interface. A total of 24 adults with neovascular age-related macular degeneration or diabetic macular edema, accompanied by self-reported metamorphopsia, participated in a single supervised test session. A 10-item System Usability Scale (SUS) was used to assess usability, and semistructured interviews were conducted to gather further insights. Quantitative data were summarized descriptively, and qualitative feedback underwent inductive thematic analysis.

Results: A total of 24 participants completed the GridMacuScan application self-assessment, the SUS questionnaire, and 11 participants completed the interview when data saturation was achieved. All eyes that showed distortion on the Amsler grid also produced positive distortion maps on the GridMacuScan application, yielding 100% diagnostic concordance. The mean SUS score was 82.1 (SD 8.7), indicating “good-excellent” usability. The inductive thematic analysis yielded four overarching themes: (1) high usability and positive overall experience, (2) perceived functional advantages, (3) shortcomings and optimization suggestions, and (4) strong willingness for continued use.

Conclusions: The GridMacuScan application demonstrated diagnostic sensitivity comparable to that of the traditional Amsler grid and received high user ratings for usability. Furthermore, it provided quantitative distortion metrics that could facilitate longitudinal disease surveillance. Future research must be conducted to validate performance in unsupervised home environments and investigate whether sustained use improves time-to-disease-progression detection and treatment outcomes.

KEYWORDS

metamorphopsia; age-related macular degeneration; diabetic macular edema; mobile health; self-monitoring; usability evaluation; tele-ophthalmology

Introduction

Macular diseases such as age-related macular degeneration (AMD) [1] and diabetic macular edema (DME) [2] are among the leading causes of irreversible central vision loss worldwide. A hallmark symptom of these conditions is metamorphopsia, a visual distortion resulting from structural changes in the macula [3]. Metamorphopsia has been identified as a sensitive functional biomarker of disease onset, progression, and therapeutic response [4,5]. In clinical settings, the timely detection of visual changes is particularly critical during intravitreal anti–vascular endothelial growth factor (anti-VEGF) therapy, where dynamic treatment decisions are contingent on subtle shifts in visual function [6].

However, suboptimal adherence remains a widespread challenge. A recent systematic review revealed that approximately 30% of patients discontinue anti-VEGF therapy before the prescribed duration, with dissatisfaction with

XSL•FO
RenderX

treatment outcomes being the most commonly cited reason (29.9%) [7], which highlights an urgent need for tools that enhance patient engagement by making treatment responses more tangible and visible. Currently, changes in visual function are primarily determined by infrequent outpatient examinations, which exhibit limited capacity for continuous patient monitoring between visits [8].

The Amsler grid, a rudimentary paper-based tool, remains the most prevalent approach for domestic monitoring of central vision due to its affordability and accessibility [9]. However, its use in daily life remains limited, potentially due to the heterogeneity of the generated data, the inability to perform quantitative assessments, the complexity of recording processes, and the difficulty in tracking trend changes [10,11], which complicates the accurate comparison of pre- and posttreatment outcomes [12]. A meta-analysis revealed substantial variability in the sensitivity and specificity of the Amsler grid, particularly in the context of AMD screening [10]. Furthermore, traditional grids may present certain challenges in terms of usability for elderly individuals, such as maintaining central fixation and accurately reporting distortions. These limitations underscore the necessity for simplified, user-friendly tools that prioritize accessibility and consistency in real-world domestic environments [13,14].

In China, structured self-monitoring of visual function among patients with retinal disease has not been widely prioritized. Although Amsler grids are occasionally distributed in paper format, especially in community and primary care settings, they are rarely integrated into standardized follow-up workflows or supported with user training [15]. This finding indicates a systemic deficiency in awareness, patient empowerment, and digital tool adoption in the management of chronic retinal disease [15].

In recent years, digital health innovations have introduced app-based tools to support remote self-monitoring of visual function [16]. Although applications such as MacuFix [17], OdySight [18], and Home Vision Monitor [19] have demonstrated efficacy in Europe and the United States, their implementation in China remains constrained by numerous barriers. For instance, the MacuFix application requires users to discriminate among 4 simultaneously presented visual fields to identify subtle distortions. This interface design presents potential cognitive and operational challenges for older adults with visual impairments [17]. In addition, the majority of these applications are deficient in localization of language, user interface design, and integration with domestic health care systems and platforms [20].

To address these challenges, we developed GridMacuScan, an application compatible with tablet devices, designed for structured, self-administered metamorphopsia assessment using a digital square grid. The name “GridMacuScan” originates from the traditional Amsler grid pattern, while incorporating the terms “macula” and “scan” to emphasize its focus on systematically monitoring and quantifying macular degeneration. The GridMacuScan application enables patients to visualize and quantify visual distortion before and after anti-VEGF treatment, providing real-time data to inform clinician decision-making and support patient self-management.

The aim of this study was to evaluate the usability and acceptability of the GridMacuScan application among individuals with macular disease using a mixed methods approach and to characterize user experience, identify potential barriers to engagement, and generate insights to inform future refinement and clinical integration.

Methods

Overview

This study followed the IDEAS (Integrate, Design, Assess, and Share) framework for developing digital health behavior change interventions [21]. According to the IDEAS framework, rigorous evaluations of digital products through large-scale randomized controlled trials should be preceded by small-scale evaluations to test potential efficacy and usability. Specifically, a questionnaire can be used to evaluate usability and satisfaction, and interviews can be conducted to gain insight into the user experiences.

Study Design

This study employed a convergent mixed methods design to evaluate the usability of the GridMacuScan application. Quantitative data were collected through a standardized survey, and qualitative insights were gathered through semistructured interviews, enabling a comprehensive assessment of the user experience. The convergent design involves the parallel collection and analysis of both types of data, subsequently merged to yield a more thorough understanding than that afforded by either method alone. This approach was selected over other mixed methods designs (eg, explanatory, exploratory, or embedded) because it allows for simultaneous triangulation of findings, balancing the strengths and limitations of each data type [22]. The study was conducted in two phases: (1) the development of the GridMacuScan application tailored for patients with macular disease and (2) a usability evaluation combining quantitative assessment and qualitative feedback.

Participation Recruitment and Eligibility Assessment

Participants were recruited from the ophthalmology outpatient department of Shanghai General Hospital between March 4 and March 22, 2025. The inclusion criteria were as follows: (1) aged 18 years or older; (2) diagnosed during outpatient consultation with AMD or DME in at least 1 eye; (3) presence of metamorphopsia, confirmed using the Amsler grid test; (4) best-corrected visual acuity ≥20/200 in the affected eye; and (5) ability to understand study instructions and complete the assessment with minimal assistance. Exclusion criteria included (1) diagnosis of advanced glaucoma, retinal detachment, or other ocular conditions known to cause metamorphopsia or interfere with central visual field assessment; (2) presence of severe cognitive impairment, motor disability, or other systemic diseases that may hinder independent operation; and (3) presence of bilateral macular disease requiring immediate intervention, which could confound the usability evaluation. For the sample size, Bastien [23] cited studies showing that the majority of usability problems can be identified in a sample of 5 to 15

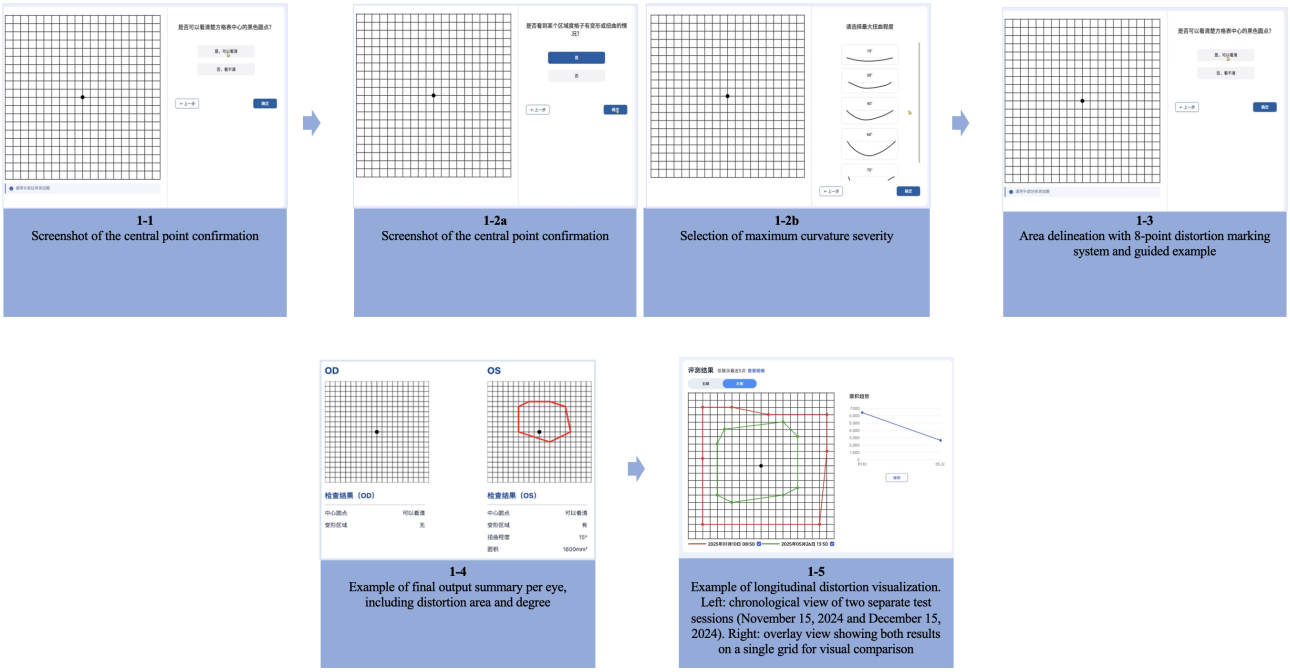
XSL•FO
RenderX

participants. Assuming a 20% dropout rate for the clinical sample, it was calculated that a minimum of 18 participants would need to be invited to participate in the study.

Development of the GridMacuScan Application

The GridMacuScan application was developed as a web-based self-monitoring tool tailored for individuals with macular disease. The name “GridMacuScan” reflects the application’s 3 core components: grid-based visualization, macular disease monitoring, and scanning for distortion. The tool was designed to enable structured, semiquantitative self-assessment of metamorphopsia via a square digital grid, providing both patients and clinicians with meaningful visual feedback over time.

This application is composed of 2 primary modules: basic information collection and dynamic disease monitoring. The basic information module is designed to collect user data, including systemic comorbidities, educational background, and other relevant demographic characteristics, which may inform the feasibility of continued follow-up and digital tool use. The dynamic monitoring module is designed to record patient-reported visual distortions, enabling the quantification of metamorphopsia changes before and after intravitreal anti-VEGF treatment.



This application also incorporates a backend management platform encompassing 2 core functionalities: data management and disease monitoring. The data module aggregates longitudinal self-assessment results to generate metamorphopsia trend profiles automatically. The monitoring module enables authorized clinical personnel (eg, retinal specialists) or system administrators to review patient-level progression patterns and intervene as deemed necessary.

Self-Assessment Workflow and User Interface Design

The GridMacuScan application’s self-assessment workflow comprises the following 3 sequential submodules:

- Step 1: Central point confirmation—Users are prompted to focus on a central black dot displayed within a digital grid and indicate whether it appears clear, blurry, or distorted. This step assesses central fixation stability and initiates the evaluation process (Figure 1).

Figure 1. Self-assessment workflow of the GridMacuScan application.

- Step 2: Severity selection—Users are required to confirm the presence of metamorphopsia (Step 2a in Figure 1). Following this confirmation, they are required to select the severity by choosing from schematic illustrations representing varying degrees of curvature (15° to 75°; Figure 1).
- Step 3: Area delineation—Users must mark the approximate spatial extent of the distortion by selecting grid cells corresponding to the affected area. A rule-based selection strategy instructs users to identify and mark the outermost boundaries of distortion along 4 cardinal directions (superior, inferior, nasal, and temporal), resulting in 8 structured anchor points. A dynamic progress bar (eg, “3/8 points completed”) and illustrative prompts were provided to enhance clarity and task completion, based on the standardized 8-point rule, which requires users to mark the outermost distorted grid lines in 4 directions (Step 3 in Figure 1).

Regarding the interface design, the GridMacuScan application prioritizes visual accessibility and ease of use. It is acknowledged that a large number of individuals with vision loss may encounter difficulties in accessing digital technologies. To address this issue, the user interface has been meticulously designed to incorporate large icons, high-contrast color schemes, and low-cognitive-load layouts. These features have been adapted for the use of older adults and individuals with low vision.

XSL•FO
RenderX

Technical Implementation and Data Visualization

From a technical standpoint, the front end was developed using Taro, a cross-platform framework based on HTML and JavaScript, ensuring compatibility across devices. The back end was implemented in Java to enhance data stability and processing efficiency. The tool was developed to be compatible with commonly available Android tablets. It was tested on an 11-inch Redmi Pad SE (Xiaomi Corporation) device designed to prioritize a basic user experience and exceptional value for money, which was selected based on its affordability, screen size, and suitability for domestic use.

In the result visualization module, the GridMacuScan application supports a multilevel display of distortion changes. After each self-assessment, the results are stored in the patient record and visualized as a quantifiable grid. Users can access their historical records and review prior results in either a chronological or layered overlay mode (Step 4 in Figure 1). The system provides date-stamped output with area and curvature comparisons, enabling users and clinicians to observe trends in metamorphopsia severity over time. In the overlay view, changes in the distortion area are visualized through color-coded outlines and anchor points, with the area growth or reduction ratios being calculated automatically to support clinical interpretation and patient engagement (Step 5 in Figure 1).

To preserve the diagnostic logic of conventional tools, the GridMacuScan application adopted a one-to-one digital replication of the traditional Amsler grid layout, as prior studies demonstrated no significant performance differences across grid densities used in electronic Amsler tests [24]. An illustration of the GridMacuScan application output interface is shown in Steps 4 and 5 in Figure 1, which display monocular detection results, including fixation clarity, distortion presence, angular distortion, and area measurement.

Procedures

To ensure the stable operation and implementation of the GridMacuScan application, a backend management team was established. This team comprised 2 research assistants, 2 ophthalmologists, and 1 software engineer. The research assistants were responsible for participant recruitment, daily user management, and backend data organization. Their duties included monitoring the usage status of all registered users, managing login activity, organizing and backing up usage data, and serving as the primary point of contact for participants encountering any operational issues while using the GridMacuScan application. The ophthalmologists conducted a clinical evaluation, with a particular focus on interpreting optical coherence tomography (OCT) images and comparing structural findings with functional outcomes captured by the GridMacuScan application. The software engineer was responsible for maintaining the technical functionality of the application, including backend monitoring of coding or logic errors, resolving system faults promptly, and performing routine updates to ensure long-term operability. The usability evaluation was conducted by the research assistants after the testing period, using both a standardized questionnaire and semistructured interviews to assess user experience and gather feedback for future refinement.

Data Collection

Testing Preparation and Participant Training

Before the initiation of the usability testing phase, the participants' baseline demographic and clinical information was collected, including age, sex, education level, ocular diagnosis, and current use of intravitreal medication. These data were then used to describe the sample characteristics and assess the generalizability of the study findings. Each participant was provided with a standardized user guide and underwent a concise, in-person training session conducted by the research staff. The training program incorporated step-by-step demonstrations using illustrative examples to familiarize users with the functions and operations of the GridMacuScan application. Participants were then invited to complete the full self-assessment procedure independently with minimal supervision.

Quantitative Evaluation of the Usability of the GridMacuScan Application

After completing the test, the System Usability Scale (SUS) is used to quantitatively assess the usability of the GridMacuScan application. All responses were collected anonymously in paper format. SUS is a widely adopted 10-item instrument for assessing the perceived usability of digital health tools [25]. The SUS comprises alternating positive and negative statements, each of which is rated on a 5-point Likert scale ranging from "strongly disagree" to "strongly agree." The individual item scores were transformed and summed by standard procedures and then multiplied by 2.5 to yield a total score ranging from 0 to 100, with higher scores indicating better usability.

Qualitative Assessment of the User Experience With the GridMacuScan Application

A semistructured interview was conducted to complement the quantitative assessment and to gain deeper insights into users' experiences with the GridMacuScan application. Each interview was conducted by a researcher who had undergone training in qualitative methods and lasted approximately 30 minutes. The interview process continued until data saturation was achieved, defined as the point at which no new themes emerged from 2 consecutive interviews. It is important to note that all interviews were audio-recorded and transcribed verbatim for thematic analysis. The interview guide was composed of three key questions: (1) What do you think are the main advantages of this self-monitoring tool? How does it help you manage your condition? (2) What limitations or weaknesses did you find? Do you have any suggestions on how to improve it? (3) Would you be willing to keep using this application to monitor your condition? Why or why not?

Data Analysis

Quantitative Evaluation Data of the Usability of the GridMacuScan Application

Descriptive statistics were used to summarize the participants' sociodemographic and clinical characteristics as well as their SUS scores. Categorical variables, including sex and education level, were reported as frequencies and percentages. Continuous variables, including age and SUS scores, were presented as

XSL•FO
RenderX

means and SDs. The analysis of the quantitative data was conducted using the R Studio software (version 2024.4.2.764; R Foundation for Statistical Computing).

Qualitative Assessment Results of the User Experience With the GridMacuScan Application

Following each interview, the interviewer completed the review of the audio recordings within 24 hours, completed verbatim transcription, and imported the transcripts into NVivo 14.0 (QSR International) for analysis. The transcripts were analyzed systematically using the inductive thematic analysis as described by Braun and Clarke [26]. Two researchers independently reviewed the transcripts multiple times to become thoroughly acquainted with the content. Subsequently, they engaged in open coding to identify significant statements and formulate meanings. The resulting codes were meticulously cross-checked, and any discrepancies were discussed and resolved through a consensus-based approach. The analogous codes were then grouped into subthemes, which were subsequently organized under broader themes that reflected the core dimensions of user experience. A series of illustrative quotations was selected to provide a supporting framework for the themes and subthemes that were identified.

Mixed Methods Integration

A convergent mixed methods approach was used to integrate and interpret the quantitative and qualitative findings [22]. The integration process comprised four distinct steps: (1) analyzing the quantitative data, (2) analyzing the qualitative data, (3) identifying areas of similarity or divergence, and (4) interpreting whether the findings confirmed, expanded, or contradicted each other. Confirmation was established when both data types exhibited analogous usability outcomes. The expansion resulted from the 2 data sources providing divergent yet complementary insights into the user experience. The discordance was identified when the survey and interview findings were inconsistent or contradictory, prompting further interpretive analysis.

Ethical Considerations

The ethical approval for the study protocol was obtained from the Ethics Committees of Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine (2022-KY-021). Before the study began, all participants provided written consent by signing an informed consent form. The participants were told that their participation in the study was voluntary, that they could withdraw at any time, and that all data would be kept strictly confidential and would only be accessible to the researchers. No monetary or material compensation was provided to the participants.

Results

Participants' Characteristics

A total of 24 participants were recruited from the ophthalmology outpatient department of Shanghai General Hospital between March 4 and March 22, 2025. All 24 participants completed the GridMacuScan application self-assessment and the SUS questionnaire. All 24 participants were also required to complete semistructured interviews.

The mean age of the participants was 60.2 (SD 13.9) years. The total number of participants in the study was 24, comprising 13 (54%) men and 11 (46%) women. Regarding education, 13 (54%) participants had attained college or university-level education. The employment status of the participants was evenly distributed, with 12 (50%) participants being employed and 12 (50%) retired. The majority of the participants were diagnosed with AMD (n=14, 58%), while 10 (42%) had DME. The mean number of intravitreal anti-VEGF injections received by participants was 3.5 (SD 1.8), with a median of 3 (IQR 2 - 5). A comprehensive overview of the demographic and clinical characteristics is provided in Table 1.

XSL•FO

Number of injections, median (IQR)	3 (2-5)

[a]AMD: age-related macular degeneration.

[b]DME: diabetic macular edema.

Quantitative Evaluation of the Usability of the GridMacuScan Application

Diagnostic Agreement With the Amsler Grid

Before the usability testing, all participants had been confirmed to have metamorphopsia based on traditional Amsler grid screening as per the inclusion criteria. The GridMacuScan application detected visual distortion in all 24 cases, resulting in 100% concordance with the traditional Amsler grid findings for the presence of self-reported metamorphopsia.

SUS Scores

The overall mean SUS score for GridMacuScan application was 82.08 (SD 8.68), indicating “excellent” usability according to established benchmarks (28). Item-level analysis revealed generally positive responses. For illustration, 96% (23/24) of the participants expressed an agreement or strong agreement with the statement “I found the test easy to use” (item 3). Conversely, for negatively framed items, participants indicated high usability. For instance, for the item “I found the test unnecessarily complicated” (item 2), the mean score was 3.50 (SD 0.83) on a scale where lower scores (disagreement) indicate better usability after reverse scoring. A parallel outcome was observed for the statement “I had to learn a lot before using the test” (item 10), for which the mean score was 3.71 (SD 0.46). None of the participants reported that the system was found to be overly complicated (item 8) or that extensive prior learning was required before its usage (item 10). Table 2 presents the mean scores and SDs for all 10 SUS items.

XSL•FO
RenderX

Table . Mean scores and SDs of System Usability Scale (SUS) items.

Item number	SUS item statement	Mean (SD)
1	I can well imagine using the test regularly (P)	3.16 (0.48)
2	I find the test unnecessarily complicated (N)	3.50 (0.83)
3	I find the test easy to use (P)	3.13 (0.45)
4	I think I would need technical support to use the test (N)	2.21 (0.78)
5	I find that the various functions are easy to use (P)	3.46 (0.59)
6	I think there are too many inconsistencies (N)	3.71 (0.46)
7	Most people can learn to use it quickly (P)	3.33 (0.56)
8	I find the operation very complicated (N)	3.38 (0.50)
9	I felt very confident in using the test (P)	3.25 (0.53)
10	I had to learn a lot before using the test (N)	3.71 (0.46)

Task Completion Time

The majority of sessions lasting less than 15 minutes entailed single-eye assessments, whereas those exceeding 20 minutes frequently involved bilateral testing.

Qualitative Assessment of the User Experience With the GridMacuScan Application

Data saturation was achieved after conducting 11 consecutive interviews with participants. The detailed characteristics of the participants are shown in Multimedia Appendix 1.

The thematic analysis of the interview data yielded 4 main themes and 7 subthemes regarding user experience with GridMacuScan. The primary themes that emerged from this analysis were as follows: (1) overall positive experience and ease of use, (2) perceived advantages of GridMacuScan, and (3) shortcomings and optimization suggestions. A detailed summary of themes, subthemes, and illustrative participant quotes is presented in Table S2 in Multimedia Appendix 2.

The participants' reports indicated a predominantly positive experience, with frequent emphasis on highlighting the tool's ease of use. Several key advantages were identified, including the ability to dynamically evaluate and continuously track visual distortion, the convenience of the tool, and an increased sense of confidence in their treatment. The suggestions for improvement primarily focused on developing a WeChat mini-program version to enhance accessibility and optimizing certain module functions, such as providing more detailed feedback on the degree of distortion. The majority of participants also expressed a strong willingness to continue using the GridMacuScan application for self-monitoring.

Mixed Methods Integration

Furthermore, the qualitative findings provided a more in-depth perspective on the specific aspects that contributed to the positive usability scores. For instance, while SUS item 3 ("I find the test easy to use") demonstrated a high score, interview data revealed that features such as a "clear and concise interface" contributed to this perception (Patient 1 quote). Similarly, the mean task completion time was 12.3 (SD 4.96) minutes, indicating the practicality of the proposed application, which was corroborated by qualitative comments on the convenience of the tool.

The quantitative finding that 23 (95.8%) participants would "imagine using the test regularly" (SUS item 1, if this is the interpretation of that item's score from Table 2) was strongly echoed in the qualitative interviews, where a dedicated theme "Hope to continue using" emerged, with participants expressing a clear willingness to integrate the GridMacuScan application into their routine monitoring.

Qualitative feedback also identified areas for future improvement that were not explicitly captured by the SUS, such as the desire for a WeChat mini-program and enhanced analytical features. These suggestions offer valuable insights for future improvements to GridMacuScan, even with its current high usability scores. In general, there was no significant discordance observed between the quantitative and qualitative results. Indeed, the qualitative data effectively served to confirm and expand upon the quantitative usability assessment.

Discussion

Principal Results

The main findings of this study were that the GridMacuScan application demonstrated excellent usability, as evidenced by a high mean SUS score of 82.08 (SD 8.68), and the quantitative result was strongly corroborated by our qualitative findings, where "High usability and positive overall experience" emerged as a dominant theme. The participants frequently described the tool as "simple and intuitive'" and "easy to use." In addition, the tool demonstrated 100% concordance with the traditional Amsler grid in detecting the presence of metamorphopsia and was completed within a feasible timeframe, with a mean completion time of 12.3 (SD 4.96) minutes.

Although traditional self-monitoring tools, such as the Amsler grid, have been employed in macular disease care, digital health innovations offer novel opportunities to overcome the inherent limitations of static, paper-based methods [27]. With the increasing use of anti-VEGF therapies for conditions such as

XSL•FO
RenderX

neovascular AMD and DME, the clinical emphasis has shifted toward long-term monitoring and adherence [28,29]. In this context, the GridMacuScan application signifies a substantial advancement in patient-centered monitoring. Through its intuitive digital interface and standardized 3-step process, it enables the structured, quantifiable, and systematic capture of distortion severity and spatial extent, making it suitable for remote use and serial tracking [6]. The integration of a patient-centered interface with quantitative output effectively addresses the key limitations of paper-based grids, which are often underused in clinical practice due to their noninteractive nature and limited ability to support disease monitoring [17,30].

The design of the GridMacuScan application was guided by the principle of maximizing usability for home-based, semiquantitative monitoring, particularly among older adults. Consequently, we deliberately avoided incorporating features such as eye-tracking or fixation correction, as the added complexity could compromise adoption and ease of use. During design discussions, the tool's visual grid structure and rule-based distortion marking were deemed sufficient for detecting meaningful changes in perceived distortion. This focus on accessible self-monitoring underscores the tool's intended role: it is not meant to replace clinical imaging modalities, such as OCT, but to complement them by supporting regular patient engagement and symptom tracking between visits.

The GridMacuScan application shows significant promise as a tool to augment standard care for patients with macular disease. Its high usability suggests that it could be feasibly integrated into clinical workflows to empower patients with structured self-monitoring, bridge the monitoring gap between clinic appointments, and improve communication and shared decision-making. The backend platform, which aggregates data for clinician review, provides a direct pathway for integrating patient-generated health data into treatment plans.

A primary strength of this study is its rigorous mixed methods convergent design. By integrating quantitative SUS data with rich qualitative insights from interviews, we achieved triangulation of our findings, providing a more robust and comprehensive understanding of the user experience than either method could alone. Furthermore, the study was conducted with the target clinical population—patients with confirmed AMD and DME recruited from an ophthalmology outpatient department—enhancing the real-world relevance of our findings.

However, this study still has several limitations that need to be acknowledged. First, the sample size, although appropriate for identifying key usability issues (N=24), is relatively small and may limit the generalizability of the findings. Second, the participants were recruited from a single, large academic hospital in Shanghai, and a high proportion (n=13, 54%) had a college-level education or higher. This population may not be representative of patients in community or rural settings, who may exhibit different levels of digital literacy. Finally, the study focused on short-term usability rather than long-term utility, which is a key limitation and a crucial aspect that should be considered in future research. Although it was determined that users could operate the tool effectively during an initial encounter, the investigation did not extend to examining whether they would maintain engagement and adhere to regular use over time. Consequently, the ultimate clinical efficacy of the GridMacuScan application, whether its sustained usage results in discernible benefits, such as the earlier detection of disease progression or improved treatment outcomes, remains unmeasured.

To address the study's limitations and build upon its potential, future research should focus on the following key fronts. First, the tool's real-world performance and quantitative outputs must undergo rigorous validation. This entails conducting both unsupervised, home-based studies and longitudinal research to correlate GridMacuScan metrics with objective OCT findings. Second, establishing clinical efficacy is of the utmost importance. A large, multicenter randomized controlled trial is required to rigorously measure long-term adherence and its ultimate impact on clinical outcomes, such as earlier detection of disease progression and changes in treatment frequency. Finally, to ensure long-term values and scalability, implementation research should investigate ways to integrate the GridMacuScan application into existing telemedicine platforms and clinical workflows, thereby ensuring its utility across larger and more diverse patient populations.

Conclusions

This mixed methods study found that the GridMacuScan application is a highly usable and acceptable tool for self-monitoring of metamorphopsia among patients with macular disease in China. It effectively addresses the known limitations of the traditional Amsler grid by providing a quantitative, trackable, and engaging user experience. However, further validation is required to ascertain its long-term adherence and clinical efficacy in a larger trial. The GridMacuScan application is a promising digital health solution with the potential to enhance patient self-management, improve engagement with therapy, and ultimately, support better clinical outcomes in the management of chronic retinal conditions.

Abstract

Background: Antenatal care has been crucial in reducing maternal mortality. Currently, screening programs of pregnant women include blood pressure (BP) measurements, urine protein tests, and the identification of risk factors. Home monitoring can enhance the early detection and management of pregnancy-related hypertension, while also empowering women to take an active role in their own health care.

Objective: This study aimed to evaluate the reliability and accuracy of contactless BP monitoring using the Anura smartphone app and to compare it to conventional manual cuff measurements. This was done in normotensive and high-risk pregnancies, as well as in women diagnosed with preeclampsia. A secondary objective was to assess women's experience using the Anura app.

Methods: Pregnant women with normotensive or high-risk pregnancies were enrolled from pregnancy weeks 8 - 14, and women with preeclampsia were enrolled at the time of diagnosis. The 3 study groups consisted of 132 women with normotensive pregnancies, 40 women with high-risk pregnancies, and 87 women with preeclampsia. They were instructed to use the Anura smartphone app and perform a 30-second facial scan, alongside manual BP measurements, throughout pregnancy. Differences between the 2 methods were analyzed with linear mixed models accounting for repeated measures, reporting beta coefficients with 95% CIs, stratified by patient group and trimester. Outliers were detected visually in the Bland-Altman plots. A digital survey was answered in the Anura app at gestational weeks 37 - 39, about their experiences using the Anura app.

Results: A total of 4932 BP measurements were recorded with Anura, of which 539 had corresponding manual measurements. In normotensive pregnancies, Anura consistently showed slightly higher diastolic values (approximately 5 - 7 mm Hg) and lower systolic values, with significant differences in the second and third trimesters. In high-risk pregnancies, both the systolic and diastolic BP were generally lower with Anura, especially in the second and third trimesters, while women with preeclampsia showed the largest differences, with Anura clearly showing lower systolic and diastolic values. Bland-Altman analyses confirmed these patterns and showed increasing variability and wider limits of agreement in the high-risk pregnancies with preeclampsia. Of 172 women with normotensive and high-risk pregnancies, 56 (32.5%) evaluated their experiences that were predominantly positive, with high perceived safety, better control, and a feeling of increased responsibility for their own health. Some experienced the measurement as somewhat uncomfortable.

Conclusions: The Anura app is well accepted by pregnant women and supported them to take an active role in their own health care. Agreement with manual BP measurements was acceptable in normotensive pregnancies but lower in high-risk and preeclamptic pregnancies. These findings indicate potential for Anura as a complementary self-monitoring tool. Further development is needed to improve the app's accuracy in high-risk groups before broader implementation can be recommended.

Introduction

Antenatal care has been the most important health care intervention when it comes to reducing maternal mortality in modern times [1]. The current national antenatal care program in Sweden includes screening of pregnant women, performing blood pressure (BP) measurements, urine dipstick tests (proteinuria), and obtaining medical history to identify risk factors [2]. Home BP measurements by pregnant women using a validated normal standard BP cuff have shown lower BP levels than measurements at the clinic and a reduced need for antenatal care visits [3,4]. However, many pregnant women find this method to be uncomfortable and cumbersome, which might increase the risk of infrequent use and, consequently, failure to discover significant BP changes associated with such pregnancy risks as preeclampsia. Noncontact and cuffless BP measurement techniques have been studied in different populations with varying results. Studies show both acceptable accuracy and significant margins of error, and reviews point to methodological limitations, particularly in studies of pregnant women [5-8].

Preeclampsia is one of the most common causes of maternal and fetal mortality worldwide and affects 3 - 8% of all pregnant women, corresponding to a total of 8.5 million women annually [9-11]. It is defined as hypertension at 140/90 mmHg after 20 weeks of gestation in combination with maternal organ dysfunction and/or intrauterine growth restriction [2]. Risk factors for preeclampsia, such as diabetes, chronic hypertension, kidney diseases, BMI >30, or African origin, are used as part of risk assessment in the first trimester of pregnancy [12,13] to provide prophylactic treatment with acetylsalicylic acid and reduce the risk of developing preeclampsia. Abnormal calcium and potassium levels have also been shown to be risk factors for pregnancy-related BP [14]. More complex screening algorithms, including biomarkers and Doppler ultrasound, such as the fetal medicine foundation model, have still not been evaluated in Sweden but recently in Denmark [15]. The fetal medicine foundation model, which combines maternal history factors with measurements of mean arterial pressure, uterine artery pulsatility index, and serum placental growth factor levels [16], is well validated but complex, requiring specially trained personnel to perform the Doppler ultrasound. Thus, it is essential to develop a more user-friendly method, available for all pregnant women for early identification of hypertension. A more straightforward and accessible BP monitoring solution would allow the women to be more involved in self-care and their health, both during pregnancy and postpartum.

Apps using smartphones may be a solution for monitoring BP in a user-friendly way. Anura is a smartphone app based on a novel imaging methodology called transdermal optical imaging (TOI) and capitalizes on the fact that light can travel beneath the skin and be reflected due to the skin's translucent properties [17]. The reflected light can then be captured by an optical sensor [18]. TOI uses video-captured images and machine-learning algorithms to extract blood flow information from the facial epidermis. The Anura app can make these measurements in 30 seconds by simply asking the patient to take a 30-second video selfie (Figure 1). Thus, the app may remove the need for cuffs or other technical equipment [19]. Based on a large video dataset from normotensive and hypertensive patients, along with their physiological measurements based on gold-standard medical devices, TOI uses machine-learning algorithms to build computational models to predict a variety of vital signs [20,21].

Figure 1. The user interface of the Anura app.

TOI technology has been shown to accurately determine BP in nonpregnant normotensive participants with a precision comparable to clinical standards using manual measurements [19]. The systolic and diastolic BP predicted from TOI resulted in measurements within 5±8 mm Hg of the reference measurements [22]. However, its performance in pregnant women remains unexplored, and the generalizability to diverse populations has not yet been established. To address this gap, the objective of this study was to evaluate the feasibility of the

XSL•FO
RenderX

Anura app as a method for antenatal BP surveillance of pregnant women.

The primary aim of this study was to evaluate the reliability and accuracy of the Anura app for BP measurement during pregnancy in normotensive pregnancies, high-risk pregnancies, and in women diagnosed with preeclampsia, compared to conventional manual cuff measurements. In addition to the BP measurements, we also evaluated women's experience of using the Anura app by a digital questionnaire.

Methods

Ethical Considerations

The study was conducted with ethical approval from the Swedish Ethical Review Board in Lund, Sweden (DNR 2021 - 03216), and performed in line with the principles of the Declaration of Helsinki. Informed consent was obtained from all participants, who signed consent forms prior to inclusion, and no compensation was provided for participation. Participant confidentiality was strictly maintained. All data were deidentified prior to analysis, and no information that could enable identification of individual participants is presented. Data were stored securely in accordance with institutional and national data protection regulations, with access restricted to the research team.

Design, Setting, and Participants

A total of 3 groups of pregnant women were recruited: those with normotensive pregnancies, those with high-risk pregnancies, and women diagnosed with preeclampsia. High-risk pregnancies were defined according to the Swedish Society of Obstetrics and Gynecology guidelines for hypertensive disorders in pregnancy [2]. Participants were classified as high-risk if they had at least one high-risk factor (eg, chronic hypertension, type 2 diabetes) or 3 or more moderate-risk factors (eg, advanced maternal age, nulliparity, high BMI). Preeclampsia was defined as hypertension (140/90 mmHg) after 20 weeks of gestation in combination with maternal organ dysfunction and/or intrauterine growth restriction [23,24]. The hemolysis, elevated liver enzymes, low platelets syndrome is a severe form of preeclampsia with general organ involvement, especially of the liver. Women diagnosed with preeclampsia were recruited when they were admitted to the hospital. The study was part of a prospective longitudinal feasibility study aiming to follow pregnant women with and without high-risk factors from early pregnancy until 6 - 8 weeks postpartum (Multimedia Appendix 1).

The study was conducted in southern Sweden at 2 large hospital maternity health care units and 9 different antenatal health clinics (AHCs) in the region, from March 2022 to December 2023. The inclusion criteria were: (1) pregnant normotensive women, high-risk pregnancies, and women diagnosed with preeclampsia, (2) having a smartphone that could download the Anura app, (3) 18 years or older, and (4) understanding Swedish. All pregnant women enrolled in AHC during the study period were screened for eligibility and invited to participate. In total, 331 women were approached, of whom 288 agreed to participate. A total of 43 women declined participation, most commonly citing reasons such as mental illness, anxiety, concerns about having high BP, or difficulties using the Anura app. The eligible women received both oral and written information and had the opportunity to consider whether they wished to participate. They were also informed to contact their midwife or the maternal health unit if they experienced symptoms such as headache, general malaise, swelling, chest pain, or if their BP was 140/90 mm Hg or higher.

The included women were asked to use the Anura app to perform facial scans for BP measurements at each AHC or hospital visits. At the visits, the BP was also measured by midwives or health care professionals using a routinely applied manual sphygmomanometer cuff method.

The pregnancies were divided into trimesters, defined as: first trimester (0 - 13+6 gestational week [GW])=0 - 93 days, second trimester (14+0 - 27+6 GW)=94 - 187 days, and the third trimester (28+1 - 42+0 GW)=188 - 283 days.

Data Collection

Demographic data for the included women (Tables 1 and 2) was collected from the medical record system Obstetrics (version 2.18.0.100, Copyright Cerner Sverige AB) [25]. In addition to the standard antenatal program [1], the women were asked to follow a scheme for BP measurements using the Anura app. The midwives or the first author of the study provided information on downloading the Anura app to their private smartphones. Basic personal information (weight, height, age, high BP, or diabetes) was entered directly into the Anura app by the women.

[e]SGA: small for gestational age.

[f]NICU: neonatal intensive care unit.

Once the app was downloaded and registered, each woman was assigned a participant code. The code key was stored under lock and key. The BPs were measured in 2 ways: by the midwife using a standard BP cuff or a validated automatic BP monitor, and by the women using the Anura app. The results were automatically stored in the Anura app. The participants manually entered the diastolic blood pressure (DBP) and systolic blood pressure (SBP) measured by the midwife into the Anura app.

In addition, the women were encouraged to measure their BP at home at least once a week, after 15 minutes of rest. For each Anura measurement, the women scanned their faces for 30 seconds at 30 frames/second imaging. The app processed the image frames and used its local algorithms to extract blood flow information. Only the extracted facial blood flow information was packaged, encrypted, and sent to the cloud server in Europe owned by NuraLogix Corporation (Toronto, Canada). The data was processed by the DeepAffex (DFX) Artificial Intelligence Engine [20]. The Anura is in full compliance with the General Data Protection Regulation. In addition, a written agreement between Lund University and NuraLogix was signed to ensure data safety, privacy, and the freedom of data use by the research team.

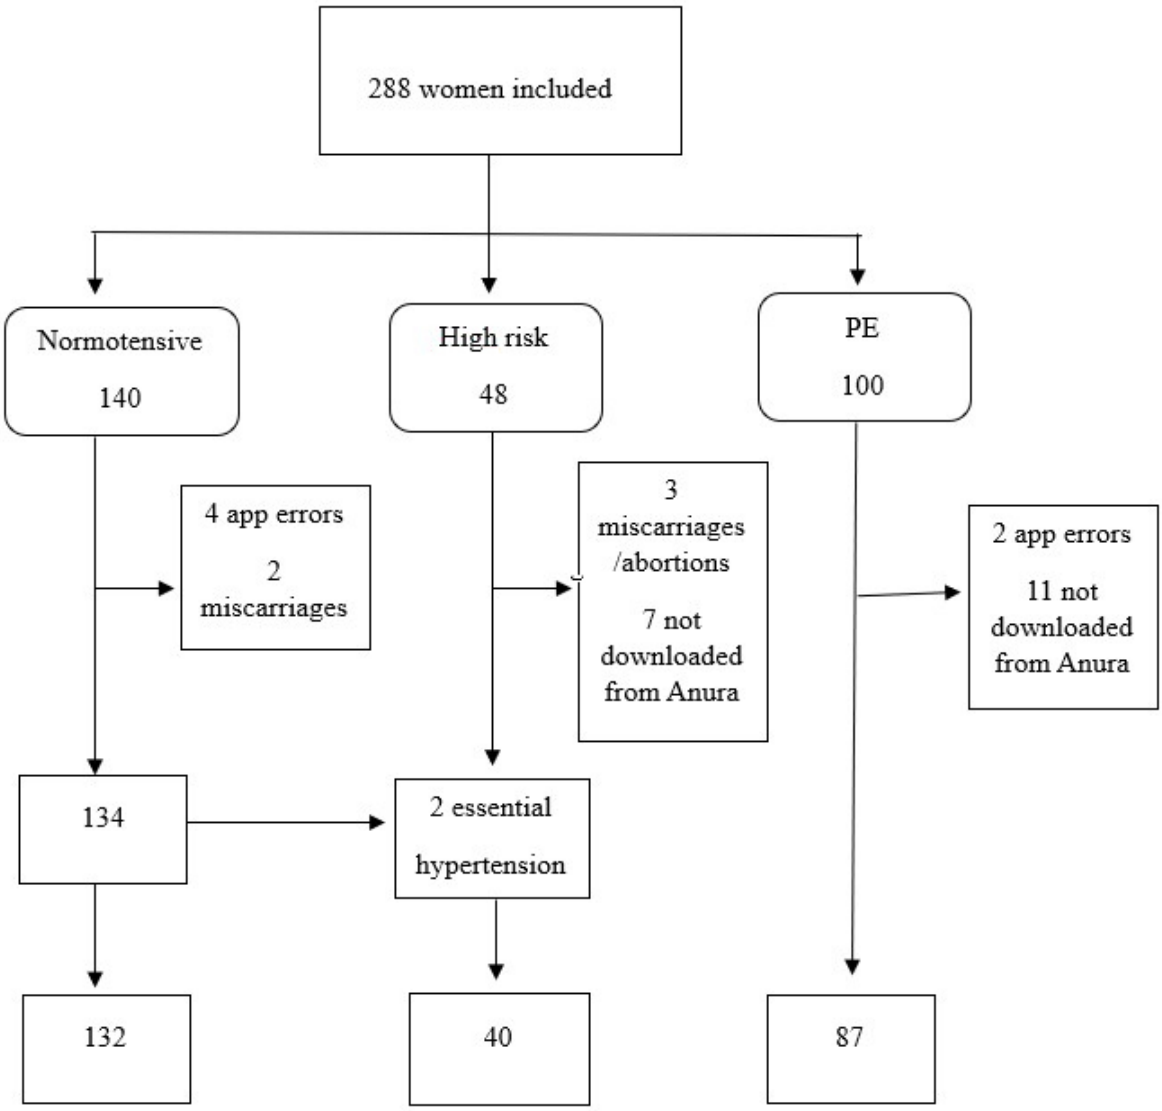
The women also answered a survey at 37 - 39 GW. The experience of using the Anura app was investigated with a survey consisting of 8 questions. The questions concerned their perceived privacy, sense of control, security, and user-friendliness. The answer options were categorical and reported as percentages for each question.

XSL•FO
RenderX

Data Analysis

In order to determine the number of women to be included in each group, a power calculation was performed using G*power [26]. To achieve adequate power of 80% with a significance level of 0.05 and a medium effect size (f=0.25), a total sample of 269 was required with 90 for each of the 3 groups (normotensive, high-risk, and preeclampsia). Data from Anura was downloaded directly from a dashboard, minimizing the risk of missing data. The clinical data were manually extracted from medical records and double-checked to ensure completeness. All analyses were performed using International Business Machines Corporation SPSS Statistics for Windows, Version 28.0. A P value <.05 was considered statistically significant. Demographic data were analyzed with one-way ANOVA. Bland–Altman analysis, including limits of agreement (LoA), was conducted in Microsoft Excel. All data points from the Anura app were downloaded from the NuraLogix DFX dashboard. For continuous variables, descriptive statistics were presented as minimum, maximum, and mean (SD). Categorical variables were presented in numbers (n) and proportions (%). All calculations for BP were performed separately for SBP and DBP values. The analyses were stratified by patient group and trimester. The data were normally distributed. To account for repeated measures, the 2 BP measuring methods, Anura versus manual BP, were compared using linear mixed models, fitted in R 4.3.3 using package linear and nonlinear mixed effects model version 3.1 - 167. Measuring methods were defined as fixed effect and pair of measurements within person as random effect using an AR1 correlation structure. The difference in measurements is presented as the beta coefficient with 95% CI. Mixed model analyses were stratified by patient group and trimester, and assumptions were assessed graphically.

Bland-Altman plots were used to show outliers and visual comparisons of the Anura measurements against the manual cuff measurements. The Bland-Altman plot, which showed systematic differences and dispersion, did not contain any CIs but instead the 95% LoA, which were calculated assuming normal distribution. All available paired Anura BP measurements were included in the analyses. For participant questionnaires, only complete responses were included. No imputation was applied for missing data.



Results

Demographics

In total, 288 women were recruited for participation, but 10.1% (29/288) were excluded due to miscarriage, abortion, or technical problems with the Anura app (Figure 2). The remaining 259 women were divided into 3 groups as follows: 132 were classified as women with normotensive pregnancy, 40 were classified as those with high-risk pregnancies, and 87 were diagnosed with preeclampsia (Figure 2). Data were successfully downloaded from the NuraLogix DFX dashboard. Data could not be downloaded for 11 women with preeclampsia, but their demographic background data are still included in the preeclampsia group shown in Tables 1 and 2, resulting in 98 for this group (Figure 2).

XSL•FO
RenderX

Figure 2. Flowchart for included women in the 3 study groups. PE: preeclampsia.

Demographic data showed that the normotensive pregnancy group was significantly different ($P<.001$) from both the high-risk group and the preeclampsia group regarding pregnancy length, age, height, weight, BMI, DBP, and SBP (Tables 1 and 2). The normotensive pregnancy group had significantly lower ($P<.001$) maternal age and BMI compared to the high-risk and preeclampsia groups. Nearly half (19/40, 47.5%) of the women in the high-risk group had a family history of high BP. Additionally, most women in the high-risk pregnancy group received prophylactic acetylsalicylic acid treatment (35/40, 87.5%).

In the normotensive group, 2/140 women developed gestational hypertensions and were therefore transferred to the high-risk group (Figure 2). Of the 140 women in the normotensive group, 3 women developed preeclampsia some weeks before childbirth and were therefore transferred to the preeclampsia group. Diseases that were identified in the normotensive group were 1 case of asthma, 1 case of Crohn disease, 1 case of epilepsy, 1 case of gestational diabetes, 6 cases of hyperthyroidism, and 1 case of polycystic ovary syndrome. The fetal sex of 2 newborns remains unknown since they were born outside of the study region. Characteristics for the included women and their newborns are shown in Table 2.

In the high-risk group (n=40), 7 women developed preeclampsia, and 6 developed gestational hypertension. Eight had essential hypertension, 1 had borderline high BP, 1 had systemic lupus erythematosus or rheumatoid arthritis, and 2 had a previous history of postpartum depression. In addition, 27.5% had a regulated BP with medication postpartum, and 22.5% were still on antihypertensive medication when discharged. Women in the high-risk group also had significantly ($P<.001$) longer hospital stays.

In the preeclampsia group (n=98), 12 women had a known family history of preeclampsia and 6 had essential hypertension. Additionally, 1 woman developed hemolysis, elevated liver

XSL•FO
RenderX

enzymes, and low platelets syndrome. In the preeclampsia group, 73.5% (72/98) had a regulated BP using medication postpartum and 66.3% (65/98) were still on antihypertensive medication when discharged from the maternity unit. Women in the preeclampsia group also had significantly (P<.001) longer hospital stays, the birthweights were significantly lower, and 36.7% (36/98) of their newborns were admitted to the neonatal intensive care unit.

Blood Pressure Measured With the Anura App Versus Manual Measurements

In total, there were 4932 BP measurements registered in the Anura app in the 3 study groups: 2993 normotensive pregnancies, 853 high-risk pregnancies, and 1072 pregnancies with preeclampsia. Of these measurements, 539 had a corresponding manual BP cuff measurement taken at an antenatal care visit (normotensive pregnancies, n=194; high-risk pregnancies, n=108; and pregnancies with preeclampsia, n=237). Manual BP of the 3 groups and during the trimesters is shown in Table 3. For the preeclampsia group, there were few measurements in the second trimester, since most preeclampsia did not develop until the third trimester.

Table . SBP[a] and DBP[b] for unpaired manual measurements for each trimester.

	Manual		
Blood pressure characteristic	Normotensive pregnancy	High-risk pregnancy	Preeclampsia
Trimester 1	n=53	n=14	—[c]
SBP, mean (SD; min-max)	113 (8.9; 97 - 132)	120 (11.3; 88 - 135)	—
DBP, mean (SD; min-max)	69 (6.1; 54 - 80)	78 (12.1; 64 - 114)	—
Trimester 2	n=57	n=37	n=4
SBP, mean (SD; min-max)	115 (9.6; 97 - 136)	121 (6.4; 109 - 135)	156 (13.8; 140 - 170)
DBP, mean (SD; min-max)	70 (5.6; 60 - 83)	80 (4.8; 70 - 92)	106 (9.7; 99 - 120)
Trimester 3	n=74	n=50	n=185
SBP, mean (SD; min-max)	115 (9.1; 100 - 134)	121 (10.2; 100 - 149)	138 (10.7; 110 - 180)
DBP, mean (SD; min-max)	70 (6.8; 60 - 88)	77 (10.4; 60 - 97)	87 (84; 63 - 113)

[a]SBP: systolic blood pressure.

[b]DBP: diastolic blood pressure.

[c]Not applicable.

Comparisons between Anura and manual BP measurements are presented in Table 4. In the normotensive group, Anura consistently measured higher DBP across all trimesters (β ranging from 4.9 to 6.9 mm Hg; P<.001), while SBP tended to be lower, reaching statistical significance in the second and third trimesters. In the high-risk group, DBP was lower in the second trimester (β –3.5 mm Hg; P=.004), whereas SBP was significantly lower in both the second and third trimesters (β –8.4 and –9.1 mm Hg; P<.001). Among women with preeclampsia, Anura showed markedly lower values, with a mean difference of –6.8 mm Hg for DBP and –16.9 mm Hg for SBP (both P<.001).

XSL•FO
RenderX

Table . Comparison Anura—manual blood pressure measurement linear mixed effects model.

Patient type and trimester	Measurements	Individuals	DBP[a] β (95% CI)	*P* value	SBP[b] β (95% CI)	*P* value
Normotensive						
First	53	46	4.9 (2.8 to 7)	<.001	−2.6 (−5.6 to 0.4)	.09
Second	57	39	5.9 (4.3 to 7.5)	<.001	−3.7 (−6.6 to −0.8)	.01
Third	75	39	6.9 (4.9 to 9)	<.001	−3.2 (−5.7 to −0.7)	.01

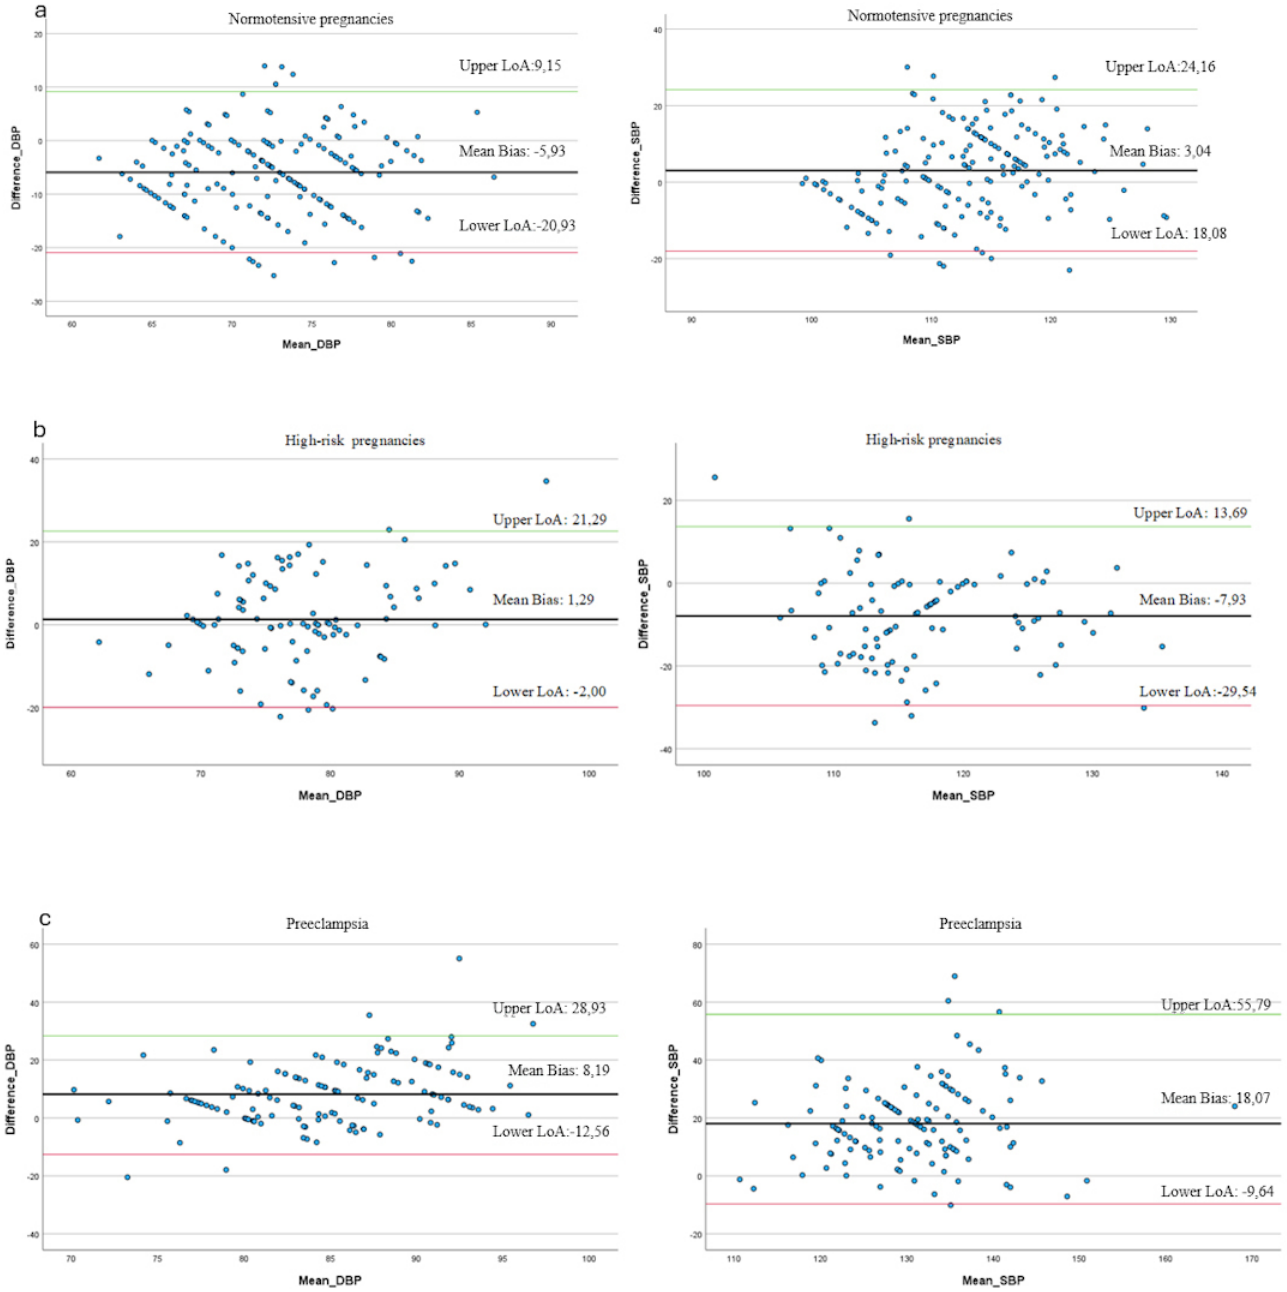
Third	184	38	-6.8 (−8.2 to −5.4)	<.001	−16.9 (−18.7 to 15.1)	<.001

[a]DBP: diastolic blood pressure.



[b]SBP: systolic blood pressure.

[c]Not available.

Bland-Altman plots (Figure 3) were created to illustrate differences between the paired BP measurements. The Bland-Altman analysis for SBP in the normotensive group (Figure 3a) shows a mean difference of 3.04 (SD 7.7) and for DBP a mean difference of −5.93 (SD 7.7). In the high-risk group (Figure 3b), the SBP shows a mean difference of −7.93 (SD 11.0) and for DBP a mean difference of 1.29 (SD 10.8). For the preeclampsia group (Figure 3c), the SBP shows a mean difference of 18.07 (SD 18.1) and for DBP a mean difference of 8.19 (SD 10.6). There was a variation in the Bland-Altman plots of the upper and lower LoA in both the SBP and the DBP in the 3 groups (Figure 3).

XSL•FO
RenderX

Figure 3. Bland-Altman plot differences in DBP and SBP for manually and Anura measurements in (a) normotensive pregnancies, (b) high-risk pregnancies, and (c) preeclampsia. DBP: diastolic blood pressure; LoA: limits of agreement; SBP: systolic blood pressure.

The Experiences of Using Anura

The results from the survey are based on 56/172 (32.3%) women who evaluated their experience of using Anura (Multimedia Appendix 2). Most of the women (48/56, 85.7%) expressed no concern regarding their privacy while using the app, whereas 8/56 (14.3%) women reported being a little worried. Almost all women (55/56, 98.2%) reported no concern about seeing their BP results, with only 1/56 (1.8%) woman indicating slight apprehension. Regarding responsibility for their own health, 31/56 (55.4%) women felt a higher degree of responsibility when using the app. Of these, 2/56 (3.6%) women reported feeling much more responsible, 7/56 (13%) women more responsible, and 22/56 (39.3%) women a little more responsible. In contrast, 25 (44.6%) women reported no increase in responsibility. Perceived safety when using the app was also high: 51/56 (91.1%) women considered it safe, of whom 30/56 (56.6%) rated it as very safe, 21/56 (37.5%) as safe enough, and 5/56 (8.9%) women as only a little safe. Most of the women (48/56, 85.7%) experienced better control of their health with the app. Specifically, 8/56 (14.3%) women reported much better control, 18/56 (32.1%) women better control, and 22/56 (39.3%) women slightly better control. A total of 8/56 (14.2%) women reported no improvement. Similarly, 32/56 (57.1%) women reported an increased understanding of their health status, with 5/56 (8.9%) women indicating much better understanding, 17/56 (30.4%) women better understanding, and 10/56 (17.9%) women a little better understanding. A total of 2/56 (3.6%) women reported no better understanding, while 5/56 (8.9%) women remained neutral. Most women (42/56, 75%) reported that sitting still and looking into the camera during the measurement went well. However, 12/56 (21.4%) women found it unpleasant or

XSL•FO
RenderX

uncomfortable, 1/56 (1.8%) woman reported it as quite unpleasant, and 11/56 (19.6%) women were neutral. The duration of the measurement was generally well accepted: 32/56 (57.1%) women considered the length just right, 22/56 (39.3%) women found it okay, and only 2/56 (3.8%) women felt it was too long.

Discussion

Principal Findings

The primary aim of our study was to evaluate how reliable and accurate the Anura app is for BP measurement during pregnancy, compared to manual cuffs for BP measurement. In addition, we asked women about their experiences of using the app. To the best of our knowledge, this study is the first to validate the Anura technology in pregnant women, including high-risk pregnancies and women diagnosed with preeclampsia, with analyses stratified across 3 trimesters. The use of smartphones for medical monitoring has previously indicated a need for a user-friendly, independent BP monitoring method during pregnancy to enable identification of hypertension. Home monitoring can enhance early detection [3,4] and management of pregnancy-related hypertension, while also empowering women to take an active role in their own health care [27]. This fact was also confirmed in this study, as most women reported a positive experience of using the Anura app and feelings of being in control of their own health.

The main finding in our study suggests that Anura agrees well with manual BP in normotensive women; however, discrepancies between the 2 methods increase in the high-risk and preeclampsia groups, especially for SBP. Among normotensive women, Anura generally showed a higher DBP (4.9 - 6.9 mm Hg) compared to manual measurements, while SBP tended to be slightly lower, with statistical significance in the second and third trimesters. This suggests that the use of Anura BP measurement may be more reliable in women with normotensive pregnancies, while caution is required in high-risk pregnancies and once preeclampsia is diagnosed. The Bland-Altman analysis confirmed this finding, showing that the normotensive group exhibited small differences between the 2 methods, indicating that Anura has good agreement with manual measurements in normotensive women. Our findings in normotensive pregnant women are in line with previous research with male patients and nonpregnant female patients [22]. Regarding the high-risk pregnancies, the analysis showed that DBP was lower in the second trimester (–3.5 mm Hg) and SBP was lower in both the second and third trimesters (–8.4 and –9.1 mm Hg), respectively. These results show that in high-risk pregnancies, the Anura app may be less reliable in the last part of pregnancy compared to earlier stages of pregnancy. The preeclampsia group demonstrated the most pronounced differences, –6.8 mm Hg for DBP and –16.9 mm Hg for SBP. Thus, while the use of Anura BP measurement may be reliable in women with normotensive pregnancies, our results do not support using the Anura app for BP screening in women with high-risk pregnancies or women diagnosed with preeclampsia, suggesting caution in high-risk pregnancies and once preeclampsia is diagnosed. These findings are further corroborated by another study showing that BP measurements were not accurate in a perioperative setting using a similar technique, video plethysmography for contactless measurement [7]. However, Anura has been reported to be highly accurate in predicting the respiratory rate and heart rate of surgical patients in a clinical setting [7,8].

The differences shown in the Bland-Altman analysis suggest that in some cases, the Anura technology either overestimated or underestimated the BP compared to the manual measurements, especially in the preeclampsia group where the deviations were the largest. These deviations are important to consider during further processing of the variables to improve the measurements in the Anura app in the future. The high variation of the upper and lower LoA in the Bland-Altman plots may indicate that the Anura app might be less reliable at extreme BP values, or that its performance varies depending on the context or conditions of the measurements [28]. One possible explanation is that women with high-risk pregnancies and preeclampsia may have more edema in their faces, which could interfere with the TOI technique that fails to make accurate BP measurements. A physiological explanation for this inconsistency in BP may lie in the cardiovascular adaptations that occur during pregnancy. Normally, the blood volume increases during the first 2 trimesters, and the peripheral vascular resistance decreases [29], leading to a 10 - 20 mm Hg reduction in BP. It reaches its lowest point at 18 - 20 weeks of gestation and then returns to prepregnancy levels by the third trimester [30,31]. In preeclampsia, however, there is a maintained vascular resistance, as well as endothelial damage, that results in general edema. Increased edema and hemo-concentrated blood might impact the measurement quality when BP is measured using TOI. Our results indicate that the Anura measurements tended to show lower values compared to manual BP measurements for both DBP and SBP in the preeclampsia group, and to some extent also in the high-risk group. In preeclampsia, the vascular endothelial cells undergo changes that result in inflammation, impaired blood flow regulation, and increased vascular permeability [10,32]. While most pregnant women experience swelling during their pregnancy, this predominantly does not occur until the third trimester in normotensive pregnancies [33].

In previous studies, BP was determined in nonpregnant individuals by Anura with high accuracy [19,22]. In this study, the technology was evaluated under controlled conditions with optimal lighting, a tripod-mounted mobile phone, and using the same device for all measurements. In contrast, this study allowed the women to use their own mobile phones, holding them manually, and having varying lighting conditions at home. Movement and lighting often affect the accuracy of contactless measurement technologies using a mobile phone [21,34]; yet, while knowing their role for accurate BP measurement, we could neither entirely control nor account for them in this study. The women were instructed to rest in a sitting position and hold their mobile phones still at arm's length in front of their faces during the 30 seconds needed for measurements. They were to measure their BP only when at least 3 stars appeared in the Anura app. One star indicates poor lighting conditions, while 5 stars indicate perfect lighting conditions [35]. Any movements of the arm and varying light qualities in the rooms at AHC and

XSL•FO
RenderX

at home could, of course, affect the measurements. This may apply particularly to women admitted to the hospital with preeclampsia, who often had to dim the lights in their rooms due to symptoms and illness related to preeclampsia. Such suboptimal conditions may have impacted the performance of the Anura measurements. However, our results contribute to the advancement of contactless BP monitoring by highlighting the challenges of implementing this technology. These insights can be used to further improve the handling of the smartphone, lighting conditions, and the algorithm in the future.

The use of smartphones for medical monitoring has increased in recent years. As information technology continues to develop, so do the opportunities to find new ways to measure BP with smartphone-based apps [36]. Compared to traditional monitoring, home BP monitoring during hypertensive pregnancies appears to be cost-saving without compromising the safety of the pregnant mother [37]. It increases accessibility and convenience for pregnant women, has the potential to decrease the number of hospital visits [3], enables the early detection of abnormalities, and promotes better control and self-management of their health. It has also been shown that BP measured at home often is lower than in a clinical setting [38]. In addition, home measurements have shown reduced stress and anxiety and enable more individualized care, which in turn can lead to better health outcomes for the women and their children. In a systematic review and meta-analysis [39], it was demonstrated that contactless monitoring technology using consumer-friendly cameras, such as smartphones, is accurate for measuring heart rate compared to other medical devices. However, more studies are needed to assess the accuracy of contactless BP measurements, particularly among pregnant women. In another review, it was also highlighted that no apps for BP had undergone sufficient testing to be recommended in a clinical practice [40]. In a recently published study, the accuracy of contactless monitoring technology for heart rate suggested limitations in accurately measuring BP in a hospital setting. However, the study showed that contactless monitoring technology was both accurate and feasible for measuring respiratory rate in a hospital setting [7]. In an earlier study using Anura, the SBP and DBP predicted from TOI fell within 5±8 mm Hg of reference measurements [22], but in our study, these criteria were not met in the paired data for the 3 groups. In yet another study using Anura, it was also shown that TOI can determine heart rate, heart rate variability, and infer stress of an individual with high accuracy [21]. Given the Anura precise measurement of heart rate and stress, the app remains an interesting tool for assessing BP. By leveraging advanced machine learning techniques and enhancing the app's sensitivity, those responsible for the app may expand its use and reliability.

In this study, most women expressed a positive experience of using the Anura app. They also reported a higher degree of responsibility and control over their health. This agrees with another study that also found the participants to be satisfied with the contactless technology and would recommend it for future clinical settings [7]. The women generally perceived the app as adequate and safe for use, with nearly all women reporting no elevated anxiety when seeing their BP results. Concerns were raised by some women regarding the accuracy of the measurements and the handling of their data, particularly in relation to privacy. These findings suggest that the app has the potential to be well-received by women during pregnancy, though addressing these concerns will be important for its future use.

Limitations and Future Solutions

A key strength of the study is the use of linear mixed models to account for repeated BP measurements within individuals, which provides a robust estimation of differences between the Anura app and manual measurements compared to simpler paired analyses. Stratifying analyses by patient group and trimester allowed us to explore potential variations across different risk profiles and gestational stages. An additional strength is that the analyses have been quality assured through independent review by a statistician.

However, some limitations should be acknowledged. The models did not adjust for potential confounding factors such as maternal age, BMI, or comorbidities, which may influence BP variability and limit the generalizability of the findings. We also acknowledge a lack of insight into the validation of the underlying technology. Our study sought to explore the use of Anura in a clinical setting with pregnant women, with the primary aim to compare measurement methods. With this aim, and the paired design, we see no benefit to adjust the analysis for maternal age, gestational age, or comorbidities. Additionally, the study focused on comparing measurement methods rather than evaluating clinical outcomes, so the diagnostic accuracy and predictive value of the Anura app for conditions such as preeclampsia remain unassessed. The sample sizes in some subgroups, particularly patients with high-risk pregnancies and preeclampsia in early trimesters, were relatively small, which may reduce statistical power and precision, particularly regarding high-risk pregnancies. Due to these limitations, future studies with larger sample sizes and better compliance are needed to further validate these observations in a clinical setting. Finally, while mixed models handle within-subject correlation, physiological variability and measurement conditions may still contribute to residual variability that is not fully captured by the models. Furthermore, while the Anura app has previously shown a measurement error of approximately 5±8 mm Hg [22], we did not conduct a formal error assessment or apply corrections in the present study. We acknowledge this as a limitation and emphasize that our findings should be interpreted as preliminary feasibility results rather than accuracy validation.

Another limitation was that only 32.6% of the women answered the questionnaire evaluating their experiences of using the Anura app, so caution is advised when interpreting these results. Completing surveys through an app shortly before giving birth may not have been an ideal time point for the women. Additionally, we were unable to send reminders within the app. To improve compliance, future studies might consider alternative methods, such as providing the questionnaires directly by the midwife at the AHC or calling the women by phone to gather their perspective on the experience.

Our results are partly in line with previous studies that reported both acceptable accuracy and significant margins of error for

XSL•FO
RenderX

noncontact BP measurements [6]. Discrepancies can be partly explained by differences in study design, population, and measurement conditions, and previous reviews point to methodological limitations, especially in studies of pregnant women [5]. We also acknowledge that Anura was not compared to 24-hour ambulatory BP monitoring in this study, and we note this as a limitation. Future studies should include such comparisons to better evaluate performance across all risk groups. Home BP measurements offer numbers of benefits [3,4,27] and the ability to measure cuffless BP in a home setting appears to be a promising solution for pregnant women in the future.

Overall, the analyses provide useful insights into the feasibility and agreement of the Anura app with standard BP measurements, but future studies incorporating larger samples, clinical outcomes, and adjustments for relevant confounders are needed to more definitively assess its clinical use. Future research should evaluate Anura in larger and more diverse populations, including women with chronic hypertension and multiple comorbidities. Longitudinal studies are needed to assess performance across pregnancy. Beyond BP monitoring, the technology may enable early detection of other pregnancy-related complications. Usability, integration with clinical systems, and data security should also be explored to support safe implementation in AHC.

Conclusion

The Anura app showed a good acceptance among women with normotensive and high-risk pregnancies. They experienced increased security and control over their health. In normotensive pregnancies, the Anura BP showed a good accuracy; however, the reliability was limited in high-risk and preeclampsia groups, especially for the SBP. The app can therefore currently only be considered as a supportive complement in normal pregnancy, but not a substitute for validated clinical equipment. Continued development and adaptation of algorithms, with data from high-risk pregnancies, is necessary to enable broader clinical use. Such development could strengthen preventive work and contribute to better care for women at risk of hypertensive pregnancy complications.

Acknowledgments

The authors would like to warmly thank all the women who participated in the study and to all midwife colleagues who helped us recruit the participants. This study is a collaboration between the Department of Obstetrics and Gynecology, Lund University, Sweden and NuraLogix, Toronto, Canada [41]. They also thank NuraLogix for their support and collaboration. A language review was assisted by AI.

Abstract

Background: Mobile health (mHealth) apps have become more commonly used in orthopedics. However, for these apps to be efficient, patients should be willing to use them, making it essential to understand patients' perspectives of mHealth interventions.

Objective: The aim of this single-center, intent-to-treat, preoperative single-cohort study of 100 patients was to evaluate the acceptability of mymobility (Zimmer-Biomet), an mHealth app designed for the postoperative care of total hip arthroplasty (THA) and total knee arthroplasty (TKA).

Methods: We measured acceptability using the theoretical framework for acceptability (TFA) preoperatively and at 3 months post operation. We also measured satisfaction with app use postoperatively using the Usefulness, Satisfaction, and Ease of Use questionnaire as well as patient-reported outcome measures preoperatively and postoperatively using the Oxford hip and knee scores and the visual analog scale for pain. Patients included were 18 years or older; underwent unilateral primary total hip, total knee, or partial knee arthroplasty; spoke and read French or English; and had a smartphone with internet access. Participants used mymobility in addition to standard government-funded physiotherapy.

Results: The preoperative overall TFA result was 4.2 out of 5, but results decreased significantly postoperatively. There was higher self-efficacy in preoperative TFAs with higher education, and lower acceptability in postoperative TFAs with TKA. The Usefulness, Satisfaction, and Ease of Use questionnaire revealed a good level of satisfaction with the use of the app. Patient-reported outcome measures showed earlier improvement in THA (31.2 d) than in TKA (89.4 d), whereas the visual analog scale showed a rapid decrease in pain with both procedures. Only 1 patient expressed privacy concerns with the use of the app.

Conclusions: There was a good level of acceptability with the use of mymobility for the postoperative management of THA and TKA, although acceptability decreased postoperatively. This decrease could signify high expectations toward the app preoperatively or higher than expected difficulty and pain in the early postoperative period. Acceptability tended to increase with higher education and decrease with TKA. These trends are consistent with prior literature and constitute a potential gap to address for app developers. The influence of the natural recovery process on acceptability remains unclear. Future studies could explore this gap by comparing results in cohorts using the app to cohorts with standard care.

KEYWORDS

mobile health; orthopedics; patient satisfaction; telemedicine; telerehabilitation; total joint arthroplasty

Introduction

In Canada, there were 60 705 hip and 70 379 knee replacements performed in the inpatient setting in 2023 - 2024 [1]. These procedures were the third and second most common inpatient surgeries, and these numbers are expected to at least double in the United States (and likely Canada) over the next 15 years due to an aging population [2,3]. Another growing sector in health care is the use of smartphones for patient care. An estimated 71% of the world population uses a smartphone in 2024, and there are more than 350 000 mobile health (mHealth) apps currently available [4,5]. This increasing use of mHealth

XSL•FO
RenderX

apps is also present in various areas of orthopedics, where numerous studies have shown that they are efficient and convenient, that they promote patient adherence and engagement with their treatment, and that they facilitate rehabilitation while promoting positive outcomes [6-13].

Although mHealth has the potential to improve outcomes, patients' attitudes toward these apps must be assessed, as they can only be effective if patients are willing to use them. User acceptability is defined as "a multifaceted construct that reflects the extent to which people delivering or receiving health care intervention consider it to be appropriate based on anticipated or experienced cognitive and emotional responses to the intervention" [14]. Acceptability is an important measure, as it not only provides information on patients' experience with mHealth apps, but also gives an insight into their cognitive and emotional response [14]. This helps determine whether patients genuinely perceive them as appropriate and valuable.

Recent studies investigated patients' perspectives of mHealth interventions in the context of postoperative hip and knee arthroplasty care. These studies found a high level of engagement and increased compliance with treatment exercises when using mHealth interventions [13,15-18]. Other findings include participants being satisfied with these interventions while also finding them easy to use and engaging, and providing better connection to their treating team [13,16,19,20]. These results are promising and could signify that patients are willing to use mHealth apps for their rehabilitation. However, these studies either did not assess acceptability or did so through surveys that were researcher-created or not primarily designed to measure acceptability. According to Perski et al [21], this reduces clarity regarding which aspects of acceptability are satisfied, and which are not. Additionally, high engagement does not necessarily reflect patients' perceptions of the intervention. Engagement might be driven by external factors, such as study participation, financial incentives, or free access to the devices and apps, while patients might still find the app to be time-consuming, repetitive, and burdensome.

Measuring acceptability, especially preoperatively, is therefore relevant as it provides a better perspective of patients' opinions prior to and beyond use, and because it "may usefully be considered an emergent property […] which in turn influences (and is influenced by) user engagement and intervention effectiveness" [21].

We started using the mymobility app (Zimmer Biomet, Warsaw, and Indiana) in 2022 in our community hospital to provide postoperative care to patients receiving outpatient total hip arthroplasty (THA) and total knee arthroplasty (TKA) [22]. This app, available on iOS and Android, currently stands at more than 50 000 downloads on the Google Play Store and is amongst the most downloaded when compared to other apps with the same objective [23]. In this context, our team sought to investigate the acceptability of mymobility, an mHealth app specifically designed for the postoperative care of THA and TKA, using a standardized framework.

Methods

Study Design

The primary aim of this single-center, intent-to-treat (ITT), single-cohort study was to evaluate pre- and postoperative patient acceptability with the use of the mymobility app for the postoperative care of THA and TKA. The secondary outcomes were postoperative patient satisfaction with the app and pre- and postoperative patient-reported outcome measures (PROMs).

Data Collection

Data collected for this study are presented in Multimedia Appendix 1. Demographic data were obtained from patient charts. PROMs were collected either directly through the mymobility app or by one of the authors contacting participants by phone or email. Details of the specific PROMs are provided later in this section. All data were stored securely and deidentified prior to analysis.

Ethical Considerations

This study received ethics approval from the Research Ethics Board of the Montreal West Island's Integrated University Health and Social Services Centers (Biomedical Subcommittee), affiliated with St. Mary's Hospital, Montreal (IRB# 2024-954). All participants provided informed consent prior to participation. Study data, including personal information, remained confidential and were deidentified. No secondary analyses were conducted. Study participants received no financial compensation, but access to the mymobility app was given for free. No identifiable images of participants were included in this manuscript. Under the Personal Information Protection and Electronic Documents ACT, the data collected by mymobility could not be used or shared with third parties, nor could cookies be collected, unless participants gave their explicit consent within the app [24,25]. If consent was given, data could be used or shared by the app following anonymization, with consent revocable at any time. Participants were not required to give consent to data use or sharing, or to cookie collection to use the app and be part of the study. This was made clear to participants as part of their informed consent.

App Description

Mymobility is an app that is accessible either through a smartphone or an Apple Watch. The app features educational content on pre- and postoperative care, exercise routines with metrics to track progress, AI-assisted gait speed analysis to determine the level of recovery, in-app PROMs, and telemedicine with the opportunity to send SMS text messages, videos, or pictures to health care providers (see Multimedia Appendix 2). The app engages patients in their recovery by sending notifications and reminders if users accept them while also keeping track of progress made. It also provides patients with basic and important smartphone functions to use (eg, Wi-Fi) for those with low digital literacy.

Questionnaires

Acceptability

Acceptability was measured using the theoretical framework for acceptability (TFA) questionnaire developed by Sekhon et al [26], which was adapted to our research question (see Multimedia Appendix 3). The questionnaire comprises 8 items answered by participants preoperatively and at 3 months post operation by phone or email. Each statement was evaluated using a 5-point Likert scale: scores 1 to 2 were classified as negative, 3 as neutral, and 4 - 5 as positive. The mean score was calculated for each of the 8 items, as well as an overall score.

Satisfaction

Patient satisfaction was measured using the Usefulness, Satisfaction, and Ease of Use (USE) questionnaire at 3 months post operation (see Multimedia Appendix 4) [27]. Satisfaction was defined as "the net feeling of pleasure or displeasure that results from aggregating all the benefits that a person hopes to receive from interaction with the information system" [27]. The questionnaire was answered by phone or email. Statements were evaluated using a 7-point Likert scale: scores 1 to 3 were classified as negative, 4 as neutral, and 5 to 7 as positive. The mean score was then calculated for each of the 4 sections of the questionnaire. Two additional questions assessing satisfaction were asked and scored on a 5-point Likert scale (see Multimedia Appendix 5).

Patient-Reported Outcome Measures

PROMs were measured using the Oxford Hip Score (OHS) and the Oxford Knee Score (OKS) as well as the visual analog scale (VAS) for pain (scored from 0 to 10) preoperatively and at 1, 3, and 6 months post operation (see Multimedia Appendices 6 and 7) [28-30]. OHS and OKS were answered directly within the app, whereas the VAS was answered by phone or email.

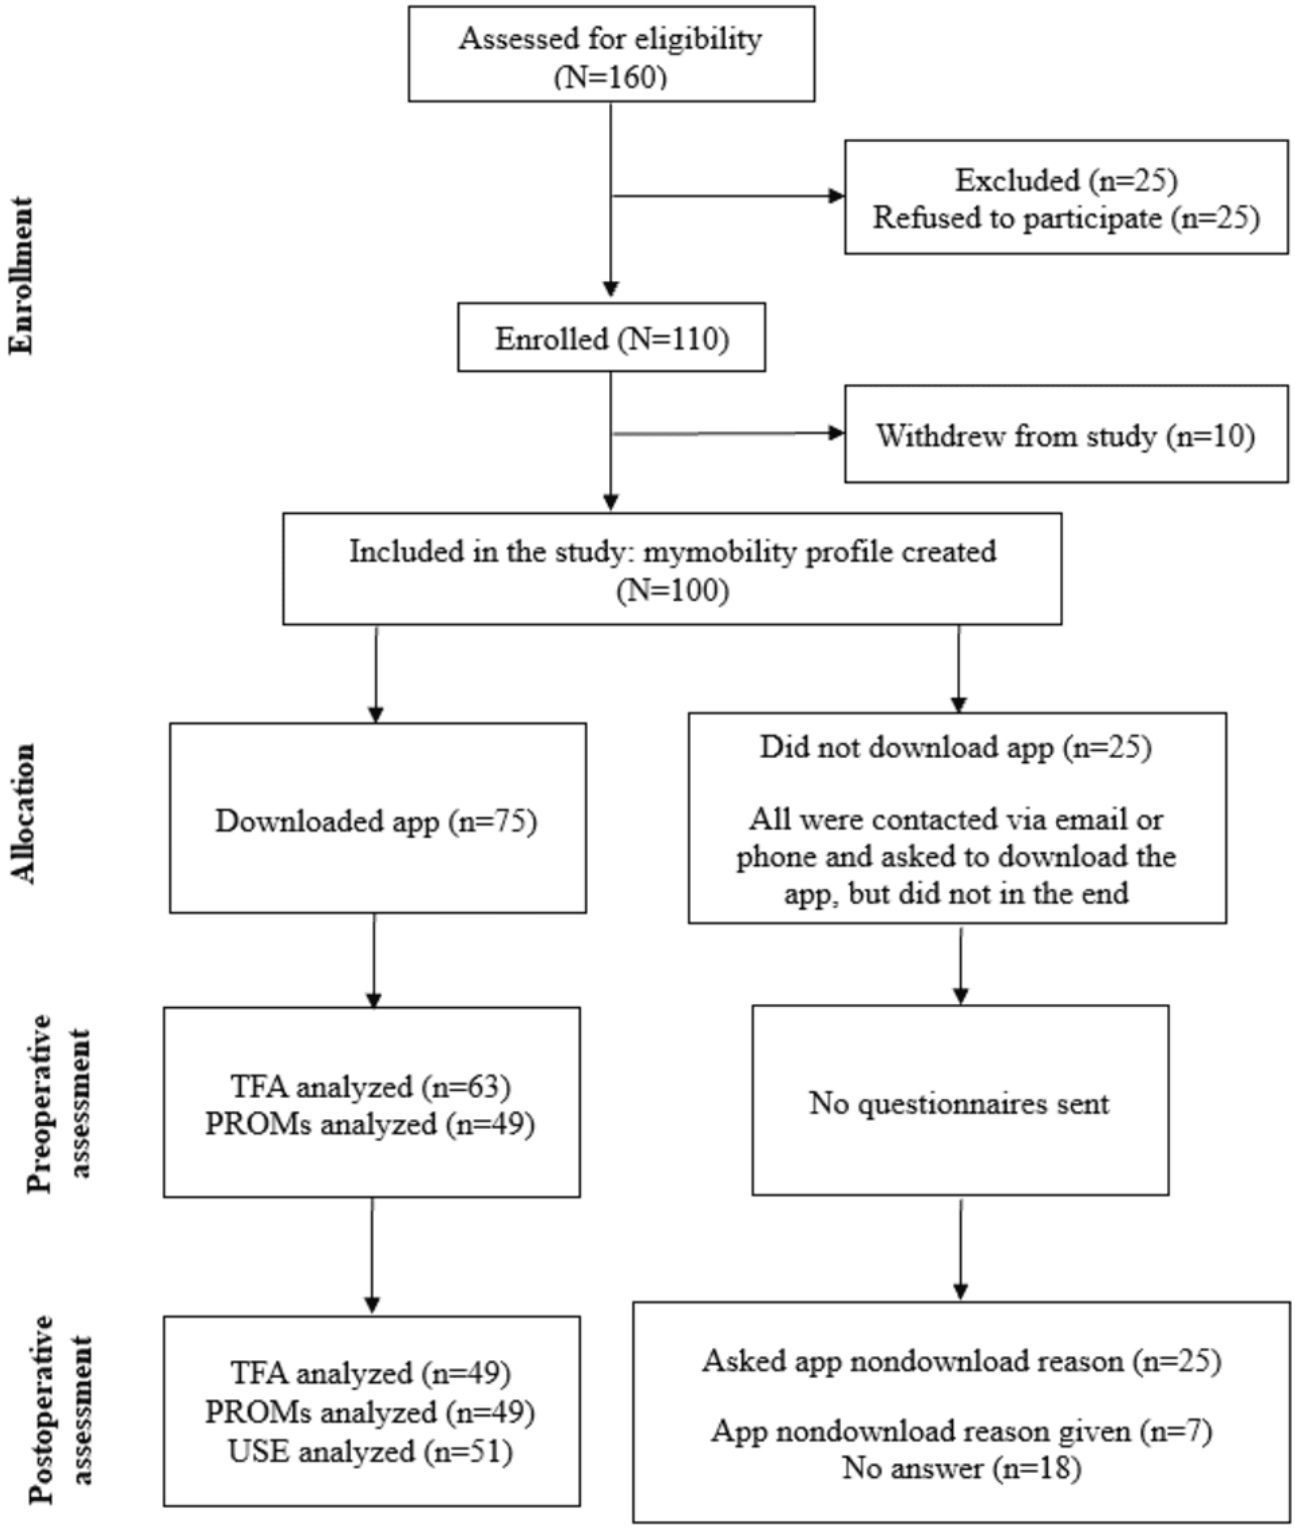
Recruitment

Patients were included in the study if they were booked for unilateral primary THA or TKA, were clinically suited for telehealth care (characterized as age ≥18 y, speak and read French or English, and have a smartphone or a tablet), had internet access, and provided informed consent to participate in the study. Patients were excluded if they did not meet the inclusion criteria, if they were unable or unwilling to provide informed consent, if they were undergoing emergency THA or TKA, or if they were undergoing revision surgeries. Participants had access to the app in addition to normal postoperative care, which included physiotherapy and postoperative follow-up visits with an orthopedic surgeon.

Patients were approached by a member of the research team during their preoperative assessment visit in the clinic. Eligible patients were provided with an informed consent form detailing the study. Once enrolled, a 1-year free access to the mymobility app was provided to the participants by the treating physician or a member of the research team, after which an email with instructions to download the app was sent. Participants were then required to download the app and agree to the terms and conditions to use it [24].

In the end, 100 participants were included in this study and had a profile created in the app. Participants who did not download the app preoperatively were sent a reminder email and given a few days following surgery, after which they were considered as nondownloaders. In the end, 75 participants downloaded the app and 25 did not. Only participants who downloaded the app were provided with the study questionnaires, as the goal was to assess acceptability, satisfaction, and PROMs with use of the app. Patients who did not download the app remained in the study in the context of the ITT format. However, since deciding not to download the app could signify low acceptability, we contacted participants who did not download the app by phone or email to ask the reason behind their decision.

Data Analysis



Study data was analyzed using the ITT principle. Data analysis was conducted and reported using STATA 17.0 and R software. Statistical significance was defined as a P value <.05.

Results

The recruitment process is summarized in Figure 1. Baseline characteristics of our population can be found in Table 1.

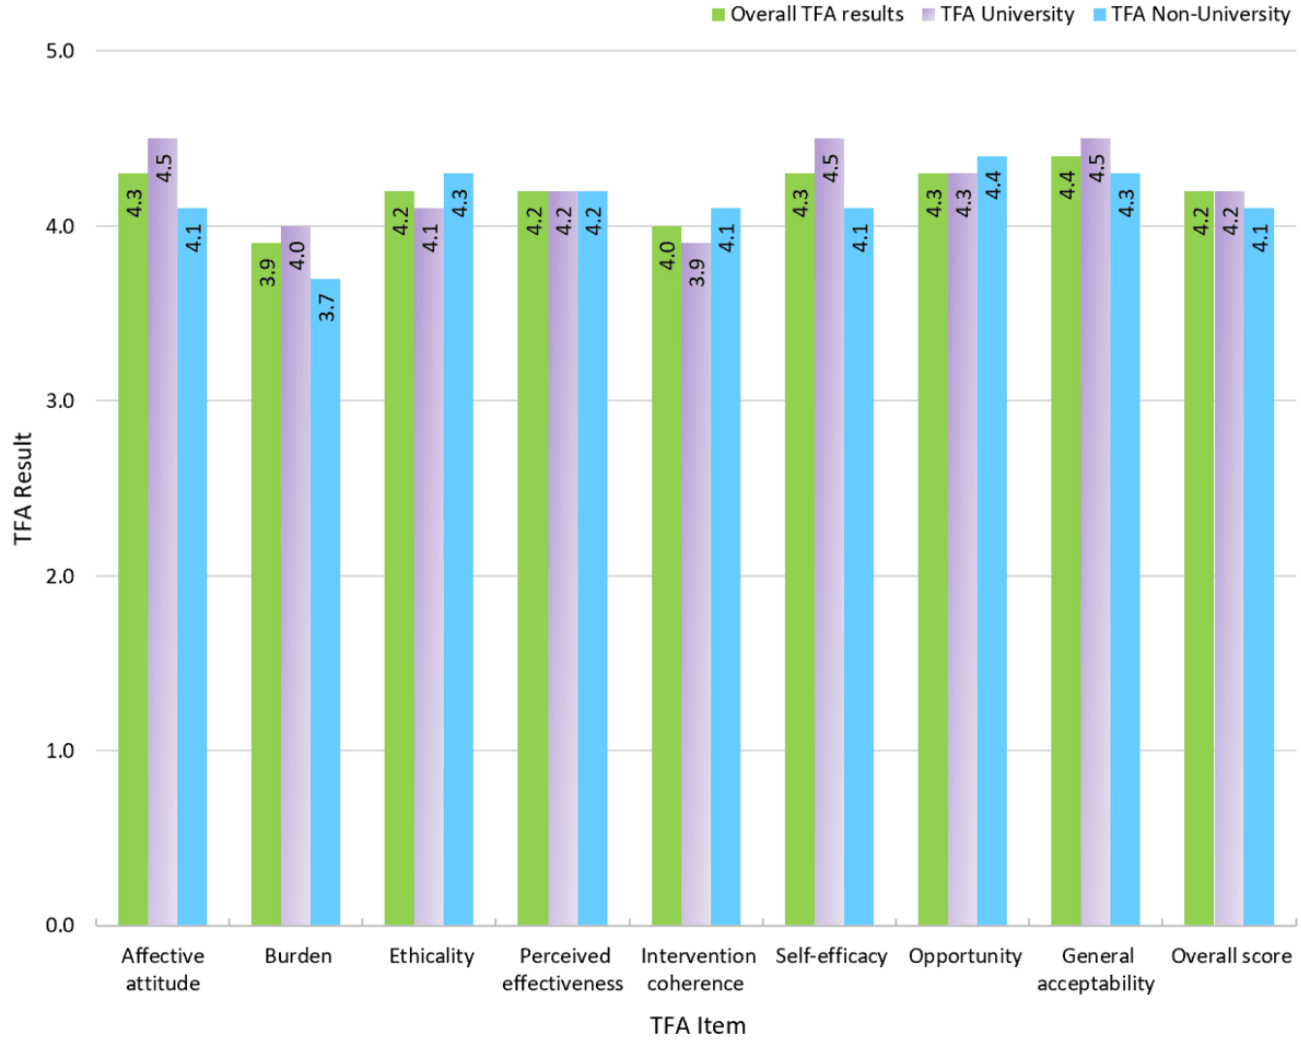
[c]THA: total hip arthroplasty.

[d]PKA: partial knee arthroplasty.

[e]UKA: unicompartmental knee arthroplasty.



[f]A currency exchange rate of CAD $1=US $0.75 is applicable.

Acceptability

The overall score for the preoperative TFA questionnaires was 4.2 (SD 0.6; Table 2). We found a statistically significant increase in self-efficacy with a university level of education compared to non-university (*P*=.04), but no difference related to age, sex, or employment (Figure 2). There was a statistically significant decrease between pre- and postoperative overall TFA (*P*=.007), as well as in pre- and postoperative perceived effectiveness (*P*=.01) and self-efficacy (*P*=.008; Table 3). Furthermore, when looking at TFA results by procedure, there was a statistically significant decrease with TKA in multiple TFA items, including overall acceptability (*P*=.008; Figure 3). There were no statistically significant differences between pre- and postoperative overall TFA nor in any of the TFA items with THA.

Figure 5. Pre- and postoperative (1, 3, and 6 mo) patient-reported outcome measure results by procedure: (A) Oxford scores and (B) VAS scores. THR: total hip replacement; TKR: total knee replacement; VAS: visual analog scale.

App Nondownload Rate

Of the 25 participants who did not download the app, 7 provided a reason. Their responses included technological concerns (n=2), feeling preoccupied and anxious preparing for the procedure (n=1), family issues (n=2), missing download instructions (n=1), and privacy concerns (n=1). The remaining 18 participants were also contacted on multiple occasions but never responded.

Discussion

Principal Findings

In this study, we investigated the acceptability of the use of the mymobility app for the postoperative care of 100 participants undergoing THA and TKA. We sought to investigate acceptability using the TFA to ensure all aspects of acceptability were measured.

Preoperatively, overall acceptability was satisfactory, with all but one TFA item scoring above 4 out of 5. The sole exception was burden (3.9/5), which may reflect lower familiarity with smartphone apps among older participants in our sample. We also found that higher education was associated with a higher level of self-efficacy. While general and overall acceptability were not significantly higher with higher education, this trend aligns with Wang et al's [15], Nuveo et al's [31], and Lee et al's [32] results, who described trends of higher engagement and adherence with higher education and lower receptivity to digital health technologies with lower education. Thus, these findings reveal the importance for app developers to consider this gap and tailor their content to diverse populations, notably

XSL•FO
RenderX

through the inclusion of images or videos, which are more easily accessible than heavy-text content.

When comparing pre- and postoperative TFAs, although overall scores were satisfactory at both time points, we found a significant decrease in overall acceptability postoperatively. We suspect this decrease is attributed to elevated expectations toward the app, which were adjusted following its use. However, we believe acceptability could also have been influenced by the natural process of recovery. Indeed, the decline in TFA was significant in TKA, but not in THA. PROM results showed the same trend, with no improvement until 3 months post operation in TKA as opposed to 1 month post operation in THA. This is consistent with Booth et al's [19] and Bourne et al's [33] results showing that TKA patients felt a higher need for in-person rehabilitation as opposed to THA and that short-term outcomes are superior in THA than in TKA. When considering the TFA items that decreased in TKA, which are linked to the perceived helpfulness of the app, this pushes us to believe that the decrease in postoperative acceptability was likely also driven by the surgical outcomes. This illustrates the possibility for app developers to better address the challenges in TKA rehabilitation, notably through adjustment of patient expectations following this procedure.

When looking at participants who did not download the app, reasons included concerns regarding technology in 2 cases, which might be due to the age of the participants (77-79 y). Additionally, 1 participant expressed privacy concerns. Although we explained how data collection and privacy functioned within the app, we still expected this number to be higher. This result is a positive sign for patient trust toward platforms used to provide care, although the need to discuss patient confidentiality within the app remains important.

Comparison With Previous Work

Multiple studies have investigated patient perspectives on the use of mHealth apps for joint arthroplasty. These studies all reported a high level of engagement, adherence, and satisfaction [13,15-19,31]. Factors that influenced the results positively included higher education and supportive environments, whereas those that did negatively included higher age, lower economic status, and worsened physical or psychological condition [15,17,31]. Patients also described better health care accessibility and reduced isolation with these interventions [20]. Our results showed that higher education was associated with greater acceptability. However, unlike prior work, we did not observe other demographic characteristics to significantly influence acceptability.

Strengths and Limitations

The main strength of this study is the measure of acceptability using a validated tool (TFA), which allowed us to assess all domains of this concept. Using this framework, we measured acceptability preoperatively, prior to exposure to the app, and postoperatively, after using the app. This allowed us to interpret how preexposure expectations were met following use of the app. Other strengths include the use of a single app, which reduced heterogeneity; the ITT design, which reflects real-world adherence; and the diverse population.

This study also has limitations. The main limitation is the absence of a control group, which limits the ability to attribute the results specifically to the app. This limitation is a result of ethical concerns brought by our institutional review board, which prohibited us from having a control group that could be denied a beneficial intervention. We also observed a high rate of unfilled questionnaires, which could have created a response bias. We believe this is due to most questionnaires being distributed by email or phone, creating a limiting step in communication. Other important limitations include the use of a single app, limiting the generalizability of the results; a potential selection bias toward patients willing to use the app; and statistical analysis being only performed with *t* tests, which might have limited the power of the conclusions. In addition, there was no assessment of baseline technological literacy, which could have affected results despite the app's technological guidance features.

Conclusion

There was a good level of acceptability with the use of mymobility for the postoperative management of THA and TKA, although acceptability decreased postoperatively. This decrease could signify high expectations toward the app preoperatively or higher than expected difficulty and pain in the early postoperative period. Higher education was associated with higher preoperative acceptability. TKA was associated with lower postoperative acceptability, which could be related to the delayed recovery in TKA when compared to THA. These 2 trends have previously been described in the literature, indicating potential gaps to address for app developers. We found a good level of satisfaction with the app, and Oxford scores showed better outcomes in THA than TKA, whereas VAS showed equally significant decreases in pain with both procedures. Privacy concerns were rare, with only 1 patient reporting them.

The impact of the natural recovery process in total joint arthroplasty on the acceptability of mHealth remains unclear. This gap could be addressed through a comparison of acceptability pre- and postoperatively in cohorts using the app and cohorts with standard care.

Acknowledgments

The authors sincerely thank St. Mary's Hospital for its support. The authors declare that no generative artificial intelligence was used in the preparation and writing of this article. All authors reviewed the results, approved the final version of the manuscript, and agreed to be accountable for all aspects of the work.
