Impact Factor (2023): 2.6
Volume 13 (2026) ISSN 2292-9495 Editor in Chief: Andre Kushniruk, BA, MSc, PhD, FACMI

Contents

Original Papers

Anesthesia Providers' Perspectives on the Redesigned Philips Acoustic Alarm System: Qualitative Pre- and Postimplementation Study (e82703)
Greta Gasciauskaite, Stefanie Senn, Cynthia Hunn, Christoph Nöthiger, David Tscholl, Tadzio Roche. 21

User Perceptions of a Large Language Model–Based Chatbot for Cognitive Reappraisal of Stress: Mixed Methods Feasibility Study (e89736)
Ananya Bhattacharjee, Jina Suh, Mohit Chandra, Javier Hernandez. 35

Redesign of Bedside Supply Carts to Improve Emergency Department Workflows: Mixed Methods Participatory Design (e80861)
Kat Hefter, Sammy Dreibelbis, Theresa Haupt, Amelia McIver, Agnes Wang, Julia Dwight, Ogechi Nwodim, Neil Ray. 52

Development of the ERATbi App, a Clinical Decision Support System for Early Recovery After Traumatic Brain Injury in the ICU: Usability Study (e79981)
Hsiao-Ching Yen, I-Hui Wu, Wei-Ling Hsiao, Sheng-Ru Lai, Chen-Hao Yang, Hsien-Chi Liao, Yin-Yi Han. 65

Overview of a User-Centered, Mixed-Methods Process for Designing Interconnected and Focused Mobile Applications on Patient Care Environment (InterFACE): Augmented-Reality Decision Support System for Pediatric Resuscitation (e78144)
Frederic Ehrler, Ana Rajic, Alexandre De Masi, Sharleen Olanka, Marco Generelli, Jennifer Davidson, Yiqun Lin, Kangsoo Kim, Pierre-Louis Rebours, Marc Ibrahim, Donovan Duncan, Ryan Kang, Sergio Manzano, Adam Cheng, Johan Siebert. 75

Designing App Interfaces to Elicit Specific Emotional Responses and Improve Attention and Short-Term Memory in Patients With Insomnia Undergoing Brief Cognitive Behavioral Therapy: Within-Subject Eye-Tracking Experimental Pilot Study (e79883)
Kuan-Chu Su, Hsiao-Yean Chiu, Ko-Chiu Wu, Chia-Chi Chang. 93

Reflections on the Inclusive Co-Design Process of a Virtual Assistant for Individuals With Complex Care Needs: Mixed Methods Study (e81941)
Julia van Calis, Kirsten Bevelander, Anneke van der Cruijsen, Jenneken Naaldenberg, Geraline Leusink. 112

The Development of a Web-Based Application to Support Informal Caregivers of Individuals With Head and Neck Cancer: Human-Centered Design Approach (e81896)
Awais Ahmad, Åsa Cajander, Ulrica Langegård, Birgitta Johansson, Anna Henriksson, Mona Pettersson, Waqas Ahmad, Ylva Tiblom Ehrsson.
1 2 8

Improving Usability of the Interrupting Prolonged Sitting With Activity Virtual Teacher Training Modules: Case Study (e83427)
Rebecca Hasson, Tiffany Tam, Lucy Myers, Anna Schwartz, Alissa Li. . . . 145

Personalizing Mobile Apps for Health Behavioral Change According to Personality: Cross-Sectional Validation of a Preference Matrix (e78939)
Laetitia Gosetto, Gilles Falquet, Frederic Ehrler. . . . 160

On the Design of a Sign Language Corpus of Medical Terms for Automatic Translation Systems: Mixed Methods Approach (e72789)
Milena Marcolino, Luiza Rosa, Elidea Bernardino, Mario Campos. . . . 178

Development, Implementation, and Preliminary Results of a Novel Social Network for Rare Disease Communities: Mixed Methods Study (e80230)
Lara Fendrich, Henriette Högl, Ralf Schmidt, David Bascom, Armin Berger, Max Lübbering, Gundula Ernst, Justus Schumacher, Sabrina Hölzer, Lorenz Grigull. . . . 190

A Mobile App (Tpro) for Symptom Management in Patients With Deep Vein Thrombosis Based on Patient-Reported Outcomes: Design and Development Using an Iterative Convergent Mixed Methods Approach (e92738)
Qiaodan Lu, Yafei Liu, Manna Shao, Lei Wang. . . . 210

An Online Epilepsy Self-Management Tool for Patients With Epilepsy: A Formative Usability Study (e79540)
Katarzyna Czerniak, Ross Shegog, Refugio Sepulveda, Robert Addy, Youngran Kim, Sahiti Myneni, Alejandra Garcia-Quintana, Kimberly Martin, David Labiner. . . . 224

Designing a Trauma-Informed Safety by Design Framework for Nonconsensual Intimate Image Removal Platforms: A 2-Phase Sequential Exploratory Study (e94438)
Ji-yeon Lee, Yejun Koh. . . . 247

Optimizing Usability of Digital Health Interventions for Nondigitally Native Adults: A Framework-Based Approach to Develop Just-in-Time Adaptive Interventions (JITAIs) and Other Adaptations (e87365)
Abby Cheng, Christine Gou, Adriana Martin, Sarah Hartz, Joanna Abraham. . . . 262

Personalized Intelligent Chatbot Based on AI-Generated Content Assists Memoir Writing for Older Adults With Cognitive Impairment: Mixed Methods Study (e83428)
Yibo Meng, Yuan Que, Zhe Yan, Bingyi Liu, Zixin Wang, Mandi Yang, Huidi Lu. . . . 281

User-Centered Virtual Clinic Services for Remote, Rural, and Underserved Sub-Saharan Africa: Development and Usability Study (e84272)
Abby Blocker, Ahmed Biyabani, Joyce Mwangama, Mohammed Datay, Bessie Malila. . . . 295

Mental Health Monitoring in Esports Athletes Using an mHealth App: Requirements Analysis and Usability Study (e90140)
Leona Stolberg, Daniel Hieber, Peter Kuhn, Michael Hebel, Johannes Schobel. . . . 314

Co-Designing a Digital Platform for the Management of Modifiable Risk Factors and Comorbidities in Patients With Atrial Fibrillation: Mixed Methods Usability Study (e95810)
Sofia Klavebäck, Frieder Braunschweig, Matthias Lidin, Emma Svennberg. . . . 328

Effect of Pharmacy Student Peer Supervision on the Accuracy of Admission Medication Reconciliation: Prospective Pre-Post Observational Study (e77486)
Basma Ammor, Morgane Masse, Anne Toulemonde, Laurine Cadart, Jean-Baptiste Beuscart, Marc Lambert, Pascal Odou, Bertrand Décaudin.

Health Information Technology–Related Loss of Central Surveillance Data in a Heart Intensive Care Unit: Multi-Framework Case Report (e92560)
Md Jabin. . . . 552

Dynamic Balance Control and Postural Adaptation in Human-Robot Collaborative Manipulation: Within-Subject Experimental Study (e79930)
Alessia de Nobile, Daniele Bibbo, Simone Ranaldi, Maurizio Schmid, Giovanni Corvini, Silvia Conforto. . . . 571

Prevalence of Work-Related Pain or Discomfort Among Urologists in the State of Florida: Results From the Florida Urologic Society Task Force on Ergonomic Challenges Experienced by Its Members (e88848)
Justin David, Austin Hill, Jared Schommer, Eric Regele, Colleen Ball, Sanoj Punnen, Joseph Costa, Adam Ball, Jamin Brahmbhatt, David Thiel, Raymond Pak, Ram Pathak. . . . 587

C8 Health, a Platform for the Implementation of Best Practices: Survey-Based Usability Study (e83547)
Faria Nisar, Nicolas D Alessandro, Jessica Suratkal, Ido Zamberg, Samantha Pope, Ali Ali, Luis Tollinche. . . . 593

Validation of the Taiwan Chinese Version of the Assistive Technology Usability Questionnaire for People With Neurological Diseases for Wearable Robotic Exoskeletons: Usability Study (e89556)
Hander Wang, Jian-Jia Huang, Yu-Cheng Pei, Huey-Wen Liang. . . . 600

Utility of Augmented Reality Glasses With Waveguide Optics and Facial Recognition Technology for Patient Verification in a Simulated Outpatient Setting: Physician Questionnaire Survey Study (e95664)
Ryo Ogasawara, Soichiro Yoshida, Kentaro Okamoto, Eiki Nagaoka, Hirotaka Sagawa, Kazutaka Sumita, Hajime Tanaka, Satoshi Shiraga, Tomohiro Amemiya, Yasuhisa Fujii. . . . 612

Feasibility and Preferences to Adopt mHealth-Based Interventions for HIV Prevention Among High-Risk Groups: Cross-Sectional Study (e81111)
Faizur Rehman, Muhammad Shahid, Mehran Riaz, Malik Umair, Farah Azhar, Adeel Siddiqui, Ali Ahmed. . . . 622

Evaluation of a Contactless Sleep Monitoring Device for Sleep Stage Detection at Home in a Healthy Population: Prospective Study in Free-Living Conditions (e77033)
Marie-Ange Stefanos, Guillaume de Laboulaye, David Campo, Martin de Gourcuff, Pierre Escourrou, Boris Matrot, Anna Islind, Pierre Geoffroy.
6 4 0

Designing for Knowledge Generalization in Medical Device Instructions Among Health Care Professionals: Qualitative Interview and Observation Study (e82405)
Qing Xia, Jeremy Opie, Tom Brookshaw, Eloy Barbarin, Ann Blandford, Clare Selden. . . . 665

Assistive Technologies for Pulse-Based Tele-Practice in Traditional Chinese Medicine: Two-Phase, Dual-Method Feasibility and Pilot Study (e77740)
Jia Ruan, Shucheng Chen, Minru Wu, Shuhan Li, Yuan Ho, Ka Fan, Wing Chow, Leung Chiu, Wing Yeung. . . . 680

Wearable Device Photoplethysmography As a Viable Tool to Longitudinally Monitor Vasoconstriction Biomarkers for Predicting Vaso-Occlusive Crisis in Sickle Cell Disease: Feasibility and Validation Study (e75465)
Payal Shah, Sabrina Sy, Mingjing Chen, Michael Khoo, Thomas Coates, Saranya Veluswamy. . . . 694

Opportunities for Improved Device Design Based on Central Line Placement Practices: Contextual Inquiry Study (e84621)
Mary Privitera, Sameer Khan, Bilal Irfan, Shayan Ali, Cecelia Arredondo, Kyrsten Sanderson, Jordan Bonomo. . . . 707

An Early-Stage Digital Therapeutic Intervention to Enhance Affective Response During Physical Activity Among Adults With Overweight or Obesity: Benchmark-Driven Formative Testing Study (e71472)
Rachel Crosley-Lyons, Lori Hatzinger, Micaela Hewus, Wei-Lin Wang, Delfien Van Dyck, Jimi Huh, Eric Hekler, Genevieve Dunton. . . . 723

A Summative Usability Evaluation of an Infusion Pump Through Simulation-Based Testing With Nurses: Mixed Approach Study (e86443)
Yingjun Wan, Yun Zhang, Yunlong Zhao, Han Yu, Kaifeng Liu. . . . 740

A Comprehensive Self-Medication Management System to Reduce Medication Errors Among People Living With Dementia: Mixed Methods Feasibility and Usability Study (e86828)
Santosh Basapur, Charles Gellman, Jamie Plenge, Amelia Troutman, Erin Yurko, Brandon Woolsey, Justin McClendon, Lisa Marceau, Neelum Aggarwal. . . . 755

Exploring Factors Influencing Nursing Task Prioritization for Supportive Information System Design: Qualitative Study With Thematic Analysis (e89940)
Kodai Iwamoto, Mayumi Toyama, Goshiro Yamamoto, Chang Liu, Kazumasa Kishimoto, Yukiko Mori, Tomohiro Kuroda. . . . 767

Contextual Assessments for Chronic Obstructive Pulmonary Disease Transition of Care Bundle Implementation Planning for the Reduce REVISITS Study: Rapid Sequential Explanatory Mixed Methods Approach (e82078)
Mahima Akula, Kim Erwin, Leah Traeger, Hannah Pick, Fei Gao, Laura Damschroder, Valerie Press. . . . 778

Improving the Efficiency of the Intravenous Medicine Preparation Pathway With an Intravenous Workflow Software Solution in Full-Capacity Pharmacy Units at Watford General Hospital: Observational Study and Economic Analysis (e85408)
Bethany Umpleby, Nick Hex, Teresa Martins, Husanain Soori. . . . 794

Organizational Tensions in the Implementation of Modifiable Off-the-Shelf Technologies in a University Hospital: Qualitative Multimethod Study (e84841)
Alessia Nowak, Carolina Gaul, Elena Hinz, Christine Knoll, Begüm Kül, Anja Wels, Julia Berkmann, Cathrin de Pasquale, Gloria Kremser, Daniel Fürstenau, Akira-Sebastian Poncette, Felix Balzer, Lina Mosch. . . . 805

Smartphone-Based Ecological Momentary Assessment to Monitor Opioid Use and Overdose Among People Who Use Opioids: Prospective Observational Feasibility Study (e95655)
Kamal Gautam, Kiran Paudel, Jeffrey Wickersham, Antoine Khati, Anushka Thapa, Sandesh Bhusal, Md Sujan, Sherry Pagoto, Toan Ha, Roman Shrestha. . . . 856

Development of a Data-Enabled Mixed Method for Designing for Patients From a Human-Centered Design Perspective: Explorative Case Study (e87677)
Yingtao Sun, Jiwon Jung. . . . 870

Developing mHealth IT for Older Adult Medication Safety: Remote Participatory Co-Design Using the RAPID Method (e82366)
Jordan Hill, Aaron Ganci, Noll Campbell, Andrew Pickett, Michelle Chui, Ephrem Abebe, Richard Holden. . . . 890

Surface Electromyography as a Method for Characterizing Mammogram Discomfort: Cross-Sectional Questionnaire Study of Procedural Stress (e83971)
Krystyna Gielo-Perczak, Riley McNaboe, Hugo Posada-Quintero. . . . 903

What Users Say About Reimbursable Digital Therapeutics in Germany: Large-Scale App Store Review Analysis Using a Large Language Model (e92415)
Benjamin Kinast, Henrik Rohde, Björn Schreiweis, Hannes Ulrich. . . . 922

Expert Views on Criteria for Evaluation of Human Factors Methods: Qualitative Interview Study (e73324)
Selvana Awad, Rachel Begg, Thomas Loveday, Andrew Baillie, Melissa Baysari. . . . 936

Interest in and Predictors of Engagement With a Virtual Reality Intervention Among People With Chronic Pain: Cross-Sectional Survey Study (e70598)
Genevieve Bryant, Samuel Holzman, Hector Perez. 945

Telemedicine Service Experience Questionnaire for Chinese Outpatients: Development and Validation Study (e60551)
Peicheng Wang, Kun Zhang, Yanhua Chen, Minan Zhao, Peiyao Li, Yi Kuang, Yanrong Du, Weiguo Zhu, Xiao Long, Leiyu Shi, Jiming Zhu. . . 9 5 3

Change Adaptation Resilience Evaluation Questionnaire for Industry 5.0 Among Workers in High-Tech Manufacturing Companies: Questionnaire Development and Pilot Evaluation Study (e83754)
Giulia Bassi, Angelo Valente, Serena Tassoni, Silvia Salcuni. 966

Feasibility of the “OA Coach” Mobile App to Support Individuals with Osteoarthritis: Development and Usability Testing (e84857)
Vicky Duong, Naomi Bloul, Jocelyn Bowden, Karen Bracken, Kate Bryce, Leticia Deveza, Jillian Eyles, Abdolhay Farivar, Robin Huang, Sarah Kobayashi, Na Liu, Carin Pratt, Charlotte Strong, Venkatesha Venkatesha, Shirley Yu, David Hunter. 991

Design and Performance of an Email-Based Patient Recruitment Campaign in Primary Care Research: Formative Secondary Analysis (e67088)
Vanessa Vaillancourt, Marie-Dominique Poirier, Amélie Fournier, Sabrina Wong, Marie-Eve Poitras. 1004

Usability Across 3 mHealth Problem-Solving Training Interventions for Diverse Neurodevelopmental and Neurological Populations: Multicase Usability Evaluation (e90379)
David Ogundairo, Shannon Juengst, Avani Modi, Shari Wade, Matthew Schmidt. 1014

Determinants of Adoption of a Mechanical Ventilation Dashboard in Intensive Care: Measurement Instrument for Determinants of Innovations–Based, Single-Center, Cross-Sectional Evaluation (e92313)
Sarah Mugge, Tobias van Leijsen, Merijn Reuland, Annelies Visser, Frederique Paulus, Dave Dongelmans. 1040

A Geospatially Customizable Culturally Tailored Just-in-Time Adaptive Intervention for Violence-Affected People Living With HIV: Mixed Methods Acceptability, Feasibility, and User Experience Study (e80705)
Simone Skeen, Stephanie Tokarz, Rayna Gasik, Ethan Smith, Katherine Theall, Gretchen Clum. 1053

Smartphone App Using Reinforcement Learning for Obesity: Single-Arm Feasibility Study (e77323)
Ken Kurisu, Yoshiharu Yamamoto, Tomohisa Aoyama, Toshimasa Yamauchi, Kazuhiro Yoshiuchi. 1073

Postural Education in School-Aged Populations: Development and Usability Evaluation of a Mobile Biofeedback App (EduBack) (e79282)
Marco García-Luna, Miguel García-Jaén, Daniel Ruiz-Fernández, Carmen Manchado, Juan Cortell-Tormo. 1084

Real-World Evaluation of the Eye+Dot Online Triage Support Tool in Community Optometry Practices: Mixed Methods Evaluation Study (e77278)
Jen Lim, Sarah Farrell, Samuel Newlands, Louise Allen. 1098

Aspects Supporting and Hindering Type 2 Diabetes Self-Management in Web-Based Educational Portals: Usability Testing Study With Updated Framework in Razavi-Khorasan, Iran (e78903)
Javad Jafari, Klas Karlgren, Hossein Karimi Moonaghi, Mohammad Mazaheri Habibi, Saeid Eslami, Italo Masiello, Stefano Bonacina. 1111

Impact of Rural Trauma Team Development Education on Prehospital Time, Referral-to-Dispatch Interval, and Neurological and Musculoskeletal Injury Outcomes: Cluster Randomized Controlled Trial (e82591)
Herman Lule, Micheal Mugerwa, Anne Abio, Benson Oguttu, Andrew Kakeeto, Fiona Walsh, Hervé Lekuya, Robinson Ssebuufu, Patrick Kyamanywa, Andreas Deckert, Till Bärnighausen, Jussi Posti, Michael Wilson. 1129

Quality of Informed Consent and Interface Usability in Primary Care e-Consultation: Cross-Sectional Study (e78483)
Caitlin Parfitt-Ford, Lisa Ballard, Adriane Chapman. . . . 1156

Grip Strength Estimation Using Input Data From a Commodity Smartphone: Model Development and Validation Study (e90316)
Komei Tajima, Kaori Ikematsu, Toshiya Isomoto, Kunihiro Kato, Yuta Sugiura. . . . 1170

Technology Acceptance of 2 mHealth Apps During an Observational Technology Evaluation Study: Qualitative Results of a Mixed Methods Study (e70873)
Johanna Graeber, Elke Warmerdam, Svenja Aufenberg, Christopher Bull, Kristen Davies, Juliane Döhring, Kirsten Emmert, Claire Judd, Corina Maetzler, Nikolay Manyakov, Ralf Reilmann, Wan-Fai Ng, Victoria Macrae, Walter Maetzler, Hanna Kaduszkiewicz. . . . 1183

A Smartphone App to Improve Intuitive Eating and Diet Quality: Design and Usability Study (e81439)
Mandy Korpusik, Delaram YazdanSepas, Hawley Almstedt. . . . 1196

Examining Telemedicine Adoption After the COVID-19 Pandemic and Evaluating the Impact of a Virtual Hospital on Clinician Engagement: Longitudinal Survey Study (e93911)
Galia Barkai, Shany Edelman-Yaron, Hadar Amir, Havi Inbar-Lankry, Rachel Sarafraz. . . . 1209

Usability and Workflow Integration of a Machine Learning–Derived Neonatal Risk Predictor in Kenyan Neonatal Units: Multisite User-Centered Pilot Evaluation (e94828)
Ronald Nyatuka, Paul Macharia, Esther Kakhata, Faith Siva, Betsy Muriithi, Md Jabin. . . . 1217

Insights on Designing the MINT (Micro-Interventions for Navigating Tension) Chatbot System for Stress Management: Collaborative Autoethnography (e89876)
Marco Bolpagni, Sofia Piffer, Marco Pozza, Munesu Maminimini, Silvia Gabrielli. . . . 1233

Patient and Designer Collaboration in Cocreating Technical Innovations in a Hospital-Based Makerspace: Qualitative Interview Study (e85926)
Jiske van der Giessen, Onno Helder, Thijs van Houwelingen. . . . 1249

Perspectives and Needs Regarding Remote Monitoring Technologies Among South Asian Individuals Living With Long-Term Conditions in the United Kingdom: Semistructured Interview and Focus Group Study (e82333)
Syed Ali, Yumna Masood, Karen Staniland, William Dixon, Sabine van der Veer, Caroline Sanders. . . . 1261

Digital Assistive Technology Acceptance and Use by Caregivers of Older Adults With Cognitive Impairment: Qualitative Interview Study (e80614)
Xingyue Su, Honglin Chen, Pasi Karjalainen. . . . 1274

Exploring Patients' Experiences in a Blended Transdiagnostic Group Treatment: Qualitative Study (e86016)
Noelia Jiménez-Orenga, Alba Fadrique-Jiménez, Azucena García-Palacios, Jorge Osma, Amanda Díaz-García, Juana Bretón-López. . . . 1287

User Perspectives on Conversational Agents for Preventive Alcohol Self-Help: Qualitative Exploratory Study (e86752)
Marissa De Vries, Melissa Begeman, Marloes Derksen, Anna Goudriaan, Matthijs Blankers. . . . 1313

Video-Algorithmic Patient Monitoring in Mental Health Inpatient Settings: Qualitative Study of Patient or Consumer, Clinician, and Vendor Perspectives (e85518)
Piers Gooding, Hamilton Kennedy, Simon D'Alfonso, Timothy Kariotis, Catherine Daniel, Bridget Hamilton. . . . 1323

Feasibility of a Mobile-Based Home Monitoring System for Patients With Heart Failure: Mixed Methods Pilot Study (e84309)
Finna Indriany, Kemal Siregar, Bambang Siswanto, Budhi Purwowiyoto, Rarsari Soerarso, Indrajani Sutedja, Benny Setiawan, Hendy Wijaya, Raymond Wong, Salvatore Di Somma, Peter MacDonald. . . . 1339

Using Theory-Based Frameworks to Identify Barriers, Facilitators, Expectations, and Willingness to Pay for Online Medical Consultation Services in China: Qualitative Study (e96448)
Shujie Dong, Qiushi Cai, Jingyi Ye, Yanya Chen, Rongsheng Zhao, Wai-kit Ming. . . . 1350

Evaluation of Wellby, a Cocreated Mobile App and Wearable to Support Stress Management and Overall Well-Being: Mixed Methods Acceptability and Usability Study (e79381)
Justin Laiti, Sina Javadpour, Jenna Mullen, Claire Conway, Elaine Byrne, Pádraic Dunne. . . . 1366

Acuity, Diagnosis, and Community Factors in Virtual and In-Person Treatment: Qualitative Study (e82863)
Brianna Cerrito, Alexa Connors, Amanda Fialk, Jamie Xiao, Josephine Usow, Frank Buono. . . . 1386

The Role of Explanations in AI-Generated Alerts: Qualitative Study of Clinical Views on Explainable AI in Predictive Tools (e81460)
Jessica Rahman, Alana Delaforce, DanaKai Bradford, Jane Li, Farah Magrabi, David Cook, Aida Brankovic. . . . 1397

Challenges and Strategies of Managing Mental Health Medication in Real-World Practices: Interview Study Among University Students (e67579)
Jiachen Li, Justin Steinberg, Elizabeth Mynatt, Varun Mishra. . . . 1414

Health Care Professionals' and Patients' Perceptions and Experiences of Who Uses Video Consultations, and Why: Qualitative Study (e68658)
Irene Muli, Åsa Cajander, Nadia Davoody, Lovisa Hagstedt, Helena Hvitfeldt, Maria Hägglund, Marina Taloyan. . . . 1431

Enhancing Data-Driven Decision-Making in HIV Care With Viral Load and Early Infant Diagnosis Data Dashboards in Côte d'Ivoire: Qualitative Study (e76550)
Yao He, Yves-Rolland Kouabenan, Paul Assoa, Nancy Puttkammer, Stephen Gloyd, Noah Hoffman, Bradley Wagenaar, Casey Iiams-Hauser, Pascal Komena, N'zi Kamelan, Adama Pongathie, Jan Flowers, Nadine Abiola, Natacha Kohemun, Jean-Bernard Amani, Christiane Adje-Toure, Lucy Perrone. . . . 1446

Patients' and Health Care Professionals' Experiences of a Digital Self-Management System for Asthma: Qualitative Study (e79866)
Lovisa Jäderlund Hagstedt, Helena Hvitfeldt, Sara Riggare, Göran Petersson, Nadia Davoody, Maria Hägglund. . . . 1458

Using the Theoretical Domains Framework to Identify Barriers to and Enablers of Patient Telemedicine Services Use in China: Qualitative Study (e78457)
Ke Liu, Yuting Yang, Zixuan Song, Huixian Li, Yanli Lyu, Ke Zhang, Xinxia Wu, Zheng Hou, Yipei Wang. . . . 1469

Hospital-at-Home for South Asian Communities in British Columbia, Canada: Qualitative Interview Study (e79675)
Emma Wong, Mahabhir Kandola, Kamal Arora, Harroop Sharda, Roman Deol, Mary Jung, Robert Paquin, Maria Montenegro, Megan MacPherson. . . . 1483

Bridging Gaps in Women's Heart Health: User-Centered Needs Assessment Informed by Patient and Clinician Interviews (e82916)
Christine Jacob, Sangeetha-Rose Puthanveettil, Patrick Vavken, Emel Kaplan, Christine Zuern. . . . 1497

Exploring Video Consultations Across the Public and Private Sectors in Norway: Semistructured Interview Study (e80812)
Mari Skoge, Sofie Aminoff, Henrik Ihler, Kari Kværner, Linn Støme, Kristin Romm. . . . 1516

Abstract

Background: Alarm fatigue caused by frequent or false alarms poses a persistent threat to patient safety. Despite technological progress, alarm acoustics remain largely unchanged and are often perceived as disruptive. To address this, Philips redesigned its patient monitoring alarm sounds through a user-centered approach aimed at improving priority differentiation and reducing emotional strain.

Objective: This study provides insights into human-technology interaction by examining anesthesia providers' experiences with the original and updated alarms, with a focus on emotional responses, usability, and guidance for the user-centered design of future clinical alarm systems.

Methods: This single-center qualitative study involved anesthesia providers who completed an online questionnaire before and after the implementation of the updated Philips alarms. Only those who completed the pre-implementation phase participated in the postimplementation phase. The questionnaire included 4 open-ended questions addressing perceptions of the current alarm sounds, suggestions for improvement, design expectations, and attitudes toward an alarm-free operating room. Responses were analyzed using thematic analysis to identify key usability and emotional response themes.

Results: A total of 90 eligible anesthesia providers participated in the preimplementation phase, and 77 (85.6%) participated in the postimplementation phase. Positive emotional responses increased in the postimplementation phase, whereas concerns regarding alarm functionality also became more prominent. Before the introduction of the updated alarm sounds, participants predominantly called for softer sounds. Following implementation, the most frequently expressed concern shifted to the need for clearer prioritization of alarms. Across both phases, the primary expectation remained the alarms' ability to effectively capture attention. The concept of an alarm-free operating room elicited concerns about increased workload and potential risks to patient safety.

Conclusions: The redesigned alarm sounds were perceived more positively in terms of emotional acceptance; however, they did not improve the recognition of alarm priority. The modest acoustic changes did not address the broader issue of alarm overload. Suggestions such as visual-only alerts for low-priority alarms show potential but must be balanced with patient safety standards. Future alarm development should combine user feedback with expert-driven and evidence-based approaches to improve both usability and clinical effectiveness.

anesthesia; auditory perception; clinical alarms; equipment design; patient monitoring; patient safety; sound; user-centered design; human-computer interaction

Introduction

Alarm sounds are essential safety mechanisms in modern clinical environments, designed to alert caregivers to potentially critical changes in a patient's condition [1]. However, high exposure to alarms, particularly those that are clinically irrelevant or false positives, can lead to alarm desensitization—a phenomenon known as alarm fatigue [2]. This is associated with delayed or missed responses to true alarms and represents a significant threat to patient safety [3,4]. Beyond the sheer volume of alarms, the lack of clarity and contextual relevance of alarm sounds

XSL•FO
RenderX

further exacerbates the problem [5]. Poorly differentiated alarm sounds or those lacking intuitive meaning may cause confusion among clinicians and impair the timely interpretation of patient status [6-8], particularly in already crowded acoustic environments where multiple devices compete for clinicians' attention.

Despite significant advances in patient monitoring technology, the acoustic design of alarms has seen little innovation over the past decades, despite extensive research in this area [9-11]. Historically, alarm sounds were designed to be as loud and attention-grabbing as possible, often by using auditory roughness and very salient, high-pitched frequencies [12]. The goal was to ensure that clinical staff would notice the alarms immediately. However, clinical staff often perceive these sounds as disruptive and emotionally taxing, with studies reporting that they are frequently experienced as stressful, difficult to interpret, and hard to distinguish from one another [8,13-15]. However, in many cases, subtle cue tones may be more appropriate as not all alarms require immediate action by health care professionals.

Philips (Koninklijke Philips N.V.), a leading manufacturer of patient monitors, has recognized these issues. In response, the company initiated a user-centered redesign process to revise the auditory characteristics of its monitor alarms. The updated system introduced changes to the acoustic cues with the aim of improving the distinction between alarm priorities and optimizing the balance between attention-grabbing and pleasant auditory stimulation [16]. The underlying logic of when and why alarms are triggered remained unchanged.

The redesigned alarm sounds attempt to address issues of poor clarity, limited contextual relevance, and negative emotional responses. However, it remains unclear whether such user-centered design changes translate into meaningful improvements in clinical practice. While the inclusion of end users in the design process is crucial, it may also limit innovation if feedback is primarily shaped by existing habits and expectations rather than by exposure to novel alarm paradigms [17]. More progressive approaches to alarm sonification, such as auditory icons or spoken cues that are easily distinguishable and convey information about the underlying cause of the alarm in addition to attracting attention, do not appear to have been considered in this redesign [9,10,18].

This qualitative study explored anesthesia providers' perceptions of patient monitoring alarms before and after the implementation of the redesigned Philips sounds. Specifically, we investigated emotional responses, perceived usability, and participants' visions for future alarm systems while reflecting on the broader implications for alarm design, innovation strategies, and patient safety.

Methods

Ethical Considerations

The Cantonal Ethics Committee Zurich reviewed the study protocol and issued a declaration of nonjurisdiction (Req-2022-00689) [19]. Before participation, written informed consent was obtained from all participants, granting permission for the use of the collected data for research purposes. Participation in the study was voluntary and without compensation. All data were deidentified prior to analysis. The data are presented in aggregated form only, and no conclusions about individual participants can be drawn from the published results.

Updated Philips Patient Monitor Alarm Sounds: Design and Implementation

While the design process behind the updated Philips alarm sounds was not part of this study, we briefly summarize its key objectives to provide context. The redesign followed a human-centered approach, combining qualitative methods (interviews and workshops) with quantitative surveys across 2 iterative development phases. During the original design process, anesthesia professionals (including nurses, residents, and attending physicians) from 7 countries contributed their perspectives on what constitutes an improved alarm sound.

Participants consistently highlighted the need to reduce the harshness and unpleasantness of alarm cues, expressing a preference for sounds that are more pleasant, natural, and less stressful. They also emphasized the importance of clearer differentiation between alarm priority levels and better distinction from other clinical acoustic signals.

In the second iteration, participants were asked to evaluate and select from a range of newly developed alarm sound options. On the basis of this feedback, the sounds were revised as follows: low-priority alarms were softened and spaced with longer tone intervals, medium-priority alarms were given distinctive pitch and timing characteristics, and high-priority alarms were adjusted to reduce shrillness while maintaining urgency. A more detailed description of the design process can be found in the publication by Hunn et al [20]. Both the original and updated alarm sounds are available for comparison in Multimedia Appendix 1.

Study Design

This investigator-initiated, single-center qualitative descriptive study was conducted at University Hospital Zurich, Switzerland, in 2 phases: before (January 2024 to March 2024) and after (August 2024 to October 2024) the implementation of the updated Philips patient monitoring alarm sounds. The aim was to explore anesthesia providers' (trainee nurses, nurses, resident physicians, and attending physicians) perceptions of the original and updated alarm sounds following their implementation and a subsequent adaptation period of 4 months.

Before implementation, clinical staff participated in a 1-hour training session to familiarize themselves with the new alarm system.

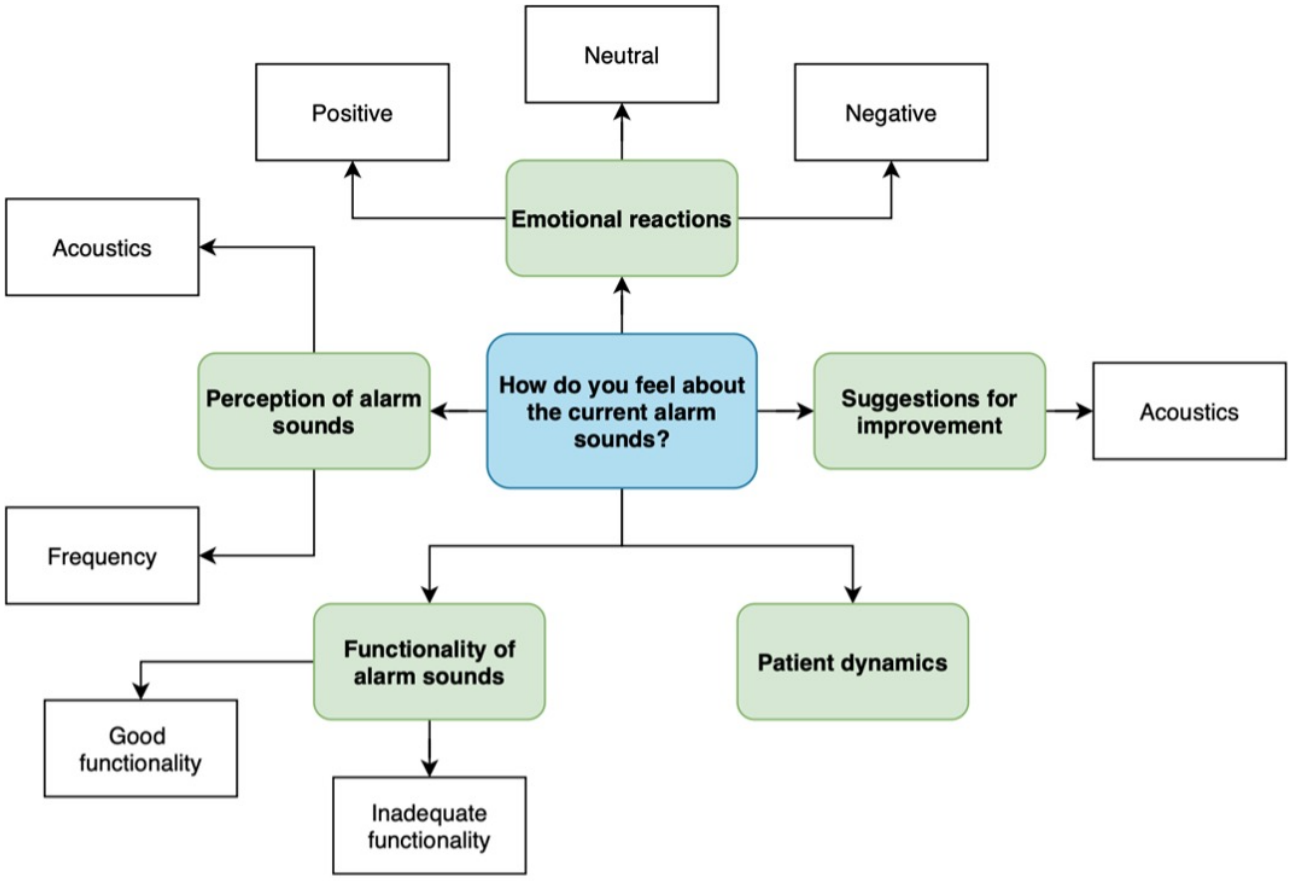
An online questionnaire consisting of both open- and closed-ended questions was completed by participants as part of a face-to-face study procedure. In the prephase, participants were eligible if they worked regularly in the operating room and were familiar with the existing alarm sounds; no additional inclusion or exclusion criteria were applied. Only participants who had taken part in the prephase took part in the postphase.

XSL•FO
RenderX

Survey Questionnaire

The questionnaire was developed using Google Forms and administered to participants at 2 time points: once during the prephase (original Philips alarms) and again during the postphase (updated Philips alarms). It comprised 2 main sections.

The first section included 4 open-ended questions designed to elicit free-text responses regarding participants' perceptions of current patient monitoring alarm sounds, suggested improvements and their underlying reasoning, expectations for alarm cue design, and vision of an operating room without acoustic alarms.



The second section contained 4 closed-ended questions to collect demographic data (age, gender, years of experience in anesthesia, and professional role) during both phases. In the prephase only, 2 additional questions were included to assess whether participants regularly played a musical instrument and whether they had attended an introductory lecture on the redesigned alarm sounds before their clinical implementation.

Data Analysis

A 6-step thematic analysis method was used to examine the open-ended responses and identify dominant themes [21]. After thoroughly reviewing the data, the research team convened to share impressions and explore potential thematic concepts. On the basis of this discussion, 4 coding templates were developed for each question to facilitate further analysis (Figures 1-4). Participants' responses were independently coded by 3 team members (GG, SS, and TRR). Any discrepancies in coding were resolved by the third coder (GG).

Closed-ended responses were analyzed using Microsoft Excel and presented as numerical values with percentage distributions or as medians with IQRs and minimum and maximum values.

Results

Participant and Study Characteristics

Of the 90 anesthesia providers initially contacted, all (n=90, 100%) completed the questionnaire during the prephase. In the postphase, 85.6% (77/90) of the potential participants submitted the questionnaire, as 14.4% (13/90) were unavailable due to a change in employment. A total of 888 comments were collected: 509 (57.3%) during the prephase and 379 (42.7%) during the postphase. A detailed study and participant characteristics are provided in Table 1.

[b]The question was not repeated in the postphase.

Main Themes From Responses to Open-Ended Questions: Impressions Before and After Implementing the Updated Philips Patient Monitor Alarm Sounds

Overview

Table 2 presents the themes and subthemes corresponding to the coding trees (Figures 1-4), as identified in participants' responses, along with illustrative examples and their numerical and percentage distributions.

XSL•FO
RenderX

Table . Identified themes and subthemes in participants' responses with examples, numerical values, and percentage distributions.

Theme and subthemes	Prephase comments, n/N (%)	Postphase comments, n/N (%)	Examples	
			Prephase (original alarms)	Postphase (updated alarms)
Question: "How do you feel about the current alarm sounds?"				
Emotional reactions				
Positive	37/139 (26.6)	46/89 (51.7)	"I am satisfied with the current alarm sounds as they help me alert to dangerous situations." [Participant 72]	"I feel less stressed with the new alarm sounds." [Participant 85]
Neutral	21/139 (15.1)	3/89 (3.4)	"Familiar alarm sounds that are well integrated into my daily workflow." [Participant 46]	"I have gotten used to it." [Participant 55]
Negative	30/139 (21.6)	7/89 (7.9)	"The more frequently and longer they sound, the more it increases my stress level while working." [Participant 22]	"I am familiar with the old sounds and prefer them." [Participant 73]
Perception of alarm sounds				
Acoustics	9/139 (6.5)	2/89 (2.2)	"The sounds are very high-pitched." [Participant 27]	"The new sounds are more high-pitched, otherwise similar to the previous ones." [Participant 22]
Frequency	10/139 (7.2)	0/89 (0)	"High-priority alarms sound too often." [Participant 85]	—[a]
Functionality of alarm sounds				
Good functionality	9/139 (6.5)	9/89 (10.1)	"I perceive them as a high level of security, and they allow me to focus on the surgical tasks as well." [Participant 38]	"The new alarm sounds capture appropriate attention." [Participant 75]
Inadequate functionality	16/139 (11.5)	20/89 (22.5)	"The alarm sounds with 'low priority' are often not noticed." [Participant 87]	"I find that the new alarm sounds often go unnoticed in hectic situations." [Participant 84]
Patients				
Patient dynamics	5/139 (3.6)	2/89 (2.2)	"I think that the alarm sounds are very unsettling for the patients." [Participant 66]	"For the patients, the new alarm sounds are certainly much more pleasant and less startling." [Participant 3]
Suggestions for improvement				
Acoustics	1/139 (0.7)	0/89 (0)	"The alarm sounds could be slightly lower in pitch." [Participant 24]	—
Question: "What would you change and why?"				
No suggestions for changes[b]	26/112 (23.2)	22/84 (26.2)	"I would not change anything. The alarms fit into my workflows." [Participant 75]	"I do not want to change anything." [Participant 90]
Acoustic design				
Sound character	26/112 (23.2)	7/84 (8.3)	"I would wish for softer tones. The saturation tone drops too quickly to a lower pitch. From 100% to 98%, it startles me." [Participant 33]	"The new alarm sounds are more pleasant." [Participant 82]

XSL•FO
RenderX

Theme and subthemes	Prephase comments, n/N (%)	Postphase comments, n/N (%)	Examples	
			Prephase (original alarms)	Postphase (updated alarms)
Differentiation	11/112 (9.8)	27/84 (32.1)	"Alarms that indicate high priority should stand out more from the 'standard tones.' A better differentiation for emergencies to quickly grab the attention of the team." [Participant 46]	"Low- and medium-priority alarm sounds are difficult to distinguish." [Participant 70]
Volume	5/112 (4.5)	4/84 (4.8)	"The volume should gradually increase." [Participant 29]	"Low-level alarms could be louder and more attention-grabbing." [Participant 65]
Interval	10/112 (8.9)	6/84 (7.1)	"For lower alarm priorities, the frequency should be lower." [Participant 6]	"I would like to increase the frequency of the middle tone a little." [Participant 89]
Reduction of alarm frequency				
Smart alarms	7/112 (6.3)	2/84 (2.4)	"Filter settings and auto-limits; more 'intelligence' in the alarm sounds." [Participant 20]	"Reduce the Apnoea alarm during anaesthesia induction from high alarm priority to medium priority." [Participant 29]
Only relevant alarms should have sound	17/112 (15.2)	8/84 (9.5)	"Most alarms are artifacts or clinically irrelevant." [Participant 71]	"I only need two alarm priorities; technical alarms (low priority) are unnecessary." [Participant 52]
Patient and staff				
Patient well-being	6/112 (5.4)	2/84 (2.4)	"For patients in the induction phase, the alarm sounds are very startling and sometimes frightening." [Participant 51]	"Some patients found the sound unpleasant and asked if it would be heard the entire time." [Participant 53]
User-friendliness	4/112 (3.6)	3/84 (3.6)	"Easily acknowledgeable alarms." [Participant 22]	"I would like a simpler way to silence the alarm tone." [Participant 46]
The old tones[b]	—	3/84 (3.6)	—	"The old alarm tones." [Participant 53]
Question: "What do you expect from an alarm sound?"				
Attention				
Attention grabbing	49/134 (36.6)	46/104 (44.2)	"A good alarm tone grabs attention and does not allow for ignoring." [Participant 5]	"Direct attention to the monitor and to the patient." [Participant 22]
Distinction	22/134 (16.4)	11/104 (10.6)	"A good alarm tone must be easily distinguishable from other sounds." [Participant 14]	"Important alarms should stand out. A low tone is distracting." [Participant 2]
Priority and differentiation				
Priority indication	18/134 (13.4)	15/104 (14.4)	"I expect a simple classification of the alarm's importance (i.e., distinction of priority)." [Participant 66]	"The ability to assess the alarm priority without directly looking at the monitor." [Participant 4]
Problem identification	14/134 (10.4)	12/104 (11.5)	"I expect a precise differentiation of the problem." [Participant 81]	"The corresponding meaning of the tone and its consequences are important." [Participant 5]
Usability				

XSL•FO
RenderX

Theme and subthemes	Prephase comments, n/N (%)	Postphase comments, n/N (%)	Examples	
			Prephase (original alarms)	Postphase (updated alarms)
Patient and staff focused	24/134 (17.9)	17/104 (16.3)	"It should convey the information but be pleasant." [Participant 31]	"The alarm tones should fulfil their purpose and not create additional stress." [Participant 87]
Customization	5/134 (3.7)	2/104 (1.9)	"Alarm only when there is a real clinical emergency. Do not alarm for any technical issues." [Participant 40]	"Alarm tones should be adjustable to the individual patient." [Participant 3]
Patient safety[b]	2/134 (1.5)	1/104 (1.0)	"Safety for the patient." [Participant 33]	"Patient safety." [Participant 3]
Question: "How do you imagine an operating room without alarm sounds?"				
Emotional reactions				
Uncertainty and stress	49/124 (39.5)	37/102 (36.3)	"It would be a very large burden for me." [Participant 38]	"It is not possible; it cannot be done." [Participant 26]
Relief and calm	29/124 (23.4)	19/102 (18.6)	"A more pleasant work atmosphere where one can stay focused for longer periods." [Participant 46]	"A calm, pleasant working atmosphere." [Participant 3]
Impact on work				
Increased workload	8/124 (6.5)	10/102 (9.8)	"It is exhausting for anaesthesiologists, as the monitor must be constantly checked." [Participant 66]	"It would make everyday tasks significantly more difficult, as it would require more frequent visual checks of the vital parameters, potentially preventing full concentration on other tasks." [Participant 84]
Lack of a perceptual input	16/124 (12.9)	6/102 (5.9)	"I am used to working a lot with my hearing, and it helps in an emergency to quickly assess and focus on the patient." [Participant 43]	"No focus because you would have to constantly look at the monitor." [Participant 62]
Alternative solutions[b]	4/124 (3.2)	6/102 (5.9)	"Visual alarms, colours on the monitor." [Participant 42]	"Further exploration/research into new ways of presenting alarms (e.g., tactile/visual) would definitely be advisable, to possibly achieve this in the near or somewhat distant future. It would certainly be desired." [Participant 68]
Patient risk[b]	18/124 (14.5)	24/102 (23.5)	"However, patients would likely be at risk." [Participant 11]	"I believe that would pose a risk to patient safety; I consider the alarm tones essential for staying focused, especially during long surgeries." [Participant 89]

[a]Not applicable.

[b]Distinct themes without subthemes.

How Do You Feel About the Current Alarm Sounds?

We identified 2 main themes in participants' responses: emotional reactions and alarm sounds' functionality. Before the implementation of the updated Philips patient monitoring alarm sounds, 26.6% (37/139) of the collected statements reported a positive emotional response. After the update, this proportion increased to 51.7% (46/89), indicating a notable improvement in the perceived emotional acceptance of alarm sounds. However, concerns about the functionality of alarm sounds remained prevalent across both phases, with related issues

XSL•FO
RenderX

reported in 11.5% (16/139) of preimplementation responses and 22.5% (20/89) of postimplementation responses, making it the second most frequently mentioned theme.

What Would You Change and Why?

The main themes identified in participants' responses differed slightly between the pre- and postimplementation phases. In the prephase, the most frequently mentioned themes were no suggestions for changes (26/112, 23.2%), sound character (specifically the need to reduce high-pitched tones and make sounds softer and more harmonious; 26/112, 23.2%), and a suggestion to present only high-priority alarms with sound while representing low-priority alarms visually (17/112, 15.2%).

In the postphase, the dominant theme was the difficulty in distinguishing alarm sounds based on priority (27/84, 32.1%), highlighting the need to make tones for different priority levels (low, medium, and high) more distinct. The second most frequently mentioned theme, as in the prephase, was that no changes were required (22/84, 26.2%).

What Do You Expect From an Alarm Sound?

The responses in the pre- and postimplementation phases differed slightly. In both phases, expectations focused primarily on an alarm sound's ability to capture attention (49/134, 36.6% in the prephase vs 46/104, 44.2% in the postphase), emphasizing the need for effectiveness even in noisy environments. The second most frequently mentioned theme in both phases was priority indication (18/134, 13.4% in the prephase vs 15/104, 14.4% in the postphase), meaning that an alarm sound should clearly convey the urgency of a situation.

In the prephase, another dominant theme was the distinction of alarm sounds from other sounds (22/134, 16.4%). In contrast, in the postphase, a new theme emerged: usability in terms of alarms addressing both staff and patient needs (17/104, 16.3%), meaning that they should be easily perceptible for staff without causing stress for patients.

How Do You Imagine an Operating Room Without Alarm Sounds?

The same themes dominated participants' responses to this question: uncertainty and stress due to increased effort and strain from the lack of auditory cues (49/124, 39.5% in the prephase vs 37/102, 36.3% in the postphase), relief and calm associated with reduced noise and a more pleasant work environment (29/124, 23.4% in the prephase vs 19/102, 18.6% in the postphase), and patient risk as the absence of alarm sounds may lead to overlooked critical situations or delayed reactions to changes (18/124, 14.5% in the prephase vs 24/102, 23.5% in the postphase).

Discussion

In this investigator-initiated, single-center qualitative descriptive survey study, we explored anesthesia providers' perceptions of patient monitoring alarm sounds before and after the clinical introduction of the redesigned Philips alarms.

While the updated alarm sounds were associated with a greater proportion of positive emotional responses among the study participants, the perceived issue of clearly distinguishing between alarm priorities persisted. Before the update, participants predominantly reported difficulties in differentiating between medium- and high-priority alarms. However, after the update, they indicated increased difficulty distinguishing between low- and medium-priority alarms.

Alternative strategies, such as user training for alarm threshold adjustment; reduction of overmonitoring [2,22]; and advanced technical solutions, such as smart alarms, multiparameter integration, and short-delay algorithms, have shown greater promise in reducing alarm fatigue than alarm design alone [23]. In addition, innovative acoustic approaches, including auditory icons, spearcons, and voice alerts, may further enhance alarm systems. Studies suggest that these formats improve speed and accuracy of interpretation while lowering cognitive load [9,24-26]. Importantly, the International Electrotechnical Commission (IEC) explicitly recommended the use of auditory icons in its revised global standard for medical equipment alarms (IEC 60601-1-8) published in 2020 [27].

Beyond acoustic design, the ergonomics of the patient bedside are also important. Limited visibility of alarm triggers may lead clinicians to rely on multiple auditory cues from multiple devices. Optimizing screen layout, integrating networked devices with hierarchical alarms, and using smart display strategies such as a patient avatar could reduce cognitive load and improve timely responses [28]. These ergonomic and acoustic considerations provide a useful framework for understanding how clinical staff actually perceive and interact with alarm sounds in practice.

In our study, participants primarily perceived the role of acoustic alarms as drawing attention to the patient monitor rather than conveying specific clinical information. It is noteworthy that participants did not suggest innovative ways in which acoustic alarms could communicate specific deviations in vital signs. Similarly, established alternative sonification approaches, as discussed in the literature [29] and reflected in the IEC 60601-1-8 international standard, were not referenced in the responses. This may suggest limited awareness or perceived relevance in the clinical context [27]. This observation may be explained by the innovation paradox inherent to user-centered design: users tend to articulate needs and preferences based on familiar concepts and experiences [17]. Thus, if design processes rely exclusively on user feedback, opportunities for more radical or transformative innovations may be overlooked. Therefore, to foster meaningful advancements in alarm systems, user-centered design should be complemented with expert-driven innovation strategies and evidence-based frameworks.

This study also explored the radical notion of eliminating acoustic alarms altogether. Surprisingly, only a small proportion of participants considered this to be a significant risk to patient safety, despite the fact that acoustic alarms are mandated as essential patient safety tools in various guidelines and industry standards [1,4,7]. This finding underscores the need for ongoing education about the safety functions of alarms and the complex trade-offs between alarm fatigue and patient risk.

XSL•FO
RenderX

One particularly interesting and easily implementable idea was repeatedly mentioned by participants: anesthesia providers suggested eliminating the auditory presentation of low-priority alarms, opting instead for visual-only indications. A closer examination reveals that low-priority alarms in Philips patient monitors predominantly signal technical issues unrelated to the patient's clinical status and typically do not require intervention of the caregiver. We believe that, depending on the clinical context—whether intensive care units, operating rooms, recovery rooms, or telemetry wards—the function and role of alarms vary significantly. Different rooms, different rules: what works in the operating room may not suit intensive care. User feedback is invaluable for evaluating these different use profiles. However, any changes to alarm management strategies, particularly the reduction of acoustic cues, must be carefully evaluated against existing safety guidelines and subjected to thorough risk assessments to ensure that patient safety is not compromised.

This study has several notable strengths. It was conducted in a real-world clinical environment at a large tertiary university hospital, enhancing the external validity and practical relevance of the findings [30]. The pretest-posttest design allowed for a direct comparison of perceptions before and after the implementation of the updated Philips patient monitoring alarms [31]. Furthermore, open-ended responses were systematically analyzed using a well-established 6-step thematic analysis method [21], with independent coding by multiple researchers to ensure analytical rigor and minimize bias. The provision of original study materials, including the questionnaire and multimedia supplements, further strengthens the transparency and reproducibility of the research.

Nonetheless, several limitations must be acknowledged. The single-center pretest-posttest design without a control group precludes causal inference, does not account for time-dependent effects, and limits generalizability [30]. However, the within-subject design, standardized training, and extended adaptation period were chosen to enhance internal and ecological validity for the evaluation of alarm sound perception in a real-world clinical setting. Participation was voluntary, which may have introduced selection bias, as individuals with greater interest in alarm systems or new technologies might have been more likely to participate. The questionnaire, although carefully designed, was not externally validated, potentially affecting the reliability of the findings. It should also be noted that while the patient monitor was evaluated in a clinical setting in the operating room, the study did not assess the monitor within the full operating room soundscape, which may influence real-world perception. Finally, perceptions were self-reported and, therefore, subject to biases such as social desirability or recall bias. Moreover, while improvements in emotional acceptance of alarm sounds were achieved, it is critical to emphasize that positive emotional responses alone do not guarantee enhanced patient safety. Functional effectiveness, particularly the rapid and accurate identification of alarm priorities, remains paramount.

Despite these limitations, this study provides valuable insights into the user experience with updated patient monitoring alarms and highlights important considerations for future alarm design, development, and evaluation efforts. When developing new technological solutions to reduce alarm frequency and false positives and improve the distinguishability and intuitive meaning of alarm signals, it is crucial not to rely solely on user-centered design [17]. Current evidence [9,24,25], international standards [27], and expert input must also be incorporated to achieve an optimal balance among usability, safety, and innovation. Future patient monitoring alarm systems could benefit from a multimodal approach that integrates conventional alarm sounds with auditory icons, voice alerts, and advanced visual displays to better support clinical decision-making and effectively mitigate alarm fatigue for both caregivers and patients [29].

Acknowledgments

The authors are grateful to the participants of the study for their investment and time. During the preparation of this work, the authors used GPT-4o (OpenAI) to improve the readability and language of the manuscript. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Funding

Philips provided support with personnel for the activation of the updated alarm sounds. The licensing of the sounds was carried out independently by University Hospital Zurich and was not related to this study. The research that led to these results was supported by the Institute for Anesthesiology and Perioperative Medicine of University Hospital Zurich with funds from the University of Zurich.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files (Multimedia Appendix 2).

Conflicts of Interest

CBN and DWT are among the inventors of the Visual Patient Avatar and Visual Patient Predictive technologies, for which the University of Zurich and Philips hold various patents, design rights, and trademarks. CBN, DWT, and TRR are listed as inventors of Visual Patient Predictive. These technologies are being developed jointly with Philips companies in Germany, the Netherlands, and the United States under agreements that provide CBN and DWT with research funding, travel support, consulting and lecturing honoraria, and royalties. TRR receives research funding, travel support, and honoraria and may receive royalties if Visual Patient Predictive is successfully commercialized. DWT also serves on the Philips Patient Safety Advisory Board. CH, CBN, and DWT are inventors of Visual Clot, and CBN, DWT, and TRR are inventors of Visual Blood—technologies for which the University of Zurich holds related intellectual property. Royalties may be awarded to the inventors if these technologies are commercialized. In addition, DWT is the inventor of Visual Hemofilter and Visual Heart, with similar intellectual property held by the University of Zurich and potential royalties pending commercialization. DWT has also received travel support and honoraria from Instrumentation Laboratory – Werfen (United States), the Swiss Foundation for Anesthesia Research (Switzerland), and the International Symposium on Intensive Care and Emergency Medicine (Belgium). None of the authors have any financial interest in the alarm sounds evaluated in this study.

Abstract

Background: Cognitive reappraisal is a widely studied emotion regulation strategy that helps individuals reinterpret stressful situations in ways that reduce their emotional impact. Digital mental health (DMH) tools often struggle to support this process because scripted templates fail to adapt to the varied and incomplete ways users describe their stressors. Large language models (LLMs) offer opportunities to increase conversational flexibility while preserving structured intervention steps.

Objective: This study aimed to examine the feasibility of an LLM-based single-session intervention (SSI) for stress reappraisal. We assessed whether the activity was associated with short-term improvements in stress-related outcomes, and explored the design tensions that arose during user interactions.

Methods: We conducted a feasibility study with 100 employees from a large US technology company. Participants completed a structured cognitive reappraisal session delivered by a GPT-4o–based chatbot within Qualtrics. Pre-post measures included situational stress intensity, stress mindset, perceived demand, and perceived resources (all 5-point scales). Paired Wilcoxon signed-rank tests were used with Benjamini-Hochberg correction. To complement self-reports, we analyzed sentiment and stress trajectories across conversation tertiles using a Robustly Optimized BERT Pretraining Approach (RoBERTa; BERT: Bidirectional Encoder Representations from Transformers) sentiment classifier, a RoBERTa stress classifier, and an LLM-based stress rater. We also conducted a thematic analysis of participants' open-ended responses covering stress impact, perspective change, liked and disliked aspects, and improvement suggestions, alongside their conversation logs.

Results: Significant reductions were observed in situational stress intensity (mean 0.29, SD 0.83, r_{rb}=0.54; P=.002) and significant improvements in stress mindset (mean 1.70, SD 4.37, r_{rb}=0.44; P=.002). Sentiment and stress classifiers showed consistent declines in negative sentiment and stress from conversation start to end (all omnibus Friedman tests P<.001). Thematic analysis of open-ended responses surfaced several patterns in how participants engaged with the activity: they valued the structured prompts for organizing their thoughts, described shifts in how they interpreted their stressors, used the interaction to identify concrete next steps, and experienced the chatbot as a nonjudgmental space for reflection. Reported design tensions included perceived scriptedness, variable preferences for conversation length, and mixed reactions to AI-driven empathy.

Conclusions: An LLM-enhanced cognitive reappraisal activity showed promise to be delivered as a brief digital intervention and is associated with short-term improvements in situational stress and stress mindset. Participants appreciated the clarity and reflection supported by the structured sequence, while noting important design challenges in balancing structure with conversational naturalness and contextual depth. These findings highlight both the promise and the design constraints of integrating LLMs into DMH interventions.

Introduction

Cognitive reappraisal is an emotion regulation strategy that involves reframing the meaning of a situation in order to change its emotional impact [1-3]. In the context of stress, this entails altering one's interpretation of a stressful event to reduce its harmful emotional effects. It is considered a form of cognitive appraisal that enables individuals to reinterpret an event, often finding new meaning or viewing the outcome as more benign [1]. By changing the way one thinks about a stressor, cognitive reappraisal can shift the emotional response from anxiety or anger to a more neutral or even positive state. For example,

XSL•FO
RenderX

interpreting a professional setback as a growth opportunity rather than a failure can diminish distress and foster adaptive coping [4].

A substantial body of research demonstrates that cognitive reappraisal is a beneficial strategy for psychological and emotional well-being. Individuals who regularly use reappraisal tend to report lower levels of depression and anxiety [2,3,5]. Over time, greater reappraisal ability has also been linked to a reduced risk of developing depressive symptoms, particularly under conditions of high stress [1]. Reappraisal has been associated with more frequent positive affect and greater life satisfaction [2]. In addition, people who use reappraisal often report better interpersonal relationships [6,7]. These benefits have been observed across diverse populations and contexts, with studies showing that habitual use of reappraisal correlates with improved psychological health over time [3]. Together, these findings highlight the substantial and wide-ranging benefits of cognitive reappraisal for well-being.

However, existing strategies for cognitive reappraisal of stress, similar to many digital mental health (DMH) interventions, often struggle to provide support that feels applicable to users' situations [8]. An important challenge lies in their reliance on scripted responses and fixed templates that proceed through a predetermined sequence without adjusting to the way users naturally describe their experiences [8,9]. Individuals may give partial descriptions, mention several elements of the situation at once, or provide information that is either too broad or too narrow for the next required step in the intervention. Scripted tools [10-12] typically move forward regardless of these variations, which can create moments when the guidance feels rigid or misaligned with what the user is attempting to communicate. Prior chatbots such as Woebot [13] and Wysa [14] demonstrated that structured cognitive behavioral therapy (CBT)-style exchanges could produce measurable reductions in stress and negative affect, though their scripted templates limited contextual responsiveness. These limitations have highlighted the need for systems that maintain a consistent intervention structure while allowing conversational adjustments within each step. Approaches that combine structured reappraisal steps with conversational responsiveness may help reduce the sense of mismatch that users often report with scripted digital interventions [15,16].

Large language models (LLMs) offer an emerging opportunity to address the limitations of traditional stress reappraisal tools that rely on fixed scripts and rigid templates [17,18]. Instead of producing predetermined responses, LLMs can engage in brief conversational exchanges that acknowledge users' descriptions and request clarification when needed [19,20]. This capacity supports a smoother dialogue within a structured intervention, helping the system remain connected to what the user has already expressed. For example, if a user introduces a stressor in broad terms, an LLM-based agent can provide a simple acknowledgment and ask for a small detail required for the next step. If a user highlights a particular source of tension, the agent can recognize that element before guiding the user forward in the predefined sequence. These conversational elements can help maintain coherence between the user's wording and the transitions across steps, which may reduce the sense of rigidity that often occurs in scripted tools [17,21].

While LLMs offer exciting possibilities, they cannot simply be inserted into well-being interventions such as cognitive reappraisal without careful design. These interventions are inherently structured, and preserving that structure is essential for delivering appropriate support. Without it, there is a risk of generating content that may be unhelpful or even counterproductive. Rather than viewing LLMs as replacements for structured interventions, we posit that their promise lies in augmenting these techniques, enabling context-sensitive interaction through natural language. By acknowledging the user's situation and adapting responses accordingly, LLMs may help structured interventions feel tailored, while still upholding the core principles that guide them [17,19,22].

Natural language processing (NLP) research has used language models to support reframing of negative thoughts, including positive reframing as style transfer [23] and identification and reframing of cognitive distortions [21]. More recent work has directly examined LLM-based cognitive reappraisal: Sharma et al [22] showed that LLMs can support identification of thinking traps and provision of contextually appropriate reframes, and Zhan et al [16] showed that LLMs guided by psychologically grounded constitutions can generate targeted reappraisals rated by clinical psychologists as more aligned with established principles than human-written responses. However, these approaches have largely focused on generating individual reappraisal responses, with less attention to the multiturn conversational process through which reframing often unfolds in real-world supportive interactions.

Motivated by these opportunities and challenges, we examined the feasibility of an LLM-enhanced cognitive reappraisal intervention delivered as a single-session intervention (SSI). SSIs are brief, structured activities that can produce rapid shifts in thoughts or feelings and have shown benefits for stress, negative thinking, and related outcomes across varied populations [8,22,24,25]. They are well-suited for early-stage exploration because they allow researchers to assess whether a short, structured activity can support users as they work through a stressful scenario. In this study, we focus specifically on situational stress, the immediate psychological tension a person experiences when confronted with a specific stressor, such as a difficult interaction with a colleague, an unresolved conflict, or an overwhelming workload. This is distinct from general perceived stress, which reflects a person's cumulative sense of feeling overwhelmed or unable to cope across their daily life over a period of weeks or months [26].

Our work was guided by the following research questions (RQs):

1. RQ1: How does engaging with an LLM-based chatbot for cognitive reappraisal of a stressful scenario impact individuals' situational stress levels?
2. RQ2: What design tensions arise when individuals interact with an LLM-based chatbot to cognitively reappraise a stressful scenario?

To examine these questions, we designed an SSI that used an LLM to guide users through a structured cognitive reappraisal

XSL•FO
RenderX

activity [24,25]. The LLM was instructed to follow a predefined sequence similar to prior work [8]. Within each step, it incorporated conversational adaptivity by acknowledging user input and requesting brief clarifications when needed, while preserving the structure of the intervention. We chose a feasibility study design to examine whether this approach, in which the LLM facilitates a structured reappraisal process instead of generating reappraisals on the user's behalf, could be delivered reliably and produce short-term shifts in situational stress. Our aim was to gather early evidence of perceived benefits and preliminary impact, and to identify design tensions that emerge when structured psychological interventions are delivered through conversational interfaces. Accordingly, our focus was on understanding user experiences and implementation considerations rather than conducting a controlled evaluation. Feasibility work is important when introducing new technological mechanisms because it can reveal practical factors that influence real-world deployment and highlight design considerations [27,28].

In a feasibility study involving 100 employees from a large US technology company, it showed that participants found the activity helpful for working through stressful situations. Qualitative feedback indicated that the structured sequence supported clearer thinking by helping participants slow down, articulate their thoughts, and reinterpret their stressors in a more constructive way. Many also described feeling validated, noting that the interaction helped them organize their emotions and provided a nonjudgmental space for reflection. These qualitative insights were complemented by promising quantitative results, with significant reductions in immediate stress (r_{rb}=0.54; P=.002) and improvement in stress mindset (r_{rb}=0.44; P=.002), further corroborated by sentiment analysis of conversation data. However, the integration of LLMs also introduced design tensions: contextualizing the experience required additional user input, and following a predetermined structure could reduce the perceived conversational quality of the interaction.

Our contributions include (1) a structured LLM-enhanced cognitive reappraisal intervention for managing stress, (2) empirical insights into how the intervention impacts users' experiences of stress, and (3) design tensions to inform future LLM-based DMH interventions. Our study demonstrates the potential of LLM-enhanced reappraisal as a brief, scalable intervention, while also drawing attention to design challenges, including how to balance conversation length, contextual richness, and expression of empathy.

Methods

Design of the Intervention

Theoretical Grounding and Sequence Design

Our intervention was designed as an SSI [24,25]. SSIs are structured, stand-alone activities intended to produce immediate effects on targeted psychological outcomes. Typically lasting 10 - 20 minutes, they offer a time-efficient way to promote reflection, reappraisal, or symptom relief, making them suitable for a wide range of populations. In addition to offering rapid support, SSIs can serve as a gateway to more comprehensive mental health care by helping individuals build insight or skills that increase their willingness to seek further support [8]. Prior research has demonstrated their effectiveness in addressing negative thought patterns, reducing stress, and alleviating symptoms of anxiety and depression in both clinical and nonclinical settings [8,22,24,25].

Unlike multisession interventions, which typically unfold over multiple weeks through repeated check-ins, skill-building exercises, and progressive assignments [12,29], SSIs are completed in a single sitting without requiring prior sessions or follow-up engagement. While multisession programs rely on cumulative exposure and gradual skill development over time, SSIs are designed to deliver focused support within a bounded interaction. Prior work illustrates how SSIs can compress core therapeutic elements into a single experience. For example, Schleider and Weisz [30] tested a brief computer-based SSI in which participants engaged with psychoeducational content and a short reflective writing task within one sitting, and observed reductions in depression and anxiety symptoms at follow-up. More recently, Sharma et al [20] demonstrated that cognitive reframing can be supported through structured, single-session interactions with language models. In contrast to multisession formats that distribute these elements across time, SSIs integrate learning, reflection, and application into a single, self-contained interaction.

We drew particular inspiration from a prior SSI reported by Bhattacharjee et al [8]. The activity was designed to be easily referenced or practiced by individuals when encountering negative thoughts and emotions in their everyday lives. Their work adapted core concepts from CBT, specifically thought records and behavioral chaining [31,32], into a guided digital reflection activity. In CBT, thought records involve documenting a situation; the thoughts, emotions, and behaviors it evokes; and then generating alternative thoughts [31]—behavioral chaining focuses on tracing the sequence from trigger to reaction to identify patterns [32]. Both techniques help individuals become more aware of their internal responses and prepare for similar situations in the future by promoting insight and reflection. Given that cognitive reappraisal is not inherently context-specific, our activity was similarly designed to be broadly applicable across a range of stressful situations, with the workplace serving as the deployment context for this study.

Our activity follows a similar structure, consisting of 11 questions. The activity was developed through an iterative process involving researchers with expertise in human-computer interaction (HCI), psychology, cognitive science, generative AI, and DMH. Members of the research team had prior experience designing DMH interventions both with and without the use of AI and have published extensively in leading HCI, psychology, and AI venues. The first set of prompts (Questions 1 - 7) operationalizes the cognitive model underlying CBT thought records, in which a situation gives rise to automatic thoughts that in turn drive emotional and behavioral responses [31,32]. Moving from the situation (Q1) to its most troubling element (Q2), to automatic thoughts (Q3-Q4), to feelings (Q5), to behaviors (Q6), and finally to an integrated trigger → thought → feeling → behavior summary (Q7) mirrors the standard structure used to build awareness of the links among cognition,

XSL•FO
RenderX

affect, and action before any restructuring is attempted [15]. Questions 8 - 11 then enact cognitive reappraisal as defined in the stress-appraisal and emotion-regulation literatures [3,5]. Q8 corresponds to examining the evidence for and proportionality of an appraisal, a core component of cognitive restructuring. Q9 draws directly on the challenge-versus-threat distinction in transactional models of stress appraisal [4], inviting users to reframe a stressor as a challenge to be met rather than a threat to be avoided. Q10 reflects reappraisal in Gross's process model of emotion regulation, in which the meaning of a situation is reinterpreted to alter its emotional impact [5]. Q11 supports generalization and consolidation, encouraging users to carry the reappraisal into future situations [3]. Reappraisal comes last in the sequence by design: examining and reframing an appraisal is difficult until the cognition, emotion, and behavior tied to the trigger have been laid out, which is the work of Questions 1-Q7.

Table 1 shows the full sequence of prompts and their intended purpose. After completing all steps, the chatbot was instructed to provide a brief summary of the conversation and clearly state that the structured part has concluded.

Table . Reflection questions used in the intervention and their intended purpose.

Question number	Questions	Purpose
1	What is the situation? Feel free to explain it in as much detail as you would like.	Provides context for the activity
2	What part of the situation is the most troubling?	Sets an agenda for the rest of the activity
3	What are you thinking to yourself?	Identifies troubling thoughts
4	What thought is the most troubling?	Focuses attention on the most troubling thought
5	What do you feel when you think this?	Reinforces the core CBT[a] principle that thoughts trigger feelings
6	When you have these feelings, what actions do you take? What do you avoid?	Identifies behaviors that are caused by the cascading effect of thoughts and feelings
7	Retype the summary of the situation in the following format: trigger→thought→feeling→behavior	Synthesizes past reflection by highlighting the connection between the trigger and its manifestations
8	Do you believe that the initial trigger justifies the intensity of your thoughts and feelings?	Challenges potentially negative thought patterns
9	How can interpreting the trigger as a challenge rather than a threat alter your response?	Encourages cognitive reinterpretation of the situation
10	What new perspectives could you adopt to view these challenges as opportunities?	Promotes a reappraisal frame focused on growth
11	How might this change in perspective influence your future reactions to similar challenges?	Encourages transfer of reappraisal strategies to future scenarios

[a]CBT: cognitive behavioral therapy.

LLM-Driven Implementation

Motivated by recent advances in LLM-based interventions that support context-aware support [17,22,33], we adapted the sequence in Table 1 to allow content to align more closely with users' specific circumstances. To implement this, we used a prompt engineering approach. The prompt was developed through an iterative process by the same research team. The complete system prompt is provided in Section A in Multimedia Appendix 1. We structured the prompt using GPT-4o with the following components:

1. Structured reflection process: The prompt was designed to guide users through a step-by-step conversation aligned with Table 1.
2. Conversational interaction through natural dialogue: Instead of presenting fixed or survey-like questions, the chatbot was instructed to respond naturally and acknowledge the user's situation. If a response was vague or incomplete, it was instructed to ask clarification questions to gather more detail. The chatbot was also instructed to avoid repeating the same phrases or prompts. The chatbot was designed as a structured facilitator; it did not produce advice, suggestions, or reframings on the user's behalf. The reappraisal questions (Q8-Q11) were designed to prompt users to arrive at these insights through their own reflection, with the chatbot's role being to acknowledge, clarify, and guide rather than to supply content.
3. Reflective instructional prompt: Prior work has shown that in longer conversations, LLMs may deviate from the intended behavior, even when following the prompt, because they try to adjust to the user's specific responses, clarifications, or context [34]. In our case, this could sometimes lead the model to drift away from the specific question or theme it was meant to address. To handle this, we added an instruction for the model to first generate a response, then check if it aligns with the current question's theme, and revise it if needed [35].

The chatbot was implemented as a text-based conversational agent and was embedded directly within the Qualtrics survey platform. It did not have a named persona or profile picture.

XSL•FO
RenderX

The chatbot opened each session with a fixed introductory message welcoming the participant and describing the nature of the interaction (Section A in Multimedia Appendix 1). The language style was conversational and reflective, with a temperature setting of 0.7 to allow for naturalistic variation in responses while maintaining coherence. A screenshot of the interface is provided in Section C in Multimedia Appendix 1.

Participants

We recruited information workers from a large US-based technology company with a broad portfolio spanning software, hardware, cloud services, and cybersecurity. Employees based in the United States were invited via email to participate in a voluntary survey. We recruited from this setting because workplace stress is well-documented as particularly prevalent in the technology sector [36,37] and because our affiliation with a technology company provided internal access to a large, geographically distributed employee population.

Participants were informed that the study focused on AI conversational agents for supporting workplace stress scenarios. A total of 100 participants completed the study. They represented multiple gender identities (69 men, 27 women, and 4 undisclosed; more options were offered) and varied in age (22 participants aged 18 - 35 years, 61 aged 36 - 55 years, and 17 aged 56 years and older). Prior to engaging with the intervention, participants completed the 10-item Perceived Stress Scale (PSS) [26] to assess their stress levels over the past month. The average score was 21.26 (SD 3.67), which falls within the moderate stress range (typically defined as 14 - 26). The PSS served as a baseline measure to characterize participants' general stress levels at the time of the study; no minimum score was required for participation. Scores on the PSS range from 0 to 40, with higher scores indicating greater perceived stress (0 - 13=low, 14 - 26=moderate, and 27 - 40=high).

Participants also reported their prior experience with text-based AI conversational agents: 34% (34/100) had 6 months to 1 year of experience, 33% (33/100) had 1 to 2 years, 22% (22/100) had 2 to 5 years, 6% (6/100) had more than 5 years, and 5% (5/100) had less than 6 months, suggesting that most participants had prior familiarity with conversational agents. A detailed breakdown of participant demographics, along with distributions of PSS scores, is available in Section B in Multimedia Appendix 1.

Procedure

Ethical Considerations

This study was approved by the Microsoft Research Institutional Review Board (IRB) through the Microsoft Research Ethics Review Program under ERP ID 10893. Participants were invited to engage in an SSI in which they reflected on a workplace stress situation through a conversation with a chatbot.

Procedure Overview

The study was disseminated through a one-time email invitation, and participants could complete the activity at any time of their choosing after receiving it. The intervention was designed as a single, one-time activity to be completed within a continuous sitting; participants were not able to return to complete additional sessions. The chatbot guided them through a series of questions designed to support reflection on their experience. Participants were encouraged to respond genuinely to each prompt. At the end of the interaction, the chatbot indicated that the conversation was complete, after which participants proceeded to the next page. They were informed in advance that the conversation would likely involve around 15 conversational turns, based on the 11 core questions programmed into the chatbot, along with potential follow-up and clarification prompts. Section C in Multimedia Appendix 1 demonstrates an example conversation between the chatbot and a user. All components of the study, including the chatbot interaction, were completed within the Qualtrics platform.

To assess the impact of the SSI, participants completed a set of self-report questions both before and after the session. To evaluate short-term changes following the intervention, we selected measures that capture both immediate subjective stress responses and theoretically relevant appraisal-related constructs. Specifically, we assessed situational stress intensity, stress mindset, perceived demand, and perceived resources, as these reflect how individuals interpret and respond to stressful situations. All responses were recorded on a 5-point Likert scale, where 1 indicated low agreement or intensity (eg, "strongly disagree" and "very low") and 5 indicated high agreement or intensity (eg, "strongly agree" and "very high"). The measures included:

Situational Stress Intensity

A single question assessing participants' stress level in relation to a workplace situation [8]. We selected this brief measure to capture immediate subjective stress relevant to the focal scenario and to minimize burden within a single-session study.

Stress Mindset

Eight statements capturing beliefs about the potential enhancing or debilitating effects of stress (eg, "Experiencing this stress facilitates my learning and growth;" "The effects of this stress are negative and should be avoided") [38]. These included both positively and negatively framed statements. We included this measure because cognitive reappraisal may shift how individuals interpret the meaning and consequences of stress.

Perceived Demand

A rating of how demanding the stressor felt [36,39]. This measure was included as an exploratory outcome grounded in the job demands-resources model [39].

Perceived Resources

A rating of the participant's perceived ability to cope with the stressor [36,39]. Alongside perceived demand, this measure captured whether the intervention shifted participants' sense of their own coping capacity [39].

Situational stress intensity served as the primary outcome measure, as it most directly captures the intended effect of the reappraisal activity. The remaining measures—stress mindset, perceived demand, and perceived resources—were exploratory and included to provide a broader characterization of participants' stress-related experiences before and after the intervention.

XSL•FO
RenderX

To gather user feedback about the intervention, participants also responded to open-ended questions about how the activity affected their stress levels and their view of the situation, as well as what aspects they liked or disliked. All open-ended questions were provided immediately at the end of the session, within the same Qualtrics survey. These questions included the following:

1. How did this activity affect your stress levels? Feel free to explain in as much depth as you would like.
2. Please explain whether and how interacting with the chatbot has changed your view of the stressful situation.
3. Please comment on what aspects of the chatbot interaction you liked or found helpful. Why?
4. Please comment on what aspects of the chatbot interaction you did not like or did not find helpful. Why?
5. Please suggest how we can further improve this activity.

All open-ended questions were mandatory except for the improvement suggestion question, which was optional. All 100 participants provided responses to the 4 mandatory questions, and 66 provided responses to the optional improvement suggestion question.

Because the study used a one-time, survey-based format, participants who did not complete the study did not submit responses and therefore were not included in the final sample. We were unable to assess dropout rates among participants who may have started but not completed the study.

Data Analysis

Overview of Data Analysis

As a feasibility study, our objective was to examine whether engagement with an LLM-based chatbot for cognitive reappraisal could lead to observable improvements in stress-related outcomes, such as situational stress intensity and stress mindset. Early-stage feasibility studies serve a distinct role in intervention research [27]; they help determine whether the conceptual approach is worth pursuing, whether users engage meaningfully with the system, and whether measurable changes occur in theoretically relevant constructs. Demonstrating even modest improvements under these conditions can support the potential viability of LLM-based reappraisal as a foundation for more controlled investigations. To contextualize these quantitative findings, we complement them with qualitative analyses that explore how users experienced and interpreted the chatbot's support, providing insight into the underlying mechanisms and perceived value of the interaction.

We conducted paired Wilcoxon signed-rank tests to assess pre-post differences across the 4 measures described in the "Procedure" section. We applied the Benjamini-Hochberg (BH) procedure to account for multiple comparisons.

To complement user-reported scores, we analyzed linguistic features of user-chatbot conversations. Each conversation was divided into 3 segments (T1=beginning, T2=middle, and T3=end), and we examined how predicted stress and sentiment varied across them using 3 approaches.

Robustly Optimized BERT Pretraining Approach Sentiment Classifier

A pretrained Robustly Optimized BERT Pretraining Approach (RoBERTa)–based model [40] (BERT: Bidirectional Encoder Representations from Transformers) that outputs a probability distribution over positive and negative sentiment for each conversation segment.

RoBERTa Stress Classifier

A pretrained RoBERTa-based model [41] estimates stress probability ranging from 0 to 1 for each conversation segment.

LLM Stress Rater

A prompting-based approach that assigns a stress score to each user message using a structured prompt informed by prior work on LLMs as evaluators [42-46]. The rater outputs a score from 1 to 5, where 1=no observable stress and 5=high stress (characterized by pronounced emotional strain or difficulty coping). The rating criteria were developed through a review of prior literature and iterative design, enabling finer distinctions in stress intensity. Further details about the prompt design are provided in Section D in Multimedia Appendix 1.

While these methods provide useful approximations of users' affective and psychological states, we recognize that their outputs can be shaped by modeling assumptions and may miss contextual nuance. We therefore interpret them as supportive evidence for our quantitative analyses rather than as definitive indicators of users' internal experiences.

For the qualitative analysis, we first anonymized and cleaned participants' responses, then conducted a thematic analysis [47]. The first author independently reviewed all participant responses and developed an initial codebook using an open-coding method. This process reflected an iterative approach that integrated both deductive and inductive techniques: the analysis of RQ1 was guided by prior work on stress reappraisal interventions, while RQ2 was approached inductively, allowing themes to emerge directly from the data. The first author then used axial coding to refine categories and develop higher-order themes. Throughout the analysis, the codes and themes were regularly discussed with other members of the research team to ensure multiple perspectives were considered. The development of themes was reviewed through detailed collaborative discussions. This approach is consistent with qualitative coding practices used in prior studies [48,49].

Ethical Considerations

This research was reviewed and approved by the IRB at the technology company where the study was conducted. Given the sensitive nature of the intervention, which included reflection on negative thoughts and potentially distressing life situations, we were attentive to ethical considerations throughout the research process and implemented safeguards to support participant well-being. All participants provided informed consent before beginning the study. To protect confidentiality, they were explicitly requested not to include any personally identifiable information in their responses. Participants were also informed that they could skip any question or withdraw from the study at any time without consequence. Additionally,

XSL•FO
RenderX

participants were provided with information about internal support resources in case they experienced stress, anxiety, depression, or emotional discomfort during or after the session.

Results

Interaction Characteristics

Participants wrote an average of 12.81 (SD 1.66) messages per conversation, contributed 283.74 (SD 243.16) words, and spent 23.09 (SD 23.99) minutes engaging with the chatbot. These results suggest that participants were responsive to the prompts and invested a reasonable level of time and effort in composing substantive replies. Building on these observations, we now examine how our study addressed the RQs.

How Does Engaging With an LLM-Based Chatbot for Cognitive Reappraisal of a Stressful Scenario Impact Individuals' Situational Stress Levels?

Overview

Participants reported significant reductions in situational stress intensity following the intervention (mean 0.29, SD 0.83, r_{rb}=0.54; *P*=.002) and significant improvements in stress mindset (mean 1.70, SD 4.37, r_{rb}=0.44; *P*=.002). The latter reflects a shift toward viewing stress as more enhancing than debilitating. Perceived resources showed improvement (mean 0.17, SD 0.83, r_{rb}=0.32; *P*=.07), and perceived demand showed a reduction (mean 0.12, SD 0.83, r_{rb}=0.22; *P*=.17), although these changes were not statistically significant. Table 2 shows these results.

Table . Pre and postintervention means (SDs) for all outcome measures. The improvement column reports change in the beneficial direction, computed as Post-pre for measures where higher is better (↑) and Pre-post for measures where lower is better (↓), so that positive values always indicate improvement. Rank-biserial correlations (r_{rb}) are likewise signed so that positive values favor the intervention. *P* values are corrected using the Benjamini-Hochberg (BH) procedure (α=.05).

Measures	Pre, mean (SD)	Post, mean (SD)	Intended direction	Improvement, mean (SD)	W	*P* value	r_{rb}
Situational stress intensity	3.38 (0.95)	3.09 (0.91)	↓	0.29 (0.83)	216	.002[a]	0.54
Stress mindset	20.71 (6.64)	22.41 (7.38)	↑	1.70 (4.37)	994	.002[a]	0.44
Perceived demand	3.40 (0.91)	3.28 (0.89)	↓	0.12 (0.83)	385	.17	0.22
Perceived resources	2.97 (0.97)	3.14 (1.00)	↑	0.17 (0.83)	306.5	.07	0.32

[a]*P*<.01.

We examined the progression of average negative sentiment and stress scores across conversation tertiles (T1-T3) for all 3 classifiers, followed by nonparametric statistical analyses. Results are presented in Figure 1 and Table 3. Across all 3 classifiers, users' messages exhibited a consistent pattern: sentiment became more positive, and indicators of stress decreased from the beginning to the end of the interaction. Friedman tests revealed statistically significant differences across tertiles for each classifier. Pairwise Wilcoxon tests showed significant changes between T1 and T3, as well as between T2 and T3, in all 3 cases. These findings suggest that as users engaged with the chatbot, their expressions of negative sentiment and stress declined over time, aligning with the observed reduction in self-reported stress scores.

XSL•FO
RenderX

Figure 1. Changes in sentiment and stress scores across conversation tertiles (T1-T3). Error bars represent SDs. LLM: large language model; RoBERTa: Robustly Optimized BERT Pretraining Approach.

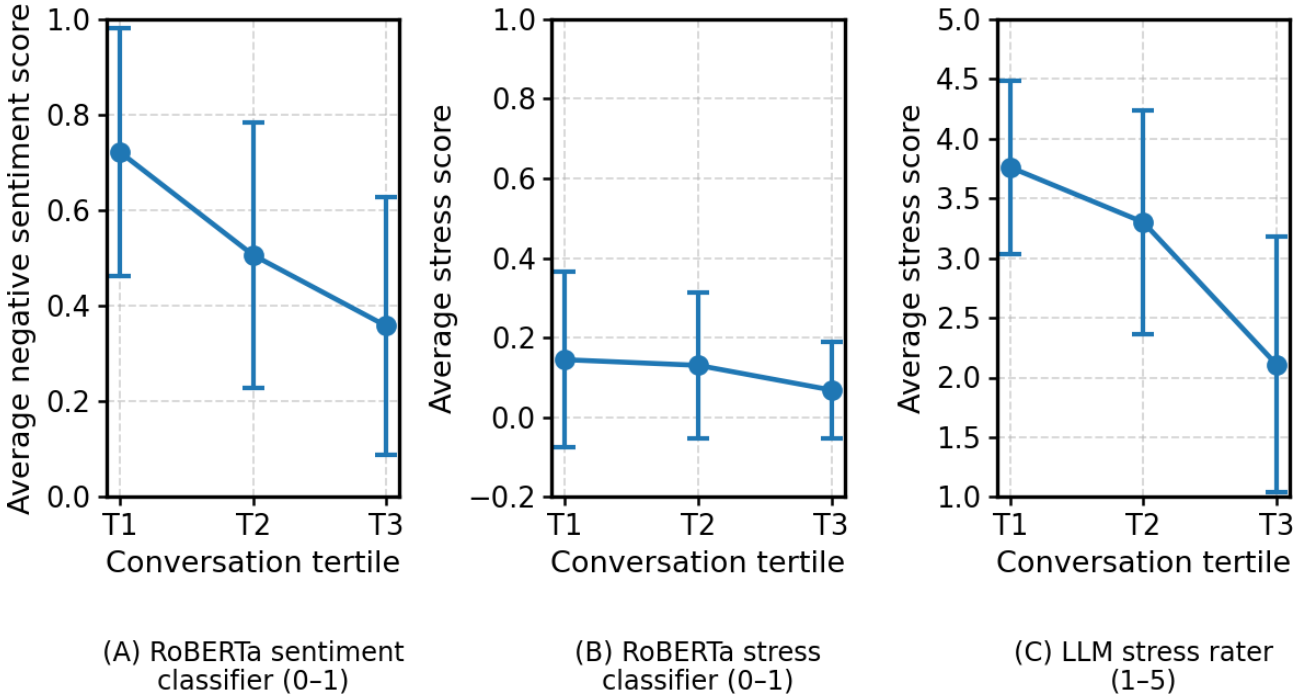

Table . Statistical tests accompanying Figure 1, assessing changes in negative sentiment and stress scores across conversation tertiles (T1-T3) for all 3 classifiers. For each classifier, we report an omnibus Friedman test across T1-T3 and 3 pairwise Wilcoxon signed-rank tests. All *P* values are corrected using the BH procedure.

Statistics	RoBERTa[a] sentiment classifier	RoBERTa stress classifier	LLM[b] stress rater
Omnibus test: Friedman across T1-T3	<.001[c]	<.001[c]	<.001[c]
Pairwise tests (Wilcoxon signed-rank)			
T1 vs T2	<.001[c]	.69	<.001[c]

[c]*P*<.001.

General Appreciation for Structured Reflection

Participants in general highlighted the value of the chatbot's step-by-step approach, noting that the ordered prompts helped them organize thoughts that might otherwise remain scattered. P55 described the session as "a good exercise in laying out the issue, my responses, and getting to why it's that way," and P42 emphasized how the sequence of questions encouraged structured analysis rather than a quick vent. Several also echoed that the structure offered a clear path through the conversation, making it easier to track what had been covered and where to focus next.

Participants often remarked that the value of the interaction lay in how it helped them arrive at their own insights through deliberate unpacking of the stressor. They acknowledged that the structured opportunity to express themselves brought a sense of relief. The act of "thinking aloud" through writing or guided dialogue was also perceived as familiar and useful. Drawing a comparison to journaling, P15 reflected:

> *This activity did decrease my stress level by allowing for a structured conversation regarding a specific stressor. It helped me reflect on my own thoughts without spiraling into anxiety. Just by explaining and going through the situation it made me feel more calm, similar to journaling but more structured. I have previously liked journal prompts in the past and this feels similar.*

Some participants also appreciated that the structured format helped shift their focus from problems to potential solutions. They noted that the prompts encouraged them to slow down and articulate their thoughts more deliberately. As P89 explained:

XSL•FO
RenderX

> *I often struggle for words, but having a chatbot to ask these questions makes me feel like I can take my time to find the right way to say what I want to say.*

These comments suggest that participants valued not just the content of the activity, but the structured way in which it guided their thinking.

Reinterpreting Stressful Situations

The shift observed in stress mindset scores, toward viewing stress as more enhancing than debilitating, was echoed in participants' qualitative comments. Several described how the conversation helped them reassess their situation from a new angle. P79 shared that it "shifted my perspective just enough to see it more as a challenge than a frustration," while P21 noted that the chatbot offered an alternative way of thinking when they felt mentally stuck, helping them move beyond unproductive thought patterns.

The conversation logs further reflect this reappraisal process. P4, who began the session feeling overwhelmed and unsupported by colleagues, wrote at Q9 that "perhaps the anger and anxiety are the result of repeated cycles and maybe I need to consider I am burnt out on the role"—a reinterpretation that emerged through their own responses to the structured questions. P65, working through anxiety about executing quickly on a difficult technical project, arrived by Q10 at a reframe of the work as "an exploration, an open mindset that allows me to explore boundaries," shifting from perceiving the situation as a threat to viewing it as an opportunity for learning.

However, not every participant experienced dramatic shifts in perspective. P30, for example, remarked that "while it did not change my viewpoint 100%, it was nice to write it out," suggesting that even partial reframing can be helpful. Others, including P15 and P48, described subtle changes in how they interpreted or emotionally responded to the stressor. These comments highlight the potential of the interaction to support gradual cognitive shifts, helping participants reinterpret their stressors and relate to stress in a more constructive way. It is worth noting that these reframings were generated by participants themselves through the structured reappraisal questions; the chatbot's role was to guide and facilitate this process rather than to supply alternative interpretations directly.

Identifying Concrete Next Steps

Beyond perspective shifts, some participants described how the dialogue helped translate reflection into concrete action. P66 appreciated "the structured approach to break down the root of my stress and ideate on solutions," while P83 noted that the activity helped them "channel stress into action." P70 shared that although their stress level did not change, the activity "helped to structure my approach to the situation," and P76 commented that the conversation "helped lead me to some useful options to help me fix my problem." These comments suggest that, for some participants, the value of the activity lay not only in processing emotions and perspectives but in arriving at a clearer sense of what to do next.

The conversation logs further illustrate how this process unfolded during the later stages of the activity. Participants who initially described interpersonal tension or coordination difficulties sometimes progressed toward specific action plans by the final reappraisal prompts. For example, P73, who began the session feeling overwhelmed by disorganized planning and strained colleague relationships, later described intentions to foster better communication and establish more regular check-ins with their team before the next planning cycle. Similarly, P61, who entered the conversation frustrated by a difficult team dynamic, moved toward articulating concrete steps such as involving a new team member in daily discussions and investing in a stronger working relationship. P59, who entered the session anxious about presenting to a large group of external customers in a nonnative language and worried about losing the audience's attention, arrived by the final prompts at a concrete plan to use auto-captioning technology in future presentations and to build in pauses for audience questions. These examples suggest that the structured questioning sequence could help some users move from diffuse stress toward more actionable coping plans.

Validation of Personal Experiences

Some participants described the chatbot as helpful in recognizing or affirming their existing efforts and emotional responses. Even when the chatbot did not introduce new ideas, it was still seen as useful for reinforcing what participants were already feeling or doing. As P16 explained:

> *Just because it didn't change my view or give me any new data to think about doesn't mean it wasn't useful… it's validation that there isn't something I'm missing, that I've explored every opportunity and tried everything I can.*

Others similarly appreciated moments where the chatbot reflected back their current state of mind. P74 noted:

> *It was great at validating my feelings and guiding me in its approach, even when I was reluctant to think about a solution.*

P82 shared that "the chatbot acknowledged my efforts as productive" in dealing with a difficult situation, and P92 mentioned it "affirmed steps planned."

For a few, this sense of reinforcement was seen as limited. As P46 commented, "Lots of validation. It might have been better if it had challenged me." Still, for many participants, the interaction was valued for offering a sense of confirmation rather than redirection.

Appreciation for Nonjudgmental Interaction

Several participants appreciated the chatbot's nonjudgmental tone, describing it as a space where they could express themselves freely. For some, this quality made the interaction feel less pressuring than conversations with people. P42 remarked that it "allowed me to vent, without fear of judgment," while P65 shared, "I liked that it was objective."

Some others described the experience as supportive precisely because it did not involve being evaluated. P66 emphasized the benefit of having "an unbiased conversation" that helped them "focus on a task at hand." This perception of the chatbot as nonjudgmental contributed to some participants' willingness to open up or think through the situation more deliberately.

XSL•FO
RenderX

Perceived Misalignment With Context or Needs

Some participants described instances when the chatbot's responses felt disconnected from the realities of their situation. In particular, a few noted that the interaction seemed to assume ideal conditions, such as collaboration or personal control, that did not reflect their experiences. As P36 explained:

> *The chatbot assumes that all the people involved in the situation are reasonable, collaborative, and want to reach a solution that's acceptable to everyone. But the nature of my situation is that the other team has already established that they are none of these things.*

P94 similarly expressed that the prompts did not adequately reflect the complexity of their stressor, stating, "I felt that I needed to double down and explain more about the stressful situation, to say it's not that easy."

Some participants also described discomfort with having to revisit a stressful situation in detail, particularly when they had already discussed it elsewhere. P59 remarked, "I already had to explain the situation to myself, then my team, and now this bot wants to know about it too, causing me to relive the situation in my mind." Others felt that, despite going through the interaction, there was no tangible outcome. As P24 noted, "I dislike the fact that it goes nowhere and there is no action to be done." These reflections suggest that for some participants, retelling the situation without any follow-up or resolution made the experience less satisfying.

What Design Tensions Arise When Individuals Interact With an LLM-Based Chatbot to Cognitively Reappraise a Stressful Scenario?

Scripted Structure Versus Conversational Naturalness

As discussed in the previous sections, participants noted that the structured nature of the chatbot's prompts helped them consider alternative perspectives and identify potential solutions. However, several participants also reflected on how this structure may have come at the expense of a more natural, conversational flow. P6 remarked that "it wanted to ask certain questions as opposed to engage in conversation," highlighting a perception that the interaction was being guided more by a fixed sequence than by mutual exchange.

Some participants further sensed that the chatbot was following a script, which contributed to a feeling of artificiality. As P75 put it, the interaction felt "not human," due to what appeared to be a scripted, predetermined flow. While certain elements of the structure, such as follow-up questions or requests for clarification, were appreciated by some, they were not universally welcomed. For example, P94 noted that these follow-ups "helped pull out some important information," but others, like P96, found them repetitive and frustrating:

> *I didn't necessarily like that it always yielded additional questions, some of which I felt I had already answered earlier in the conversation.*

Together, these responses underscore a tension between the benefits of a structured, goal-directed dialogue and the desire for a more natural and responsive conversational experience.

Balancing Contextual Understanding and Conversation Length

Some participants expressed a desire for more questions to allow them to elaborate on their situation—particularly when their stressors were complex or nuanced. P7 noted the difficulty of condensing their experience, remarking, "It's the writing it down, trying to cover the important topics with brevity. Tough nut to crack." Similarly, P57 wished for a longer "getting to know each other" period to help the chatbot better personalize its responses.

Conversely, some participants felt that even the current level of interaction was somewhat extended. P12 commented that the exchange lasted "much longer than I cared for." They expressed that the number of questions, often accompanied by clarifications and follow-ups, made the experience feel more effortful than necessary. This concern was particularly salient among participants dealing with less intense stressors, where a longer interaction felt disproportionate. As P23 explained, "My stress trigger was basic and didn't need to have that many turns." These perspectives reveal a core design tradeoff: while deeper context can enable more tailored and relevant responses, excessive questioning may lead to user fatigue or disengagement in some cases.

Perceptions Toward AI and Artificial Empathy

Although the study did not explicitly ask about participants' attitudes toward AI, some participants shared comments that reflected preexisting skepticism about the use of AI and technology for well-being support. Several participants indicated that their discomfort stemmed not from the content of the conversation, but from their underlying beliefs about what makes an interaction feel helpful. P29 shared that "the fact that it was a chatbot made it annoying," and P37 expressed discomfort with "the fact that it was not a real person." These comments suggest a reluctance to view nonhuman agents as appropriate partners for discussing personal or emotional matters. P51 further expressed mistrust toward the system, stating that they do not trust a software entity that cannot feel emotions.

These views extended to how participants interpreted the chatbot's attempts at empathy. Some reacted negatively to what they perceived as artificial emotional cues. P14 stated, "The whole mimicking empathy is annoying," and P41 described the interaction as "trying too hard, like mimicking empathy but not quite getting there." In contrast, others responded more positively to the chatbot's empathic tone. P44 noted that the message felt "kind," even though they knew it was automated. P58 similarly shared, "I could tell it was a bot, but it still felt like it was trying to be understanding." These contrasting reactions highlight how users' preconceptions about AI—and particularly their expectations around empathy from AI—impacted their perceptions of AI support.

Discussion

Overview

In this work, we present a cognitive reappraisal intervention design that leverages LLMs to provide conversational interaction. Our SSI incorporated a structured conversational

XSL•FO
RenderX

scaffold to guide the reappraisal process, enabling individuals to revisit initial interpretations, examine different aspects of their challenges, and consider alternative explanations. This combination of a structured SSI format with LLM-driven conversational flexibility addresses a well-documented limitation of scripted tools, which typically cannot adapt to the varied ways users describe their experiences. Our deployment showed that this approach can retain many benefits of past cognitive reappraisal interventions, including reducing negative emotions, increasing clarity about one's situation, and encouraging reflection on potential growth opportunities [2,8,22]. However, integrating LLMs introduced several design tensions, particularly in balancing contextualization with the number of questions asked, maintaining a structured flow while preserving conversational quality, and managing perceptions of AI tone and empathy.

In the remainder of this section, we reflect on the key findings of our study, discuss how they align with or extend existing literature, and propose relevant directions for future research. We conclude with a discussion of the limitations of the study.

Principal Results

Our findings suggest that the LLM-based cognitive reappraisal activity can retain many of the benefits associated with more traditional reappraisal techniques. Participants reported reductions in situational stress and improvements in stress mindset after engaging with the intervention. These shifts were supported by the structured nature of the activity, which guided users in breaking down the elements of their stressful experiences. This process enabled them to reassess their initial interpretations and consider alternative perspectives, an outcome consistent with prior research on the role of cognitive reappraisal in fostering more adaptive emotional responses [1,2,6,50].

In addition to promoting perspective shifts, the activity helped some participants reflect on possible actions they could take to address their situations. Several described recognizing specific next steps or reframing their experiences as opportunities for growth [2,22]. These qualitative observations were further corroborated by 3 independent classifier-based measures, which showed consistent reductions in expressed stress and negative sentiment across conversation tertiles, providing convergent evidence beyond self-report. This highlights how structured LLM-enhanced interventions can support cognitive reframing while helping users identify concrete ways to respond to their stressors.

Even when substantial cognitive shifts did not occur, participants described experiencing subtle emotional changes through their engagement with the structured, LLM-enhanced activity. In particular, the process of externalizing a stressful situation (ie, expressing internal thoughts and emotions outwardly [51]) was seen as helpful in itself. Several participants likened the experience to journaling, which can offer a sense of release and promote clarity [52-54]. These findings suggest that the value of reappraisal-based interventions may extend beyond cognitive reframing, by also offering structured opportunities for reflection and emotional processing through expressive dialogue.

At the same time, participants' responses surfaced a tension between the benefits of a structured sequence and the desire for a more naturalistic conversational flow. While the structure was widely valued for organizing reflection, some described the interaction as feeling scripted, particularly when follow-up questions appeared to repeat information already provided. Designing LLM interactions that move smoothly between structured progression and responsive acknowledgment, without drifting from the intended sequence, should be an active research area for future work.

However, we also observed that cognitive reappraisal may not be appropriate in all scenarios. Participants pointed out that, although support was directed at a single individual, the source of stress could be more complex and involve multiple people within their network. This challenge is not unique to cognitive reappraisal but reflects a broader limitation in much of the literature on health interventions, which often emphasizes individual-level support [55,56]. In response to this gap, a growing line of research is exploring group-level interventions that engage multiple individuals in jointly addressing shared or relational challenges [57-59]. Building on this momentum, future work could explore the design of technology-mediated cognitive reappraisal interventions that support group-level reflection [60]. For example, digital platforms could facilitate shared appraisal by prompting teams to surface collective stressors, reflect on interpersonal dynamics, and co-construct alternative interpretations. By embedding reappraisal within team interactions, these technologies may have the potential to foster shared understanding, strengthen social support, and address the relational nature of stress more effectively than individually oriented interventions.

Considerations for Broader Applications

Our designed activity can function as an SSI, offering a brief, structured opportunity for individuals to engage in cognitive reappraisal in response to everyday stressors. SSIs have been shown to produce meaningful psychological benefits with minimal time commitment [24,25], so they could be well-suited for integration into demanding professional environments. We emphasize that LLM-based cognitive reappraisal interventions need not follow the exact structure used in our study. Our results point to the trade-off between contextual depth and conversation length. Some participants wished for more opportunities to elaborate on complex stressors, while others found the number of prompts excessive when their stressor felt straightforward. Future LLM-based interventions could explore adaptive mechanisms that modulate the depth and length of the interaction based on the complexity of the stressor [9], while ensuring that shortening the interaction does not come at the cost of the reappraisal process itself.

We note that while this study was conducted in a workplace setting, the cognitive reappraisal sequence was designed to be applicable across a broad range of stressful situations rather than tailored exclusively to occupational stressors. The workplace context shaped our recruitment, participant population, and the types of stressors participants brought to the activity, but the generality of the intervention was intentional: cognitive reappraisal as a strategy is not inherently

XSL•FO
RenderX

context-specific, and a broadly applicable sequence may be more easily adapted across deployment settings in future work.

We also note that these interventions alone are not sufficient to address the broader challenges of well-being and may serve as modular components within a more comprehensive framework alongside other strategies [29]. These SSIs could be embedded within larger DMH programs spanning multiple weeks and complement practices such as mindfulness activities or psychoeducational content [29]. When our activity is repeated over time, future work should explore how to maintain a sense of freshness and avoid monotony by incorporating variations in structure, tone, or content of the responses. However, the use of LLM-generated content for more severe mental health conditions, including posttraumatic stress disorder or suicidal ideation, would likely require additional safeguards such as clinical review and supervision prior to delivery.

A related design concern that warrants attention as these interventions scale is the tendency of LLM-based systems toward overvalidation [61,62]. While participants in our study generally appreciated the nonjudgmental and affirming tone of the chatbot, some noted that the interaction offered little challenge or pushback. This reflects a broader pattern documented in the literature, where LLMs acting in therapeutic or supportive roles have been found to overvalidate users' beliefs without promoting the kind of cognitive flexibility that can underlie reappraisal [62]. Future design efforts should explore how to calibrate the balance between validation and constructive challenge, for instance by incorporating adaptive feedback mechanisms that respond to the depth and quality of a user's reappraisal attempts.

More broadly, as LLM-based mental health tools become more widely adopted, important questions arise about their relationship to professional care. These tools have the potential to extend support to individuals who would not otherwise access services, but if users come to rely on AI for emotional support in lieu of professional help, there is a risk of eroding motivation to seek human care precisely among those who may need it most. Future work should examine how LLM-based interventions can be designed to complement rather than substitute professional relationships, for example by incorporating referral pathways or escalation mechanisms for users who may require more intensive support [19].

Perceptions of AI Tone and Empathy

Participants shared a range of preferences and reactions regarding the tone of the chatbot and its attempts to convey empathy. Many appreciated the nonjudgmental tone, noting that it offered a space where they could articulate their thoughts without fear of being judged, similar to prior benefits of nonjudgmental care [63,64]. At the same time, the structured sequence of prompts, while helpful for reflection, sometimes made the interaction feel more like a scripted exchange than a fluid conversation. This sort of perception can reduce the potential of DMH interventions [65].

A related tension emerged around the expression of empathy. While prior work has emphasized the importance of empathetic responses in mental health interventions [33,66], some participants were skeptical of AI's capacity to provide genuine emotional support. In some cases, these preexisting beliefs contributed to how participants interpreted the chatbot's attempts at empathy, with some finding them helpful and others perceiving them as forced or artificial.

Future work could address these tensions by reducing the perceived scriptedness of the interaction and more deliberately shaping the agent's persona. A growing body of research has explored the use of human-like traits in conversational agents, and incorporating elements such as tone, conversational style, and empathy level based on models of anthropomorphism [67] or personality frameworks (eg, the big five [68]) could improve user satisfaction. These traits could be either predefined or adapted dynamically based on user preferences and expectations [69]. Designing agents that are also sensitive to how users perceive AI's role in providing support, particularly in sensitive contexts, may help ensure that the tone and level of empathy feel appropriate rather than artificial.

Limitations

Our study has several limitations. First, although pre-post measures allowed us to capture within-subject changes, such designs may be susceptible to response shift bias [70] or demand characteristics [71]. Participants' awareness of being measured before and after the intervention may have influenced how they interpreted or reported their experiences. In addition, several outcomes were assessed using brief or single-item self-report measures selected to reduce participant burden in a single-session study, which may provide less precision than longer validated instruments. Future work deploying similar interventions in a longitudinal or multisession format should prospectively track engagement and assess reasons for noncompletion. Additionally, as a feasibility study, the absence of a control condition means we cannot isolate the contribution of the structured reappraisal sequence from the general effects of expressive writing or conversational engagement.

In our study, we used the GPT-4o model, a state-of-the-art LLM at the time of the study, to generate responses for the reappraisal activity. We designed custom prompts to structure the interaction, which participants generally found appropriate and helpful. However, different models may vary in how they respond to similar prompts, and these differences could influence the perceived quality and usefulness of the interaction. Smaller or less capable models may also struggle to interpret user input or maintain coherence across multiturn conversations. As such, caution is warranted when generalizing the effectiveness of our prompt design or findings across other LLMs. Future research should examine how different models perform in similar interventions and explore alternative strategies, such as fine-tuning, to ensure consistency and relevance in generated content.

Our sample was drawn from a single large technology company, which may limit the generalizability of our findings to other populations and organizational contexts. Future work should examine whether similar results hold across different industries, demographic groups, and cultural settings, and should also prospectively collect time zone and contextual information to examine how the time and setting of engagement influence

XSL•FO
RenderX

outcomes. Additionally, future longitudinal deployments should assess reasons for noncompletion to better understand barriers to sustained use.

Finally, our study primarily examined participants' perceptions of the LLM-enhanced cognitive reappraisal activity, their reflections on the experience and its perceived usefulness. We did not systematically evaluate the quality or fidelity of the chatbot's responses. While the activity was designed to follow a structure informed by evidence-based psychological strategies, future work should assess whether the generated content aligns with those strategies and avoids content that may be inappropriate or counterproductive. Involving clinicians or domain experts in reviewing responses could help ensure that the content remains consistent with established psychology principles.

Conclusions

This study demonstrates the promise of LLMs in delivering structured, adaptive support for stress. Our single-session cognitive reappraisal intervention helped employees reinterpret stressful experiences, leading to significant reductions in immediate stress and improvements in stress mindset. Participants appreciated the guided structure, which offered clarity and validation, while also enabling personalized reflection through contextual responses by the chatbot.

At the same time, integrating LLMs surfaced important design tensions, particularly around the balance between contextualization and user effort, and between structured guidance and conversational naturalness. These insights underscore the need for careful orchestration of structure and flexibility in LLM-based mental health tools. Future work should explore how such interventions can evolve beyond single sessions, adapt dynamically to individual and organizational contexts, and extend to other domains. Our findings contribute both empirical evidence and practical guidance for designing LLM-enhanced DMH interventions.

Acknowledgments

We acknowledge Kori Inkpen, Andy Wilson, Kael Rowan, Ann Paradiso, and Jieun Kim for their help in testing early versions of the research prototype.

Generative AI Use

During manuscript preparation and revision, the authors used OpenAI ChatGPT and Anthropic Claude to assist with language refinement, copyediting, and formatting. The authors reviewed and edited all AI-assisted text and take full responsibility for the content of the manuscript.

Funding

Abstract

Background: Emergency departments are often chaotic environments where delays can significantly impact patient care. Key items are stored in supply carts in or near patient rooms to promote efficiency and enable nurses to spend more time assisting patients. However, disorganization, lack of standardization, and lack of stocking can cause significant delays and negatively impact the quality of care.

Objective: This study utilized human-centered and participatory design to improve the workflow for supply acquisition in an emergency department.

Methods: Using a mixed methods, participatory design approach following the double diamond framework, the team worked with nursing staff and physicians in an urban emergency department to understand the root causes of frustrations with the current supply carts. Qualitative findings about bedside nursing workflows were integrated with quantitative observations of inventory and supply usage to drive a rapid-cycle prototyping process to optimize supply management in the bedside cart.

Results: A lack of clinical staffing exacerbates preexisting challenges with restocking the medical supplies in the bedside carts. This problem is compounded by the misallocation of supplies, with high-frequency items underrepresented and low-frequency items overrepresented in the bedside carts. This leads to wastage of the seldom-used supplies and a lack of access to the most used supplies. The reorganization of the cart through co-design with nursing staff sped up supply acquisition by approximately 20% overall, tripled the availability of the most important supplies, and reduced the need for restocking from once per shift to once per 3 shifts, thus producing tangible improvements even within institutional limitations.

Conclusions: A participatory design process, using human factors principles in tandem with extensive input from end users, enables improvements to stocking. Implications for practice include (1) lack of easy access to appropriate supplies negatively impacts patient care and contributes to nurse burnout and frustration, (2) human factors engineering can improve access to patient care supplies through redesigning the layout of hospital supply carts to better align with workflows, and (3) co-design with frequent collaboration from stakeholders and end users ensures that solutions address the issues that matter most in a sustainable way.

Introduction

In a busy emergency department (ED), every second counts. Medical professionals require access to key supplies and medication in an efficient and timely manner [1,2]. These key items are often stored in supply carts in or near patient rooms in order to promote efficiency [3-6]. However, disorganization and lack of standardization can delay patient care and negatively impact outcomes [1-3,7-9]. The lack of supplies is also a frequent cause of operational failures. Studies have shown that

XSL•FO
RenderX

access to supplies is a leading factor in "time wasted" in an emergency setting [3,9,10], and a lack of familiarity with a cart system has been identified as one of the most common factors adversely affecting the quality of care in a high-stakes medical setting [11].

Human factors engineering has emerged as a dominant method to address challenges in stocking [1,2,4,7,8,12-15]. For instance, one study found that reorganizing and standardizing the contents of a resuscitation cart in a children's hospital according to the 5S Lean design method reduced the time needed to acquire supplies by 46% [7]. Similarly, the reorganization of a hospital medication cart based on usability testing and simulation reduced the number of wasteful actions taken while searching for the proper supply [12].

While groups vary in the methods they used, one thing remains true in each case: the first step requires understanding who is most affected by the challenges caused by the existing system.

The burden of a disorganized supply system often falls heavily on nursing staff, who are already struggling with staffing shortages and heavy workloads [16,17]. Nurses report frequently having to leave rooms to search for supplies, increasing job frustration, delaying patient care, and reducing the time available to spend with patients [9,18]. One study found that more than one-third of nurses' time is spent looking for equipment, with an annual estimated cost of US $1 million in lost time per year [10].

Nurse feedback and input are therefore a crucial component of any redesign [14,15], both to optimize any new system based on nurses' lived experience [17] and to promote approval and uptake of a new system [1,19,20]. Nurse feedback and participation also give nurses a voice in their workplace, increasing satisfaction, improving work performance, and helping to provide an environment for safe, quality patient care [14,21].

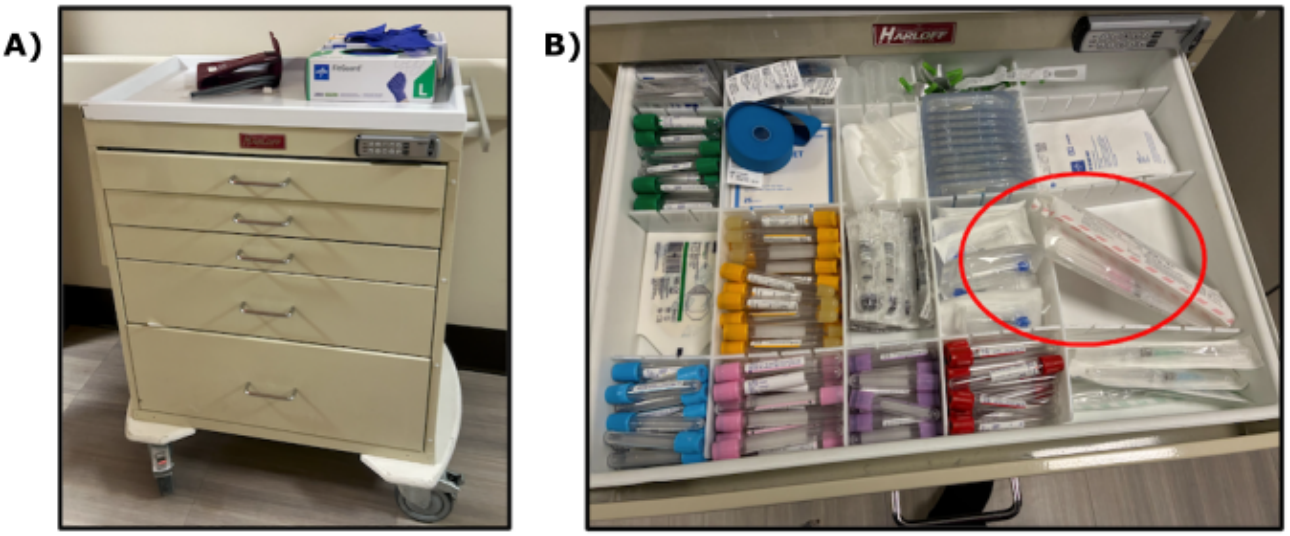
Here, we discuss the use of a participatory human factors approach to redesign the bedside cart supply in the ED of a low-resourced urban community hospital. The aim of this mixed methods co-design intervention was to understand the challenges associated with restocking and access to patient care supplies and implement a strategy to improve reliable and efficient access to supplies for nurses in an ED. Our novel approach, which combined the use of the double diamond design framework with a participatory design, allowed us to reduce the time required to access supplies by reorganizing the carts to hold more of the most crucial supplies and minimizing wasted space.

Methods

Overview

In this paper, we report on the use of a data-driven and participatory design approach to address the supply shortage in ED bedside carts. Our approach followed the double diamond design framework [22]. The double diamond design framework is a human-centered framework that breaks a design into 2 main phases, each composed of a divergent step of discovery and ideation, followed by a convergent step distilling findings into a concise and workable next step. In addition, we relied heavily on principles of co-design [23], working closely with stakeholders at every step of the process to ensure any solutions fit within the constraints of the setting and appropriately addressed their concerns.

Following this framework, the design process was broken into 3 main phases. In the first phase of the double diamond, the team immersed itself in the clinical environment and engaged with stakeholders to gather information. Based on these observations, they then performed a root cause analysis to discover and define the true problems affecting supply accessibility. Finally, they underwent a co-design process with hospital staff to develop and deliver a new bedside cart prototype that successfully addressed the issue. The results are organized according to the SQUIRE (Standards for Quality Improvement Reporting Excellence) reporting guidelines for quality improvement in health care [24].



Study Background and Location

This study was conducted in the Emergency Department of the Hospital of the University of Pennsylvania's campus at Cedar Avenue (HUP-Cedar), a low-resourced urban ED in eastern Pennsylvania. The ED serves more than 48,000 patients every year and has inpatient medical and psychiatric services, with very little specialty coverage. Children, patients who are critically injured, or patients with trauma are generally sent to other hospitals in the region, and the admission rate for patients is 10% to 13%. The department is split into a 23-bed high acuity area staffed with a 1:4 nursing to patient ratio and a 10-bed low acuity area staffed with 1 to 2 nurses.

The ED utilizes a lockable 5-drawer Harloff ''bedside" cart positioned in the hallway outside each patient room. Drawers have varied heights; the top 3 are each approximately 2.5″ tall, the fourth drawer is 5.5″ tall, and the bottom drawer is 8.5″ tall. Supplies are separated by thin, $\frac{1}{8}$″ acrylic dividers in compartments that often fail to accommodate longer items such as needles and syringes (Figure 1). In addition, heavy items such as intravenous (IV) bags have deformed many of the carts over the years. Carts are often understocked given limitations in staff availability, causing nurses to search 3 or 4 carts to find necessary supplies. In addition, the underutilized supplies may linger in the cart for years well past their expiration dates. The research team was embedded within the ED from January 2025 to May 2025; the full process can be seen in Figure S1 in Multimedia Appendix 1. The team members included multiple engineers with specialties in mechanical design, product design, data science, human factors, and systems engineering and 2 emergency medicine physicians. The project also included a nurse who provided significant input and helped the embedded team interface with other members of the nursing staff.

Figure 1. Original cart system. (A) Lockable 5-drawer Harloff "bedside" cart positioned in the hallway of the emergency department. (B) Original layout and dividers in drawer 1 (topmost drawer) of the bedside carts. Note that needles (indicated by the red circle) are stored at a diagonal because the allocated space is too short.

Clinical Immersion and Key Stakeholder Interviews

The team began by observing users interacting with the bedside cart and interviewing key stakeholders (Multimedia Appendix 2) to understand the key challenges and concerns that they saw with the current carts, and to understand the supplies they needed the most. Interviews were semistructured [25] with a predetermined list of questions, but conversations varied according to participant interests. Interviews were conducted with multiple team members present; 1 person led the conversation, while others took detailed notes to ensure no information was missed. After 60 hours of observation, and after the insights from observation and interviewing had reached saturation [26,27], the team used a thematic analysis [28] to identify the key unmet needs (Table 1). These needs were subsequently validated through conversations with nursing staff.

Table . Sample thematic analysis of user statements.

Insight	Example statements
Unreliable or unavailable supply puts patient lives at risk.	• *[When I try to use the carts,] the things I need to save my patient's life aren't there.* • *I'd rather save patient lives than have a clean cart. I can clean the cart later, but I can't bring them back.* • *I can't leave a seizing patient to go look for oxygen masks because my cart didn't have any.*
Stocking is time-consuming and irritating, and there is often no one to do it.	• *The techs are pulled to do other tasks like 1-on-1, and no one has time to restock the carts.* • *If we had safer ratios, I'd be more willing to stock the carts.* • *I just want my carts stocked. The rest, I can work with.* • *Anything to make things a little easier or streamlined, especially with refilling the carts, would be huge.*
Nurses do not trust the carts to have the supplies they need and often use workarounds.	• *If cart supplies are low, I'll get a basin of the most used things and put them on a cart so I know where to find them.* • *I run from cart to cart all day, then say 'F** it, I'm just going to the stockroom'.* • *I get things from the Clean Supply rather than the carts so I don't waste my time looking.*
There is not a perfect consensus over what should be in the carts.	• *I've been going from drawer to drawer looking for socks for my patient.* • *After the emergency, that's when we can put on socks.*
Cart contents do not match what nurses actually need.	• *A lot of things in the cart are rarely used - they're a waste of space.* • *I really want a space for the ultrasound needles.* • *When there are things in the cart that aren't used, they expire and we have to throw them out.*

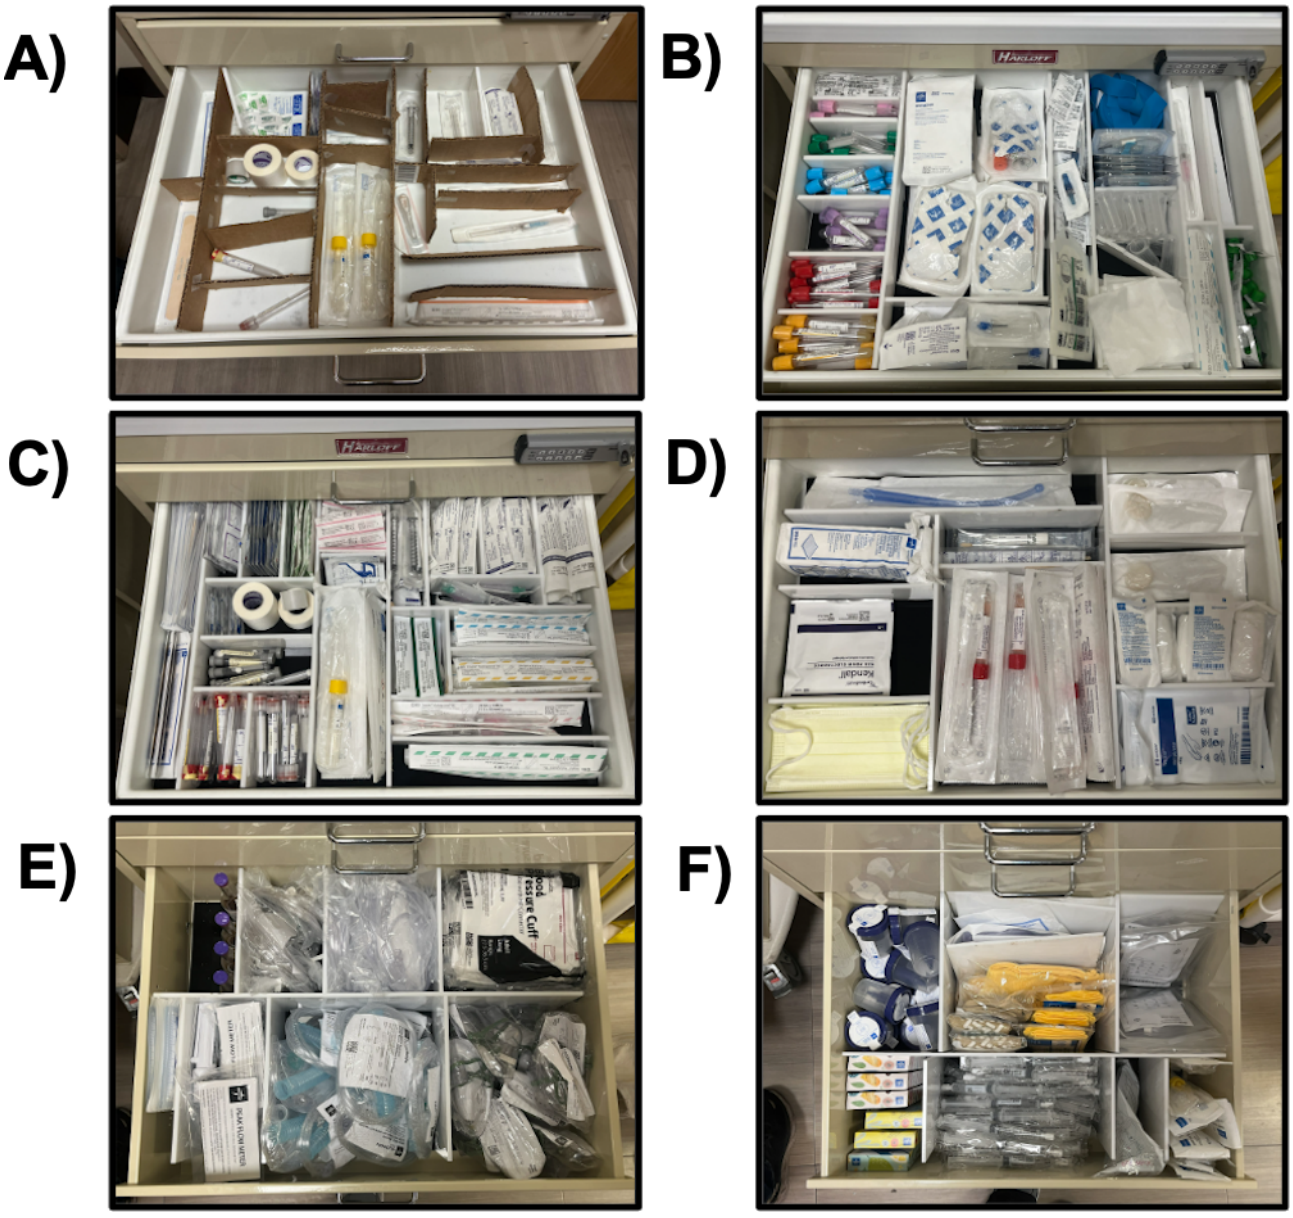
Co-Design With Key Stakeholders and Initial Solution Selection

Focused solutions to the supply problem were addressed in a series of co-design sprints to determine how to reform the supply distribution system. A multidisciplinary group of stakeholders (including the research team, additional physicians, and nurses) underwent a series of design thinking brainstorming exercises to generate over 40 potential solutions. From there, ideas were screened for viability (whether the solution addressed the core problem), desirability (whether the stakeholders would like and use the solution), and feasibility (whether the solution would be possible given other constraints). From the session, the team identified 6 key domains—accessibility, legality, reliability, ease of restocking, capacity, and feasibility—required for a successful solution based on the unmet needs. Subsequently, screening and scoring matrices were implemented to identify the top solution [29]. Although the original solution selected was to pull out the key items used most often by nurses and put them in their own designated carts, obtaining additional carts would have become a challenge. The team sought to determine whether a similar result could be obtained merely by reallocating the proportions of various items in the existing carts to align with usage and need.

Quantitative Analysis of Current Inventory System and Item Usage

An inventory of 6 different carts throughout the ED was obtained to understand the current supply state. Maximum capacity was calculated as the highest value from each of the carts. During the observation period, the team also collected data on the supplies used to care for 17 different patients with different chief complaints (16 h of observation). This allowed the team to see supplies being used in real time and observe nursing micromovements as well as get a sense of overall inventory throughout the department.



From there, the team ran a k-means clustering analysis on the supply usage data to identify if there were any clusters of supplies that were frequently used together. While preliminary data were too limited to generate many solid clusters, the initial results using k-means with 2 clusters revealed a small cluster of high-use items and a much longer list of less frequent items. These high-use items were then compared with reports given by nurses (Multimedia Appendix 3).

Rapid Prototyping of New Drawer Organization System

Through conversation with nursing staff, the team obtained (1) a list of all of the supplies nurses wanted in the supply carts, (2) suggestions for changes in quantity for items already present, and (3) requests for layout changes to improve workflow. The team compared the wish lists to the inventory lists and eliminated unnecessary items, then integrated the qualitative suggestions with their previous quantitative results to create prototypes for drawer dividers to better allocate cart space. This was done in a “jigsaw” fashion [8]: the team built early prototypes from cardboard and tape using real supplies as a guide, then asked the nurses to move around the dividers as needed (Figure 2A). The team also asked nurses to model the movements needed to acquire items so that the new compartments had an ergonomic flow.

XSL•FO
RenderX

Figure 2. Prototype to finalized product. (A) Cardboard prototype used in an interactive design process with nurses (drawer 1); (B) finalized, fully stocked prototype for drawer 1; (C) drawer 2; (D) drawer 3; (E) drawer 4; and (F) drawer 5.

Prototypes were designed according to the following principles, all based in human factors engineering: (1) items that were used together should be located in the same drawer and in close proximity, (2) higher-frequency items should be on higher shelves to optimize body posture, (3) compartments should conform to the size and shape of the item, (4) items should fit enough supply for at least 1 full shift for a nurse, and (5) designs should minimize exterior changes to the cart to minimize relearning.

Once nurses provided feedback on the cardboard prototypes, the team incorporated those changes into new prototypes (Figure 2B-E). Team members created computer-assisted design drawings using OnShape [30] for each of the drawer bases and inserts based on the final cardboard models, then laser-cut prototypes made from ¼″ acrylic using a laser cutter.

Simulation and Evaluation of Design

To ensure that the dividers were an improvement over the original models, the team ran a variety of simulations with the help of nursing staff. The team created four scenarios that would require different combinations of supplies: (1) a patient ready for discharge, (2) a patient with fever and a recurrent headache, (3) a patient with chest and abdominal pain, and (4) a patient with multiple constitutional complaints. The number of scenarios was based on nurses' estimates of how many patients they would see in each room throughout the duration of their 12-hour shift; scenarios were intentionally left vague.

The team fully stocked both an existing cart and the prototype and asked on-shift nurses to collect the necessary supplies for each of the patient scenarios. Items removed from the cart were not replaced but instead set aside; nurses were told that if an item was not present in the cart when they needed it, they should go about their normal routine, whatever that was. This often involved searching another cart, or going to the clean supply,

XSL•FO
RenderX

substituting a different item or collection of items, or foregoing that item altogether. Nurses were quasi-randomly assigned, in equal numbers, to start the simulation with either the prototype cart or the current standard to grab items from either the old or new carts first so that the time required to figure out what items to select did not bias the overall time. When all 4 scenarios were conducted with 1 cart, they would then run the same scenarios with the other cart.

Carts were not restocked between sets of simulations ("shifts"). This was to mimic real-time usage, where stockers often would not be able to resupply carts until multiple shifts had elapsed. After 3 shifts had elapsed without restocking, the carts were fully restocked, and the simulations were run again with different nurses.

Ethical Considerations

The University of Pennsylvania's Institutional Review Board (IRB) waived the need for ethics approval and participant consent for the collection, analysis, and publication of the anonymized data for this quality improvement initiative. Informed consent was obtained verbally before participation. All data have been anonymized. No identifying information about the nurses was collected, and the team was not assessing their responses for clinical accuracy. Nurses were not compensated for their participation.

Results

Clinical Immersion and Key Stakeholder Interviews

The team spoke with a wide range of stakeholders, hoping to engage with people throughout the entire supply workflow. This included nurses, doctors, and physician assistants who used the carts; technicians who stocked the carts; and even the supply manager who oversaw stocking and ensured that the department remained in compliance with hospital policy and external regulations. The full chart of interviewees can be found in Multimedia Appendix 2.

During the observation period, the team was told that the bedside carts were fully stocked by emergency technicians and were positioned outside patient rooms so that nurses could efficiently provide patient care. In practice, however, carts were constantly understocked, and nurses frequently visited multiple carts searching for supplies. As a result of this, some nurses no longer relied on the carts and instead went to the central supply closet every time they needed something or carried a personal bucket of supplies they thought they might need, contrary to hospital policy.

After roughly 60 hours of observations and thematic analysis of statements obtained during the interviews (Table 1), it became clear that the current setup did not meet the supply and demand for current nursing staff. For example, each cart could hold only 2 IV start kits, while nurses reported using at least 1 per patient. In addition, the cart could only hold up to three 1-L bags of IV fluids, when a nurse went through an average of 5 to 10 bags per shift across all of their rooms. As a result, these key supplies were constantly in short supply and frequently depleted.

Second, while technicians were responsible for restocking these carts, they lacked sufficient time to do so amid widespread staffing shortages and a host of other, often more critical responsibilities such as sitting with patients who required continuous monitoring or helping to transport patients. Nurses could assist with restocking when time permitted, but ED shifts were often busy, and this was usually impossible. Carts often remained unstocked for several shifts, often for days on end.

In addition, while there was a photographic guide on top of the cart to assist with stocking, there was a lack of consistency in the items inside the cart. Over time, nurses had begun to stock the carts with their preferred items and formats. The clean supply room was aptly labeled with items in their respective categories—IV, wound care, comfort, respiratory, fluids, and so forth—but this system did not correspond to the organization in drawers.

Finally, the observations and interviews demonstrated the importance of buy-in for any potential solution. Nurses expressed concern that any additional work from a proposed solution would fall upon their already-overloaded shoulders and stated outright that there were certain proposals that they would simply not implement.

Co-Design With Key Stakeholders and Initial Solution Selection

The interdisciplinary team held a design sprint workshop with several nurses to generate over 40 potential solutions. Solutions ranged from developing new technologies and processes to detect when a cart was empty, to hiring a new person with the sole job of restocking carts, to altering the workflows of staff members in other departments to help assist with restocking, to even assigning each nurse their own cart to be responsible for and stock as they wished. However, solutions were limited by resources and by staffing shortages and workload. The hospital was unable to allocate money to hire a new person or replace the existing carts, and the team did not identify anyone in the environment with the extra time and ability to add restocking to their workflow. In addition, policy restrictions meant that each cart needed to be standardized. Additionally, nurses and doctors rejected any solution that involved making restocking their responsibility entirely. Given these limitations, the most feasible solution involved a reorganization of the cart system, utilizing the existing space but reconfiguring it to increase capacity for high-use items.

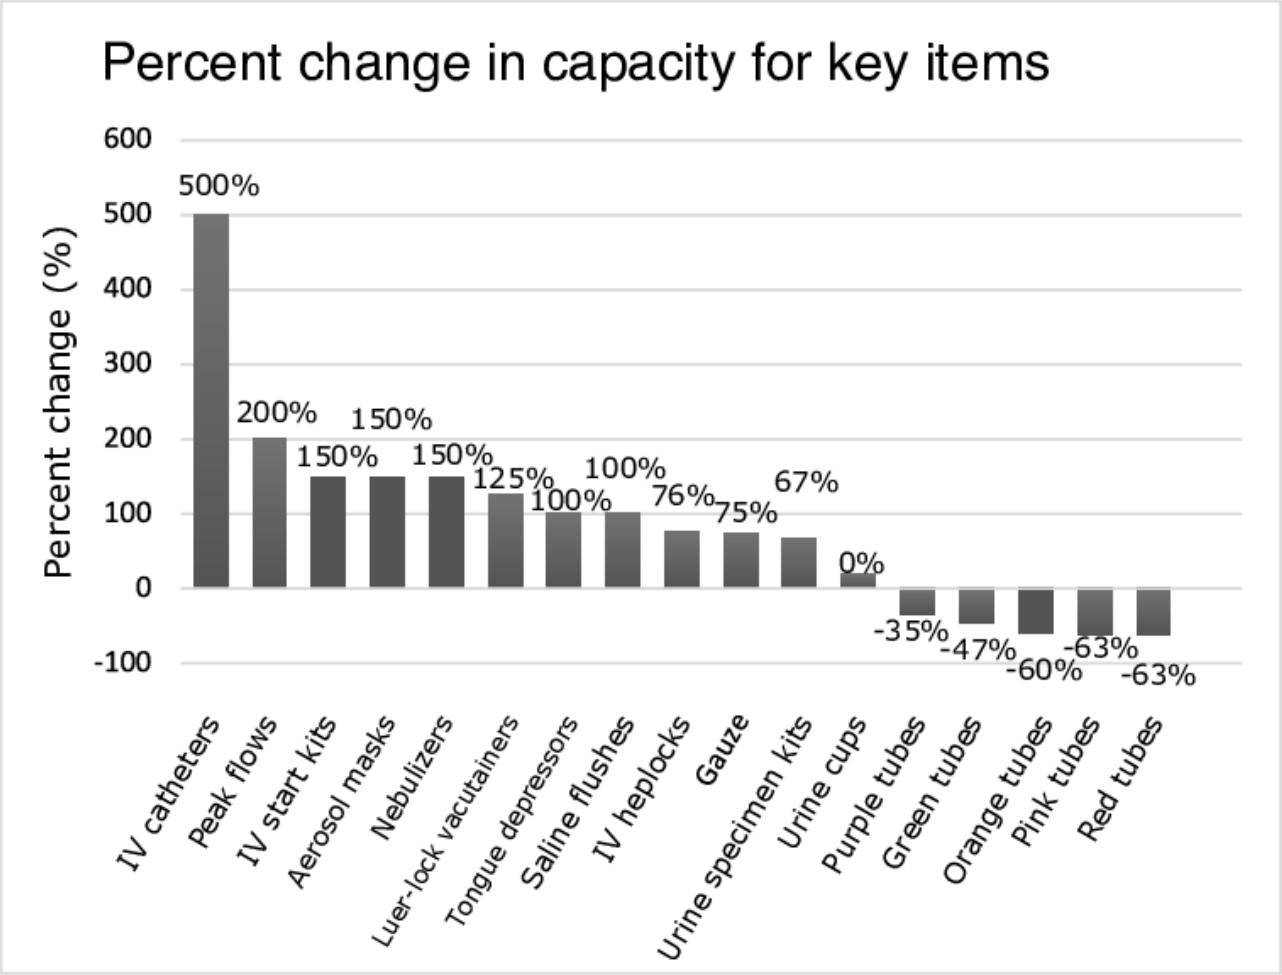
Quantitative Analysis of Current Inventory System and Item Usage

Before making any attempts to redesign the cart capacity, the team needed to understand both the original layout and typical patterns of item usage. The team thus developed an inventory to track supply usage for nurses across a total of 16 hours to capture the relative frequency of supply usage, as well as the types of supplies often used in conjunction with each other. From this information, and through consultation with nursing staff, the team was able to isolate 3 key clusters of highly used supplies: IV, diagnostics, and respiratory supplies. The contents of each of these clusters can be found in Multimedia Appendix 3. They also obtained an approximate estimate of the amount

XSL•FO
RenderX

of each of these supplies needed per day. IV start kits were the most highly used item, as they were used with nearly every patient. Along with the kits, nurses also used flushes, heplocks, and vacutainers.

Rapid Prototyping of New Drawer Organization System



After undergoing the rapid prototyping process described above and shown in Figure 2, the new design provided a marked improvement over the old model. The layouts for the old versus original designs can be seen in Figure 3, and the difference in capacity between the 2 designs can be seen in Figure 4 (key supplies only; full list in Multimedia Appendix 4). Specifically, for the IV kits, the new carts comfortably held 9 kits, while previous models held only 2 or 3—a 200% increase for the most highly used supply. Co-occurring supplies, such as the flushes (100% increase), vacutainers (125% increase), and heplocks (75% increase), similarly increased in capacity. Given the total number of carts on the floor, this meant that the number of IV kits stored in the carts jumped from approximately 100 to approximately 300—enough to make it through multiple shifts without restocking. The new cart design similarly doubled the size of spaces allocated for key respiratory supplies such as peak flow meters (200% increase), nebulizers (150% increase), and aerosol masks (150% increase).

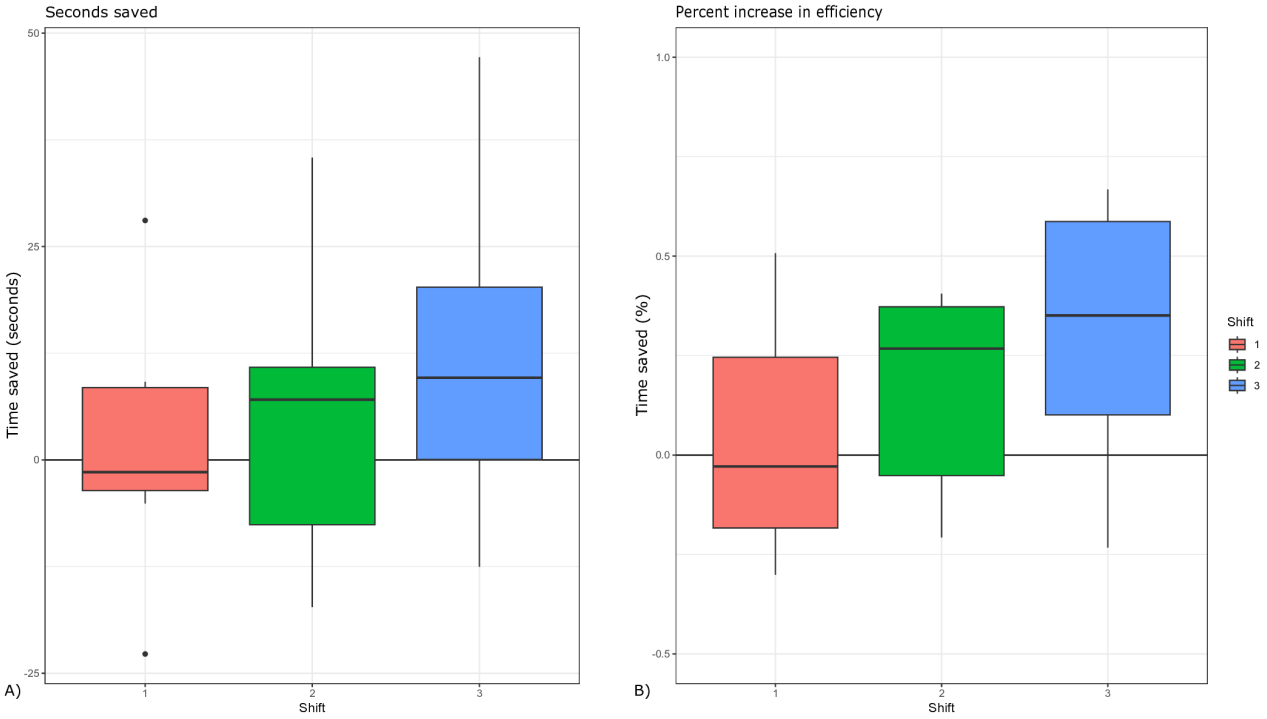
Figure 3. Drawer 1 original versus new layout. Colored boxes highlight key changes that were made. Blue: Needles are no longer stored at a diagonal with no decrease in capacity. Purple: Hep-lock capacity increased by 75%. Green: Intravenous start kit capacity increased by 200%. Orange: Storing all tubes in 1 column makes for a more ergonomic workflow; capacity decreased to avoid wastage.

XSL•FO
RenderX

Figure 4. Cart redesign corrects supply allocation. After redesign, critical items like those used with intravenous (IV) or for urine collection and testing increased in capacity, while overrepresented test tubes decreased in capacity.

In many cases, this was achieved by removing low-frequency items that were rarely used and could be more effectively stored in the central supply closet. In other cases, it was achieved by ensuring each compartment fit the size of the tool it was meant to contain, eliminating wasted space and reducing the chances of needles being damaged or bent by attempting to force them into the cart. The new design also allowed space for the addition of other supplies, such as a speculum, that were highly sought after by physicians and nurses and could not fit in the cart previously. The design met with approval from nursing and administrative staff at all stages of the process.

In addition, the finalized model was both sturdier and less prone to breakage than the original model. This was the result of several iterations: the first draft, which used an acrylic solvent, proved unstable and snapped upon construction, so the team reconfigured the designs to use a press-fit layout instead. With this approach, drawers were easy to assemble and sturdy enough to withstand constant use.



Simulation and Evaluation of Design

Once the prototypes were completed, they were tested for practical usage. After completing the simulation described above, the novel carts outperformed their older counterparts. On average, nurses were able to acquire needed supplies from the new cart nearly 6 seconds faster (21% faster) than they were able to get supplies from the old cart (2-tailed paired *t* test, time to acquire item from old cart=38.2 seconds; time to acquire item from new cart=32.4 seconds; degrees of freedom=23; P=.097). The lack of statistical significance was likely a limitation of low sample size; in addition, this simulation likely overestimated the time required to get samples from the newer cart because nurses were unfamiliar with the new configuration.

In addition, the time saved only increased as the carts went longer intervals without needing to be restocked. During the first shift, the new cart only saved about 1.5 seconds on average. During the second shift, the new cart saved an average of 4.7 seconds. On the third shift, the cart saved an average of 11.3 seconds (Figure 5). This time is a direct reflection of an improvement in capacity. While the old cart ran out of IV start kits by the third patient, forcing nurses to search for kits in nearby carts for every subsequent patient, the new cart contained all of the needed supplies for every patient. On average, a trip from a cart to the clean supply room (the preferred solution for nurses who did not trust that supply carts contain the proper equipment) took 1 minute; these trips were entirely eliminated by the use of the new prototype.

XSL•FO
RenderX

Figure 5. Time savings as a function of new cart. (A) The new cart saved an average of 5.8 seconds per simulated patient, and the time saved increased as the cart went longer without being restocked. (B) As the cart went longer without restocking, the percentage of time saved while accessing needed supplies increased, from about even when both were fully stocked, to 40% after 2 shifts. Boxplots show distribution of data (n=8 per shift). Sample size was too low to assess statistical significance.

Furthermore, the team noticed that the number of supplies taken from the new cart was much higher than those taken from the old cart. Specifically, there were several items that nurses were not willing to go to another cart for, such as speculums or certain test kits, but were happy to grab if they were present. This implied that having carts stocked with these supplies meant that nurses would actually use them, providing more timely patient care.

Plans for and Barriers to Full Implementation

Due to resource constraints, the new drawers are not fully implemented throughout the department. Full implementation would require a large up-front cost: due to the reorganization of supplies, some supplies were moved to different drawers. Because hospital policy requires that all carts contain the same organization, it is not possible to gradually phase in new carts over an extended period. In addition, because of this reorganization, it is not possible to replace the cart drawers for all carts, 1 drawer at a time, since incomplete adoption would mean that some items would no longer be included. This is certainly a limitation of the team's design process—had considerations about gradual or modular adoption been considered earlier in the process, this would not have been an issue. However, the team is working to find the lowest-cost way to implement these new designs.

They are also working to mitigate unintended consequences arising from adjustments to the new cart system. Specifically, to improve the ease of adjustment, they have created a pamphlet showing an updated schematic of the cart with pictures of the contents of each full cart. A written list of the cart's contents and approximate capacity will also be provided to keep at each nursing station for training purposes and reference. They will label carts with the contents of each drawer (ie, drawer 1 will be labeled with IV supplies; drawer 2 will be labeled with wound care, diagnostics, and extra needles; drawer 3 will be labeled with miscellaneous small supplies; drawer 4 will be labeled with respiratory supplies; and drawer 5 will be labeled with flushes, urine cups, catheters, tubing), and the bottom of each section of the drawer will have a photo of the supply that belongs inside it. These improvements will facilitate stocking, assist with the transition, and make it easier to onboard new nurses. In addition, it will decrease the likelihood of drift over time, ensuring that staff use the partitions as directed.

Discussion

Principal Findings

This participatory design process highlighted the importance of co-design for improving workflow and supply management in an ED. By observing, interviewing, and directly working with the people who use the system the most, the team was better able to understand the key challenges that influenced the effectiveness and constrained the solution space. The final prototype increased the capacity for key items by up to 200%, enabling cart capacity to last 36 hours (3 shifts) rather than requiring restocking within the first 12-hour shift. In addition, similar to other studies [15,31], the reduction in response time finding supplies did not reach statistical significance, but trended toward a statistical result. This is in spite of the fact that the new design meant participants spent more time looking for objects that had been moved, a metric that would improve as users became more familiar with the new system. Notably, the improvement here is likely due to the new design reducing the number of trips to the clean supply room or searching for

XSL•FO
RenderX

supplies from other carts, rather than from the more logical organization of the cart itself.

Overall, the findings of improved supply accessibility are in line with reports from other human factors–based redesigns of supply carts in other departments of the hospital [1,2,4,7,12-14]. While the constraints of this setting are not entirely analogous to other settings—here, the challenge was less about disorganization and more about a limited availability of stockers—they nevertheless suggest that cart organization, tailored to the needs of the staff and built with human factors principles in mind, plays a critical role in departmental workflows.

Even when the carts were fully stocked, nurses noted that the items that were present were there in the wrong quantities. Low-frequency items were present in large quantities, while there were hardly any of the most commonly used supplies. In fact, the supply manager told us that she had gone through the carts and had to toss hundreds of dollars' worth of unused supplies that had expired, an enormous waste of money and space for a department that had little to spare of either. This finding of overstocked items leading to wastage has been found in other sites as well [3,32] and suggests that periodic evaluation to ensure that carts can contain appropriate quantities of each supply is necessary. Our discovery of clusters of items frequently used together also matches the findings reported elsewhere [33].

In addition, the success of the quality improvement demonstrated the importance of participatory design, particularly the frequent consultation with stakeholders during the ideation and prototyping process, ensuring that the team's proposed solution was both effective and acceptable. Stakeholders were glad to be able to address a problem that mattered a great deal to them and helped to ensure that the new designs addressed their particular concerns about the old model. Co-design processes and design sprints are widely used in applied health research and are critical for ensuring that solutions focus on outcomes that are most important to end users [23,34,35].

Tailoring the cart's contents to the user workflow, and specifically minimizing the number of drawers that needed to be opened, improved user experiences. Although the cart's organization changed slightly, and users were less familiar with it, they still found it easier to use and preferred it over the standard cart. This is similar to prior findings that nurses preferred to use a cart that only required them to open 1 drawer per patient rather than a cart where everything was organized by tool but required multiple accesses [13].

In addition, nurses discussed how eager they were to be able to participate in the process. While this has been a persistent problem, engaging nurses in the redesign process gave them a voice, helping them feel like change was possible. This matches with previous research that found that nurse involvement in the co-design process improves nurse satisfaction [14].

The prototype created by this team is an example of how participatory design can create substantial improvement in a nursing workspace. The team was able to identify the key items nurses needed most and provide enough of those items to last multiple shifts without restocking, substantially improving workflow. The organization was designed according to nurses' priorities, focusing on ergonomics and efficiency using the same principles found in other studies [14,15]. While the solution could not solve the root causes of the issue—low funding and staffing shortages—it still made a meaningful, actionable contribution within the preexisting constraints by reducing the frequency of needed restocking. Once fully implemented, it is expected to save nurses a substantial amount of time per shift looking for items, reducing frustration and increasing the amount of time available for providing quality patient care. In addition, the durability of the acrylic, the work done to document and improve the ease of replicability of the system, and the buy-in from stakeholders all help to cement its durability and reduce the drift in restocking practices.

While the final design of the drawers in this project is customized to the specific hospital, the co-design process used demonstrates how stakeholder contribution and co-design can enable teams to make a meaningful impact in a low-resourced setting, working around structural barriers to improve nurse workflow and patient care.

Limitations

This project, while useful, was unable to address the root cause of the problem of supply shortages: the lack of a dedicated person who could simply restock all of the carts on a reliable basis. Despite this challenge, the implemented solution managed to ameliorate these effects by decreasing the time needed to restock and increasing the time the cart could go without restocking.

The project also encountered challenges regarding implementation—specifically, that because some items were moved to different drawers, and institutional policy required that all carts be organized the same way, implementation would need to occur all at once rather than being phased in gradually, requiring a larger up-front cost.

In addition, the data collection for the simulations was limited due to team availability and the availability of nursing staff to assist during their own busy shifts. The simulations also relied on convenience sampling: working with whatever staff were available at the time. Staff received the same prompts for both carts in the simulation; it is possible that thinking through the supplies beforehand made them faster at accessing the supplies the second time. We attempted to mitigate this response by randomizing which cart the team used first. Variable levels of experience with both the old and revised carts may also have led to bias in how quickly nurses found supplies in each cart [15]. Despite the lack of significance in time saved, the team was able to validate the use of the intervention through the increase in capacity for key supplies and through positive qualitative feedback from nursing staff indicating that, based on their past experiences, the cart would make a substantial improvement.

Finally, the designs for the cart interiors created during this project were tailor-made for this specific department and the cart system already in place, and would not necessarily generalize to other EDs. However, the processes used to design

XSL•FO
RenderX

and validate the solution are readily transferable, and the designs could be tweaked to fit the unique contexts of other departments.

Conclusion

The co-design process used in this study demonstrates the importance of stakeholder engagement and contribution to quality improvement and the use of the double diamond approach in a health care setting. Stakeholder input was crucial for navigating around institutional barriers and ensuring that any proposed solutions would be accepted and implemented, rather than ignored. Indeed, the buy-in generated from participatory design ensured that the changes made would be sustainable. While the team's designs were specific to the ED's context, the process and insights can be applied to any other type of workplace improvement process. Specifically, we recommend engaging with stakeholders at every step of the way, particularly during the rapid prototyping phase. However, we suggest that future teams consider the ease of implementation, especially gradual implementation for budgetary reasons, while evaluating their designs.

Abstract

Background: Early rehabilitation in neurocritical care is often underutilized due to fragmented workflows, interdisciplinary coordination challenges, and the absence of structured digital decision support. Traditional clinical decision support systems (CDSS) often address single domains and lack adaptability to the dynamic, multiprofessional workflows of intensive care units (ICUs).

Objective: To develop and evaluate the usability of the ERATbi App (Early Recovery After Traumatic Brain Injury App), a modular, tablet-based CDSS was designed to streamline early rehabilitation planning and strengthen interdisciplinary coordination for patients with moderate-to-severe traumatic brain injury (TBI) in intensive care settings.

Methods: The ERATbi app integrates four functional modules—delirium risk management, precision nutrition, stepwise early mobilization, and respiratory care for rib fractures—into a unified interface. A simulation-based usability study was conducted with 18 ICU clinicians. Evaluation metrics included System Usability Scale (SUS) scores, task completion rates, error rates, and task durations. Additional user feedback was collected via a 5-point Likert satisfaction survey and semi-structured qualitative interviews.

Results: The app demonstrated high usability (mean SUS score 83.6, SD 7.4), a 100% (18/18 participants) task completion rate, and a low error rate (4.2%). Average module completion time was 6.5 minutes, and user satisfaction was high (mean 4.7, SD 0.5). Users highlighted the value of the app's visual logic, real-time alerts, adaptive thresholds, and modular workflow integration for enhancing team coordination and decision consistency.

Conclusions: The ERATbi app demonstrated excellent usability, high user satisfaction, and clinical relevance in simulated ICU workflows. Its logic-driven, workflow- integrated design may support scalable, interdisciplinary implementation of early rehabilitation in neurocritical care settings.

Introduction

Epidemiology and Clinical Burden of Traumatic Brain Injury

Traumatic brain injury (TBI) is a major global public health concern and a leading cause of death and long-term disability worldwide [1]. In Taiwan, the annual incidence of hospitalized head injuries is approximately 126.1 per 100,000 population, equivalent to nearly 29,000 cases each year. Among these, an estimated 20.5% involve moderate-to-severe TBI, which is frequently associated with impaired consciousness, mechanical ventilation, and polytrauma [2].

Barriers to Early Rehabilitation in the Acute Phase

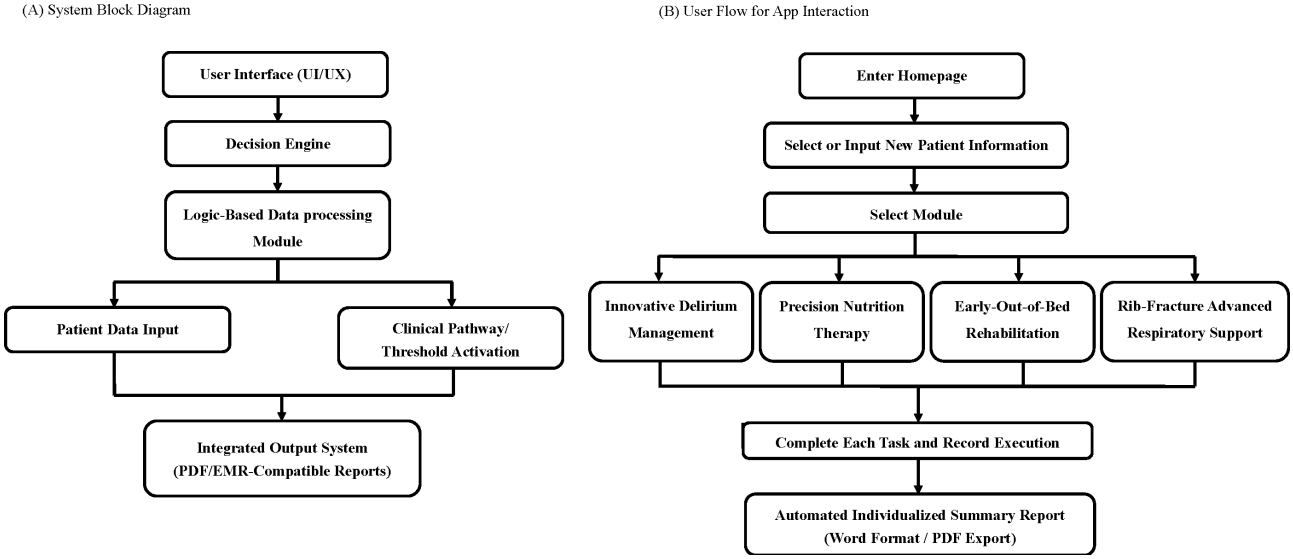
Although the benefits of early rehabilitation are increasingly supported by evidence [3,4], its implementation in the acute phase remains limited. Major barriers include safety concerns, fragmented workflows, and the absence of structured clinical decision-support systems [5-8]. Clinical hesitation often stems from hemodynamic instability, fluctuations in intracranial pressure (ICP), and the complexity of managing multiple invasive devices. These challenges force clinicians to balance therapeutic benefits against physiological risks, contributing to variability in decision-making and delayed initiation of rehabilitation.

Gaps in Multidisciplinary Integration and Decision Support

Early mobilization, nutritional therapy, delirium prevention, and respiratory management show positive impacts on outcomes of critically ill patients [9-15]. However, these interventions are typically delivered by separate disciplines with limited cross-team coordination, resulting in inconsistent implementation and delayed functional recovery. Most existing electronic medical record (EMR) systems do not provide process-based visualization or real-time interdisciplinary decision support. As a result, clinicians often depend on paper-based tools, fragmented documentation, and manual communication, further hindering timely and coordinated early rehabilitation.

Study Rationale and Objectives

To address these challenges, we developed the Early Recovery After Traumatic Brain Injury (ERATbi) app, a modular, web-based clinical decision support system (CDSS) designed to assist ICU clinicians in delivering structured early rehabilitation for patients with moderate-to-severe TBI. The system integrates four evidence-based modules: (1) delirium risk management, (2) precision nutrition therapy, (3) stepwise early mobilization, and (4) respiratory care for rib fractures. It incorporates standardized safety thresholds (eg, mean arterial pressure ≥65 mm Hg, ICP <20 mm Hg), automated alerts, and decision checkpoints to support safe and consistent clinical decision-making.



Grounded in user-centered design and interdisciplinary collaboration, this study describes the ERATbi app's theoretical framework, system architecture, and simulated clinical workflows, and evaluates its usability, clinical relevance, and potential to enhance safety, standardization, and interdisciplinary coordination in early neurocritical rehabilitation.

Methods

System Design and Development Approach

The development of the ERATbi app followed a user-centered design methodology, which is widely recommended for CDSS development in high-acuity settings due to its emphasis on workflow integration, context alignment, and stakeholder engagement [16-18] (Figure 1). A multidisciplinary co-design team—comprising intensivists, physical therapists, dietitians, critical care nurses, and software engineers—collaboratively identified workflow gaps and defined the functional requirements for a neuro-ICU–specific decision-support system. The development process consisted of three iterative stages:

Figure 1. System architecture and user workflow diagram of the ERATbi (Early Recovery After Traumatic Brain Injury) app.

XSL•FO
RenderX

Needs Assessment Phase

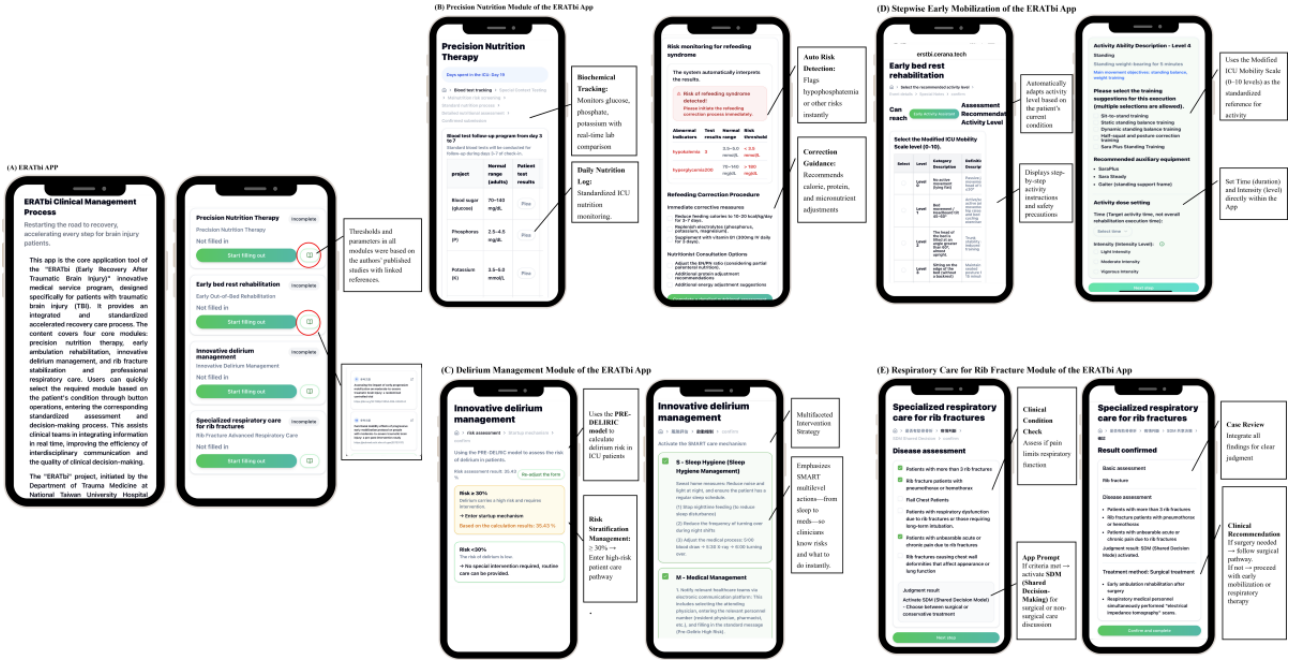
Direct observations and stakeholder interviews were conducted to map existing ICU rehabilitation workflows for patients with moderate-to-severe TBI and to identify barriers to timely intervention. Key gaps included inconsistent interdisciplinary coordination and the absence of real-time patient stability assessment tools.

Prototype Development Phase

Modular logic trees and interactive wireframes were constructed based on key clinical variables—such as Glasgow Coma Scale (GCS) score, time since admission, vital signs, and device constraints (eg, chest tubes, external ventricular drains). These algorithms were designed to emulate expert reasoning while supporting real-time, safety-focused decision-making.

Simulated Use Phase

Preliminary usability testing was conducted using mock clinical scenarios, enabling iterative refinement of the interface, navigation structure, and backend decision logic in response to user feedback [17].



Ethical Considerations

This study did not involve human participants or the collection of personally identifiable information. Usability evaluations were conducted exclusively in a simulated environment using standardized case scenarios developed from deidentified patient data. These data were originally obtained from an institutional review board-approved study at National Taiwan University Hospital (IRB No. 202306107RIND). The original informed consent and IRB approval covered secondary analyses of the existing data without requiring additional consent. All data used in this secondary analysis were deidentified prior to analysis, and no personally identifiable information was accessible to the study team. All participants were ICU clinicians (physicians, nurses, therapists, and dietitians) who evaluated only the app's interface and workflow. No patient contact occurred, and no clinical interventions were performed. In accordance with institutional policy, the study was deemed exempt from additional IRB review, as it did not constitute human subjects research.

Modular Architecture and Embedded Clinical Logic

The ERATbi app consists of four functional modules, each corresponding to a core domain of early neurocritical rehabilitation (Figure 2). This modular structure supports process-based clinical reasoning and enhances interdisciplinary alignment.

Figure 2. Interface storyboard of the ERATbi (Early Recovery After Traumatic Brain Injury) app demonstrating the stepwise workflow across four functional modules: precision nutrition, delirium management, stepwise early mobilization, and respiratory care.

Precision Nutrition Module

This module identifies ICU patients at risk of nutritional deficiency within the first 7 days of admission using real-time GCS and BMI calculations. Consistent with ESPEN (European Society for Clinical Nutrition and Metabolism) and ASPEN (American Society for Parenteral and Enteral Nutrition) guidelines, it stratifies patients into intervention tiers and provides individualized caloric, protein, and micronutrient recommendations [19-21]. Embedded calculators further ensure accurate risk estimation and streamline nutritional decision-making [10,22,23].

Delirium Management Module

This module incorporates the "Sweet SMART Home" protocol [24] to guide delirium risk stratification based on patient age, cognitive function, and sedation level. It emphasizes nonpharmacologic strategies such as circadian regulation and reorientation, consistent with contemporary ICU guidelines for delirium prevention [11,25].

XSL•FO
RenderX

Stepwise Early Mobilization Module

Algorithmic logic trees stratify patients according to consciousness level (GCS), physiological thresholds, and device attachments. Based on these criteria, the system generates graded activity recommendations and automated alerts for contraindicated conditions. The framework draws on established ICU mobilization models emphasizing phased recovery and functional readiness [3,26,27].

Respiratory Care for Rib Fracture Module

This module addresses comorbid thoracic trauma by supporting shared decision-making for surgical fixation and integrating electrical impedance tomography data to guide respiratory management. It includes structured prompts for pulmonary hygiene, analgesia assessment, and individualized weaning plans, aligning with ICU pain and ventilation protocols [28,29].

User Interface and Decision-Support Design

The ERATbi interface uses a process-based visual workflow that enables clinicians to navigate each module in a structured, stepwise manner. The dashboard displays real-time patient status across the four domains. Core features include auto-calculated clinical thresholds and alert mechanisms triggered by physiological or procedural contraindications.

Although full EMR integration is not yet available, the system generates structured visual summaries and consolidated recommendations to support clinical review. Data-entry fields incorporate real-time validation—such as missing-value alerts and format checks—particularly within the nutrition and mobilization modules. Guided prompts and sequential navigation are designed to reduce cognitive load and enhance data completeness during clinical use.

Simulation-Based Usability Evaluation

A simulation-based usability evaluation was conducted in the trauma ICU of a tertiary medical center. Eighteen clinicians participated, including physical therapists (n=8), ICU nurses (n=5), attending physicians (n=2), respiratory therapists (n=2), and one dietitian (n=1), all with previous experience in neurocritical care and early mobilization.

Each participant completed two standardized case vignettes reconstructed from de-identified patient records, representing moderate and severe TBI. Each vignette contained five consecutive ICU days of physiological parameters (eg, GCS, MAP [mean arterial pressure], FiO_2 [fraction of inspired oxygen], and ICP), nutritional data, and mobility progression to simulate continuous monitoring. Participants initiated a "new patient entry" and sequentially updated data to reflect daily changes, mirroring real-world decision-making workflows. Although each vignette contained data for multiple ICU days, task-level analysis was based on discrete user interactions, which were counted independently of the number of simulated days.

Case vignettes were tailored to professional scope: physical therapists emphasized activity planning, nurses focused on safety and delirium monitoring, and physicians emphasized interdisciplinary coordination. Participants used hospital-issued tablets or smartphones to complete workflows for at least two modules. All interactions were recorded via screen-capture software for subsequent analysis.

Assessment Approach

Usability was assessed using a mixed-methods approach integrating quantitative and qualitative data. Quantitative measures included the System Usability Scale (SUS) [30], task completion rate, error rate (eg, incorrect pathway selection, data-entry mistakes), and average task duration. After each simulation, participants completed a customized satisfaction questionnaire with a 5-point Likert scale (Multimedia Appendix 1) and participated in a 10 - 15-minute semi-structured interview (Multimedia Appendix 2).

Interviews were conducted face-to-face by a trained observer, audio-recorded with participant consent, and designed to explore usability facilitators, barriers, and improvement opportunities. Example prompts included the following questions. "Which parts of the interface were most intuitive or confusing?" "Were there any steps that slowed your workflow?" "What features would you modify or add to enhance clinical applicability?"

Interview recordings were transcribed verbatim and analyzed thematically following Braun and Clarke's inductive approach. Two independent researchers coded themes related to facilitators, barriers, and design recommendations. Quantitative and qualitative findings were integrated to develop a comprehensive understanding of user experience and system performance. Sessions were monitored using validated ICU CDSS evaluation frameworks [16,17].

Methodological Rigor

To further enhance the rigor of this mixed-methods design, several strategies were implemented. For the quantitative component, task-completion metrics and SUS scores were cross-validated by two reviewers to ensure data accuracy. For the qualitative component, two researchers coded the open-ended responses using an inductive thematic approach. Coding discrepancies were discussed and resolved through consensus, and an audit trail was maintained to document analytic decisions.

Data triangulation was achieved by comparing usage metrics, task-performance patterns, and qualitative feedback. Integration of quantitative and qualitative findings followed a convergence model, whereby qualitative themes were compared with performance trends to enhance interpretive depth. Collectively, these approaches strengthened the credibility, dependability, and confirmability of the study.

Results

System Architecture Overview

Eighteen ICU professionals participated in the simulation-based usability evaluation using standardized case vignettes. All participants independently completed workflows in at least two ERATbi modules, with their interactions fully recorded for analysis. The ERATbi App integrates four core modules, Delirium Management, Precision Nutrition, Stepwise Early Mobilization, and Respiratory Care, into a unified, logic-driven clinical decision support system tailored for neurocritical

XSL•FO
RenderX

rehabilitation. Each module automatically adapts recommendations based on patient-specific variables such as vital signs, level of consciousness (GCS), and device conditions. Safety features include real-time alerting, visual cue signaling deviations from physiological thresholds, and auto-generated clinical summaries. Together, these mechanisms support interdisciplinary coordination and help clinicians maintain a consistent understanding of patient status and safety priorities.

Usability Metrics

The ERATbi App demonstrated strong usability across all quantitative indicators. The System Usability Scale (SUS) yielded a mean score of 83.6 (SD 7.4), corresponding to the "excellent" usability range [31]. All participants successfully completed their assigned workflows, resulting in a 100% (18/18) task completion rate. The mean time to complete a single module was 6.5 minutes (SD 1.3). The overall error rate was 4.2% (2 errors out of 54 total interactions), primarily involving minor data-entry or selection issues.

User satisfaction, measured via a 5-point Likert scale, averaged 4.7 (SD 0.5), indicating high perceived usefulness and acceptance. Participants consistently highlighted the interface's logical visual organization, which facilitated intuitive navigation and supported clinical reasoning, particularly beneficial for junior staff. Features such as real-time alerts, automated summaries, and visualized physiological thresholds were frequently cited as improving confidence and enhancing interdisciplinary discussions.

Qualitative Feedback

Open-ended feedback and observer field notes revealed three major themes: (1) Clarity and cognitive alignment: Participants reported that the stepwise logic structure closely aligned with their real-world ICU decision-making processes, reducing cognitive burden and supporting rapid clinical reasoning; (2) Enhanced interdisciplinary coordination: The integration of rehabilitation, nutrition, delirium, and respiratory considerations within a single interface promoted a shared mental model, enabling more coherent team discussions and planning. In this study, "shared mental model" refers to the alignment of understanding among ICU physicians, nurses, dietitians, and physical therapists regarding safety priorities, patient status, and rehabilitation goals, allowing teams to interpret clinical information consistently and coordinate care more efficiently; (3) Implementation potential: Users expressed confidence in the system's clinical applicability and highlighted the value of future EMR integration to support handoffs, documentation consistency, and safety review workflows.

Overall, the ERATbi App demonstrated strong feasibility, high user acceptance, and operational efficiency in simulated ICU environments, supporting its potential for broader deployment in neurocritical care workflows.

Discussion

Principal Findings

This study developed and evaluated the ERATbi App, a modular CDSS designed to support early rehabilitation planning for ICU patients with moderate-to-severe TBI. In simulation testing with 18 multidisciplinary ICU clinicians, the system demonstrated excellent usability (mean SUS 83.6, SD 7.4), complete task success (100%), a low error rate (4.2%, 2/54 tasks), and high user satisfaction (mean 4.7, SD 0.5). Participants reported that the app's structured, modular interface enhanced clarity, reduced cognitive burden, and facilitated interdisciplinary communication and real-time decision-making. Collectively, these findings indicate that ERATbi is highly feasible, operationally efficient, and well-positioned for clinical implementation in neurocritical care environments.

Overcoming the Fragmentation of Early ICU Rehabilitation Support

Prior CDSS research in ICU settings has predominantly focused on single-domain applications, including delirium screening [32,33], primary palliative care [34], rare disease diagnosis [35], fall prevention [36], or early mobility-related decision-making [37,38]. Although these systems have demonstrated benefits within their respective domains, most operate as stand-alone tools lacking interoperability, limiting their ability to support the complex, interdisciplinary workflows required in neurocritical care.

This fragmentation is compounded by EMR-integrated CDSS platforms that largely emphasize documentation or retrospective data retrieval rather than offering adaptive, real-time clinical guidance. These systems rarely adjust recommendations in response to rapidly changing physiological parameters or evolving clinical contexts, reducing their effectiveness in high-acuity decision-making.

To address these persistent gaps, the ERATbi app was conceptualized as a workflow-embedded, multi-domain CDSS specifically tailored for neurocritical care. Its design reflects the multifactorial demands of early rehabilitation in moderate-to-severe TBI—including fluctuating consciousness, invasive device management, physiological instability, and the interactions of multiple disciplines.

Evidence supporting this approach is aligned with recent studies. In 2024, Dunn et al [37] emphasized the need for standardized terminology and safety thresholds in ICU mobility tools, demonstrating high expert agreement (Content Validity Index=0.93). Similarly, in 2025, Wilson-Jene et al [38] demonstrated that algorithm-based guidance improved adherence to safety protocols and reduced mobilization delays. These studies reinforce the necessity of structured, logic-driven, and adaptive CDSS frameworks such as ERATbi.

Modular Integration and Workflow-Embedded Design in the ERATbi App

The ERATbi app was intentionally engineered as a multidomain CDSS to meet the interdisciplinary and dynamically evolving needs of neurocritical care. Unlike traditional single-domain tools, ERATbi integrates four pillars of early rehabilitation—delirium management, precision nutrition, stepwise mobilization, and respiratory care—within a unified modular interface. This architecture enables clinicians to navigate shifting consciousness levels, invasive device

XSL•FO
RenderX

constraints, physiological instability, and interdisciplinary workflows with improved clarity and consistency.

Aligned with evidence-based guidelines and developed using a user-centered design methodology, ERATbi reflects contemporary recommendations that prioritize usability, workflow integration, and team-wide accessibility [39,40]. At the system's core is a decision engine that synthesizes validated physiological thresholds and individualized risk factors to generate real-time, context-aware recommendations—marking a shift from retrospective documentation tools to proactive, adaptive CDSS design.

Visual logic pathways, real-time alerts, and dynamic thresholds were incorporated to reduce cognitive load while preserving decision accuracy. Prior studies demonstrate that such features improve protocol adherence [41], reduce ICU errors [42], and enhance decision consistency during high-acuity transitions [43]. Additionally, intuitive interfaces with clearly presented thresholds have been shown to strengthen user trust, situational awareness, and adoption across multidisciplinary teams [44-46].

By embedding these technical and human-centered principles within a modular architecture, the ERATbi App provides a scalable and interoperable platform capable of standardizing early rehabilitation workflows and improving safety and communication in complex neurocritical care settings.

Clinical Implications

This study highlights several important clinical implications. First, the structured, logic-driven design of ERATbi supports consistent clinical decision-making and reduces variability across shifts and providers. Second, its visual dashboards and auto-generated summaries enhance interdisciplinary communication by providing a shared reference for physicians, nurses, dietitians, and physical therapists. Third, the app demonstrates utility as both an educational and an implementation tool, particularly for onboarding new personnel, reinforcing protocol adherence, and supporting quality improvement initiatives. Participants also noted that the modular framework could be adapted to other neurocritical populations, including stroke or post-neurosurgical patients, suggesting the system's broader clinical scalability.

Scalability and Data Integration Potential

The ERATbi app was designed for future interoperability with the hospital's HIS through HL7-FHIR–based data exchange. Structured data entered into the app (eg, GCS, MAP, ICP, FiO_2 , mobility level, and nutritional parameters) is planned to be stored using standardized FHIR Observation and Encounter resources. Physiological and biochemical data, such as vital signs, blood gas analyses, and laboratory results, are planned for future automated retrieval from the HIS within the preceding 24 - 48 hours to reduce manual input.

Upon full integration, the system is planned to generate AI-assisted summary reports that consolidate the four rehabilitation modules into a single interface. These structured reports are intended to be documented in the EMR and made accessible during interdisciplinary rounds. This planned automated data exchange is expected to improve accuracy, reduce clinician workload, enhance scalability across ICUs, and enable predictive analytics by linking rehabilitation trajectories with clinical outcomes such as mobilization timing, extubation readiness, and ICU length of stay.

Limitations

This study has several limitations. First, the evaluation was conducted in a simulation-based environment rather than during real-time clinical deployment, which may affect generalizability. Although case scenarios reflected real moderate-to-severe TBI encounters, certain dynamic or emergent ICU conditions may not have been fully captured. Second, the ERATbi app was assessed as a stand-alone prototype without EMR integration, which may limit immediate scalability and clinical adoption.

Future Work

Beyond its clinical decision support function, the ERATbi system will be expanded into an educational and quality improvement platform. A planned B2C extension will provide simplified dashboards and interactive modules for patient- and family-centered education to support health literacy and post-ICU self-management. A real-world pilot study is planned at the neuro-ICU of National Taiwan University Hospital, followed by multicenter evaluations examining outcomes such as mobilization timing, delirium incidence, ICU length of stay, and safety events. Future iterations will incorporate a continuous, data-driven feedback mechanism linking clinician decisions with patient outcomes to refine decision thresholds. This iterative framework will enable adaptive modeling and sustained quality improvement in neurocritical rehabilitation.

Conclusion

The ERATbi app is a modular clinical decision support system designed to address the complex demands of early rehabilitation in neurocritical care. Simulation-based usability testing demonstrated high user acceptance, excellent usability, and strong potential to support workflow standardization, enhance interdisciplinary coordination, and promote patient safety. By integrating evidence-based clinical logic with user-centered design, the system helps to close critical gaps in ICU rehabilitation for patients with moderate-to-severe traumatic brain injury. With planned EMR integration and real-world implementation, the ERATbi app offers a scalable foundation for disseminating early rehabilitation strategies across broader neurocritical care populations.

Abstract

Background: Pediatric cardiopulmonary resuscitation (CPR) is a highly complex and time-critical process that demands precise team coordination and strict adherence to pediatric advanced life support (PALS) guidelines. In real-world practice, adherence often deteriorates due to cognitive overload, fragmented communication, and disruption of information flow under stress. Although digital cognitive aids have shown potential to improve adherence, existing tools are often limited to single tasks, lack team-wide integration, or fail to adapt in real time to dynamic clinical environments.

Objective: This study aimed to design and evaluate InterFACE (Interconnected and Focused Mobile Applications on Patient Care Environment), an integrated, augmented reality (AR)–enabled digital health system developed to support real-time PALS adherence and enhance team coordination during pediatric resuscitation.

Methods: A structured, mixed methods, user-centered design process was used. Persona development and spatial analysis characterized the needs and positions of key resuscitation roles. A 3-round Delphi process with experts identified critical information elements for display. Iterative user experience (UX) prototyping was performed, followed by simulation-based evaluations of three system components: (1) TeamScreen, a wall-mounted team display providing a shared overview of the resuscitation process; (2) Guiding Pad (developed by Pierre Louis Rebours and Marc Ibrahim), a tablet-based app for documentation and algorithm navigation; and (3) AR head-mounted displays (HMDs) for team leaders and medication nurses, delivering role-specific, context-aware guidance. Usability was assessed with standardized instruments, including the System Usability Scale (SUS), Technology Acceptance Model (TAM), and User Experience Questionnaire (UEQ).

Results: The Delphi study achieved consensus on 20 core information elements, distributed across the 3 interfaces. Usability testing demonstrated high acceptance across all modalities. The Guiding Pad supported effective navigation of resuscitation algorithms with a 78%-100% task completion rate. The TeamScreen achieved an overall task success rate of 81%, improving situational awareness despite some confusion in high-density regions. AR HMDs received favorable evaluations, with SUS scores rated “Good” to “Excellent,” and UEQ ratings indicating high intuitiveness, stimulation, and attractiveness. Participants consistently described InterFACE as intuitive, useful for real-time decision-making, and supportive of team synchronization. Reported challenges included interface complexity, incomplete integration with patient monitors, and potential cognitive load from simultaneous information streams.

Conclusions: InterFACE represents a significant advancement in digital cognitive aids by combining shared displays, tablets, and AR guidance into a synchronized, role-specific ecosystem. The system shows promise in enhancing adherence to PALS,

XSL•FO
RenderX

reducing cognitive load, and improving team coordination in simulated pediatric resuscitations. While results demonstrate strong usability and acceptance, further research is needed to evaluate clinical effectiveness in real-world settings, including randomized controlled trials, integration with hospital information systems via Fast Healthcare Interoperability Resources (FHIR) standards, and potential artificial intelligence–driven decision support to optimize adaptability and long-term skill retention.

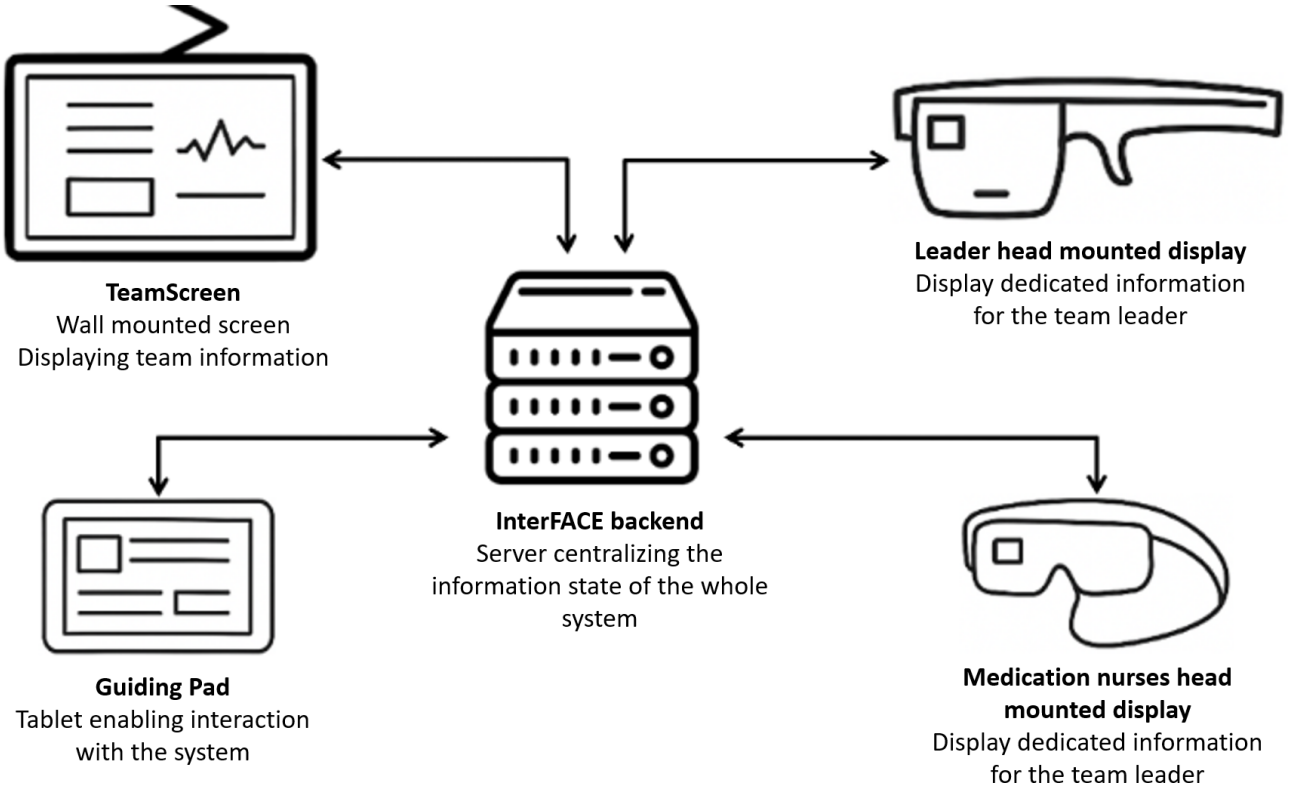
implementation; rescucitation; augmented reality; pediatric; team coordination; digital cognitive aids; situational awareness; user-centered design

Introduction



Cardiopulmonary resuscitation (CPR) in pediatric and adult emergencies is a complex, time-sensitive process requiring precise team coordination. Adherence to pediatric advanced life support (PALS) guidelines, such as those from the American Heart Association (AHA) [1] and European Resuscitation Council [2], is crucial for optimizing CPR quality and patient outcomes [3]. Yet, the high-stress environment of CPR often disrupts guideline adherence due to cognitive overload, miscommunication, and fragmented information flow, impairing decision-making and delaying critical interventions.

Digital health technologies offer promising solutions to support resuscitation teams in maintaining guideline compliance and coordination. Previous research has investigated digital resuscitation tools like head-mounted displays (HMDs) [4], tablet-based guidance systems [5,6], and mobile apps to support caregivers, enhance adherence to resuscitation guidelines, and minimize drug preparation errors [7,8]. While these technologies have demonstrated potential benefits, they also reveal limitations in usability, team-wide information sharing, and real-time adaptability to dynamic clinical scenarios.

To address these limitations, we developed InterFACE (Interconnected and Focused Mobile Applications on Patients Care Environment), an integrated digital suite designed to enhance pediatric CPR performance through real-time, role-specific guidance and improved team coordination aligned with pediatric PALS algorithms. InterFACE comprises three core components: (1) a wall-mounted display delivering a dynamic, real-time resuscitation overview for the team; (2) a tablet app, operated by the documenting (script) nurse, enabling CPR algorithm navigation and task documentation; and (3) mixed reality (augmented reality, AR) HMDs, worn by the team leader and medication nurse, providing context and role-specific, interactive guidance (Figure 1). Unlike traditional AR, which overlays static digital data, InterFACE leverages AR technology to integrate spatially anchored, interactive virtual elements into the physical environment to enhance situational awareness and enable hands-free access to critical information. InterFACE aims to deliver accurate, context-specific information to each team member in real time, enhancing CPR efficiently through improved team alignment and PALS guidelines adherence.

XSL•FO
RenderX

Figure 1. System architecture of InterFACE, illustrating the conceptual flow of information between the backend and user interfaces. InterFACE: Interconnected and Focused Mobile Applications on Patients Care Environment.

Unlike existing solutions that typically address a single aspect of the resuscitation process, such as medication preparation or algorithm visualization, InterFACE proposes a comprehensive, multirole synchronized system integrating wall-mounted displays, tablets, and head-mounted AR interfaces. This integration aims to improve shared cognition, role-specific guidance, and real-time adaptability—key elements often missing in previous digital resuscitation tools.

This paper aimed to present the user-centered design process and formative usability evaluation of InterFACE, an integrated, AR-based decision support system for pediatric resuscitation. Rather than providing exhaustive detail on each methodological step, we offer a cohesive, high-level overview of the mixed methods process, including Delphi consensus, usability testing of AR interfaces, and informatics architecture, which guided the system's development. Each component has been or will be the subject of dedicated manuscripts; here, our goal is to highlight how these complementary approaches were integrated into a coherent design framework for a complex clinical decision support system.

Methods

Overview

The InterFACE was designed and developed using a structured, multiphase, mixed methods approach, blending qualitative and quantitative methodologies to create a user-centered resuscitation decision support system aligned with clinical needs and real-world dynamics.

Persona Development and Spatial Analysis

Personas representing key pediatric resuscitation roles (eg, team leader, medication nurse, proceduralist) were developed based on direct field observations and a series of semistructured interviews with clinical experts. Each persona captured role-specific responsibilities, cognitive workload, and critical information needs during high-stress resuscitation scenarios. The purpose of these personas was not to be directly evaluated but to serve as design scaffolds that informed the overall architecture of the InterFACE system. Specifically, they were used to: define role-specific interface requirements; guide how information was distributed across the 3 system components (tablet, AR head-mounted display, and team screen); ensure that each interface aligned with the cognitive workflow and situational demands of its corresponding clinical role.

In parallel, a spatial analysis was conducted within the actual resuscitation environment. This consisted primarily of mapping the typical positions and movement patterns of team members, assigning them to defined spatial zones (eg, head of bed, medication zone, and documentation area). This approach allowed us to identify where each team member typically stands or moves, and how they interact during various phases of care. Combining persona insights with spatial analysis ensured that digital information was presented in a way that matched both the cognitive and physical workflows of pediatric resuscitation.

Expert Consensus Process: Delphi Study

A 3-round Delphi study established essential system information elements via expert consensus.

XSL•FO
RenderX

Round 1: Item Generation

Resuscitation experts from our research team reviewed 4 personas (team leader, scribe, medication nurse, and other team members) and current PALS guidelines, identifying critical real-time resuscitation data elements via open-ended responses. These data elements, such as heart rate, oxygen saturation, time of drug administration, and the next expected algorithm step, were thematically analyzed to generate an initial item list representing the minimal critical information required for decision-making and situational awareness during pediatric resuscitation.

Round 2: Prioritization

Each item was rated for importance on a pediatric 5-point Likert scale by resuscitation experts (emergency doctors and nurses) from Geneva Children's Hospital and Alberta Children's Hospital. Items with mean scores <3 were excluded; those with high variability (SD>1.5) were discussed further for agreement to decide their inclusion. Qualitative feedback refined the list.

Round 3: Final Consensus

Experts finalized the list, with ≥80% agreement defining inclusion.

Iterative User Experience (UX) Design

A human-centered process ensured usability and workflow alignment.

Static Prototyping

Initial prototypes visualized layout, role-specific interfaces, information architecture, and functionality, undergoing internal testing for readability, functionality, and clarity.

Dynamic Prototyping

Refined static prototypes added interactivity, minimizing cognitive workload and aligning with resuscitation constraints, validated through iterative testing.

Simulation-Based Evaluation

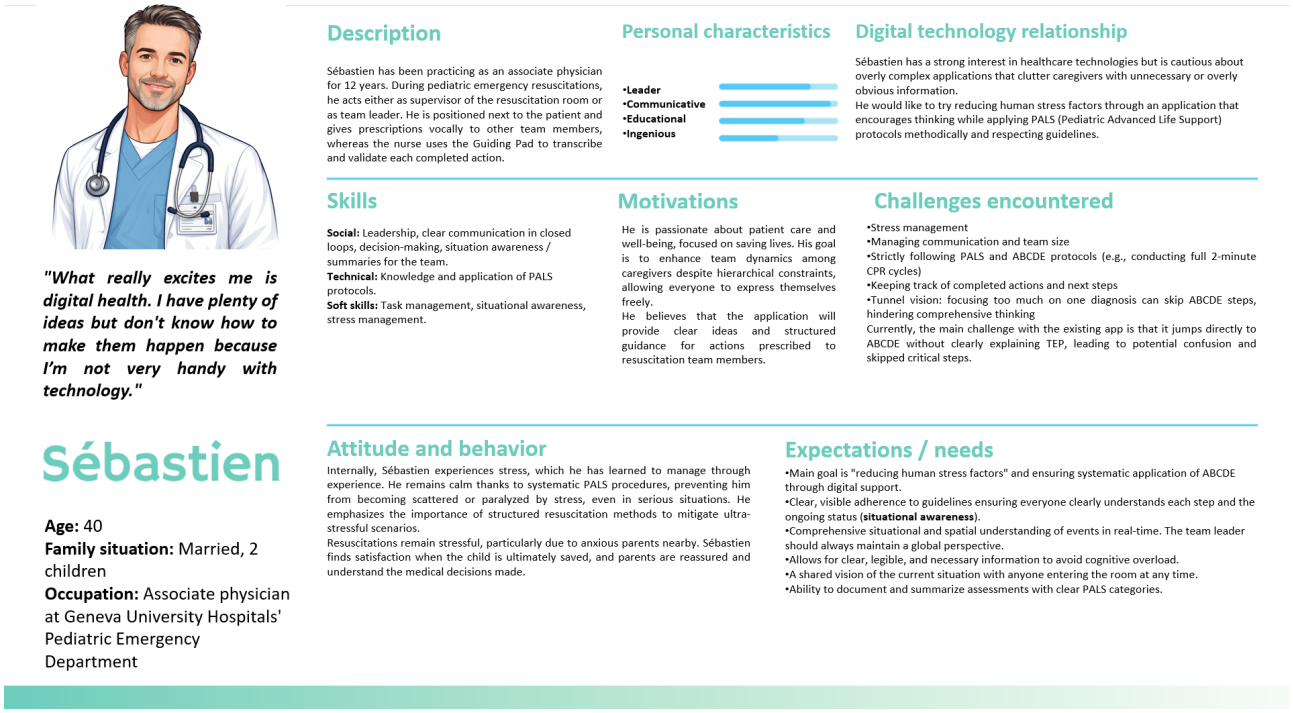
The usability and feasibility of the InterFACE suite was evaluated through simulated resuscitation scenarios designed to mimic real-world pediatric cardiopulmonary arrests. Each system component was independently tested to assess its performance, usability, and integration into clinical workflows. For the wall-mounted display, namely TeamScreen, participants completed 21 information-retrieval tasks, with performance gaged by task success rates, completion times, and score from the Post-Study System Usability Questionnaire (PSSUQ) [9]. The tablet underwent testing with 27 interaction tasks, where effectiveness was measured through task success, time-to-completion, and PSSUQ scores, ensuring the app's alignment with dynamic resuscitation demands. The AR HMDs were assessed following a simulated CPR scenario, during which the team leader and medication nurse received guidance via Microsoft HoloLens 2. Usability was evaluated using the System Usability Scale (SUS), a 10-item questionnaire measuring perceived usability (effectiveness, efficiency, satisfaction) [10]; Technology Acceptance Model (TAM), a 12-item questionnaire assessing perceived usefulness and ease of use [11]; and User Experience Questionnaire (UEQ), a 26-item questionnaire evaluating 6 user experience dimensions [12] to capture both practical and experiential feedback. This stepwise evaluation provided comprehensive insights into each component's strengths and areas for refinement, prioritizing clarity, accessibility, and real-time utility in high-pressure settings.

Informatics Development and Integration

Following the usability evaluations, informatics development synthesized insights from previous testing phases into a cohesive final system. This process emphasized user needs, cognitive ergonomics, and compatibility with clinical workflows, achieved through iterative refinement rather than a single overhaul. By addressing feedback on usability and functionality, the development phase ensured that InterFACE seamlessly integrated into resuscitation practices, balancing technical sophistication with practical application. The result was a system designed to minimize cognitive workload while maximizing support for pediatric CPR teams, ready for broader validation in future studies.

Ethical Considerations

This study did not involve patients, patient representatives, or the collection or use of identifiable personal health data. All study activities were limited to health care professionals participating in system design workshops, semi-structured interviews, and simulation-based usability evaluations of the InterFACE system. According to institutional and regional policies at the Geneva University Hospitals (HUG) and the University of Calgary, studies that exclusively involve health care professionals for the purposes of system design, usability testing, and simulation-based evaluation, without involving patients or identifiable personal data are not classified as human subject research and are therefore exempt from formal review by a Research Ethics Committee / Institutional Review Board. All participants were informed about the study objectives, procedures, and voluntary nature of participation and provided informed consent prior to participation. Data collected during usability sessions and interviews were anonymized, and no personally identifiable information was recorded or retained. No financial compensation was provided.



Results

Persona Development and Spatial Analysis

To explore the behaviors, information needs, communication methods, and expectations of key actors involved in pediatric resuscitation, we conducted in-depth face-to-face interviews with 4 nurses and 4 physicians. These interviews offered valuable insights into team roles and interactions during resuscitation, identifying areas where effective information flow enhances performance and where communication gaps may hinder outcomes. A total of 4 distinct personas were developed, each representing a key resuscitation role. First, the team leader, a central coordinator, focuses on decision-making, information synthesis, and communication, requiring real-time, comprehensive patient data and clear channels, as detailed in the persona profile example in Figure 2.

XSL•FO
RenderX

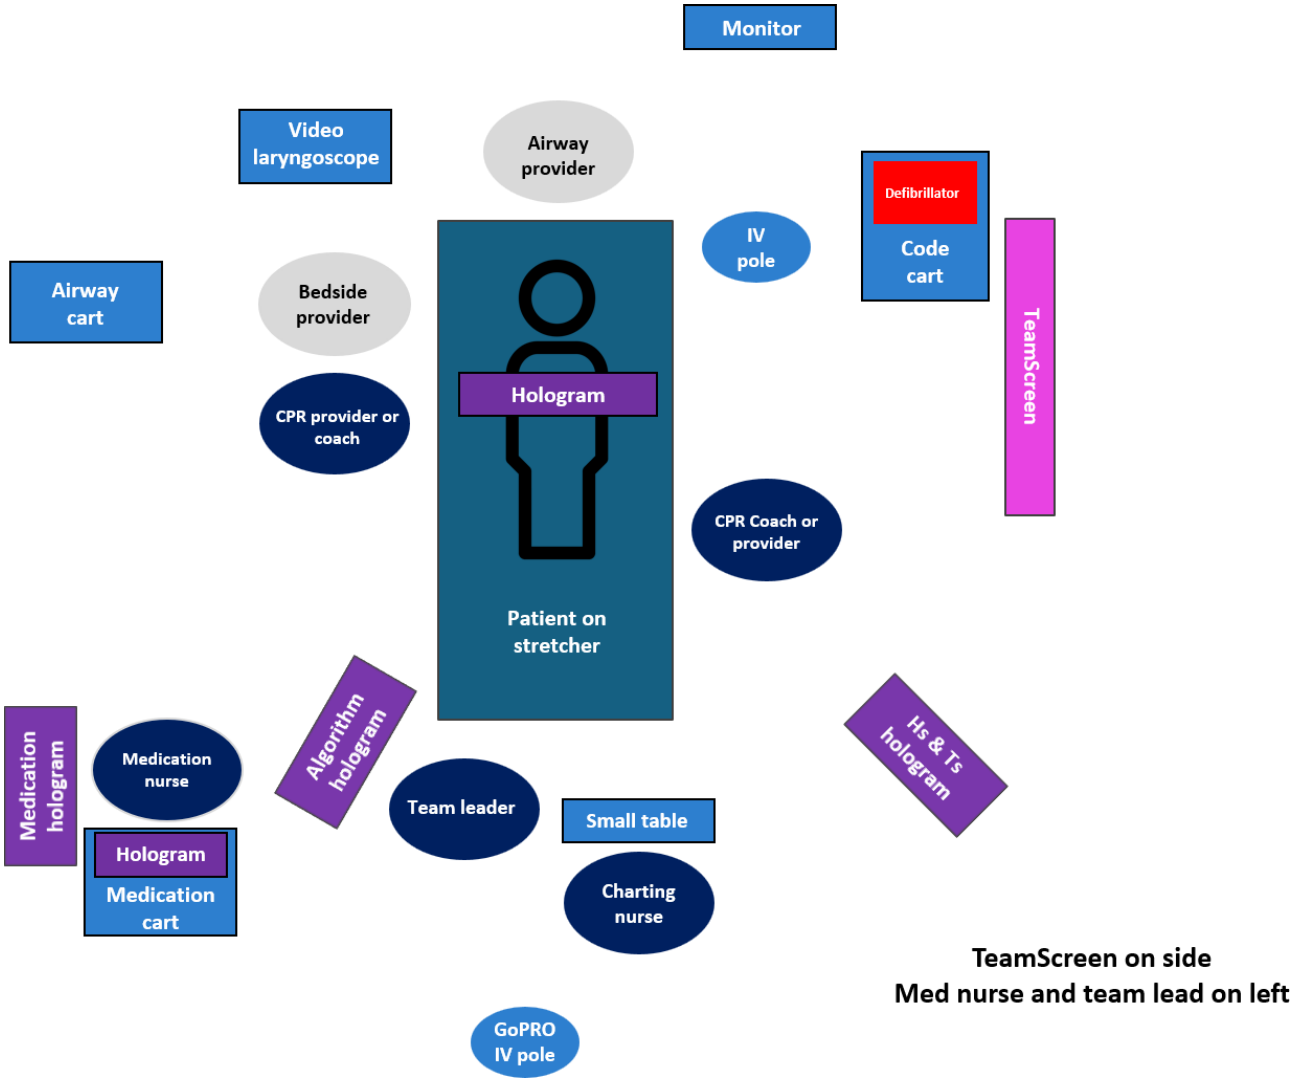


Figure 2. Persona profile of the team leader in pediatric resuscitation. This figure depicts a pediatric emergency physician with 12 years of experience as the team leader, detailing his responsibilities, competencies, motivations, challenges, and interaction with digital health technologies. The team leader plays a pivotal role in decision-making, coordination, communication, guideline adherence, and team performance under high-stress conditions.

Second, the documenting nurse (scribe), responsible for real-time documentation, emphasized the need for a streamlined interface to record events while tracking verbal directives. Third, the medication nurse, tasked with drug preparation and administration, highlighted the importance of quick access to drug information and dosage guidelines through an error-minimizing interface. Fourth, the rest of the team, encompassing supporting roles with dynamic responsibilities, stressed the need for flexible communication tools to enable real-time collaboration, task coordination, and problem-solving. A spatial analysis, conducted through mapping and observation during two pediatric cardiac arrest simulated resuscitation scenarios, revealed consistent positioning patterns (Figure 3): the team leader was centrally located at the head of the bed for optimal oversight, the scribe was nearby for rapid documentation access, the medication nurse was positioned close to medication for swift access, and the rest of the team adapted dynamically to support primary roles.

XSL•FO
RenderX

Figure 3. Cardiopulmonary resuscitation (CPR) provider placement in the study setting. Arrangement of team members and equipment around the manikin on a stretcher for effective resuscitation.

Delphi Study

The Delphi study's first round generated 40 distinct information items, grouped into 8 thematic categories: Patient status (7 items), Change of status (6 items), Presentation of clinical task (4 items), Running timer (4 items), Drugs (5 items); CPR and defibrillation (4 items); PALS (7 items); and Teamwork (3 items; Figure 3). In the second round, a panel of 15 pediatric emergency nurses and 15 physicians rated these items on a 5-point Likert scale (Table 1). Strong consensus emerged for most items, except for displaying intravenous drug doses on the AR HMD where nurses and physicians held divergent views, prompting further discussion on optimal presentation. No significant differences were observed between groups, with both preferring the team-wide screen over AR HMD for real-time information, suggesting the TeamScreen's role as the primary interface despite AR's potential.

XSL•FO
RenderX

Table . Selection of 40 information items from the first round of the Delphi study. An item was considered selected if a participant rated it above 3 on the Likert scale. The selected items are organized into 8 thematic categories related to effective cardiopulmonary resuscitation (CPR) and pediatric advanced life support (PALS) management.

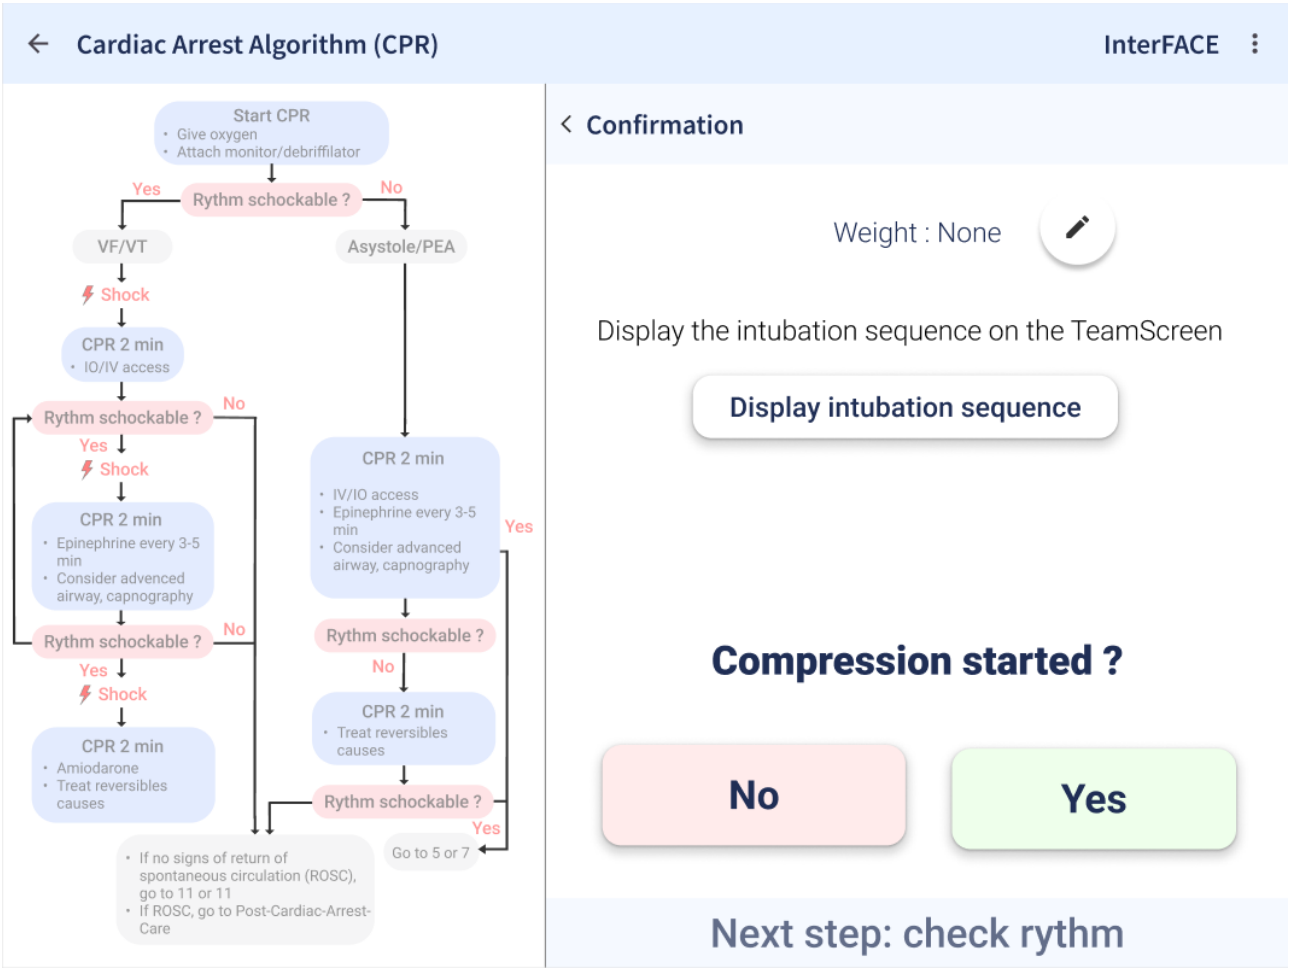
The third round finalized a refined list, achieving over 80% consensus for inclusion. Although over two-thirds of experts strongly supported including patient vital signs, these were excluded due to technical constraints requiring monitor integration, which was beyond this version's scope. A total of 7 items, primarily medication, timer, and tasks information, were selected for the medication nurses' HMD, while the team leader's HMD included these plus CPR and advanced life support data, totaling 20 items. The TeamScreen displayed the most items, adding 3 more—previous task, overall resuscitation duration, and ETT/LMA size. While physicians and nurses showed similar preferences, nurses favored broader visibility on the TeamScreen for monitoring patient status and rhythm changes, aligning with their assessment role, whereas physicians were more accepting of HMDs for immediate alerts. Both groups prioritized shared screens for critical and retrospective data, underscoring team coordination's importance.

Static Prototyping



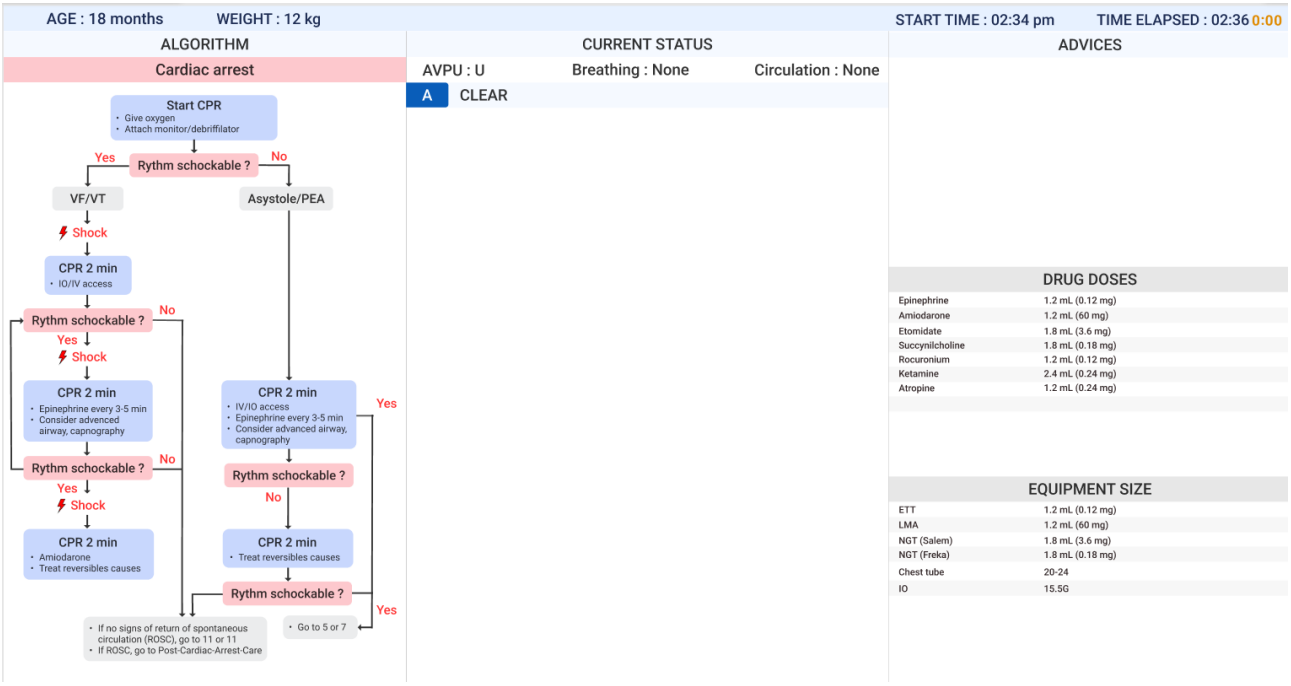
The initial system design was developed using Figma, a cloud-based collaborative graphic design and user interface prototyping software. The interface was structured around role-specific needs and PALS guidelines. Through internal testing and iterative refinement, the focus was on optimizing readability, functionality, and clarity, ensuring the prototype was ready for end user evaluation.

Mobile Tablet App Design

The Guiding Pad tablet app was designed based on user interaction and cognitive workload analysis, resulting in a 2-zone interface (Figure 4). The left zone supports advanced interactions, such as navigating PALS algorithms, accessing clinical data, and adjusting to evolving patient conditions, while the right zone focuses on primary task execution, offering real-time, context-sensitive prompts aligned with PALS algorithms.

XSL•FO
RenderX

Figure 4. Screenshot of the guiding pad tablet app. This screenshot illustrates the guiding pad interface, with the left panel displaying the cardiac arrest algorithm as a visual workflow guide and the right panel presenting an interactive confirmation prompt to ensure adherence to critical steps, such as verifying chest compressions before proceeding.



Team Screen Design

The team-wide display was organized into 3 functional sections to enhance situational awareness, prioritize actions, and streamline information retrieval (Figure 5). The left section visually represents the full PALS algorithm, enabling the team to track progress and anticipate steps. The center section highlights current required actions, ensuring team-wide awareness. The right section provides rapid access to critical drug information and ABCDE assessment results, minimizing workflow disruptions.

XSL•FO
RenderX

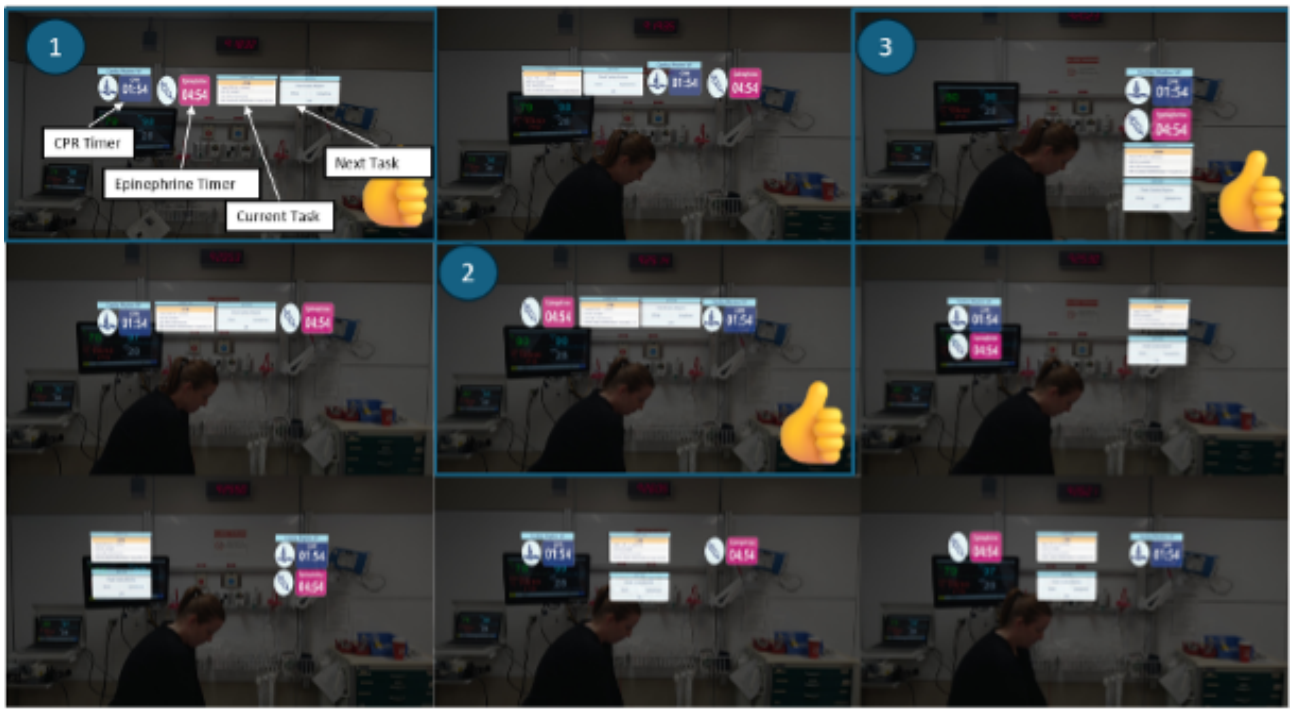


Figure 5. Early design for TeamScreen interface for PALS Cardiac arrest algorithm. Algorithm panel: cardiac arrest algorithm flowchart. Current status panel: progression in the ABCDE evaluation. Advices panel: advice for the current resuscitation step and information about drug doses and equipment size.

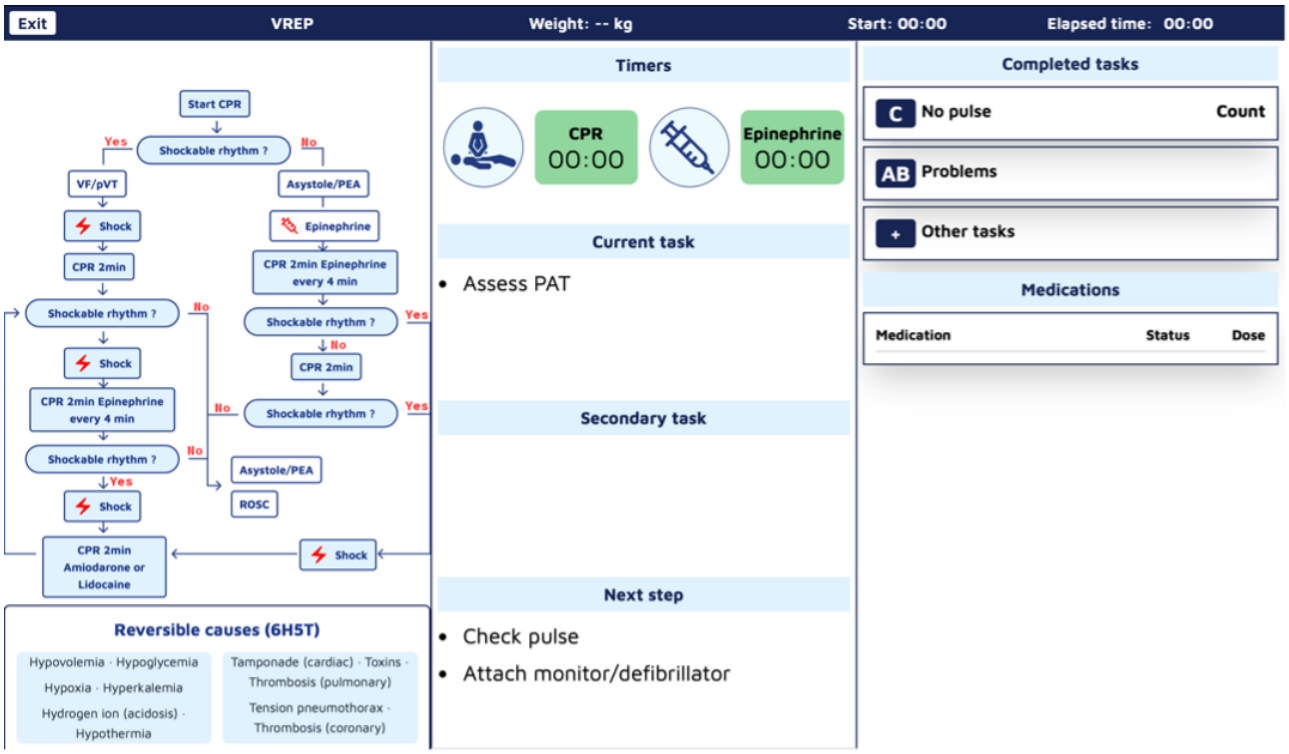
AR HMD Design

Based on the information prioritized during the initial design phase, several static layout prototypes were developed to explore different ways of presenting content within the AR display for the team leader (Figure 6). These mock-ups aimed to evaluate the most effective positioning of information in the field of view, with a focus on readability, prioritization of critical data, and minimizing cognitive load. Particular attention was paid to key AR design heuristics, including peripheral clarity (ensuring that essential information remains accessible even when not in central vision) and anchoring consistency (maintaining spatial predictability of interface elements).

Figure 6. Static layout propositions for the augmented reality (AR) head-mounted display (HMD) of the team leader.



XSL•FO
RenderX

Dynamic Prototyping

Mobile Tablet App and Team Screen

Dynamic prototypes, developed in Figma, incorporated interactive elements simulating structured resuscitation workflows, task progression, and patient data visualization (Figure 7). A dozen weekly reviews with pediatric emergency and intensive care physicians, nurses, and system developers gathered qualitative feedback on information hierarchy, interaction efficiency, role-specific views, and guidance clarity. This ensured critical information was accessible, key actions required minimal steps, interfaces were tailored to roles, and system prompts supported clinical decision-making effectively.

Figure 7. Screenshot of the TeamScreen. This screenshot depicts the interface for cardiac arrest management, comprising multiple panels. Left panel: pediatric advanced life support (PALS) cardiac arrest algorithm detailing steps for VF/pVT and asystole/PEA, including emergency drugs and shock decisions. Center panel: visual representation of the patient with cardiopulmonary resuscitation (CPR) and epinephrine timers, current tasks, secondary tasks, and next steps. Right panel: completed tasks log with categories (no pulse, AB problems, other tasks) and medication dosing section. Bottom panel: reversible causes (6H5T). AB : airway/breathing; PEA: pulseless electrical activity; VF: ventricular fibrillation; pVT: pulseless ventricular tachycardia.

User feedback drove key adjustments and interaction logic. The Guiding Pad adopted a 2-zone layout with the left zone for advanced interactions and the right zone for primary task execution and information access. The TeamScreen featured algorithm visualization on the left, prioritized actions in the center, and real-time ABCDE assessment and drug data on the right. Interaction flows were streamlined for seamless transitions between algorithm steps, enhancing usability and clinical alignment.

AR HMD

In the dynamic prototyping phase, the static layouts were implemented within a functional AR environment to evaluate their behavior under real-time conditions. This phase focused on assessing how interface elements responded to user movement, task switching, and environmental complexity. A particular emphasis was placed on occlusion management, ensuring that critical real-world visual cues—such as team members, medical devices, and patient access—remained unobstructed by virtual overlays. The prototypes were tested using simulated clinical scenarios, allowing the team to refine spatial placement, interaction timing, and adaptive content behaviors based on contextual relevance and physical positioning. These evaluations informed iterative adjustments to optimize both usability and clinical safety in dynamic, high-pressure environments.

Usability Testing of Individual Components

Guiding Pad

The Guiding pad usability test showed overall effectiveness, with the 15 participating nurses demonstrating ease of use during 27 tasks. Of these, 21 tasks achieved a 100% completion rate, while the remaining six ranged from 67% to 93% completion, indicating areas for refinement. The most frequently encountered issue involved advanced interactions, such as selecting the appropriate endotracheal tube size and insertion depth. Some participants were unaware that default values had been preselected. Another commonly failed task was the manual prescription of drugs; since the system automatically prescribed certain drugs, participants were sometimes uncertain about the required actions. Tasks completion times varied significantly, ranging from 2.93 seconds to 33.53 seconds on average, reflecting differences in task complexity.

XSL•FO
RenderX

TeamScreen

The TeamScreen evaluation, conducted with 5 clinicians and 15 nurses, highlighted the clear organization and meaningful presentation of information, with an 81% overall task success rate, reflecting participants' ability to locate and interpret essential data under time pressure. Interface elements like shock logs, intubation timestamps, and reversible - causes guidance were clear and easy to retrieve, but challenges in distinguishing ongoing CPR status and impending interventions (eg, epinephrine administration) highlighted the need for more intuitive visual structuring or prompts in high-density regions, as participants reported confusion over critical updates. Tasks completion times varied significantly, ranging from 2.35 seconds to 18.45 seconds on average, reflecting differences in task complexity.

AR HMD

In the usability evaluation of the AR HMD with 5 pediatric emergency physicians and 5 participating nurses participating, the system was found to be intuitive and efficient. Both the team leaders and medication nurses reported "Good" and "Excellent" SUS scores, respectively, with medication nurses benefiting from clear, task-specific prompts. The UEQ results indicated high attractiveness and positive evaluations in pragmatic qualities (intuitiveness, efficiency, and dependability), facilitating smooth task execution, and hedonic qualities (stimulation and novelty). The TAM confirmed high acceptance, with users perceiving the system as useful and easy to use during resuscitation scenarios.

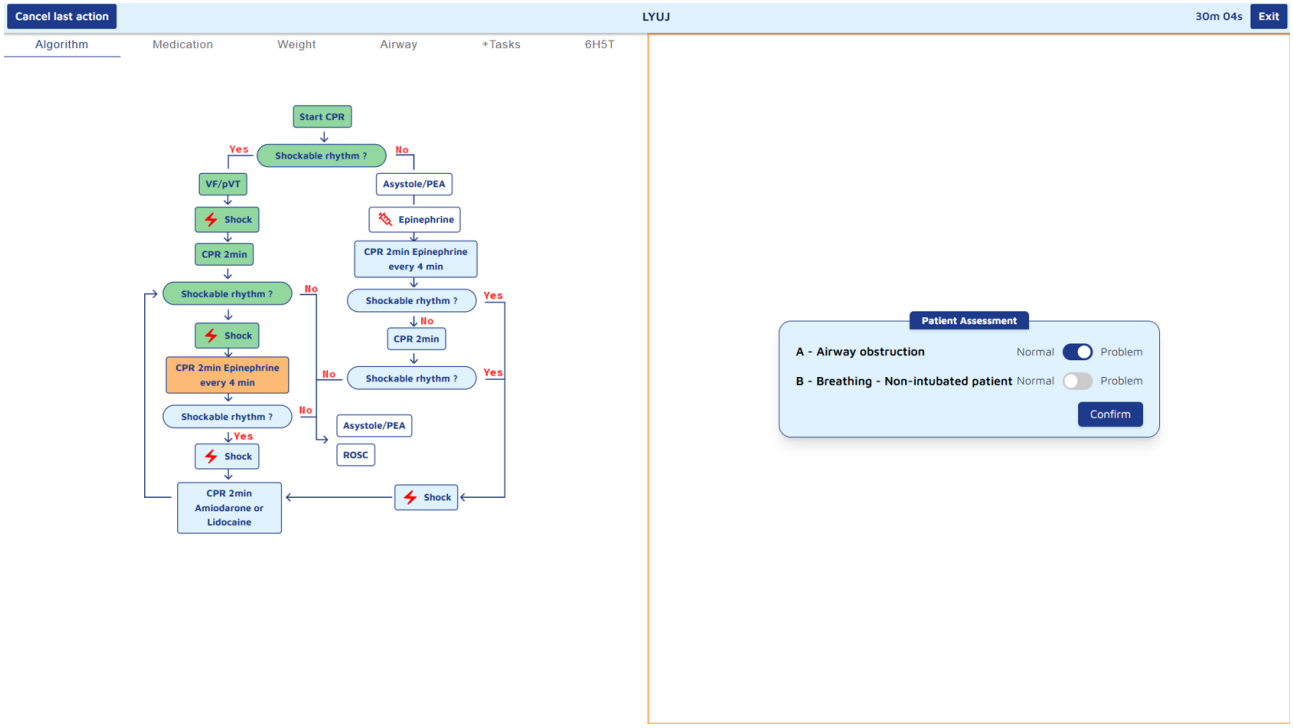
Informatics and System Architecture Development With Final Integration

The InterFACE system was designed as a real-time digital support tool for pediatric resuscitation, following a task tree model akin to a business process modeling notation (BPMN) [13], with each PALS algorithm step represented as a cursor (open, in progress, completed, or canceled) to support sequential execution and decision-driven adjustments based on clinical inputs. The system comprises a backend microservice (emergency-guideline-service) and role-tailored frontend applications. The backend, built as a Spring Boot microservice [14], handles business logic via a Representational State Transfer (REST) application programming interface (API) for data exchange and a server-sent events (SSE) API for real-time updates, following a domain-driven design approach with a root aggregate managing PALS algorithms, drugs, and clinical observations. An event-driven architecture [15] with event sourcing (ES) ensures data consistency and low latency, logging events in MongoDB (version 8.0) for real-time broadcasting via SSE, without requiring continuous polling.

Frontend modules, developed in Angular 17 JavaScript framework, include the Guiding Pad user interface (UI) for the scribe (supporting documentation, algorithm adjustments, and both sending commands and listening backend events; Figure 8), the TeamScreen UI for the team (displaying algorithm steps, prompts, and parameters in read-only mode while passively receiving real-time updates via SSE; Figure 9), and the AR HMD UI for the medication nurse and team leader (enabling hands-free data access; Figures 10 and 11). Event sourcing transmits incremental changes to frontend clients—reducing data load by avoiding the need to send the entire state—with events timestamped and logged in MongoDB for full process reconstruction and auditability. For deployment, the backend runs as a Docker container, frontends are served via an NGINX server, and a short code identifies each resuscitation process, supporting concurrent sessions within the hospital network and remote guidance, allowing experts to assist or lead resuscitations from a distance. However, for performance optimization, real-time data is stored in memory and not persisted after server shutdown, as this proof-of-concept targets simulated patients in future studies, without authentication.

XSL•FO
RenderX

Figure 8. Implemented version of the guiding pad. The left side shows initially the CPR algorithm but enables also the access to advanced interaction such as medication prescription, weight input, airways documentation, and reversible causes documentation. The right part of the screen is dedicated to documenting the main tasks of the current step of the algorithm.



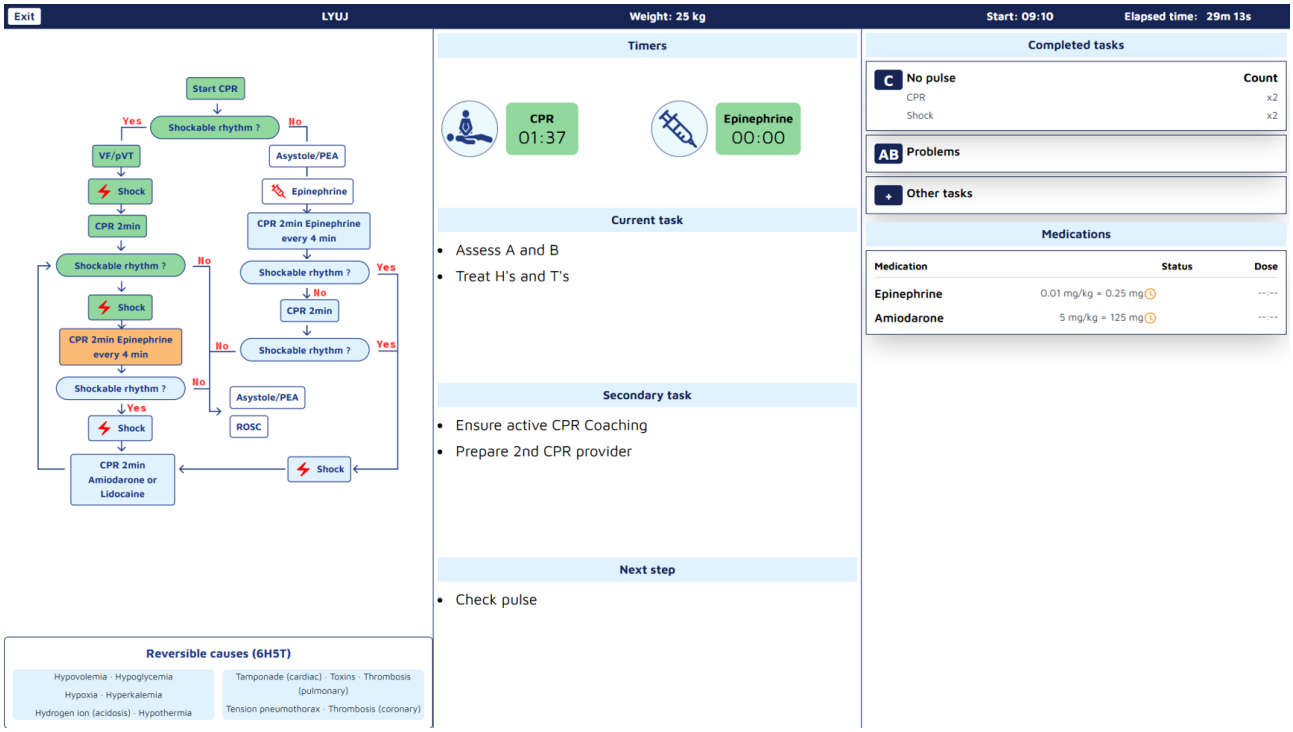


Figure 9. Implemented version of the TeamScreen. The left part contains the cardiopulmonary resuscitation algorithm showing the executed steps in green and the current one in orange. Underneath, we found the reversible causes. The middle column displays the most important information. Two counters indicate the cardiopulmonary resuscitation remaining time and the time to epinephrine administration. The middle part displays the current primary and secondary tasks, and the last part is dedicated to the next step. Finally, the right column provides information about the ABCDE assessment as well as a view on the administered medication.

Figure 10. Vision of the team leader in the augmented reality (AR) display. The same information displayed in TeamScreen, such as the algorithm, the reversible causes, the current and next tasks, as well as the counter, is available on the field of vision.

Figure 11. Final augmented reality (AR) head-mounted display (HMD) interface for the medication nurse showing role-specific information, such as drug doses, timers, and administration prompts.

Discussion

InterFACE System as a Cognitive Aid in Pediatric Resuscitation

InterFACE represents an advancement in digital cognitive aids for pediatric resuscitation, as evidenced by its design and evaluation through simulation-based approaches. The system integrates AR HMDs, tablets, and large displays within the resuscitation room, aiming to enhance shared cognition and temporal coordination among teams. This support is intended to ensure adherence to PALS guidelines, manage cognitive workload, and augment, rather than replace, clinical judgment, addressing key needs in high-stakes emergency situations. Although the personas themselves were not directly evaluated in the usability testing phase, they provided the conceptual

XSL•FO
RenderX

scaffolding for the system's architecture. By structuring the distribution of information and interaction logic around role-specific personas, the subsequent prototypes and evaluations could directly test whether these design assumptions translated into improved usability, workflow fit, and team coordination.

Comparison With Existing Digital Resuscitation Tools

Several digital tools have been developed to support pediatric resuscitation, focusing on improving guideline adherence, reducing cognitive overload, and enhancing coordination. Previous research, such as studies on HMDs [4,16], team situation displays [17,18], mobile apps for medication administration [7,8], CPR corrective feedback devices [19,20], and tablet-based resuscitation guidance tools [5,6], highlights their benefits in specific areas. However, these technologies often lack comprehensive team-wide information sharing, role-specific guidance, and real-time adaptability to evolving clinical situations. InterFACE addresses these limitations by synchronizing multiple role-specific interfaces through an event-driven architecture with event sourcing, ensuring continuous real-time, context-adaptive updates without manual intervention. This facilitates seamless communication and coordination. Compared to PediAppRREST [6] and similar tools, InterFACE stands out by offering synchronous, role-specific guidance across multiple interfaces, including immersive AR displays, and by leveraging an event-driven architecture to ensure consistent, low-latency updates across the care team. This enables shared situation awareness and real-time decision support that is both context-sensitive and visually anchored in the physical care environment.

Advancing Resuscitation Support With Mixed Reality

AR has shown promise in both resuscitation training and real-time procedural support. A recent systematic review highlighted the potential of AR in these areas ([21]). For example, an AR CPR feedback system provided real-time visual feedback on chest compression quality, significantly improving performance with compliance rates increasing from 18% - 21% to 87% - 90% ([16]). However, such devices are limited to specific tasks, like compression feedback, and do not offer comprehensive guidance for the entire resuscitation process. AR extends beyond AR by offering spatially anchored, interactive digital elements that provide hands-free, dynamic, and context-aware prompts. This technology enables a more holistic approach to resuscitation support. Via AR HMDs, InterFACE delivers real-time, role-specific decision support for critical tasks such as airway management, drug administration, and adherence to PALS algorithms. By providing a shared digital platform, InterFACE enables seamless team coordination to support the delivery of high-quality CPR.

While AR and virtual reality have been explored for resuscitation training, demonstrating potential in skill acquisition and knowledge retention, current evidence does not consistently show their superiority over traditional training methods [21]. This inconsistency limits their direct application in clinical settings. InterFACE addresses this gap by transitioning from static training models to real time, adaptive clinical support. By structuring digital support around team coordination and integrating directly into emergency workflows, InterFACE aims to optimize resuscitation performance beyond what is achievable through simulation alone, ultimately improving patient outcomes.

Technical Contributions and Innovations

InterFACE is built on a microservices architecture to structure critical care workflows effectively, with a key innovation being its event-driven model using SSE for real-time updates, minimizing latency, reducing unnecessary data polling, and enhancing scalability in time-sensitive settings. It replaces BPMN-based execution with a flexible task-tree model, acknowledging the dynamic, nonsequential nature of resuscitation workflows in high-intensity environments.

Challenges and Limitations

Several limitations must be acknowledged. First, the current evaluation focused exclusively on usability and acceptability in simulated environments and did not assess clinical outcomes in real resuscitation cases. While simulations provide a controlled setting to test usability and workflow integration, they cannot fully reproduce the stress, variability, and unpredictability of real emergencies. This may limit the generalizability of the findings. To mitigate this, scenarios were designed to be as realistic as possible, involving experienced clinicians. Future research should include randomized controlled trials in clinical settings.

Second, the complexity of pediatric resuscitation inherently increases cognitive load, particularly given the variability in patient age, size, and drug dosing. ([22]). Balancing comprehensiveness with simplicity in the interface was challenging. Iterative prototyping and multiple rounds of user feedback were used to refine the information hierarchy, but residual risks of information overload may persist. Future versions should explore adaptive content delivery and integration with patient-specific data.

Third, technical constraints limited system integration. The current prototype did not connect with live patient monitors or hospital information systems, which prevented inclusion of real-time vital signs—an item highly requested during the Delphi study. This may have reduced ecological validity. To mitigate this, placeholders and manual data inputs were provided to simulate the functionality. Future iterations should incorporate interoperability standards such as Fast Healthcare Interoperability Resources (FHIR) to enable seamless integration.

Fourth, the system was deployed in a single-instance Docker server without load balancing, restricting scalability for broader trials or multi-site use. Although this setup was sufficient for proof-of-concept testing, it may limit performance in high-demand contexts. Cloud-based deployment with redundancy and load balancing should be considered for larger clinical implementations.

In addition, the current version of InterFACE does not include core CPR quality metrics, such as compression-to-ventilation ratio, ventilation rate and volume, or end-tidal CO_2 , all of which are crucial indicators of resuscitation performance and highly relevant for team leader oversight. This omission reflects

XSL•FO
RenderX

the early-stage focus on workflow coordination and feasibility in simulation contexts, as well as technical constraints around integration with monitor data and CPR feedback devices. Future iterations of the system should prioritize the incorporation of these metrics through integration with patient monitors, compression sensors, and $ETCO_2$ waveforms, in order to provide the team leader with a more comprehensive, real-time view of resuscitation quality.

Fifth, some participants reported discomfort or distraction during prolonged use of AR HMDs. While refinements prioritized concise alerts and minimized unnecessary overlays, usability in extended real-world resuscitations may be affected. Gesture-based or multimodal interactions may improve user comfort in future versions.

Taken together, these limitations emphasize the need for further development, technical integration, and large-scale clinical validation before InterFACE can be widely adopted in routine pediatric resuscitation.

Future Directions

Future work should prioritize clinical validation through randomized controlled trials, assessing impact on guideline adherence, response times, and error reduction across different hospital settings. Artificial intelligence–powered decision support, leveraging machine learning on large-scale CPR data, could offer predictive guidance by dynamically adapting to patient-specific factors, historical resuscitation patterns, and evolving clinical conditions. These advancements may reduce clinicians' cognitive burden load while enhancing decision-making in time-sensitive situations. Scalability and multisite deployment, supported by cloud-based architectures with load balancing, are essential for broader adoption. Finally, integration with hospital information systems via FHIR standards would enable seamless data exchange with electronic health records and medical device data streams, positioning InterFACE as a transformative tool in pediatric resuscitation.

Conclusion

This study provides a high-level overview of the user-centered, mixed methods process used to design and formatively evaluate InterFACE, an integrated augmented-reality decision support system for pediatric resuscitation. Usability testing across tablets, wall-mounted displays, and AR head-mounted devices demonstrated good acceptance, feasibility, and perceived usefulness in simulated scenarios. While clinical outcomes were not assessed, the results indicate that InterFACE can enhance team coordination and adherence to pediatric resuscitation guidelines in a controlled environment. These findings support the feasibility of deploying multimodal, AR-enhanced cognitive aids and provide a blueprint for further clinical evaluation.

Abstract

Background: Patients with insomnia have difficulty in both falling asleep and maintaining sleep. Individuals with long-term sleep deprivation are prone to poor concentration and impaired memory; however, these problems can be alleviated following brief behavioral treatment for insomnia (BBT-I). This study involved the design of an app called “Sleep Well” that enables individuals with insomnia to easily record their sleep behavior. The app guides users to recall and record sleep-related information, acquire sleep hygiene knowledge, and communicate with therapists online.

Objective: This study examined how specific sleep diary interface design features in a brief cognitive behavioral therapy for insomnia (BBT-I) app influence users’ attention and short-term memory. Using a combination of objective eye-tracking measures and subjective attention assessments, the study compared 3 interface designs to determine how visual layout, input modality, and interaction style interact with insomnia symptoms to affect attentional performance, memory accuracy, and user preference.

Methods: Three sleep diary interfaces were designed, varying background mode (day vs night), color scheme (blue vs green), box shape (circular, rounded rectangular, or rectangular), and input method (slide-in, tap, or type-in). A total of 33 participants completed standardized diary-entry tasks while eye movements were recorded using an eye tracker to capture gaze trajectories and visual attention patterns during app interaction. User experience, subjective attention, and interface preferences were assessed using structured questionnaires. Data were analyzed using descriptive statistics, nonparametric tests, Pearson correlation analysis, cross-tabulation analysis, and exploratory factor analysis to examine associations among interface design, attentional performance, memory accuracy, and user characteristics.

Results: A total of 33 participants (n=13, 39.4% male and n=20, 60.6% female) aged 20 to 64 years completed this study. Based on the Insomnia Severity Index, 6 of 33 (18.2%) participants had clinical insomnia and 13 of 33 (39.4%) reported insomnia symptoms. Most participants reported staying up late (22/33, 66.7%), and more than half of participants reported drinking tea (17/33, 51.5%). Interface design significantly influenced objective attentional performance, as measured by eye-tracking indicators of task efficiency and visual allocation. Sleep quality and insomnia symptoms were consistently associated with attentional and short-term memory outcomes, with memory accuracy varying across interfaces and showing particular sensitivity to sleep maintenance difficulties. Subjective attentional control was strongly associated with both eye-tracking metrics and memory performance, and interface preferences differed by insomnia status.

Conclusions: Interface design significantly modulates attention and short-term memory performance in users with insomnia. Eye-tracking revealed that insomnia symptoms and sleep quality influence visual attention and task efficiency, whereas subjective attentional control showed stronger and more consistent associations with memory accuracy than physiological eye-movement indicators. These findings suggest that cognitive processing during sleep diary completion relies more on internal attentional

XSL•FO
RenderX

states than on observable gaze behavior. Designing low-load, attention-supportive interfaces may therefore improve usability and data accuracy in digital BBT-I interventions.

Introduction

Background

Good sleep quality (SlpQ) not only improves learning, memory, retention, and recall, but it also facilitates the creation and innovation of solutions from new information [1]. Sleep further consolidates memories by transferring them from short-term to long-term memory. Sleep deprivation can affect the basal state of attention when performing simple tasks [2]. In addition to affecting memory consolidation, sleep deprivation also reduces attention, alertness, concentration, and problem-solving ability, thereby affecting work and daily life [3-6].

Cognitive behavioral therapy is currently the recommended first-line treatment for insomnia [7]. However, nearly half of patients prefer to receive such treatment online, which is often more convenient and efficient [8]. Cognitive behavioral therapy for insomnia (CBT-I) has been applied to different cohorts of patients with insomnia, such as mobile phone app–based CBT-I for adolescents of different genders [9] and internet-based CBT-I for patients with insomnia who continue to experience symptoms after drug treatment [10]. As mobile technology becomes more integrated into daily life, research on the use of mobile phones to treat insomnia has increased. In addition to strengthening sleep retraining through smartphones [11], CBT-I apps and platforms have also been developed, and the usability of such systems has been thoroughly reviewed [12].

Brief cognitive behavioral therapy for insomnia (BBT-I) retains the behavioral therapy component of CBT-I but shortens the treatment duration from approximately 6 to 8 weeks to just 4 weeks. BBT-I and CBT-I share the use of 2 key behavioral principles (ie, sleep restriction and stimulus control) to enable patients to sleep in a predictable and reliable manner. Sleep restriction limits the time a person spends in bed, whereas stimulus control refers to creating a clear and positive association between bed and sleep.

Owing to the shortened treatment time, BBT-I has been widely adopted for insomnia treatment. The benefits of BBT-I are comparable to those of CBT-I [13]; thus, BBT-I has been suggested as an effective intervention for insomnia management [7]. However, accurate information recording by patients with insomnia and clinicians remains key to effective treatment.

During the COVID-19 pandemic, researchers developed a digital brief therapy for insomnia and explored its adherence and efficacy [14]. In this treatment, patients with insomnia are required to operate a mobile phone interface, recall details of their daily life and sleep from the previous day, and complete a sleep diary. Individuals with insomnia therefore prefer specialized interface designs that allow them to maintain control of their pace of life and sleep patterns [15].

Because diagnostic criteria for categorizing insomnia and cognitive measures vary widely, there is a need to standardize methods for assessing insomnia and cognitive performance in research [5]. Currently, there is limited research on the usability of BBT-I app interfaces for information input and retrieval among patients with insomnia who experience memory and attention impairments.

Interface Design and Cognitive Considerations in Insomnia

According to the theory of working memory, individuals can remember only 4 to 6 pieces of information within a 20-second timeframe. In mobile application design, the commonly used waterfall layout may lead to reading times that exceed the limitations of human memory. In previous work, we employed a grid layout to highlight important information and demonstrated significant improvements in interface content memory [16]. Moreover, symmetry, order, simplicity, and regularity of interface layout reduce the difficulty of memory formation [17]. These qualities enhance esthetics, facilitate memorization, and reduce cognitive load. When developing an interface, designing elements symmetrically and arranging them in an ordered pattern based on size are recommended. In particular, aligning the edges and starting points of elements as much as possible also improves memorization.

From a physiological perspective, reading in dark mode under low ambient lighting reduces eyestrain. Visual fatigue in nighttime environments is related to color and screen brightness, such that lower screen brightness can reduce visual fatigue. In contrast, under normal lighting conditions, there appear to be no differences between using dark or light mode [18].

The colors green, blue, and black result in the least visual fatigue under low screen brightness conditions, whereas red results in the highest visual fatigue. In a study reviewing the effects of color on visual fatigue, blue was rated as the most favorable color for overall interface design [19]. Blue conveys calmness and stability, white conveys purity and peace, and green is considered a healthy color that can reduce stress and anxiety and elicit positive emotions [20,21].

Interface shape is an important factor in the emotional responses to interface design [22]. Many studies have used corner shape (eg, circular vs angular) to reduce cognitive load in the brain and obtain a better user experience. Patients rate circular elements higher because circles convey tenderness and caring emotions, whereas squares evoke a stronger sense of power, which may create pressure and is less likely to inspire positive emotions [23]. The use of boxes can change the spatial distribution of attention, affect the apparent size of objects, change potential visual perception, and thus affect user attention,

XSL•FO
RenderX

maintain device controllability, and reduce cognitive load [24,25].

For the design of a medical app interface, a previous study recommended that the page be operated using click and slide gestures and that instant suggestions be provided during the operation. To enhance readability, clear text in a font size no smaller than 14 points should be used. To distinguish function buttons, a blue-and-white background is recommended, and placing an icon in the upper-left corner of the page can improve visibility. This ensures that there is sufficient distance between function keys for user operations [26].

Eye Tracking and Cognitive Measures in Interface Evaluation

During information retrieval, eye movements, particularly fixation rate, are predictive for recovering previously remembered details but not for newly generated details. This suggests that during memory recall, the primary function of eye movements is to reproduce already perceived information rather than to generate entirely new details [27]. Moreover, blink frequency, total number of blinks, maximum blink duration, and pupil diameter are positively correlated with mental workload [28]. Thus, eye tracking provides insight into information processing during intensive tasks as the user manipulates interface features. Functional evaluation of the interface is combined with finding the best functionality to achieve the best design [29]. Eye-tracking metrics such as first fixation time, total fixation time, and total number of fixations allow detailed measurement of the psychological characteristics of online cognitive processes [30-32].

Study Aims

The aim of this study was to investigate how sleep diary interface design in a BBT-I app influences users' attention, visual attention patterns, and short-term memory. Three sleep diary interfaces with systematically varied visual layouts, color schemes, box shapes, and input modalities were developed and evaluated. A mixed methods approach was used: objective eye-tracking measures were used to assess distribution of attention and task efficiency during interface interaction, whereas subjective attention scales, memory recall tasks, and user preference questionnaires captured cognitive performance and user experience. The study further examined how insomnia severity, SlpQ, and related symptoms moderated these outcomes. It was expected that interfaces with lower cognitive load and clearer interaction structures would support more stable attention, higher memory accuracy, and greater user satisfaction, particularly among individuals with stronger insomnia-related cognitive vulnerability.

Methods

Introduction to Sleep App Functions

The functions of our app were developed according to the requirements of BBT-I. Under the guidance of specialist clinical psychologists and physicians, patients with insomnia were asked to complete a sleep diary and the Dysfunctional Beliefs and Attitudes about Sleep: Validation of a Brief Version-16, which helped therapists to diagnose and understand the distinct causes and types of insomnia for each patient. According to the type of insomnia, a sleep-aid behavioral plan was tailored, including sleep hygiene education, stimulus control, and sleep restriction. The content of sleep hygiene education included paying attention to the sleeping environment, adjusting indoor temperature and humidity, timing of caffeine intake, ensuring sufficient physical activity during the day, and controlling the length of naps.

In this study, we developed an app front-end and back-end management system named "Sleep Well." The front-end structure for patients consisted of the following components: (1) sleep timer, (2) sleep diary, (3) BBT-I health education, and (4) system settings. The sleep timer calculated bedtime and wake-up time. If the patient was unable to fall asleep, they could choose relaxation guidance videos or sleep-inducing music for assistance. The sleep diary was used to record various sleep-stage times, daytime habits from the previous day, and self-assessments of SlpQ and mental state (MS) after waking up. BBT-I health education conveyed correct knowledge related to sleep, which consisted of sleep hygiene, sleep behavior therapy, relaxation guidance, and sleep-inducing music. System settings included basic settings and message functions. During treatment, users could consult and interact online with dedicated therapists through the messaging area, and therapists could observe patients' usage status in the background (Figure 1). The back-end structure of the app consisted of the following components: (1) data center, (2) patient management, (3) message management, and (4) system settings. The data center collected statistics on physiological characteristics, lifestyle habits, recovery time, and sleep conditions of all patients with insomnia, enabling an understanding of the treatment results for a certain period or a certain group of people. Patient management reviewed daily sleep data, diary records, and consultation results. Message management was used by patients to send messages and by therapists to respond to patient queries. System settings contained therapist account management, permissions, and notification settings.

Sleep Diary: Three Interface Design Features

Sleep diaries primarily record the sleep time and daily routine of patients with insomnia, providing therapists with an assessment of the factors affecting sleep and planning sleep hours for patients.

This study extracted the core function of the app (ie, the sleep diary record page) and extended it into 3 different interface designs by varying background (day vs night), color scheme, box shape, input information, and interactive operation methods. Interface A used night mode with a blue color scheme, circular boxes, and a card-style appearance; the time input format was mainly sliding. Interface B used day mode with a blue color scheme, rounded rectangular box, a pop-up appearance, and tap-based input operation. Interface C used day mode with a green color scheme, rectangular boxes, a keyboard-based appearance, and direct manual input (tape-in) interaction (Figure 2).

The day-night background used a light background to imply daytime and a dark background to simulate nighttime. Matching icon colors and box shapes could stimulate the users' feelings toward the interface, and the input information and interactive operation methods could measure operation preferences. Furthermore, participants completed subjective questionnaires, and an eye tracker was used to measure the gaze duration, gaze position, saccade duration, number of saccades (NS), and saccade direction (SDir) to provide an integrated analysis of the factors that affected the differences in attention and memory for the 3 interfaces.

XSL•FO
RenderX

Figure 2. Visual comparison of sleep diary interfaces (from left to right: interfaces A, B, and C).

Experiment Methods

In the first phase, participants completed standardized recall tasks using all 3 sleep diary interfaces (A, B, and C). The order of interface presentation was counterbalanced across participants using a Latin square design to control for potential order and learning effects, which are common concerns in within-subject experimental designs [33,34]. Each interface was operated twice, and both task accuracy and differences in completion time between the first and second trials were recorded to assess learning-related performance changes.

Eye-tracking data were collected during a predefined task round for each participant, with the specific interface assigned according to the counterbalanced sequence. This approach ensured consistent measurement conditions while minimizing fatigue and carryover effects across interfaces, in line with established eye-tracking methodology in human–computer interaction and cognitive task research [29,30,32].

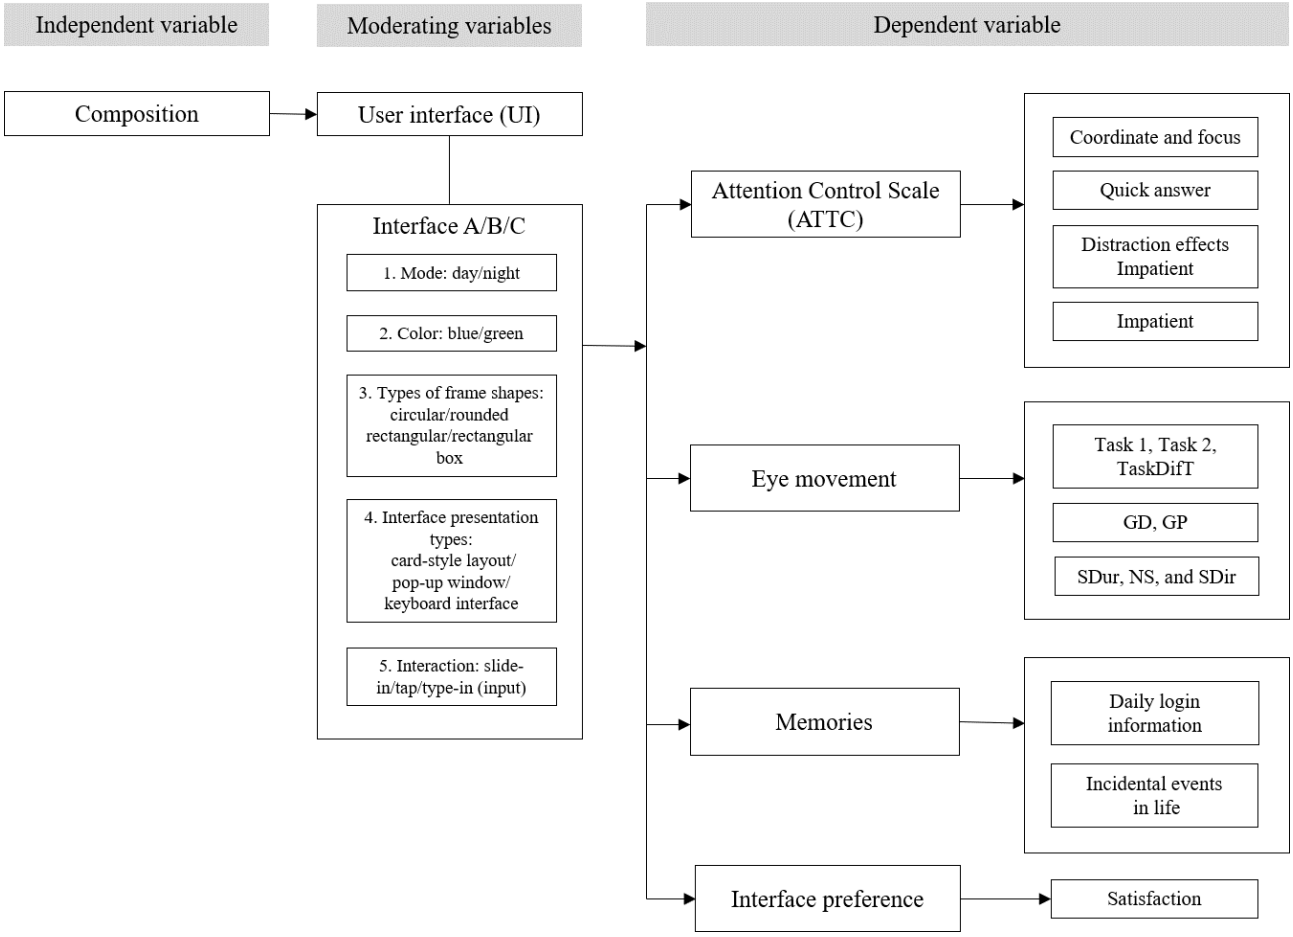
Primary and Secondary Outcomes

The primary outcome of this pilot study was attentional performance during sleep diary interface interaction. Attentional performance was assessed using both objective eye-tracking indicators, including task completion time, NS, gaze stability, and SDir, and subjective attentional control, measured by the Attention Control Scale (ATTC). These measures were selected to capture complementary aspects of visual attention allocation, cognitive load, and attentional regulation during interface use.

Secondary outcomes included short-term memory performance during diary recall tasks and interface preference and user experience. Memory outcomes were examined to explore downstream cognitive effects associated with attentional demands, whereas preference-related measures were included to inform practical interface design implications for digital BBT-I applications.

Participant Recruitment and Eligibility Criteria

The study was conducted between April 1 and May 15, 2023. A total of 33 participants aged 20 to 63 years were voluntarily recruited through Taipei Medical University. All participants provided written informed consent and completed a self-administered questionnaire that included demographic information and the Insomnia Severity Index (ISI) [35]. Clinical insomnia was defined as meeting at least one of the following criteria more than 3 times per week for a minimum duration of 3 months: (1) difficulty initiating sleep, defined as taking more than 30 minutes to fall asleep after going to bed; (2) difficulty maintaining sleep, defined as being awake for more than 30 minutes after sleep onset (SlpOn); or (3) early morning awakening, defined as waking at least 30 minutes earlier than desired. In addition, participants with an ISI total score of 15 or higher were classified as having clinical insomnia [35]. Participants without clinically significant insomnia were defined as those with ISI total score of 14 or lower and no subjective complaints of insomnia symptoms.



Data Collection

Independent variables included demographic characteristics (personal characteristics, lifestyle habits, sleep assessment [ISI-1a to 1c items], and insomnia [ISI-2 to 5 items]) and a MS questionnaire were analyzed through interface characteristics (screen polarity, box design, and layout, and information input method) and 4 dependent variables: (1) interface preference, (2) subjective attention (including coordinate and focus, quick answer, distraction effects, and impatient), (3) eye movement

XSL•FO
RenderX

data (operation time 1 [task 1], operation time 2 [task 2], difference in operation time [TaskDifT], gaze duration, gaze position, saccade duration, NS, and SDir), and (4) memories (daily login information and incidental events in life) (Figure 3). All study variables were categorized into conceptual domains, including population characteristics, lifestyle factors, sleep assessments, eye-tracking indicators, and memory recall measures. A complete classification of variables by name and type is provided in Multimedia Appendix 1.

Figure 3. Correlations between population characteristics (independent variables) and 4 dependent variables (ATTC, eye movements, memory recall, and interface preference). GD: gaze duration; GP: gaze position; NS: number of saccades; SDir: saccade direction; SDur: saccade duration; TaskDifT: difference in task operation time.

We examined whether the demographic characteristics in the 4 dimensions contained other factors that could influence a user's operation. Subjective attention measured the mentality of a user and their response to the operating interface. The eye tracker presented the attentiveness of a user and other physiological signals. Recall involved short-term and long-term memory as well as cognitive load.

Age, gender, lifestyle factors, sleep status (sleeping <7 h or below average sleep duration), severity of insomnia, and attention level were collected based on questionnaires and attention scales (Table 1). Eye movements were measured using an eye tracker (GP3 webcam, Gazepoint), and subjective opinions of the users for all 3 interfaces were collected through a postquestionnaire.

The recorded variables of the app operation were recall tasks that required inputting sleep information daily, including SlpOn, out-of-bed time, and wake after sleep onset (WASO; life events such as drinking (drinking items and drinking time [DrkTi]); exercise items (ExcsIm), exercise start time, and exercise end time, and nap start time and nap end time.

XSL•FO
RenderX

Table . Factor classification of the Attention Control Scale, with ATN[a] denoting item numbers, based on exploratory factor analysis.

Classification and question	Content	Detailed description
Coordinate and focus		
ATN5	Difficulty in coordinating recall	When filling out the sleep diary, I find it difficult to coordinate attention between completing optional information and recalling the task description
ATN6	Ease of responding after distraction	After being interrupted or distracted, I can easily refocus on the content I am filling out
Quick answer		
ATN2	Difficulty recalling information quickly	It is difficult to quickly recall the description of the task
ATN3	Filling in the form to generate interest	When I have a sleep task, I quickly become interested in filling out the sleep diary
ATN4	Time-consuming adaptation to operation	It takes me a while to get used to the mode of operation of filling out the sleep diary
Distraction effects		
ATN7	Unable to think simultaneously	It is impossible to think about two fields in the sleep diary at the same time
ATN8	Distraction from others	I easily become distracted when someone is in the same space as I am when filling out the sleep diary or doing a recollection
ATN9	Rapid switch mode	I can quickly switch from the previous interface operation mode to the current interface operation mode
ATN1	Inattention to surroundings	I can easily concentrate when filling out the sleep diary without being aware of what is happening around me
Impatient		
ATN10	Impatience while answering questions	I rush to answer the questions in the sleep diary before I finish reading them.

[a]ATN: Attention Control Scale item number.

Ethical Considerations

The TMU Joint Institutional Review Board from Taipei Medical University approved this study, which was planned, carried out, analyzed, and interpreted independently of any industry partners (approval number N202302007). All participants provided voluntary, informed, and written consent. The capability of the patients to participate in the study was ensured. During data analysis, the information of the participants was pseudonymized and coded using identification numbers. Only researchers assigned to the study had access to the data. No compensation was provided to participants for their participation and no images of individual participants or identifiable features are included in the paper or Multimedia Appendix 2.

Statistical Analysis

Statistical analyses were performed using IBM SPSS Statistics (version 26; IBM Corp). Analyses included descriptive statistics, nonparametric tests, Pearson product–moment correlation coefficient analysis, cross-tabulation analysis, and exploratory factor analysis. Each participant completed the questionnaire 3 times, corresponding to the 3 different interfaces. To control for multiple comparisons, the Bonferroni correction was applied. The significance level (α=.05) was divided by 3, resulting in an adjusted *P* value threshold of .017 for each individual test. Eye-tracking data were collected using the GP3 webcam eye tracker (Gazepoint). Recorded data were processed and analyzed using Gazepoint Analysis software, which is supported exclusively on the Windows operating system.

Results

Participant Characteristics

A total of 33 participants (n=13, 39.4% male and n=20, 60.6% female) of age 20 to 64 years completed this study. Based on the ISI, 27 out of 33 (81.8%) participants were classified as those without clinically significant insomnia, and 6 out of 33 (18.2%) were classified as having clinical insomnia. Based on subjective reports, 13 out of 33 (39.4%) participants were categorized as having self-reported insomnia (SRI), and 20 out of 33 (60.6%) were categorized as having no self-reported insomnia (NSRI). Demographic and sleep-related characteristics are summarized in Tables 2 and 3.

In total, 22 out of 33 (66.7%) participants reported staying up late, including 12 NSRI and 10 SRI individuals. Daily tea

XSL•FO
RenderX

drinking was reported by 17 out of 33 (51.5%) participants, of whom 11 were NSRI. Daily coffee drinking was reported by 15 out of 33 (45.5%) participants. In addition, 5 out of 33 (15.2%) participants were current smokers, 2 out of 33 (6.1%) reported alcohol drinking, 7 out of 33 (21.2%) reported long-term medication use, and 18 out of 33 (54.5%) reported having a regular sleep schedule.

Table . Cross-analysis of gender and age group (N=33).

Age group (y)	Male, n	Female, n	Total, n (%)
20 - 29	4	6	10 (30.3)
30 - 44	6	10	16 (48.5)
45 - 64	3	4	7 (21.2)
Total, n (%)	13 (39.4)	20 (60.6)	33 (100)

Table . ISI[a] and cross-analysis table of patients with SRI[b] and NSRI[c].

ISI score	NSRI, n (%)	SRI, n (%)	Total, n (%)
0-7 (no insomnia)	14 (70)	0 (0)	14 (42.4)
8-14 (mild insomnia)	6 (30)	7 (53.8)	13 (39.4)
15-21 (moderate insomnia)	0 (0)	5 (38.5)	5 (15.2)
22-28 (severe insomnia)	0 (0)	1 (7.7)	1 (3)
Total	20 (100)	13 (100)	33 (100)

[a]ISI: Insomnia Severity Index.

[b]SRI: self-reported insomnia.

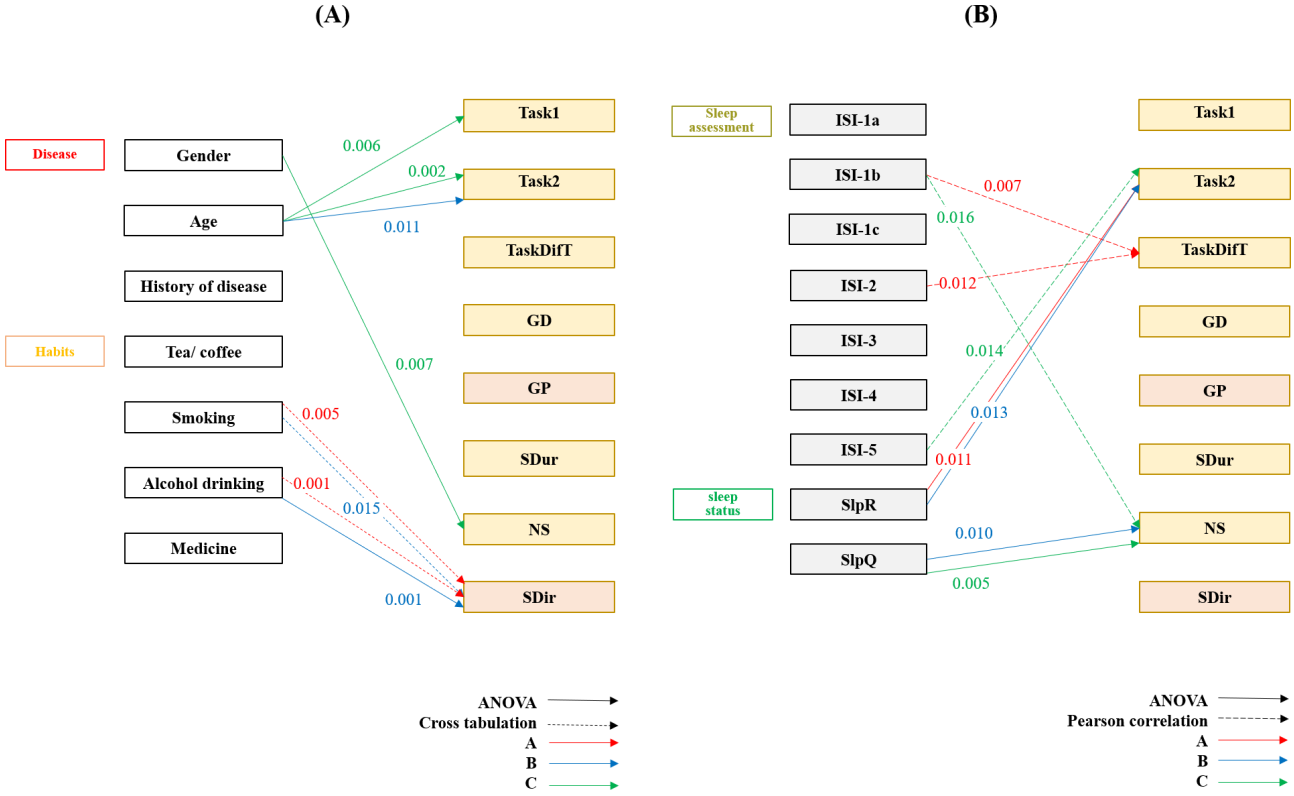
[c]NSRI: no self-reported insomnia.

Attentional Performance (Eye-Tracking Measures)

Task efficiency differed by demographic and sleep factors. Age was associated with longer task completion times on Interface B (H=8.943, P=.01) and Interface C (task 1: H=10.075, P=.006; task 2: H=12.472, P=.002). Gender differences were observed in saccade counts on Interface C (H=7.294, P=.007).

Sleep characteristics were consistently associated with eye tracking outcomes. Poorer SlpQ was associated with a higher NS on Interface B (r=−0.448, P=.01) and Interface C (r=−0.491, P=.005). Sleep maintenance difficulty (ISI-1b) was associated with longer optimal operation time on Interface A (r=0.462, P=.007) and increased NS on Interface C (r=0.430, P=.02). Worry about sleep (ISI-5) was negatively associated with operation time 2 (task 2) on Interface C (r=−0.426, P=.01), indicating altered task dynamics.

Lifestyle factors also influenced gaze behavior. Smoking and alcohol drinking were associated with SDir variability on Interfaces A and B (χ^2=18.942 - 28.562, P≤.02; Figure 4).



Eye-tracking results indicated that visual attention allocation and task efficiency differed across interfaces. Older age was consistently associated with longer task operation times, particularly on Interfaces B and C, indicating age-related reductions in interaction efficiency. Gender differences were observed in NS in Interface C, suggesting distinct visual scanning strategies.

Sleep-related factors played a central role in attentional performance. Poorer SlpQ and irregular sleep patterns were associated with increased NS and longer operation times, reflecting higher cognitive workload during interface interaction. Lifestyle behaviors, including smoking and alcohol drinking, were associated with altered SDir on Interfaces A and B, indicating changes in visual exploration patterns.

Among the 3 designs, Interface A (night mode, circular boxes, sliding input) was characterized by fewer saccades and more stable gaze transitions, suggesting reduced attentional dispersion and lower cognitive demand during task execution.

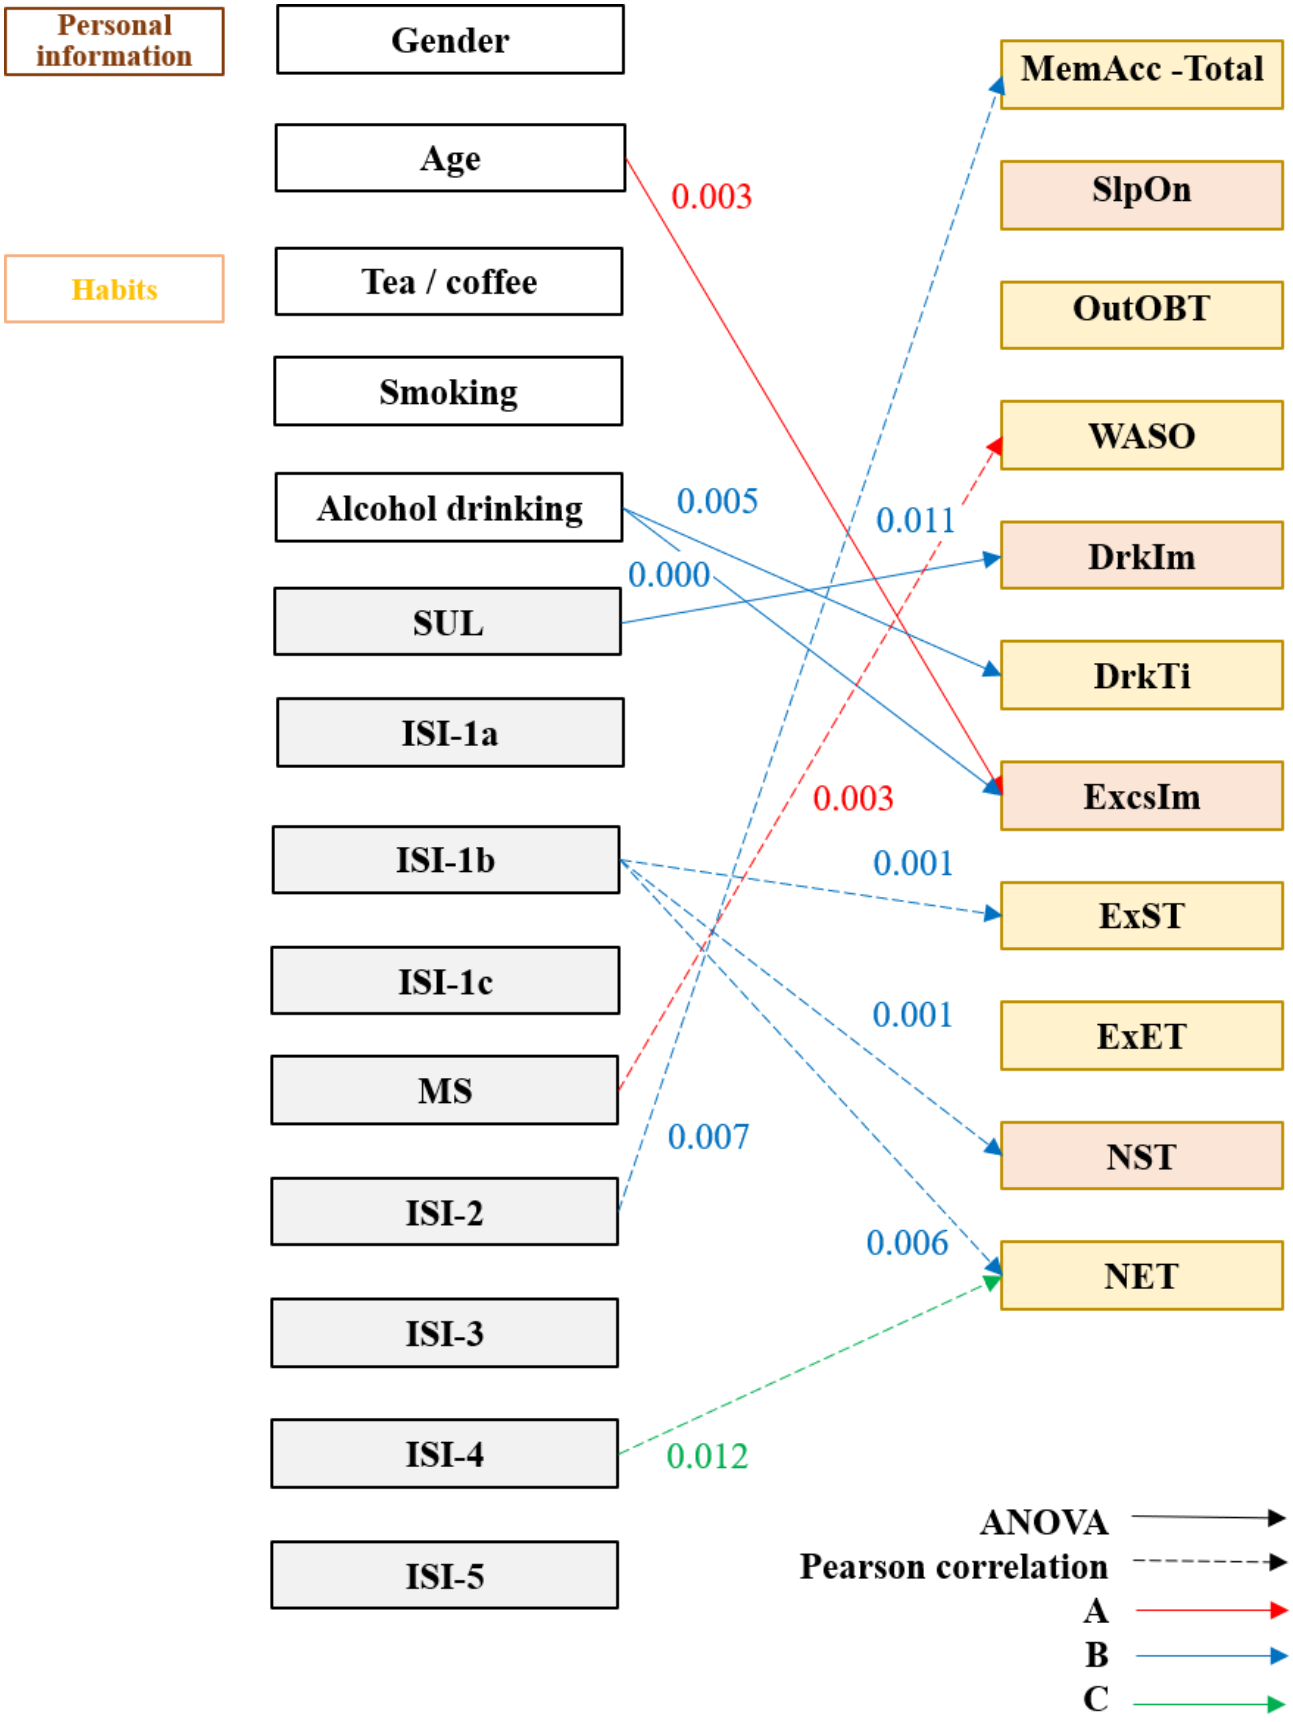
RenderX

Figure 4. Relationships between (A) population characteristics and (B) insomnia symptoms (ISI) and eye-tracking information. GD: gaze duration; GP: gaze position; ISI: Insomnia Severity Index; NS: number of saccades; SDir: saccade direction; SDur: saccade duration; SlpQ: sleep quality; SlpR: sleep regularity; TaskDifT: difference in task operation time.

Short-Term Memory Performance

Age was significantly associated with the task of remembering ExcsIm in Interface A (H_2=11.886, P=.003).



Alcohol drinking showed significant effects on the task of DrkTi in Interface B (H_2=10.551, P=.005) and the task of ExcsIm in Interface B (H_2=15.500, P<.001). Staying up late was also associated with drinking items in Interface B (H_1=6.400, P=.01).

Current sleep status was related to memory accuracy (total) on Interface A (r=–0.505, P=.003) and Interface A (r=–0.558, P<.001), as well as nap end time on Interface B (r=–0.468, P=.006).

ISI-2 was associated with memory accuracy total (r=–0.407, P=.007), and ISI-4 was associated with DrkTi in Interface C (r=–0.431, P=.01; Figure 5)

XSL•FO
RenderX

RenderX

Subjective Attentional Control (ATTC)

The Kruskal-Wallis *H* test showed that age was significantly associated with ATN6 (ATTC item number 6) on Interface B (*H*=10.643, *P*=.005). Among lifestyle factors, smoking was significantly associated with ATN1 on Interface B (*H*=8.585, *P*=.01). In addition, tea drinking was significantly associated with ATN6 on both Interface B (*H*=10.641, *P*=.01) and Interface C (*H*=10.519, *P*=.02).

Associations were observed between sleep-related factors, insomnia symptoms, and specific subjective attention (ATN) domains across interfaces. Sleep regularity was positively associated with ATN9 (distraction effects) on Interface B (*r*=0.460, *P*=.007). Regarding sleep initiation difficulties, ISI-1a was positively associated with ATN2 (quick answers) on Interface C (*r*=0.461, *P*=.007), and ISI-1b was positively associated with ATN5 (coordinate and focus) on Interface C (*r*=0.434, *P*=.01). Early morning awakening (ISI-1c) was positively associated with ATN3 (quick answers) on Interface A (*r*=0.467, *P*=.006) and with ATN5 (coordinate and focus) on Interface B (*r*=0.563, *P*<.001). In contrast, sleep interference with daily functioning (ISI-3) was negatively associated with ATN3 (quick answers) on Interface A (*r*=−0.487, *P*=.004), but positively associated with ATN9 (distraction effects) on Interface B (*r*=0.528, *P*=.002) and ATN8 (distraction effects) on Interface C (*r*=0.417, *P*=.02). ISI-4 showed a positive association with ATN4 (quick answer) on Interface C (*r*=0.417, *P*=.02). Worry about sleep (ISI-5) was negatively associated with ATN3 (quick answers) on Interface A (*r*=−0.426, *P*=.01), but positively associated with ATN9 (distraction effects) on Interface B (*r*=0.505, *P*=.003) and Interface C (*r*=0.463, *P*=.007). In addition, MS was negatively associated with ATN5 (coordinate and focus) on Interface A (*r*=−0.412, *P*=.02; Figure 6).

Figure 6. Associations between (A) population characteristics and (B) insomnia symptoms (ISI) and subjective attention scale across interfaces. ATN: Attention Control Scale item number; ISI: Insomnia Severity Index; MS: mental state; NSRI: no self-reported insomnia; SlpR: sleep regularity; SRI: self-reported insomnia; SUL: stay up late.

Specific ATTC subdomains were selectively associated with demographic and lifestyle factors. Age was related to attention refocusing ability in Interface B, while smoking and tea drinking were associated with distraction-related indices.

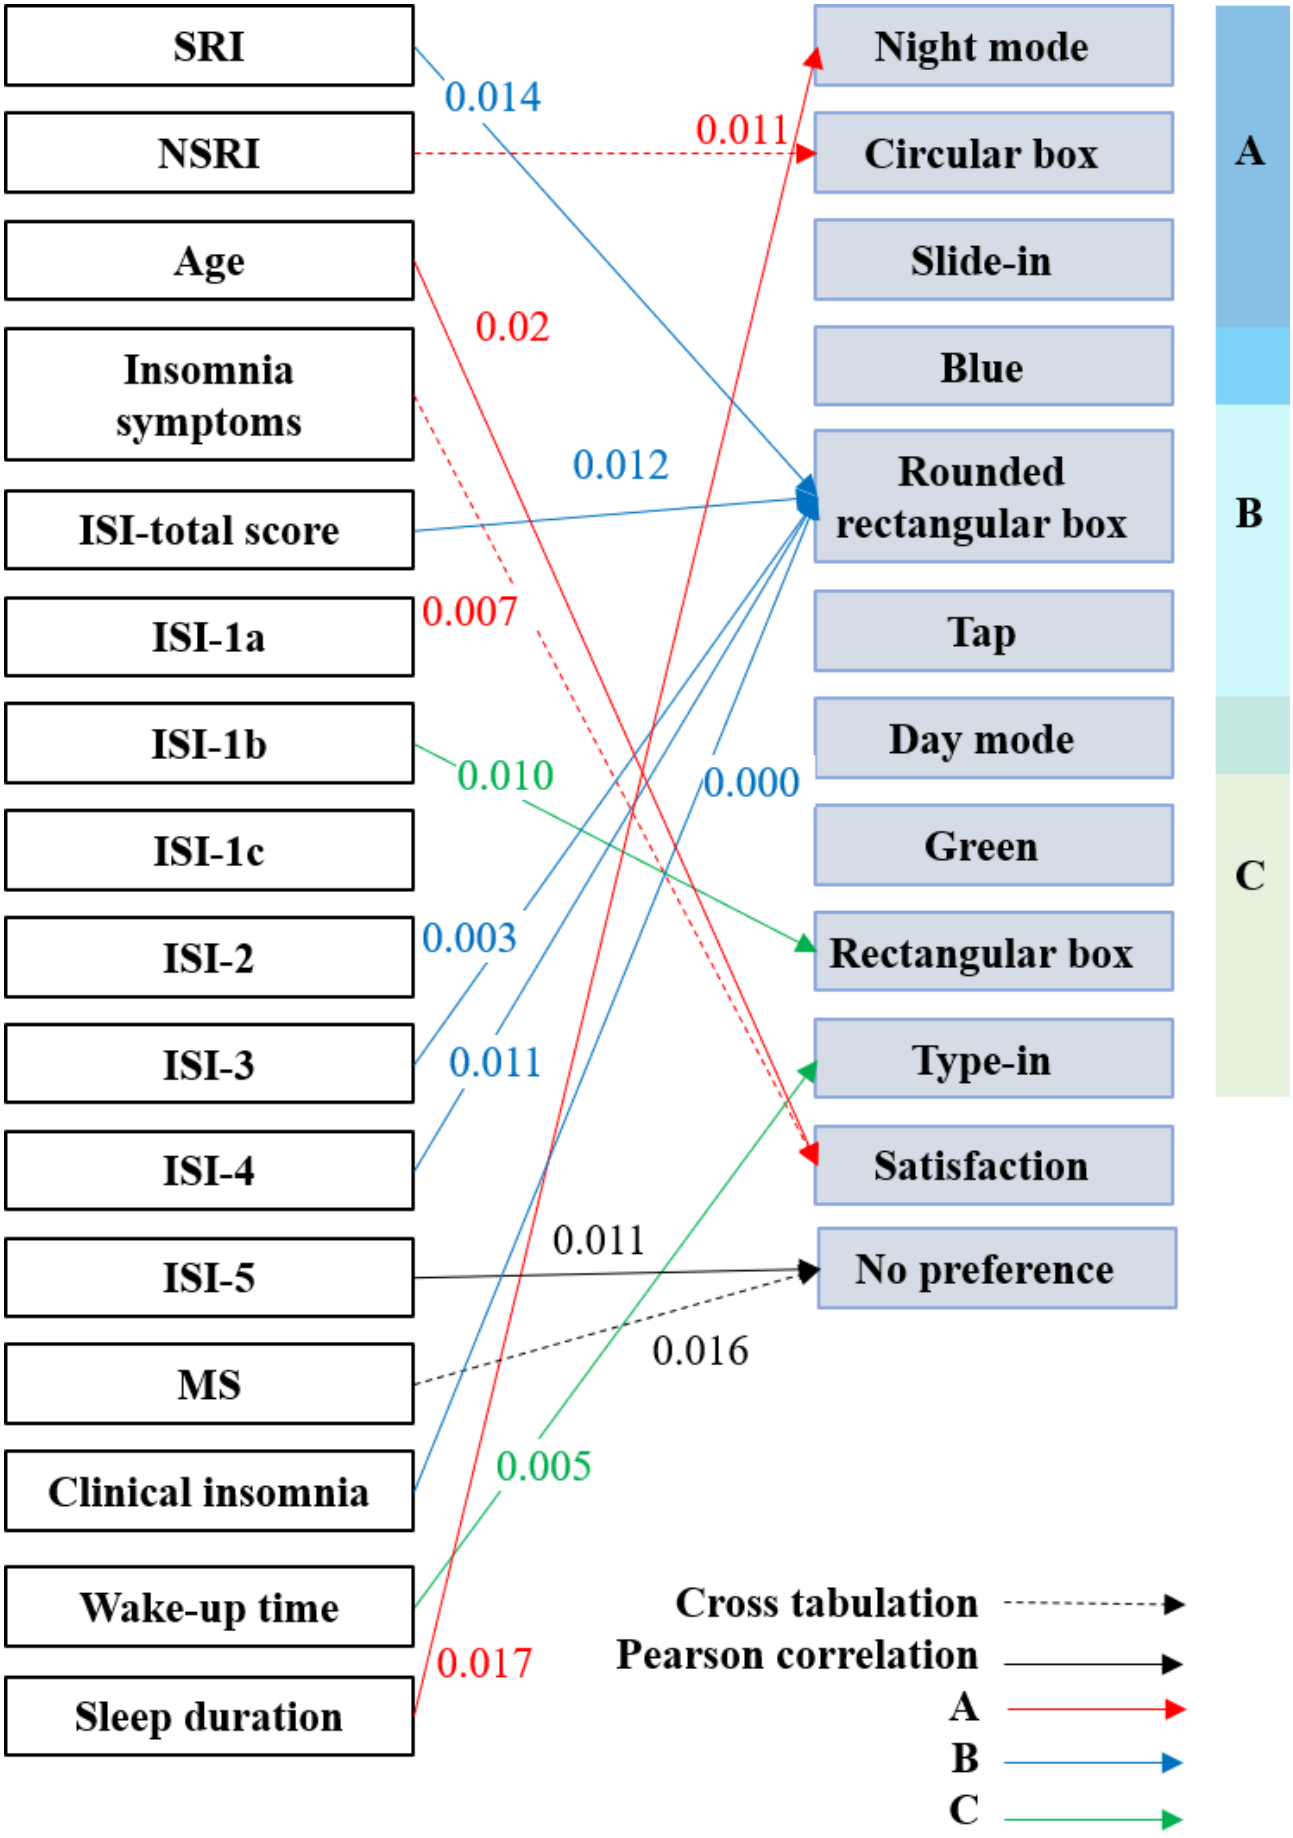
Insomnia symptoms demonstrated robust associations with subjective attention. Greater sleep initiation and maintenance difficulties, early morning awakening, and daytime dysfunction were associated with increased distractibility and reduced attentional coordination across interfaces. Worry about sleep was consistently associated with impulsive responding and reduced sustained attention.

MS showed a negative association with attentional coordination, highlighting the interaction between emotional condition and cognitive control during interface use.

Interface Preference and User Experience

Under normal daylight conditions, no significant differences were observed between SRI and NSRI participants in preference

XSL•FO
RenderX



for night versus day mode. NSRI participants showed a greater preference for circular boxes (χ^2_1=6.421, *P*=.01), whereas SRI participants preferred rounded rectangular boxes (*r*=0.424, *P*=.01). Insomnia symptoms participants reported higher satisfaction with Interface A (χ^2_{12}=27.094, *P*=.007), while those with clinical insomnia showed a lower preference for rounded rectangular boxes (*r*=0.593, *P*<.001).

The ISI total score was positively correlated with preference for rounded rectangular box (*r*=0.431, *P*=.01). ISI-1b was associated with rectangular box (*r*=0.440, *P*=.01), whereas ISI-3 and 4 were associated with rounded rectangular boxes (*r*=0.498, *P*=.003; *r*=0.437, *P*=.01). ISI-5 was associated with indifference toward interface interaction design (*r*=0.439, *P*=.01). Wake-up time was negatively correlated with preference for type-in (*r*=−0.479, *P*=.005), and sleep duration was positively correlated with preference for night mode (*r*=0.414, *P*=.02).

Between MS and the interface interaction mode, there was no preference (χ^2_3=10.313, *P*=.02; Figure 7).

Figure 7. Pearson correlation and cross-tabulation analyses of insomnia measures and interface preferences. ISI: Insomnia Severity Index; MS: mental state; NSRI: no self-reported insomnia; SRI: self-reported insomnia.

XSL•FO
RenderX

Using K-means clustering, participants were first divided into 2 clusters based on those without clinically significant insomnia and those with clinical insomnia to examine differences in preferences among Interfaces A, B, and C. Significant between-cluster differences were observed in satisfaction with Interface A ($F_{1,31}$=18.164, P<.001), overall interface satisfaction ($F_{1,31}$=7.691, P=.009), interaction duration ($F_{1,31}$=38.214, P<.001), and consistency of interface interaction ($F_{1,31}$=44.574, P<.001). Day mode also differed significantly between clusters ($F_{1,31}$=10.333, P=.003).

A second K-means analysis divided participants into 4 clusters based on insomnia symptoms. Significant cluster effects were found for satisfaction with Interface A ($F_{3,29}$=4.726, P=.008), Interface B ($F_{3,29}$=11.824, P<.001), and Interface C ($F_{3,29}$=6.519, P=.002). Clusters also differed significantly in interaction duration ($F_{3,29}$=5.800, P=.003), overall interface satisfaction ($F_{3,29}$=15.501, P<.001), and consistency of interface interaction ($F_{3,29}$=36.099, P<.001). In addition, significant differences were observed in preferences for color modes (eg, color mode 1: $F_{3,29}$=3.643, P=.02; color mode 2: $F_{3,29}$=4.233, P=.01) and interaction methods, including slide-in ($F_{3,29}$=3.522, P=.03) and tap input ($F_{3,29}$=5.446, P=.004).

Participants without SRI showed a significantly greater preference for rounded rectangular visual designs and reported higher satisfaction with Interface A. In contrast, participants with clinical insomnia preferred rounded rectangular designs. Sleep characteristics further influenced preferences. Longer sleep duration was associated with preference for night-mode displays. Cluster analyses based on insomnia status and symptom severity revealed significant differences in interface satisfaction, perceived task duration, and preferred interaction methods, with Interface A most frequently rated as the most efficient overall.

Integrated Relationships Between Attention, Eye Tracking, and Memory

Across the 3 interfaces, several subjective attention (ATN) indicators showed significant negative associations with task memory performance during operational tasks. On Interface A, task memory performance was negatively correlated with ATN7 (distraction effects; r=−0.446, P=.009), ATN1 (distraction effects; r=−0.498, P=.003), and ATN10 (impatient; r=−0.456, P=.008), indicating that greater distraction and impatience were associated with poorer task recall. On Interface B, a significant negative association was observed between task memory performance and ATN5 (coordinate and focus; r=−0.410, P=.02), ATN2 (quick answers; r=−0.564, P<.001), and ATN7 (distraction effects; r=−0.477, P=.005), suggesting that reduced attentional coordination, quick answers, and distraction were related to lower recall accuracy. On Interface C, task memory performance was negatively correlated with ATN7 (distraction effects; r=−0.488, P=.004), ATN1 (distraction effects; r=−0.511, P=.002), and ATN5 (coordinate and focus; r=−0.430, P=.01; Table 4).

Table . Associations between subjective attention (ATN[a]) indicators and task memory performance across interfaces.

Interface	ATN indicator (domain)	*r*	*P* value
A	ATN7 (distraction effects)	−0.446	.009[b]
A	ATN1 (distraction effects)	−0.498	.003[b]
A	ATN10 (impatient)	−0.456	.008[b]
B	ATN5 (coordinate and focus)	−0.410	.02
B	ATN2 (quick answers)	−0.564	<.001[b]
B	ATN7 (distraction effects)	−0.477	.005[b]
C	ATN7 (distraction effects)	−0.488	.004[b]
C	ATN1 (distraction effects)	−0.511	.002[b]
C	ATN5 (coordinate and focus)	−0.430	.01

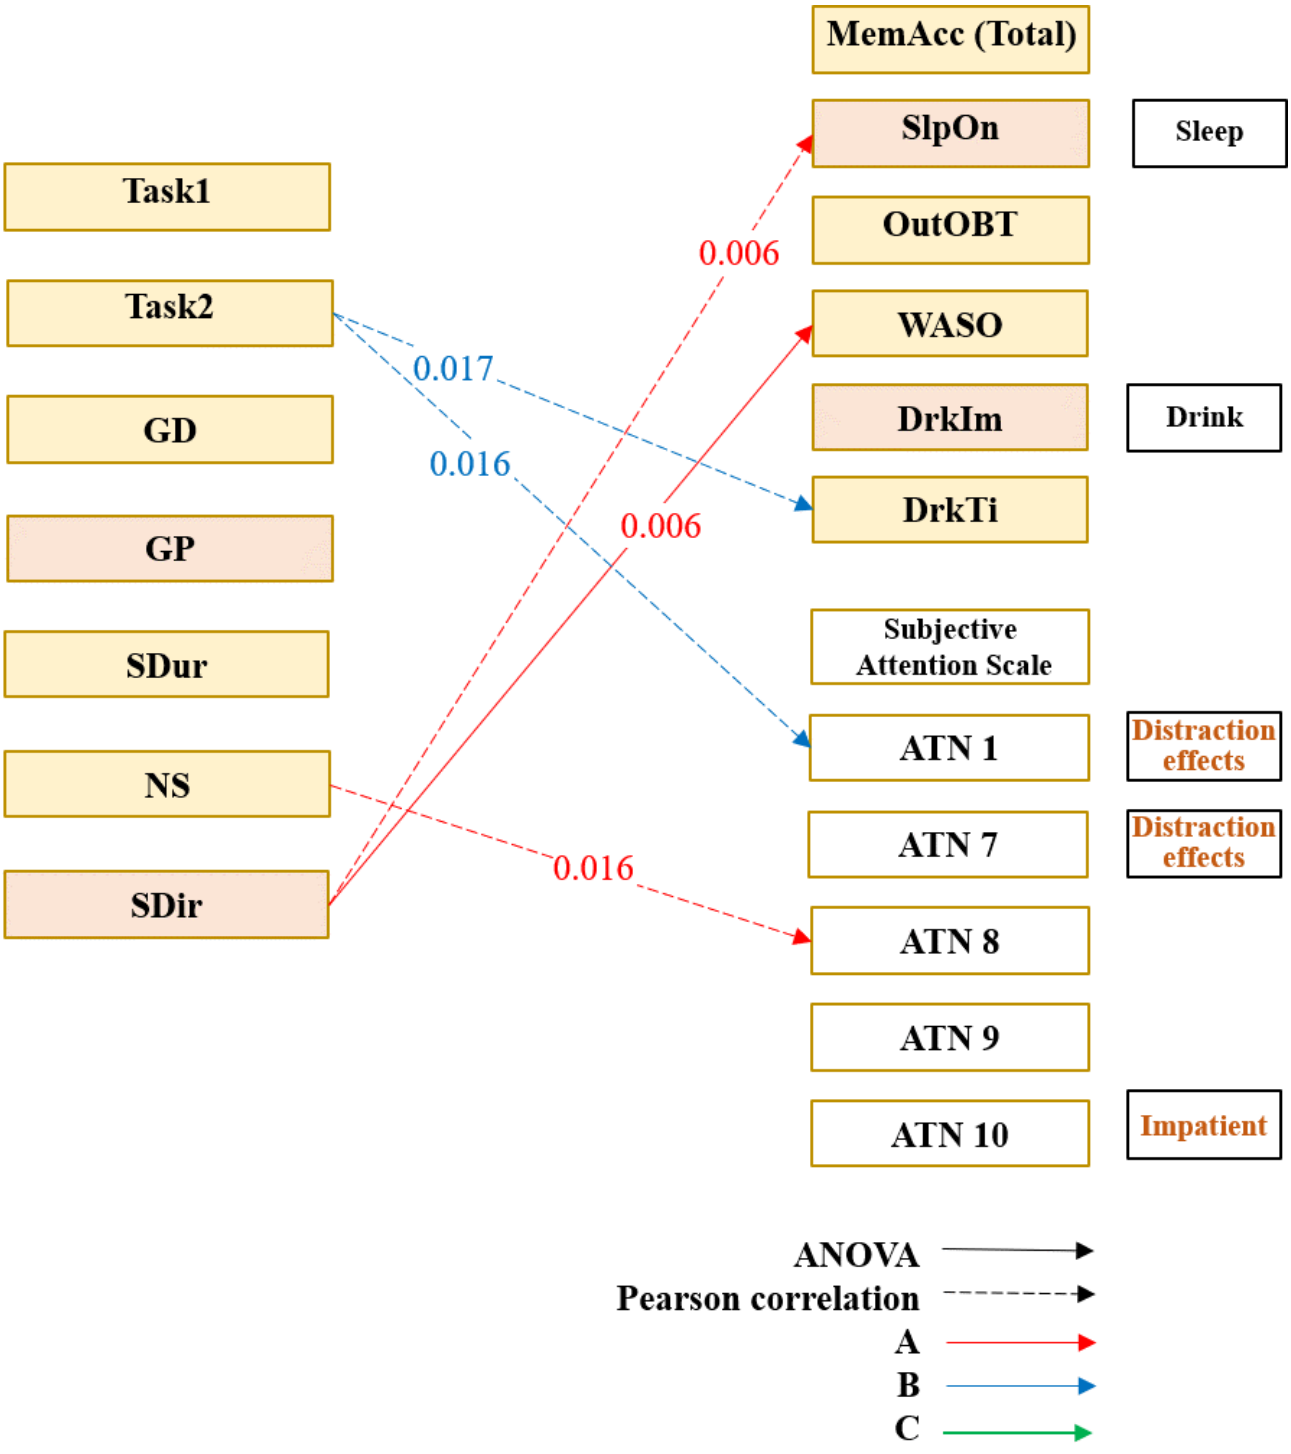
[a]ATN: Attention Control Scale item number.

[b]P<.02.

Overall, higher levels of subjective attentional difficulty (eg, distraction, impatience, reduced coordination) were consistently associated with lower task memory accuracy. Eye-tracking measures supported these findings: faster operation times and more stable saccade patterns were associated with better recall of time-based diary entries.

These convergent results indicate that interface designs that reduce attentional fragmentation also facilitate more accurate short-term memory during sleep diary completion.

Associations were observed between eye-tracking metrics, task memory performance, and subjective attention (ATN) indicators across interfaces. On Interface A, SDir was negatively correlated with SlpOn (r=−0.475, P=.006) and significantly associated with WASO (H_4=14.500, P=.006), indicating that greater directional variability in gaze was related to longer memory-encoding time and nocturnal sleep fragmentation. On Interface B, task 2 was negatively correlated with memory recall duration (r=−0.411, P=.02), suggesting improved task efficiency during secondary operations. With respect to subjective



XSL•FO
RenderX

attention, task 2 on Interface B was negatively correlated with ATN1 (distraction effects; r=−0.415, P=.02), whereas on Interface A, the NS was positively correlated with ATN8 (distraction effects; r=0.424, P=.02). Collectively, these findings indicate that interface-specific eye-movement patterns are associated with both cognitive workload during task execution and subjective attentional control, with gaze stability reflecting more efficient memory processing and reduced attentional disruption.

Eye-tracking metrics showed selective associations with memory: greater SDir variability on Interface A was associated with longer sleep-onset recall (r=−0.475, P=.006) and WASO (H_4=14.500, P=.006). Faster second-trial task times on Interface B were associated with improved recall (r=−0.411, P=.02; Figure 8).

Detailed statistical results for all nonparametric and correlation analyses are provided in Multimedia Appendix 1.

Figure 8. Associations between eye-tracking metrics, task memory performance, and subjective attention. ATN: Attention Control Scale item number; DrkIm: drinking items; DrkTi: drinking time; GD: gaze duration; GP: gaze position; MemAcc-Total: total memory accuracy; NS: number of saccades; OutOBT: out-of-bed time; SDir: saccade direction; SDur: saccade duration; SlpOn: sleep onset; WASO: wakefulness after sleep onset.

Discussion

Principal Results

This study investigated how interface design features of a BBT-I sleep diary app influence attention, visual processing, and short-term memory in individuals with varying insomnia severity. By integrating eye-tracking metrics, subjective attention ratings, behavioral memory accuracy, and interface preferences, the study provides a multidimensional understanding of how insomnia-related cognitive vulnerabilities interact with digital interface design.

Interface design was associated with differences in objective attentional performance, as reflected in task completion time, saccade count, and gaze stability. Second, SlpQ and insomnia symptoms—particularly sleep maintenance difficulty and sleep-related worry—were consistently associated with impaired attention and reduced memory accuracy. Third, short-term memory performance varied across interface designs and was especially sensitive to sleep disruption during event-based recall. Fourth, subjective attentional control showed strong convergence with both eye-tracking indicators and memory outcomes. Finally, interface preferences differed by insomnia status, with participants without clinically significant insomnia favoring visually softer, lower-load designs.

Interface Design and Attentional Load

Differences in eye-movement patterns across interfaces indicate that layout structure and interaction modality directly shape attentional demands. Interfaces requiring more visual scanning or manual input elicited higher saccade activity and longer task durations, particularly among participants with poorer SlpQ. In contrast, designs characterized by simpler layouts and guided interactions were associated with more stable gaze patterns and reduced attentional dispersion. These findings support cognitive load theory, suggesting that insomnia amplifies sensitivity to interface complexity and visual fragmentation.

Insomnia Symptoms and Memory Vulnerability

Memory accuracy was particularly vulnerable to sleep maintenance difficulties and daytime dysfunction, especially for event-based diary items such as exercise and nap timing. Routine sleep information (eg, bedtime and wake time) was less affected. This selective impairment aligns with prior evidence that insomnia disproportionately affects episodic and temporally ordered recall. Interface designs that increase cognitive effort during data entry may therefore exacerbate memory errors in users with insomnia.

Subjective Attention as a Key Predictor

One of the most robust findings was that subjective attentional difficulties—such as distraction, impatience, and reduced coordination—were stronger predictors of memory accuracy than eye-tracking measures. While eye-tracking captured physiological effort and scanning behavior, subjective attention better reflected the internal cognitive state governing successful recall. This suggests that memory recall during sleep diary completion is primarily an internally driven cognitive process, rather than one dependent on overt visual behavior.

Limitations

The following limitations should be considered when interpreting the results of this study:

1. Our findings represented regional population characteristics. The participants were of Asian descent between the ages of 20 and 64. Their lifestyle habits and insomnia conditions may have been influenced by factors such as age, occupation, and region of residence.
2. One limitation of the present study was the difficulty in recruiting participants with insomnia, which led to an underrepresentation of individuals with severe insomnia. Future studies with larger samples are warranted to enhance statistical power and generalizability.
3. The sleep diary interface of the app used in our study was based on the log recording method of CBT-I, and we only investigated user experience as well as the preference, attention, and memory status of participants. The therapeutic effect of our interfaces on insomnia was not within the scope of our study.
4. The mobile device used was running iOS. Other mobile application systems would require additional designs.

Conclusions

This study demonstrates that interface design plays a critical role in shaping attention, visual processing, and short-term memory performance in users with insomnia. Insomnia symptoms—particularly sleep maintenance difficulty and sleep-related worry—were consistently associated with attentional disruption and reduced memory accuracy during sleep diary completion. Notably, subjective attentional control was a stronger and more reliable predictor of memory performance than eye-tracking measures, indicating that cognitive processing during recall is driven primarily by internal attentional states rather than observable gaze behavior. For designers of digital insomnia interventions, these findings highlight the need to reduce cognitive load through simple, structured layouts; prioritize low-effort input methods such as tapping over typing; support sequential recall with guided, step-by-step data entry; and use visually soft, predictable designs that minimize distraction. Interfaces should also be adaptable to insomnia severity, offering more guided and low-complexity interactions for users with greater sleep disruption. By aligning interface design with the cognitive characteristics of insomnia, digital BBT-I applications may improve usability, data accuracy, and user engagement.

Abstract

Background: The digitalization of society has transformed daily life and health care, offering opportunities for accessibility and independence for individuals with complex care needs. However, users with limited digital skills still experience challenges because the technologies do not to align with their needs. Inclusive research and design approaches can improve technology by actively involving end users and stakeholders.

Objective: This study investigated the experiences of co-researchers with a mild intellectual disability or autism spectrum disorder and other key stakeholders over time regarding the inclusive design process for a digital tool for individuals with complex care needs that was developed in a transdisciplinary consortium.

Methods: The project that was examined applied an inclusive design process to develop a sensitive virtual assistant using the Vision in Product Design method and the design thinking approach. Nine consortium members, including 3 co-researchers, participated in semistructured interviews and a group discussion about the inclusive design process after each of the project's 5 work packages (WPs). This resulted in 31 interviews and 5 group discussions in total. Individual experiences were gathered during interviews, and group discussions facilitated collective reflection. During the interviews, an adapted questionnaire was used for each WP with Likert scales and open-ended questions. The data analysis was conducted using a thematic approach and descriptive statistics for the questionnaire data.

Results: Quantitative findings from questionnaires were complemented with qualitative insights from interviews and group discussions, with results presented chronologically per WP. The qualitative analysis resulted in 3 main themes: project approach, collaborative dynamics, and co-design in practice. Project approach showed how the team adapted its inclusive collaboration through expectation management, structured processes, and accessible materials. Collaborative dynamics described how communication and support evolved and how inclusive design principles were applied in practice. Co-design in practice outlined co-researcher involvement and content adaptations across the 5 WPs, highlighting how experiential knowledge directly informed design decisions. These findings show that inclusive collaboration developed over time and contributed meaningfully to both process and content.

Conclusions: This study shows that, to accommodate an inclusive research and design process, tensions between project efficiency and meaningful inclusion need to be addressed, underlining the importance of continuous coordination, collaboration, and flexibility in transdisciplinary settings. Further, applying a stepwise approach in inclusive collaborations supports coordination, continuous evaluation, and flexibility. Inclusive methods, like preparatory activities, clear role division, accessible materials, and iterative feedback, enabled active co-researcher participation. These methods contributed to a shift in ownership, allowing co-researchers to gain greater influence and co-shape both the development process and the content. The findings provide insights into how to enhance equity and relevance in inclusive technology design for individuals with complex care needs, such as individuals with a mild intellectual disability or autism spectrum disorder.

Introduction

The rapid digitalization of society has transformed the way in which individuals interact with technology in health care and in their daily lives [1,2]. As digital innovations become more integrated within society, it is essential that they meet the needs of diverse user groups such as those requiring complex care. These individuals often rely on a wide range of health and social support services, making accessibility to digital health tools particularly relevant. However, such tools can be difficult to use and less accessible for individuals with limited digital skills. For example, individuals with a mild intellectual disability (MID) or autism spectrum disorder (ASD) often experience difficulties acquiring digital literacy skills and using digital devices or the internet [3,4] because of limited cognitive skills and challenges with processing information efficiently [5]. Both groups frequently struggle with understanding complex instructions, problem-solving, and adapting to new technologies [5,6]. This can place them in a vulnerable position, as it limits their ability to fully participate in today's complex society [7,8]. Digital tools designed to fit their living situation may reduce challenges, increase their empowerment, and contribute to more effective care, ultimately decreasing health disparities in these populations [9,10].

Although digital health tools can enhance accessibility and independence, they are often not developed to align with these users' specific needs and skills [2,11,12]. Despite the growing inclusion of these target groups in technology research and design projects [11,13,14], the participation of end users with MID and ASD remains limited [15-17]. This gap highlights the need for inclusive research and design approaches that incorporate the perspectives of these end users in the development of health technologies [18-20]. In this study, inclusive design is defined as an approach to make the design and development process accessible, equitable, and participatory for individuals with diverse abilities and experiences. Drawing from the Vision in Product Design (ViP) methodology [21] and design thinking [22], inclusive design refers to a flexible, iterative process that values multiple forms of expertise, including experiential knowledge, and adapts its methods, materials, and facilitation strategies to ensure meaningful involvement of all participants.

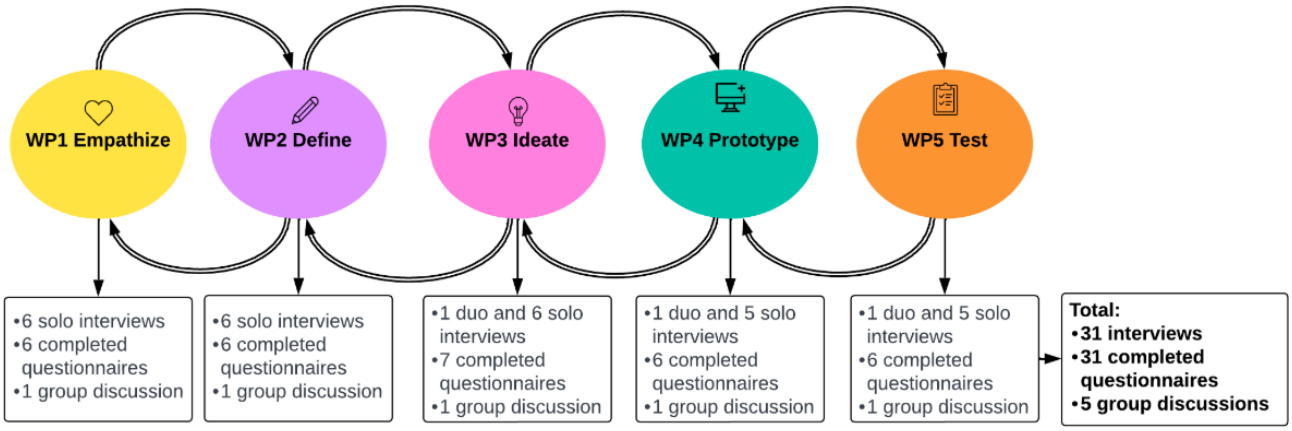
User-centered approaches [23] place user groups at the center of the design process by using tailored methods to address their specific needs [24,25]. These approaches follow an iterative process, applying rapid prototyping and prioritizing end user experiences by collaborating within interdisciplinary teams [26]. Inclusive, flexible, and adaptive approaches have been shown to be well-suited to involving people without prior experience in technological design [11,14]. Recent work in inclusive participatory design further demonstrates how design processes can be adapted to respect diverse sensory, cognitive, and communicative modes of engagement [27-30]. These studies provide important methodological insights into how participation can evolve into equitable collaboration, ensuring accessibility and involvement across all stages of technological development. In research, inclusive approaches such as inclusive research or citizen science actively involve end users in all phases of technological research and development processes. In these approaches, end users are experts-by-experience and co-researchers [31,32] who serve as advisors, cooperators, or nonprofessional researchers alongside those with academic or design training to add value through the sharing of their lived experiences [13,33]. User-centered and inclusive research and design approaches can be applied to develop (health) care technologies that are not only functional but also accessible and usable for all [14,34]. However, no research has been conducted into how end users with limited digital skills experience collaboration in technological research and development processes or into the adaptations that are necessary to involve them.

In addition to the participation of co-researchers and experts-by-experience, the involvement of other stakeholders in technological research and development is essential [20,26]. Examples of these stakeholders include (informal) caregivers, support workers, IT developers, or other specialists to align with the end user context and support in practice [35]. This gives technologies a greater chance of successful implementation and use [18,36,37]. However, previous studies have found that less attention is given to involving key stakeholders and end users throughout all design iterations or to the continuous monitoring of the design process during implementation [20,26]. Reflecting on the collaboration during technology development and implementation phases can provide practical insights valuable for (future) development [26]. Therefore, this study aimed to examine how inclusive design methods facilitate the development of digital health tools, focusing on the experiences of co-researchers with MID or ASD and other stakeholders over time on the inclusive design process of a digital tool for individuals with complex care needs, developed within a transdisciplinary consortium. Rather than assessing the design outcomes of the digital tool itself, the research focused on the process-level learning, that is, the iterative adaptations, facilitation strategies, and collaborative dynamics that enabled or hindered inclusive participation over time. The research question guiding the analysis was: *What process modifications and content adjustments were made over time to accommodate an inclusive design process with co-researchers with MID or ASD in the development and implementation of a digital tool for individuals with complex care needs?*

Methods

Study Setting

Within this study, the inclusive design process for a digital tool in the form of a sensitive virtual assistant (SVA) for individuals with complex care needs was investigated. A consortium of transdisciplinary partners aimed to develop an SVA that could guide individuals with complex care needs toward appropriate support for questions related to mental and physical care [10]. Artificial intelligence technology was used to enable the SVA to adapt its responses in a sensitive manner.



The consortium consisted of 5 partners: (1) a university department with expertise in technology and chatbots in service settings; (2) an academic collaborative conducting research with and about people with intellectual disabilities; (3) a social design

XSL•FO
RenderX

agency; (4) a foundation for social care organization informing, advising, supporting, and employing people with complex care needs such as individuals with ASD and intellectual disability; and (5) an IT company. In this project, 3 individuals with ASD or MID, representing the target group, participated as co-researchers and experts-by-experience throughout the entire research and design process. The co-researchers work for the academic collaborative and the social care organization. Their involvement enabled the consortium to consider the challenges underlying the complexity of different living and care situations. Their roles varied across project phases such as sharing lived experiences, co-designing prototypes, recruiting participants, co-moderating focus groups, and preparing data collection materials. By combining inclusive research and user-centered design, the project aimed to ensure meaningful participation.

The SVA was developed using the ViP method [21], incorporating the design thinking approach [22]. Each design thinking phase was operationalized as a separate work package (WP1-WP5), aligned with the steps of the ViP method (Figure 1) [22]. In the Empathize phase (WP1), the focus was on identifying and mapping the needs of the end users through focus groups and a literature review. The Define phase (WP2) analyzed the insights from WP1 to develop a user profile, which included user needs and desired experiences. In the Ideate phase (WP3), a wide range of creative solutions was generated. Among these activities, personas were created, representing fictional user profiles designed to represent typical users' behaviors, motivations, and needs. Additionally, the development of user scenarios and user journeys helped define functional requirements and typical user experiences. In the Prototype phase (WP4), these ideas were turned into early-stage functional designs (ie, low-fidelity prototypes) and tested for usability and performance. This phase also included making the ethical approval application for user testing. Finally, the Test phase (WP5) involved developing 3 functional versions of the SVA, each with a different interaction style. These were tested with real users in actual care settings to evaluate and refine the solution.

Figure 1. Flowchart of the sensitive virtual assistant (SVA) project and data collection for the reflection on the inclusive design approach.

Study Design

This study used a mixed methods approach to reflect iteratively with co-researchers and consortium members on the SVA's inclusive design process over time; see Figure 1. The SVA functioned as a context and illustrative case that allowed the research team to analyze inclusive processes in practice rather than to evaluate the final design outcome. Qualitative data were gathered through (1) semistructured interviews with co-researchers and key stakeholders followed by (2) group discussions with co-researchers at the end of the 5 phases or respective WPs. During the group discussions, the co-researchers reflected together on the insights from the interviews. Quantitative data were collected during the semistructured interviews by filling in a digital questionnaire adapted for each WP. The integration of qualitative and quantitative methods ensured structural reflection over time across the entire process with all participants. Further, this study was conducted in collaboration with a co-researcher with an MID, whose perspective was actively integrated into the research process.

Participants

Representatives from all 5 consortium partners participated in the study, with a total of 9 participants, including the 3 co-researchers. The other 6 participants were consortium partners involved in various roles: researchers, social designers, project leader, and technology developers. Table 1 shows the participants' distribution in the interviews and questionnaires. The first 3 group discussions took place with 3 co-researchers, and the last 2 discussions took place with 2 co-researchers.

XSL•FO
RenderX

Table . Participant distribution in the interviews.

Total participants per work package (WP)	Co-researchers, n	Researchers, n	Social designers, n	Project leader, n	Technology developers, n
WP1 (n=6)	3	1	1	1	0
WP2 (n=6)	3	1	1	1	0
WP3 (n=8)	3	1	1	1	2
WP4 (n=7)	2	1	1	1	2
WP5 (n=7)	2	1	2	1	1

Ethical Considerations

Primary data collection was conducted in compliance with the current data protection regulations of the General Data Protection Regulation and the Declaration of Helsinki. Each participant received an information letter and provided informed consent via a comprehensible consent form. Both documents were co-created with the co-researcher with MID to enhance accessibility (eg, by incorporating simple text, graphic support, large font, and increased white space). Data collection was anonymous, and no conclusions can be drawn about individuals in the presentation of results. Since the participants were part of the consortium and were compensated for their input as members, they were not compensated separately for this study. The entire study was submitted for ethical review to the Research Ethics Committee CMO Radboudumc and waived from further ethical assessment (reference number 2023 - 16400) because it does not constitute medical scientific research according to the Medical Research Involving Human Subjects Act (WMO) [38]. This waiver is consistent with national and institutional policies that specify that research falling outside the scope of the WMO does not require further review. Relevant guidance can be found in the CCMO framework for non-WMO research (CCMO, *Niet-WMO-onderzoek*)[39], as well as the CMO Radboudumc policy on non-WMO assessment[40].

Procedure and Data Collection

The aim of this study was to identify key adaptations in both the collaborative process and the content of inclusive research practices over time (May 2023–May 2024). After each WP was completed, semistructured interviews were conducted with the consortium members, including the co-researchers. These semistructured interviews focused on participants' engagement, lessons learned, and overall experiences and were conducted with 6 to 8 participants per WP. As the interviews were conducted after each phase, experiences were still recent and therefore easier to retrieve. During the interviews, quantitative data were collected using digital questionnaires adapted for each WP. The interviewer filled in the quantitative responses using *I Co-research* (*IkOnderzoekMee*; Crowdience), an inclusive digital research platform for accessible dissemination of questionnaires [14,41]. The questionnaires consisted of quantitative elements using Likert-scale items (see Table 2), incorporating simplified text, graphic support, large fonts, and increased white space to facilitate the participants [14]. Examples of how the scales were used in the questionnaires can be found in Multimedia Appendix 1. During the interviews, open-ended questions were asked regarding specific activities of the WP and the clarity of roles and tasks within these activities, experiences within the collaboration in the consortium, goals of the WPs, lessons learned, and individual reflections. The open-ended questions provided a deeper understanding of how adaptations were implemented and experienced. Multimedia Appendix 1 provides the interview guide combining the interview questions and a WP1 questionnaire. Following the interviews with questionnaires, a group discussion was held with the 3 co-researchers involved in the project. During these discussions, insights, and areas of interest from the interviews and questionnaires such as participant engagement, challenges, and overall perceptions were discussed. An independent researcher (JFEC) moderated these sessions. In line with the paradigm "nothing about us without us" of the international treaty from the United Nations Convention on the Rights of Persons with Disabilities [42], the data collection process was designed to ensure that the voices of co-researchers with MID or ASD were central. At the same time, consortium members without disabilities were included to investigate how inclusive collaboration was experienced and facilitated across roles. This comprehensive inclusion allowed us to identify how the participatory process was shaped. Importantly, although all perspectives were collected, the reflections of co-researchers in the group discussions formed the primary reference point for interpreting and discussing results in later stages of the analysis.

Table . Scales used in the questionnaire.

Type of scale	Color	Points	Distribution (lowest to highest)
Visual analog scale	Black and white	10	1=Totally not clear, 10=Very clear; 1=Totally not nice, 10=Very nice
Stars	Yellow	5	1=Very negative, 5=Very positive; 1=Little contribution, 5=Great contribution
Smileys	Green, yellow, orange, and red	4	1=Very good, 4=Bad
Thumbs	Green, yellow, and red	3	1=Yes, 2=Partially, 3=No

Data Analysis

Descriptive statistics were applied to analyze the quantitative data from the digital questionnaires. Microsoft Office Excel was used to calculate frequencies, median scores, and range distributions, allowing for a clear overview of participants' response patterns, medians, and range distributions.

All interviews and group discussions were recorded and transcribed for analysis. Table 3 presents the consecutive steps of the qualitative data analysis, which was conducted in multiple phases using a thematic approach. After each WP, the transcripts of the semistructured interviews were rapidly coded [43,44] to gain an initial impression of participant engagement, challenges, and overall perceptions. The results from this phase were included in the subsequent group discussions with the co-researchers. During these discussions, key themes based on the research questions were identified, forming an initial framework to guide the analysis of the semistructured interview data of the corresponding WP. This framework guided further rapid coding of the interview and discussion data to identify overarching themes and subthemes [43-45]. The analysis process was conducted separately for each WP, ensuring a structured and iterative evaluation of the data.

In addition to the thematic analysis of interview and group discussion data, a structured analysis of co-researcher involvement and activities per design phase was conducted (Table 3, step 8). This analysis, based on data extracted from the interviews, focus groups, and a logbook, resulted in a table summarizing the activities conducted within each WP, the content adaptations made, and the involvement of co-researchers in these activities, supported by participants' experiences.

Table . Consecutive steps, actions, and aims of the coding process.

Step	Action	Aim
1	Reading transcripts of interviews	Become familiar with data and sections of the transcripts
2	Initial rapid coding (JFEC, AWCC) of the semistructured interviews and questionnaire responses after each work package (WP)	Gain first impression of interview data and explore areas of interest such as participant engagement, challenges, and overall perceptions
3	Using first impression on which to reflect in the subsequent group discussions with the 3 involved co-researchers (JFEC, AWCC)	Identify key themes and reflections based on research question and create initial coding framework with thematic categories
4	Applying initial coding framework and using rapid coding approach to guide second analysis	Conduct bottom-up coding, identify overlap and connections between codes, and ensure collective reflection
5	Clustering of codes into broader themes relating to the research question (JFEC, AWCC, KEB)	Identify emerging and overarching themes and subthemes
6	Discussing clusters of codes using insights from group discussions (JFEC, AWCC, KEB, JN)	Refine subthemes and analyze their relationships within each main theme, creating the final coding structure
7	Repeating steps 1-6 for each WP separately	Generate an overview of insights per WP
8	Collectively analyzing WPs	Develop a comprehensive overview of the full process and conduct qualitative data analysis, which resulted in 3 main themes: project approach, collaborative dynamics, and co-design in practice

Results

Themes

The thematic analysis resulted in 3 main themes that together describe how inclusive collaboration was shaped and experienced throughout the design process. The thematic coding map of the inclusive design process is visualized in Figure 2. The first 2 themes show how the team adapted methods, facilitation, and collaboration over time. The subthemes are first represented by quantitative results from the questionnaires then further illustrated by qualitative results with quotes from the interviews and group discussions. The last theme gives an overview of the core activities, co-researcher involvement, and content adaptations to the inclusive research and design process during each WP illustrated by participants' quotes about experiences. The results are described chronologically structured by the 5 WPs. Because the SVA functioned as a use case, the emphasis here is on process adaptations rather than design evaluation of the tool itself. Where relevant, the results indicate whether adaptations were particularly beneficial for the co-researchers with MID or ASD or more generally valuable for all consortium members.

All quantitative outcomes have been integrated into a single comprehensive table. Table 4 presents these results collectively, offering a consolidated overview of the rating ranges and median scores across all WPs.

XSL•FO
RenderX

Figure 2. Thematic coding map of the inclusive design process.

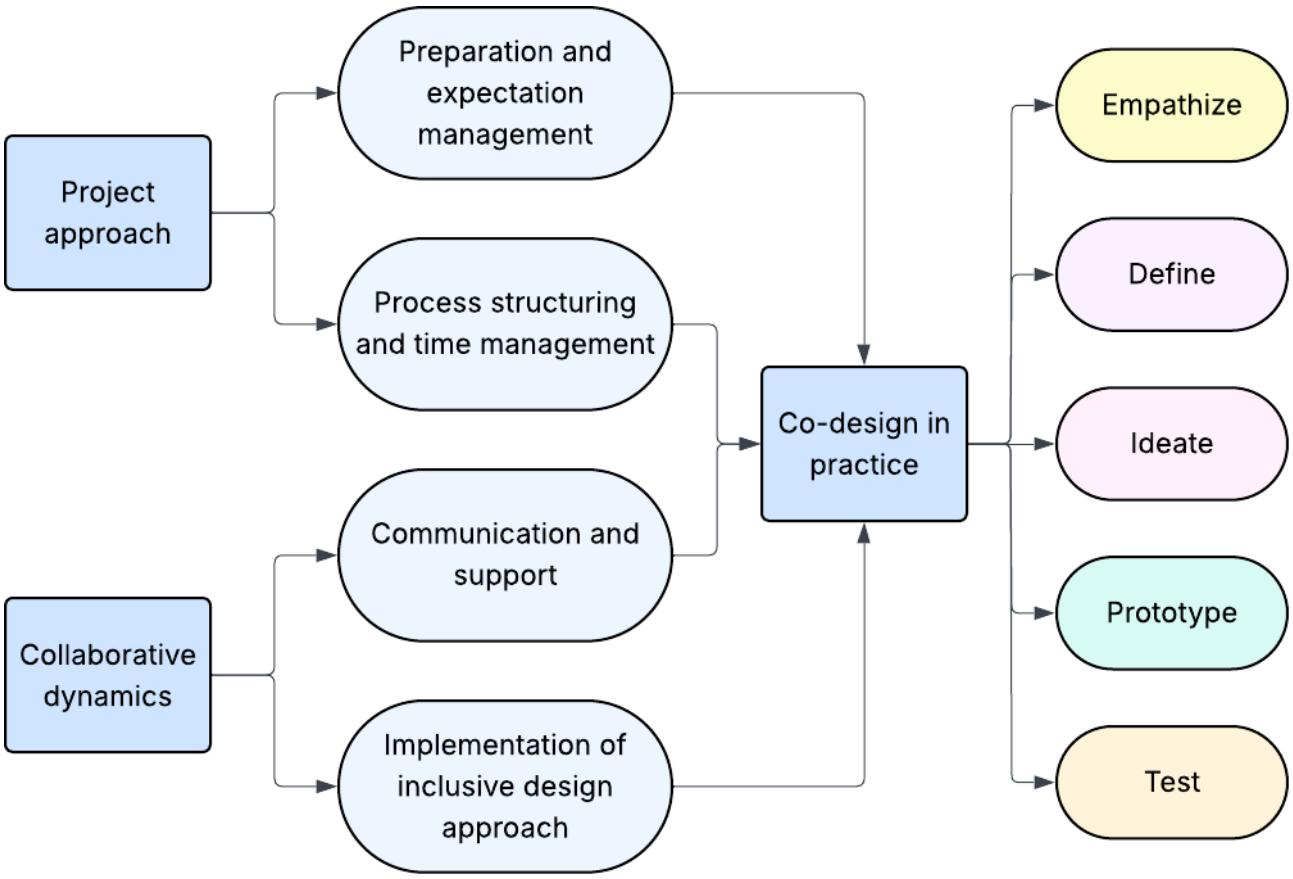

Table . Quantitative outcomes of the grading of all work packages (WPs).

Grading for	Scale	WP1 grade (n=6)		WP2 grade (n=6)		WP3 grade (n=7)		WP4 grade (n=6)		WP5 grade (n=6)	
		Range	Median	Range	Median	Range	Median	Range	Median	Range	Median
Contributions from the co-researchers to achieving the goals of the WP	1 - 5 stars (Low to High)	2 - 3	3	3 - 4	3	3 - 4	3.5	2 - 5	4	3 - 5	4.5
Clarity of tasks within each WP	Visual analog scale 1 - 10 (Low to High)	5 - 8	7.5	2 - 10	6.5	2 - 8	7	3 - 10	7	5 - 9	7.5
Overall experience of the collaboration within each WP	Visual analog scale 1 - 10 (Low to High)	3 - 5	4	3 - 5	4	3 - 5	4	3 - 5	4	3 - 5	4.5

Project Approach

Three subthemes describe how the team adapted the project approach to facilitate inclusive collaboration: preparation and expectation management, process structuring and time management, and the accessibility and clarity of materials and meetings.

Preparation and Expectation Management

Table 4 shows the grading for the co-researchers' contributions to achieving WP's goals. The median ratings went from low to

XSL•FO
RenderX

medium to high across the WPs, with a widening grade range particularly in WP4, suggesting both improvements as well as ongoing difficulties in the contributions in achieving the goals of each WP.

In WP1, considerable time was spent preparing the project and designing the research approach. This led to a strong methodological foundation by combining the ViP approach with clearly defined research questions aimed at developing the SVA in a grounded and well-substantiated way. This preparatory phase was experienced as valuable by the participants: "A lot of work before the start, especially substantiating the fundamental research. That intensive pre-application phase is paying off now" [Group discussion WP1, co-researcher 1]. Although these efforts were experienced as beneficial, participants emphasized that role clarity and mutual expectations were not sufficiently addressed in this phase. Co-researchers noted that roles and meeting purposes were not always clear, thereby hindering inclusive participation: "The division of roles and their descriptions should be clearer in advance, and the purpose behind a meeting should also be better explained" [Group discussion WP1, co-researcher 3].

In WP2, the co-researchers' role was more clearly defined, and preparatory work was focused on aligning tasks with their expertise and ensuring that they were adequately informed to contribute meaningfully to the research activities. The participants stated that, in WP3, issues identified in WP1 and WP2 were addressed, such as more structure and explicit planning, leading to process improvements. In WP4, expectations were more explicitly defined, as indicated by co-researchers. Preparations for WP5 were also experienced as well-structured. However, uncertainty about project progress remained a recurring point, especially regarding coordination with external partners. Despite the high workload and challenges, WP5 was experienced as successfully completed. Nevertheless, reflections on the full project indicated that expectation management on roles and expectations should have been addressed earlier. Clarifying roles and meeting purposes proved beneficial for all team members, while the clearer explanation of individual tasks and meeting goals was particularly important for the co-researchers to understand their expected contribution.

Process Structuring and Time Management

Process structuring and time management varied across the WPs. In WP1, a co-researcher was present at all focus groups acting as a second chairperson, contributing to continuity. In WP2, the team revisited earlier steps when clarification was needed and repeated certain elements of the methodology; this was experienced as supportive and necessary: "More attention was paid to repeating and explaining the steps, so planning those extra sessions was really helpful" [Interview WP2, consortium member 1]. These repetitions and slower pacing were adaptations that specifically supported the co-researchers by providing predictability and reinforcing understanding, while improved scheduling and process visibility benefited the entire consortium.

Co-researchers reported that certain steps in the process had been skipped or insufficiently addressed. They felt they had not been adequately informed, which led to uncertainty about their role in specific sessions. This was especially apparent in WP2, where feedback loops discussing and revisiting important aspects of the care setting were not applied consistently over time, leading to confusion, a feeling of unpreparedness, and missing structure among some co-researchers: "I didn't get enough explanation about what was expected of me, so it felt like some steps were missing and I wasn't well prepared. It felt like the structure was missing a bit" [Interview WP2, co-researcher 3]. In WP3, the design process was structured using personas and value scenarios. These tools helped visualize user needs and supported decision-making. The use of visual tools was initially introduced to make abstract information more accessible for the co-researchers but later proved equally valuable for all team members to align perspectives and trace decisions. However, not all choices made during the design process were clearly traceable to earlier input, consequently raising questions about the origin of decisions: "It's still unclear where some decisions and information come from, but I do have confidence in the process and what it will lead to" [Group discussion WP3, co-researcher 2]. In WP5, the fast pace of data collection limited opportunities for deeper engagement, particularly among co-researchers not involved in day-to-day activities. This moderate level of involvement indicates the tension between project deadlines and inclusive participation.

Accessibility of Meetings and Clarity of Materials

The low to high gradings indicated varying experiences with the clarity of the tasks within each WP (Table 4). These variations are reflected in both improvements and persistent challenges in the clarity of materials and meetings.

Throughout the project, accessibility of documents and the clarity of meeting structures were important for structuring inclusive collaboration. In WP1, the importance of aligning language and terminology across disciplines was raised. One co-researcher explained how this led to misunderstandings: "There was a moment I got stuck on the terminology, some explanations were missing, so I misinterpreted terms like 'advisory group' and focus group'" [Interview WP1, co-researcher 1].

In WP2, the team experienced difficulties with access to shared documentation because of unclear file structures and inconsistent uploading of materials. Despite this, valuable insights were still generated through collaborative analysis sessions. In addition, some participants found the abstract language used by the social designer difficult to follow, particularly during the initial explanation of the design concepts and framework. This suggests that the issue was not limited to participants with MID or ASD. Sessions about the design requirements were considered too complex or intensive, thereby negatively impacting participation. There was a clear need for better guidance and coordination: "That session was much harder than I expected. I underestimated the approach, reading all the design requirements aloud was too much for 1 co-researcher, especially with all 3 co-researchers in 1 session. Better preparation would have helped" [Interview WP2, consortium member 3]. Simplifying terminology and using concrete examples primarily supported the co-researchers, whereas improvements in file organization, consistent upload

XSL•FO
RenderX

practices, and meeting agendas were generally beneficial for all participants.

During WP3, difficulties in managing large amounts of information were expressed, particularly regarding working with personas. This emphasized the need for better preparation and briefing. Collaboration in smaller groups improved clarity, and strategic selection of who attended meetings helped structure discussions more effectively: "It was helpful that we could build on earlier experiences and realized that sometimes it's better to meet in smaller groups and have a clear agenda with a focused question for the co-researchers" [Interview WP3, consortium member 4]. This adaptation was initially designed to meet the communication preferences of the co-researchers but was later appreciated by the entire team for improving efficiency and focus. In WP4, the inconsistent involvement of co-researchers in different sessions revealed the need for a more transparent selection and planning process; this was subsequently addressed by clarifying the tasks and communicating planning and agendas more openly and in advance.

Collaborative Dynamics

This theme describes how the team experienced and shaped collaboration throughout the project. We identified 2 subthemes: (1) communication and support and (2) the implementation of the inclusive design approach.

Communication and Support

Over the course of the project, the importance of structured communication and tailored support became more evident, with improvements throughout all phases. In WP1, the involvement of a researcher with experience working with the target group contributed significantly to inclusive interaction and understanding. This early investment in a collaborative dynamic created a foundation that contributed to more effective coordination and inclusive dialogue in later phases, although some team members indicated that communication within the broader group was occasionally fragmented in WP2 and WP3. The team became more aware of the need for regular status updates and accessible coordination, particularly for co-researchers. These structured updates were introduced to help co-researchers stay connected and informed. In WP3, this learning resulted in more targeted communication and the introduction of structured feedback sessions. One co-researcher reflected: "I sometimes miss status updates, and, as a result, I feel less connected to the group and the project" [Group discussion WP3, co-researcher 3].

From WP4 onwards, lessons from earlier phases were applied. Project roles became more clearly defined, and coordination across team members and with co-researchers improved. For example, responsibilities for preparing test sessions were allocated in advance, and co-researchers were actively involved in reviewing prototypes, leading to smoother collaboration and more targeted feedback. In WP5, external factors such as delays in receiving feedback from the tests posed challenges, partly because of scheduling difficulties and the time required for internal approvals. The team members emphasized the value of having expertise with inclusive approaches embedded within the team from the start: "Looking back, I now see how important it is to have knowledge and experience with the target group. This must be secured in advance" [Interview WP5, consortium member 2]. Overall, the experiences with communication and support illustrate a learning trajectory in which the team increasingly recognized and applied the conditions required for sustainable inclusive collaboration. The growing emphasis on inclusive communication was therefore both a targeted accessibility measure for the co-researchers and a general facilitator of cohesive teamwork.

Implementation of an Inclusive Design Approach

Consistent gradings were present for the overall experience of the collaboration within each WP (Table 4), indicating that this was experienced as fairly stable.

In WP1, the team paid attention to aligning tasks with co-researchers' strengths and availability. These early decisions, such as involving co-researchers in defining project goals and choosing methods, helped create a foundation for shared ownership and equitable participation. This was reflected in how co-researchers took the initiative during planning meetings and felt empowered to provide critical feedback on design choices. In WP2, several team members and co-researchers described stronger group dynamics and increased peer support during meetings, suggesting a growing sense of cohesion. The team became more responsive to individual needs and made deliberate choices about when and how to involve co-researchers. This thoughtful approach contributed to a respectful and adaptive working environment: "There is a conscious decision whether or not to involve specific consortium members or co-researchers in certain activities. Their added value or potential overload is always considered carefully" [Group discussion WP2, co-researcher 2]. Adjusting task complexity and workload was particularly beneficial for the co-researchers, supporting autonomy and confidence in their role.

In WP3, the inclusive approach was further strengthened. Co-researchers suggested setting up a test group; this marked a shift toward more proactive engagement. Their suggestion was adopted and built upon in WP4 and WP5, where co-researchers played active roles in testing and presenting outcomes to various stakeholders, including care and support organizations, technology developers and intended target users. These contributions were experienced as motivating and valuable: "For me, it was a real highlight that I got to join and answer questions at an event. It made me feel even more part of the team" [Interview WP5, co-researcher 1]. Throughout the project, the team also gained insight into how different forms of experiential input could be used effectively. The distinction between experiential expertise (derived from personal lived experience) and experiential knowledge (the ability to reflect on and articulate that experience for others) became more visible, leading to more intentional use of individual contributions. For example, during user testing phases, some co-researchers contributed best by evaluating content based on their personal experience, whereas others translated those insights into concrete design suggestions. This initiative specifically empowered the co-researchers, reinforcing their

XSL•FO
RenderX

agency within the design process while also fostering a stronger sense of shared ownership of the team.

Co-Design in Practice

A summary of the core activities within the design phases, co-researcher involvement, and content adaptations to the inclusive design process made across the 5 different WPs is provided in Table 5. The adaptations were informed by the input from and collaboration with co-researchers. The following section elaborates on the rationale behind these adaptations resulting from this input, and reflects on participants' experiences with the content adaptations made.

XSL•FO
RenderX

Table . Summary of core activities, co-researcher involvement levels, and content adaptations.

Phase, core activities, and level of co-researcher involvement	Description of co-researcher involvement	Content adaptations to inclusive research practices
Empathize (map the end users' needs): conducted focus groups to gather insights from end users and performed a literature review to identify user challenges and context		
High	Co-researchers were actively engaged throughout all phases of the focus group (preparation, recruitment, data collection, and evaluation).	Themes for the focus groups were refined collaboratively with co-researchers to ensure inclusiveness by representing diverse care perspectives.
Limited	In the literature review, co-researchers were kept informed, contributed to discussing the research question, and reviewed summaries.	The literature review content was contextualized using insights raised by co-researchers during earlier discussions.
Define: (analyze insights from Empathize phase to create a user profile of the intended end users with the needs and desired experiences): identified and clustered contextual factors into core care intentions and developed an interest framework to capture users' underlying motivations		
Low	Co-researchers contributed to reviewing the contextual factors but were not involved in clustering them.	Terminology and categories were adjusted in response to co-researcher feedback to improve clarity and accessibility for all consortium members.
Moderate	Reasonably active contributions in developing the interest framework were supported through peer conversations and guided sessions.	Interest profiles (summaries of key user motivations) and design missions (goals guiding the design process) were co-developed with co-researchers and refined based on their feedback to ensure alignment with users' real needs.
Ideate (generate a wide range of creative solutions): created user scenarios based on complex care experiences, mapped user journeys and defined functional needs and designed personas (fictional profiles representing typical users), and formed test groups to explore concepts collaboratively		
High	The co-researchers co-created scenarios.	Scenarios were modified to reflect lived experiences and concrete examples provided by co-researchers.
Moderate	Feedback was provided by the co-researchers during sessions on the mapped journey and functional requirements.	Personas and requirements were refined based on feedback from the co-researchers to ensure alignment with real-world user experiences. Tools were used to visualize the input of the co-researchers.
High	Test groups were formed and initiated by a co-researcher.	Recruitment effort via the consortium network resulted in diverse groups, including individuals with lived experience and professionals.
Prototype (create functional designs and explore them through performance and usability tests): created and tested low-fidelity prototypes (simplified early versions) of the sensitive virtual assistant and prepared and submitted an ethical approval application for user testing		
High	The co-researchers actively interpreted and responded to user feedback.	Prototype elements, such as navigation, instructions, and tone of voice, were adapted by the co-researchers during user feedback sessions.
Moderate	A co-researcher supported the drafting of the ethical application to test the prototypes.	Ethical approval documents, such as the information and informed consent letter, were edited in consultation with a co-researcher.
Test (evaluate functional designs with real users to refine and improve the solution): developed 3 functional sensitive virtual assistant versions with different interaction styles and evaluated these versions in real care environments with end users		
Moderate	Co-researchers contributed insights during evaluation sessions, which informed improvements to the sensitive virtual assistant.	Adjustments to interaction styles (eg, tone, responsiveness) in the 3 tool versions were explicitly informed by earlier co-researcher feedback regarding communication preferences.
Moderate	Co-researchers played a key role in guiding the evaluation, interpreting user feedback, and expressing a strong sense of ownership in the process.	Adjustments were made to enhance usability, clarity of instructions, and emotional accessibility based on real-world feedback from participants and co-researchers.

In WP1, the focus group themes and literature review content were collaboratively refined with co-researchers, enabling diverse care perspectives to shape the discussions and ensure inclusive representation and contextual relevance. One consortium member reflected that they unintentionally excluded co-researchers from the later stages of the literature review, as they still saw it as a task that they had to carry out individually: "I did discuss with the co-researchers what would be a relevant

XSL•FO
RenderX

research question, but after that, I unconsciously no longer really involved them because I still had the idea that this was something I had to do myself" [Interview WP1, consortium member 1].

WP2 showed that structured feedback rounds were used to discuss and cluster contextual factors. The process and individual roles were initially unclear to some co-researchers, which led to adaptations to improve task explanation and structure for greater accessibility: "My task was not explained well. This made it unclear what my specific contribution was. We discussed this, and it was clearer afterwards" [Interview WP2, co-researcher 2]. The iterative co-development of an interest framework was supported by facilitation from the researcher; these sessions involved a process of adaptations: "It was very helpful that the postdoc supported the translation of the interest framework so that it could be properly presented, even though it took some trial and error" [Interview WP2, consortium member 3]. Terminology, categories, interest frameworks, and design missions were adapted based on co-researcher input to enhance clarity and alignment with user perspectives.

The scenarios and personas were informed by the co-researchers' concrete input; their contributions reflected real-life situations and ensured the inclusion of diverse user experiences. Tools, like an interactive online board where team members could brainstorm and collaborate, enhanced clarity and enabled their lived experiences to be visibly integrated: "There was a strong sense of contribution; you can see that on the board with all the input we have generated" [Group discussion WP3, co-researcher 3]. One co-researcher illustrated the challenges, caused by strict ethical requirements, regarding the planning of test groups: "I found setting up this plan challenging, especially because of the strict requirements of the ethics committee" [Interview WP3, co-researcher 1].

In WP4, prototype elements and ethical documents were co-developed with co-researchers to support usability, comprehensibility, and accessible communication. Co-researchers' clear understanding of their role, as exemplified during feedback sessions, appeared to support their engagement and involvement in the testing process, as suggested by their proactive participation and comments on ownership: "When testing, I knew exactly what to do, that worked very well" [Group discussion WP3, co-researcher 2]. However, ethical procedures caused frustrations among the team, with 1 co-researcher describing his frustrations: "Meeting all these requirements was time-consuming and sometimes frustrating" [Interview WP4, co-researcher 1].

In WP5, interaction styles and instructional clarity were refined based on participant and co-researcher feedback to improve responsiveness, accessibility, and emotional engagement. The initial design of the functional tool versions was shaped more by prior input than by direct co-creation in this phase, contributing to stress and frustration when delays in deployment occurred: "I really had no idea if it would work; that was stressful" [Interview WP5, co-researcher 1]. Despite this, the testing phase was positively evaluated because of adequate preparation: "My tasks during the testing were clear because the postdoc had provided good explanations in advance" [Interview WP5, co-researcher 2].

Together, the adaptations and accompanying reflections demonstrate that co-researcher involvement shaped not only the content but also the form and accessibility of the research process. They highlight how continuous feedback and flexible collaboration were essential to aligning the design with real-world needs. Overall, accessibility-focused adaptations such as simplified language, smaller group sessions, and pacing adjustments were particularly supportive of the co-researchers, whereas measures like role clarification, structured planning, and consistent documentation were more generally beneficial for all consortium members.

Discussion

General Findings

This study reflects on an inclusive and iterative design approach involving co-researchers with MID or ASD in the development of a digital health tool, examining how inclusive design methods facilitated the development of the tool and shaped collaboration within the consortium. Through adaptations, such as thorough preparation, role clarity, accessible communication, and iterative feedback, co-researchers made meaningful contributions to the inclusive research and design process. Three overarching themes, project approach, collaborative dynamics, and co-design in practice, provided insights into how inclusive collaboration was accommodated throughout different design phases. The inclusive collaboration was supported by structured engagement, cognitive accessibility strategies, and iterative methods, which collectively facilitated a greater sense of ownership and active involvement over time.

This study showed that the use of a flexible, inclusive framework deepened stakeholder engagement and enabled concrete content adaptations through its stepwise approach, in this case through design thinking [22,46]. However, design thinking is not the only framework suitable for inclusive development. Inclusive design frameworks such as design for the whole population by Clarkson et al [47], universal design by Goldsmith [48], and user-sensitive inclusive design by Newell et al [25], offer complementary approaches that emphasize accessibility, user diversity, and context-sensitive solutions. In addition, complementary frameworks such as the CeHRes (Center for eHealth Research) Roadmap [26] and the NASSS (Non-adoption, Abandonment, Scale-up, Spread, and Sustainability) framework [49] are other valuable approaches emphasizing stakeholder alignment and long-term implementation contexts, respectively. The ViP method used to develop the digital tool draws from these traditions and emphasizes collaborative approaches, shared ownership, and flexibility across project phases [21]. Involving co-researchers in the design process made it possible for them to actively influence both the collaborative workflow and the development of the tool itself. This participatory approach not only shaped the structure of the design meetings and the inclusivity of the design materials but also enhanced the value and the applicability of the outcomes [32,50]. This study contributes experiential and theoretical insights into how inclusive design

XSL•FO
RenderX

methods can be operationalized within transdisciplinary (health care) technology development.

Within the flexible and iterative approach, the tension between project efficiency and meaningful inclusion emerged as an ongoing challenge, as it required increased time, support, and adaptive capacity from the team. This tension has also been shown in previous studies, particularly in the context of complex design environments where timelines are tight and deliverables fixed [51,52]. Future research could therefore investigate how inclusive design practices affect collaborative dynamics and decision-making processes in project environments such as planning or iterative technology development. This would help clarify how to balance inclusivity with time constraints and resource limitations and offer practical strategies for managing this tension [31,51]. Understanding the value of shared expectations [53] and how teams navigate this can inform inclusive design processes that aim for meaningful inclusion throughout all phases of research and design [32].

Further, a shift toward co-researcher ownership emerged in the collaboration. In the earlier phases of the project, co-researchers were involved primarily in predefined tasks, whereas, in later phases, they initiated concrete activities such as forming user test groups. This illustrates how lived experience can transition from consulting to initiating in the design process [54]. The active involvement of co-researchers enhanced both the usability and the real-world relevance of the tool. This finding aligns with previous research suggesting that long-term, repeated engagement with end users allows them to influence the design process more deeply and ensures outcomes that better reflect their needs [50,55]. Cognitive accessibility, through visual aids, simplified materials, repetition, and small group formats, was particularly important in early phases and supported the meaningful contributions from the co-researchers [56,57]. This relates to prior literature on accessible formats [52] and dedicated support time [56] in inclusive research and technology development. Future research could further explore how to embed these inclusive practices in technology development projects with interdisciplinary teams and the involvement of co-researchers while maintaining methodological integrity and meaningful participant roles [13,31,32].

Strengths and Limitations

A key strength of this study is its design, which included structured reflection moments after each of the 5 design phases. This approach enabled the participants to share their experiences immediately after each phase while also identifying changes and adaptations across the full design trajectory. Another strength lies in the mixed methods approach, which combined qualitative interviews and group discussions with tailored quantitative questionnaires executed within an inclusive digital platform [14]. Using both experiential insights and continuous group reflections allowed the team to adapt the collaboration dynamically. As a result, the co-researchers could engage more meaningfully, which led to deeper, more context-specific findings [54]. Some limitations must be acknowledged. The study was conducted within a single consortium, working on 1 digital (health) tool in a specific context. Additionally, the relatively small sample size may limit the diversity of perspectives captured and the broader applicability of the results [58]. Therefore, future research should examine other and larger settings.

Recommendations

Drawing from the findings of this study, a set of practical recommendations for researchers and designers aiming to conduct inclusive design with individuals with complex care needs, such as individuals with MID or ASD [59,60], was formulated. These recommendations translate the experiential insights of the inclusive design process into actionable guidance for future research and practice:

- *Engage end users early and continuously*. Involve individuals with MID or ASD from the start of the project and maintain their involvement across all design phases. Early participation fosters ownership, while continuous engagement ensures that adaptations remain relevant as the project evolves.
- *Adapt sessions to fit participants' abilities and needs*. Prepare accessible materials and ensure that meetings are structured, predictable, and easy to follow. Use clear and jargon-free language, concrete examples, and visual supports. Naming, visuals, and text should be recognizable and understandable.
- *Build long-term and trusting relationships*. Sustainable collaboration requires time to establish mutual trust. Create a safe and comfortable setting where participants can meaningfully shape the design process. Especially in early stages, consider including trusted stakeholders (eg, family members or support workers) to facilitate familiarity and confidence.
- *Address power dynamics and clarify roles*. Discuss expectations, roles, and decision-making responsibilities early and explicitly. Move beyond consultation by showing participants how their input has influenced decisions. Continuous reflection and transparent communication strengthen mutual respect and shared accountability.
- *Use methods close to lived experience*. Apply participatory methods that connect to everyday contexts, such as contextual interviews, observations with discussion, cognitive walk-throughs, or think-aloud sessions. Conducting co-creation activities in familiar environments ensures that insights reflect participants' real-life experiences and capacities.
- *Monitor group dynamics*. Be attentive to how participants experience group settings. Some individuals with MID or ASD may find large groups overwhelming. Adjust group size and facilitation to participants' comfort levels and communication styles.

Conclusions

Reflection on an inclusive research and design process revealed that attention must be paid to tensions between project efficiency and meaningful inclusion, underlining the importance of ongoing coordination of the design process, collaboration, and flexibility in transdisciplinary settings. A stepwise approach, such as design thinking, proved helpful in structuring the process, continuous evaluation, and reducing these tensions. Inclusive methods, such as preparatory work, clear roles, accessible materials, and

XSL•FO
RenderX

iterative feedback, supported active engagement throughout the project. These methods led to a shift in ownership, allowing co-researchers to gain more influence and actively shape both the development process and the content of the technology. These findings extend understanding of how inclusive design methods facilitate development processes and provide insights into how to enhance equity and relevance in inclusive technology design for individuals with complex care needs, such as individuals with MID or ASD.

Acknowledgments

We thank the team for participating in the interviews with questionnaires and group discussions.

Funding

This study was funded by the Ministry of Health, Welfare, and Sport, the Netherlands (reference: 325418) and ZonMw (reference: 427003016). The funding sources had no role in the study design, data collection, data analysis, data interpretation, or writing of this report.

Data Availability

Anonymized data is available within the Radboud Data Repository upon reasonable request (eg, for research purposes on a similar topic).

Authors' Contributions

JFEC, KEB, AWCC, JN, and GLL designed the study. JFEC collected the data. JFEC and AWCC conducted the analysis. JFEC and KEB drafted the manuscript. AWCC, KEB, JN, and GLL provided critical feedback, and all authors provided critical inputs on multiple iterations. All authors have approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Informal caregivers (ICs), often family members or close friends, provide essential support to individuals with head and neck cancer. However, they are frequently unprepared for the emotional, practical, and medical challenges involved. Web-based applications offer promising opportunities to support ICs, but their long-term adoption and acceptance remain uncertain.

Objective: This paper presents the development of Carer eSupport, a web-based application to support ICs' well-being and preparedness for caregiving. We detail the design and functionality of the Carer eSupport application and explain how it responds to both the functional and psychological needs of ICs. Additionally, we report findings from the pilot study and highlight the initial challenges ICs faced when engaging with the application, along with the strategies used to overcome them.

Methods: The study involved a multicenter research trial across ear, nose, and throat clinics and oncology and radiotherapy clinics at 4 university hospitals in Sweden. The application was developed through 3 human-centered design (HCD) iterations involving ICs, health care professionals, and researchers in human-computer interaction and cancer care.

Results: The results present an overview of the current version of Carer eSupport (developed during the third design iteration), with a focus on features that address the psychological needs of ICs, including competence, autonomy, and a sense of connection to others. The pilot study achieved a 66.7% (20/30) consent rate, a 75% (9/12) successful login rate among participants, and a 13.3% (4/30) attrition rate, meeting the established criteria. The pilot study confirmed the application's readiness for further evaluation in an ongoing randomized controlled trial. It also identified challenges, including the time constraints of ICs, login and authentication issues, limited IT infrastructure, and gaps in digital literacy.

Conclusions: Findings from the HCD process and pilot study indicate that a personalized, interactive application like Carer eSupport can provide meaningful support for ICs of individuals with head and neck cancer. The integration of HCD and health care science offers early guidance for developing digital tools that are both evidence-based and empathetic, with potential relevance beyond caregiving contexts.

Introduction

Background

Health care systems worldwide face mounting pressure as they contend with limited resources and the increasing care needs of an aging population [1,2]. These strains are particularly evident in home-based care, where access to professional support is often limited. In cancer care, the shift from hospital-based treatment to outpatient and home settings has transferred much of the day-to-day responsibility to family members and close friends [3,4]. These individuals, commonly referred to as informal caregivers (ICs), provide unpaid support and are often the primary source of informal care for people with cancer [5,6]. They often struggle to navigate their roles because they lack access to the essential information, guidance, and resources needed to provide adequate care at home [7-10].

The emotional and physical toll of caregiving can be significant, affecting ICs' overall well-being. It often leads to mental health challenges such as anxiety, depression, and symptoms of post-traumatic stress [11-15]. Over time, ICs may begin to lose a sense of their own identity as their lives become increasingly centered around the illness of their patients. These difficulties are made worse when the support systems and information needed to manage care at home are limited or hard to access [16]. Therefore, ICs often express a strong need for external support and guidance to feel more confident and capable in their roles [17,18]. This is where the concept of preparedness for caregiving becomes relevant. Preparedness refers to ICs' perceived ability to provide physical and emotional support while also managing the stress of caregiving [19]. Higher levels of preparedness have been linked to lower caregiver burden and better outcomes for both ICs and patients [3]. Given these challenges, digital tools such as web-based applications offer promising opportunities to support ICs. These eHealth systems can serve as accessible platforms for delivering tailored information, emotional support, and practical guidance to those providing cancer care at home [12,16]. However, acceptance and use of eHealth systems remain uncertain, highlighting the need for further research on design strategies that ensure the meaningful involvement of relevant stakeholders throughout the development process [20-23].

Human-centered design (HCD) is a foundational approach for developing technology in the human-computer interaction (HCI) field. HCD emphasizes placing users' needs, preferences, and contextual factors at the core of the design and development process to create effective and user-empowering systems [23]. Even though HCD is widely accepted and used, it often falls short of meeting users' specific needs, making them feel disconnected and unsupported [24,25]. One major reason for this gap is how HCD is applied. When used in a limited or inconsistent way, especially without genuine and ongoing stakeholder involvement, it can become more of a label than a clear design method. Consequently, although HCD holds significant potential to enhance the usefulness and user-friendliness of technology, its impact remains limited when it is not implemented consistently and systematically in practice [25-28].

The HCD process has primarily focused on usability and functionality, but there is growing recognition that technology should also support users' well-being [29-34]. Well-being is a multifaceted concept that includes physical health, mental and emotional stability, social relationships, economic security, access to education and health care, environmental conditions, cultural aspects, personal safety, and overall life satisfaction [35]. People tend to use technologies that satisfy their functional needs and enhance their physical and psychological well-being [34]. In the field of psychology, well-being is often understood in two ways. Hedonic well-being is about feeling good, seeking pleasure, and avoiding discomfort. On the other hand, eudaimonic well-being is about personal growth, having a sense of purpose, and reaching one's full potential [36,37]. Eudaimonic motivation is a person's inner drive to grow, learn, and seek meaningful experiences in life [36]. Research on hedonic aspects is more established. For instance, the well-known extended Unified Theory of Acceptance and Use of Technology (UTAUT2) model evaluates technology acceptance by integrating hedonic motivation as a key factor in technology acceptance and use [38]. However, there is a noticeable scarcity of research that explicitly examines how eudaimonic motivation can be systematically integrated into the HCD process [39-42].

Some recent studies have sought to evaluate eudaimonic motivation quantitatively [33,42,43]. For instance, Woźniak et al [42] combined insights from psychology to develop the Eudaimonic Technology Experience Scale, which aims to quantify the meaningful interaction of users. Similarly, Kuriakose and Nagasubramaniyan [39] extended UTAUT2 to assess the acceptance of digital entertainment applications. Despite some attempts to evaluate eudaimonic motivation quantitatively, a significant gap remains in the qualitative understanding of how eudaimonic motivation influences technology acceptance and use, particularly in complex and emotionally sensitive domains such as caregiving for relatives with serious diseases. Moreover, these studies focus exclusively on the evaluation phase of the HCD process. This study integrates eudaimonic perspectives from the early stage of the HCD process, with the aim of supporting users' psychological well-being.

The Carer eSupport Project

Carer eSupport is a multidisciplinary project combining HCI, software engineering, cancer nursing, and medical and health care science expertise. It seeks to develop a web-based application that improves ICs' preparedness for caregiving and promotes their overall well-being [3,44]. By equipping ICs with targeted, accessible, and user-friendly resources, the project aims to reduce caregiver burden and positively support the overall health of individuals with head and neck cancer (HNC).

We applied the integrated HCD process with a eudaimonic perspective to guide the development and evaluation of Carer eSupport. The HCD process involved 3 iterative cycles, engaging ICs, health care professionals (HCPs), an expert group of ICs, and technology designers and developers. The collaboration of different stakeholders enabled us to continuously refine the application to understand and address

XSL•FO
RenderX

the practical and psychological needs of ICs. The project is currently conducting a randomized controlled trial (RCT) to evaluate the effects of Carer eSupport on ICs' self-reported preparedness for caregiving, caregiver burden, and well-being, compared to support as usual [44]. A pilot study was conducted at the early stage of the RCT to investigate the feasibility of the procedures and the current version of Carer eSupport. This paper presents the results of the pilot study, which determined whether it was appropriate to proceed with the full-scale RCT.

Study Aim

This paper aims to present how a web-based application can be designed to support ICs' well-being and preparedness for caregiving through the HCD process. We detail the design and functionalities of the Carer eSupport application and explain how it responds to both the functional and psychological needs of ICs. By integrating HCD with a eudaimonic perspective, this research also intends to provide insights into design approaches that prioritize user well-being in web-based application development.

Additionally, we report findings from the pilot study and highlight the initial challenges ICs faced when engaging with the application and the strategies used to overcome these issues.

Methods

Development of Carer eSupport

Human-Centered Design Process

We conducted 3 iterations of the HCD process to develop the Carer eSupport application. HCD is an iterative approach that prioritizes users and other stakeholders at the core of the design process [45]. This iterative process ensured that the application addressed the needs of ICs by incorporating their direct feedback in different design phases. As highlighted in previous research [46,47], continuous refinement based on user input enhanced usability, relevance, and support for both the practical and psychological challenges of caregiving.

The first step in the HCD process involves understanding users and their context through comprehensive research methods, including interviews, observations, surveys, and focus groups, to define user requirements. Thereafter, the design team defines the problem and establishes specific requirements based on these insights. They then produce design solutions through brainstorming and concept development, which are evaluated through user testing to assess usability, functionality, and overall satisfaction. The design is iteratively refined based on feedback until the final product effectively meets user needs and expectations [48].

As a multidisciplinary project combining health care research and computer science expertise, we integrated health care research methods, such as feasibility studies and RCTs, with HCD to develop and evaluate Carer eSupport. In the following sections, we detail the 3 iterations that shaped the final version of the application. Findings from the first and second iterations have been presented in detail elsewhere [15,49]. This study primarily focuses on the third iteration, with its key findings presented in the Results section. Table 1 provides an overview of all 3 HCD iterations, including the major activities conducted and a summary of their outputs during the design and development of Carer eSupport.

Table . Overview of the human-centered design (HCD) iterations in the development of Carer eSupport.

HCD iterations	Key activities	Outputs
1: Prototype design	• Focus groups • Prototyping • Developed the initial content of Carer eSupport • Evaluation with the expert group of ICs[a]	Interactive prototype and initial content of Carer eSupport
2: Feasibility study	• Developed the initial version of Carer eSupport • Mixed methods evaluation (surveys, application usage logs, interviews) • Extended the UTAUT[b] model with eudaimonic motivation	Confirmation of the feasibility and acceptability of Carer eSupport and suggestions for improvements before the randomized controlled trial
3: Pilot study	• Developed the current version of Carer eSupport • Pilot study evaluation	Confirmation to continue the full-scale randomized controlled trial and improvements of its procedures

[a]ICs: informal caregivers.

[b]UTAUT: Unified Theory of Acceptance and Use of Technology.

Iteration 1: Prototype Design

Understanding ICs' Needs and Specifying Their Requirements

To identify the challenges and needs of ICs, we conducted focus groups with ICs and HCPs. These sessions provided essential insights into user preferences and the functional requirements for the Carer eSupport application. In this iteration, we explored both hedonic and eudaimonic aspects of well-being. Using a deductive thematic analysis, we examined factors such as virtue, autonomy, competence, relatedness, achievements, and engagement derived from the focus group data. Our findings

XSL•FO
RenderX

indicate that pleasure, as a component of hedonic motivation, is not applicable in the caregivers' context—a point we discussed in detail in our previous study [49].

Three main stakeholder groups took part in this phase. ICs shared their experiences and highlighted the complexity of caregiving, stressing the need for support in patient care and their well-being. HCPs, including nurses, doctors, dietitians, and speech therapists, ensured the application was clinically relevant. A caregiver expert group also reviewed the content in several sessions and gave feedback that helped refine and improve the application. This expert group comprised ICs who had more extensive and continuous involvement in the design process, working closely with the research team to review, discuss, and refine both the application structure and its content. Their role differed from that of ICs participating in focus groups or later study phases, such as the feasibility study and the RCT, as they were engaged in repeated sessions and contributed more deeply to design decisions. In recognition of their sustained contribution and level of engagement, members of the expert group were financially compensated for their participation.

Prototype Development

Building on these insights, we developed an interactive prototype of Carer eSupport using Figma, a collaborative tool for designing and evaluating responsive prototypes [50]. The prototype was created to address the identified needs and preferences of ICs. It included key functions such as information on HNC treatment, resources to support ICs' well-being, a web-based discussion forum, and an online meeting space. The project team reviewed all the functionalities collaboratively to ensure they aligned with user requirements.

Prototype Evaluation

The caregiver expert group preliminarily evaluated the prototype. To collect their feedback, 2 meetings were organized, 1 online and 1 in person. During the online meeting, 2 health care researchers and the HCI researcher presented the initial prototype, along with early versions of the portal content, to the expert group.

The second meeting was a full-day, in-person session held at Uppsala University. During the first 2 sessions, the group was introduced to the application's video content, including demonstrations, lectures, and presentations. These sessions enabled discussion of the relevance and usefulness of the materials for caregiving. In a subsequent session, the prototype's main functions were demonstrated, which supported more detailed feedback on usability and navigation.

The expert group reported overall satisfaction with the interface but also identified areas for improvement in both content and functionality. Their suggestions were incorporated into the design, and the prototype was refined before proceeding to the feasibility study in the second iteration of the HCD process.

Iteration 2: Feasibility Study

Development of the Initial Version of Carer eSupport

Based on feedback from the first iteration, the initial functional version of Carer eSupport was developed and structured around 3 major categories. The first category provides educational content on HNC diagnosis, treatment, and management. All the content was provided through text and video to facilitate diverse user needs. The second category provides critical interventions and practical advice on managing symptoms, side effects, and caregiving challenges, focusing on areas such as oral health care, nutrition, and fatigue. The third category, Self-Care for ICs themselves, provides resources to support ICs' well-being by addressing issues such as everyday life support, sleep difficulties, tiredness, and a diary for finding balance. All content was curated in collaboration with HCPs and researchers specialized in HNC to ensure clinical accuracy and relevance.

Evaluation of Initial Version Carer eSupport

A feasibility study using a mixed methods approach was conducted in accordance with the Medical Research Council's guidelines for developing and evaluating complex interventions [51]. Quantitative data, such as survey responses and application log usage, were combined with qualitative insights from semistructured interviews [44]. The evaluation confirmed the application's relevance, acceptability, and usability, with recommendations for further refinement. Positive feedback from ICs also highlighted the application's potential to support their caregiving responsibilities and to improve their well-being. We also extended the UTAUT model in the feasibility study by integrating the eudaimonic motivation construct and proposed an extended UTAUT framework for analyzing the application's impact on ICs' well-being.

Iteration 3: Pilot Study

In the third iteration of the HCD process, building on insights from previous iterations, the current version of Carer eSupport was developed and is currently being evaluated through an ongoing RCT [44]. Widely considered a gold standard for examining the effectiveness of interventions in health care and behavioral research [52], RCTs use a rigorous methodology where study participants are randomly assigned to either an intervention group or a control group. The random allocation of participants ensures an unbiased comparison by minimizing the influence of confounding variables and helps researchers establish a causal relationship between the intervention and its outcomes [53]. Before proceeding to a full-scale RCT, the last step was to conduct a pilot study to evaluate feasibility, refine procedures, and assess the application's potential for large-scale implementation. Although this paper outlines the entire HCD process for designing and developing Carer eSupport, it primarily focuses on the outcomes of the third iteration, the pilot study.

Procedures

In this section, we present the procedures for the RCT and pilot study conducted in the third iteration of the HCD process. Patients aged 18 years or older with HNC scheduled to receive radiotherapy with or without surgical or oncology medical treatment were identified and screened by nurses from ear, nose, and throat or oncology and radiotherapy clinics. Eligible patients were approached by a clinical or research nurse, in person or by telephone, and were provided with detailed information about the study. Consent was obtained to contact an IC nominated by

XSL•FO
RenderX

the patient and access information from the medical record about the HNC diagnosis, treatment, and outcome.

Once the patient provided informed consent, the identified IC was contacted using their preferred method (in person, by telephone, or by email) and was provided comprehensive information about the study before obtaining their oral and written consent. Enrolled ICs were then provided with credentials to complete an internet-administered baseline assessment. These credentials included a web address, a unique user ID, a temporary password, and a detailed user guide with screenshots to facilitate navigation. After completing the baseline assessment, ICs were randomly assigned to 1 of 2 participant groups: (1) the Carer eSupport plus standard care group or (2) the standard care-only group. ICs in the Carer eSupport plus standard care group received additional login credentials to engage with the application. The data collection methods, including the primary outcome (preparedness for caregiving), secondary outcomes, and assessment points, are presented in detail in the study protocol [44].

Pilot Study Analysis

A pilot study was conducted to confirm the feasibility of the study procedures and the Carer eSupport application. Pilot studies in RCTs are essential for gauging the likely success of the main trial and, if needed, refining its design [54]. Thirty ICs participated in this phase. Feasibility was analyzed using predefined progression criteria to determine whether the study could proceed to a full-scale RCT. These criteria were as follows: at least 45% of eligible ICs providing written consent, at least 50% actively using the Carer eSupport application, and an attrition rate below 30% one month after randomization. Meeting these benchmarks would allow the study to proceed to a full-scale RCT; otherwise, recruitment would be discontinued. If the criteria were not met, ICs assigned to the Carer eSupport plus standard care group would retain access to the application for the entire 18-week intervention period. However, no further follow-up assessments would be conducted. Please refer to the study protocol for more detailed insights into the study methods and procedures [44].

In addition, qualitative data were collected and analyzed during the pilot study. One week after the login details were distributed, ICs who had not logged in were contacted by telephone to check whether they required assistance. Two researchers conducted these calls and took detailed notes, which were discussed jointly to ensure a shared understanding of the content. One researcher then analyzed the notes using thematic analysis following Braun and Clarke's framework [55]. The analysis involved familiarization with the data through repeated readings, generation of initial codes, and organization of these codes into broader themes. Themes were iteratively reviewed and refined to ensure they were grounded in the data and aligned with the study aims. The final set of themes was discussed and agreed upon within the research team, which strengthened the credibility and trustworthiness of the analysis.

Ethical Considerations

All research procedures in the project were approved by the Swedish Ethical Review Council (Dnr: 2020-04650), and the feasibility evaluation is also registered on ClinicalTrials.gov (NCT05028452). The feasibility study was registered at ClinicalTrials.gov (NCT05028452), and the RCT is also registered at ClinicalTrials.gov (NCT06307418).

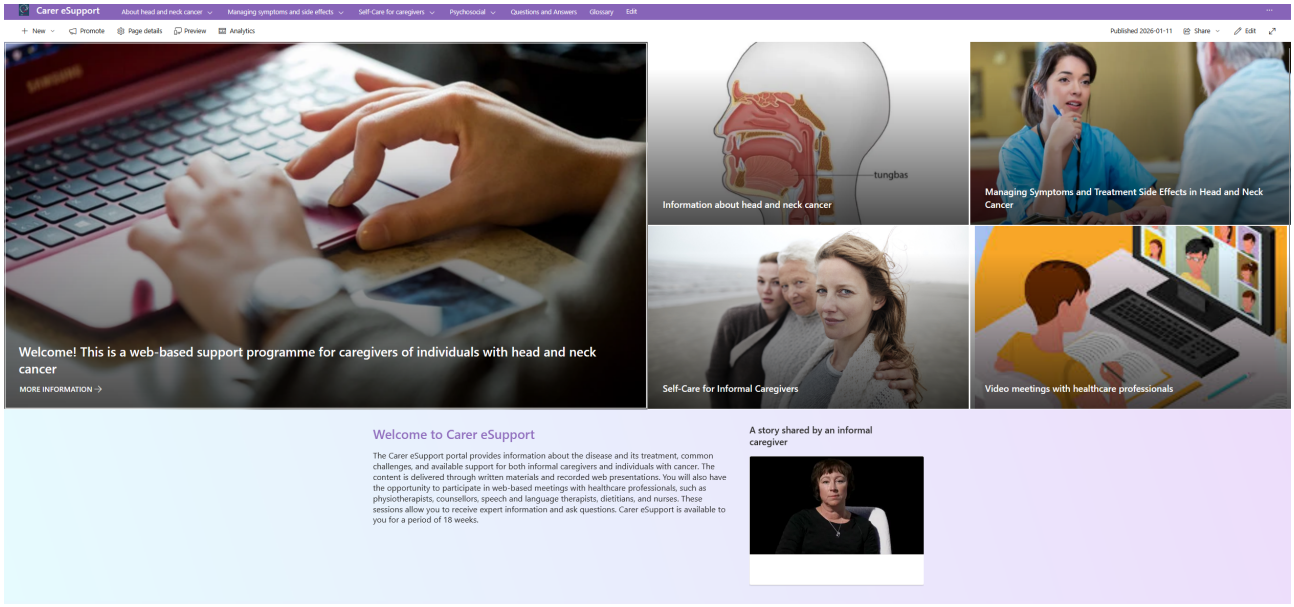
Informed consent was also obtained from patients, their ICs, and HCPs before their enrollment in the study. Before participating, ICs received a written information letter outlining the study's purpose and data collection procedures and signed an informed consent form. In addition, a verbal explanation was provided prior to the focus groups and interviews to ensure participants had a clear understanding of the study. No compensation was provided to the participants in this study.

Safeguarding anonymity and privacy was a key ethical priority. Participants were informed that no identifiable personal information would be disclosed in any publications or reports. All interviews were audio- and video-recorded and transcribed verbatim. The recordings were stored securely in Uppsala University's database and were accessible only to authorized members of the research team.

Results

Overview

This section first gives an overview of the current version of the Carer eSupport application, developed during the third iteration of the HCD process. We present the application's main modules and explain how the eudaimonic perspective is integrated into them. It serves as a practical example of how a web-based application is developed using an iterative HCD process, with a special focus on eudaimonic motivation to enhance ICs' well-being and improve their preparedness for caregiving. We then present the findings from the pilot study, which indicate that the predefined progression criteria were achieved, supporting the continuation to a full-scale RCT. Finally, we present the initial challenges ICs faced during the pilot study phase when using the application and describe the strategies implemented to improve its usability and accessibility.



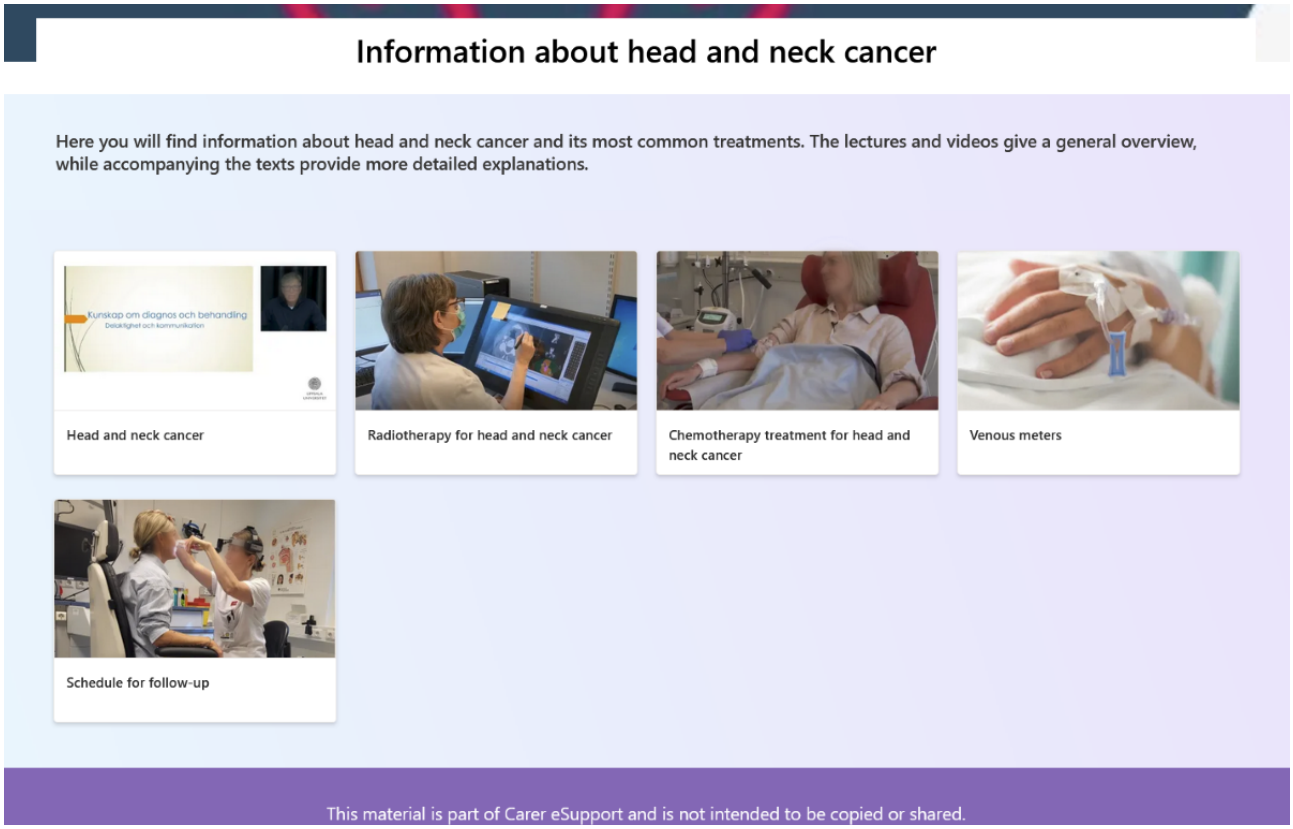
Carer eSupport Application

Overview

The main page of Carer eSupport is organized into 5 modules: Information About HNC, Managing Symptoms and Side Effects of HNC, Self-Care for ICs, Psychosocial Support for ICs, and Interactive Video Meetings with HCPs and ICs (see Figure 1). In addition to these modules, the application features a Frequently Asked Questions section. This section addresses common queries related to HNC, caregiving, and the broader health care system. A glossary is provided to clarify medical terms and expressions, which helps ICs understand complex information with greater ease. Most of the content is provided in multiple formats, including lectures and written text, allowing ICs to choose the format that is easier for them. The application was initially developed in Swedish; however, the main page and module pages were explicitly translated into English for this paper to support a broader audience. To protect participants' privacy, all screenshots were anonymized by blurring any faces that could lead to identification.

XSL•FO
RenderX

Figure 1. The main page of Carer eSupport.



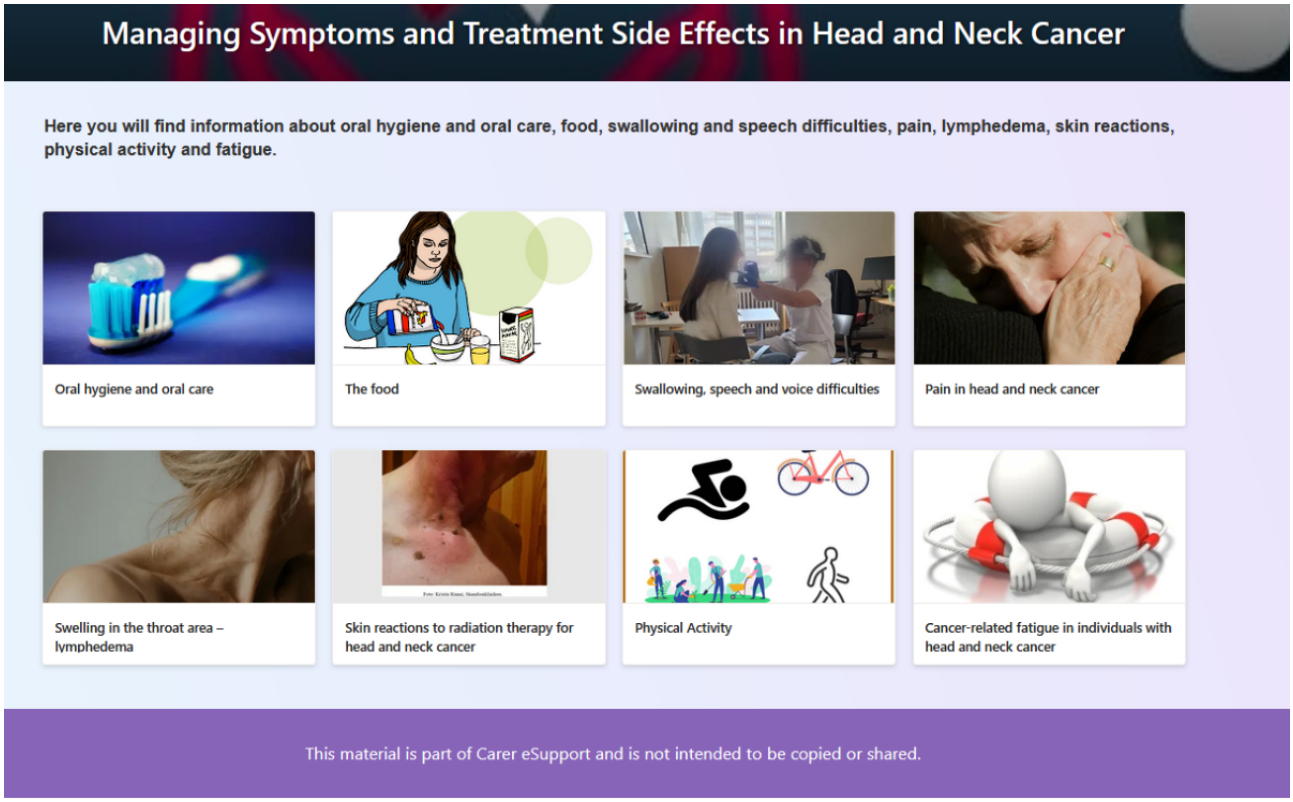
Information About HNC

This module, as presented in Figure 2, provides a comprehensive resource on HNC and its common treatments to enhance the preparedness of ICs. It is designed to empower ICs by offering precise and detailed information on HNC and its treatment options, thereby improving their ability to manage the consequences of the disease and its treatment. The module addresses different aspects of HNC care and is anticipated to enhance a sense of competence and help ICs make autonomous and informed decisions aligned with a eudaimonic perspective.

The module is organized into 5 sections. The first section offers an overview of HNC, presenting essential information about the disease, its risk factors, and its typical progression. The following sections focus on treatment-specific details. One section provides a detailed explanation of radiation therapy, outlining its protocols, potential side effects, and strategies for managing these effects. Another section in this module is dedicated to chemotherapy, describing treatment regimens and common adverse reactions and offering practical advice for supporting patients during this modality. Moreover, the module includes guidance on using and managing venous catheters and presents the best practices to ensure patient safety. The final section, a follow-up schedule, explains the purpose and importance of each posttreatment visit and equips ICs with the knowledge necessary to support patients effectively during recovery.

XSL•FO
RenderX

Figure 2. Module for information about head and neck cancer.



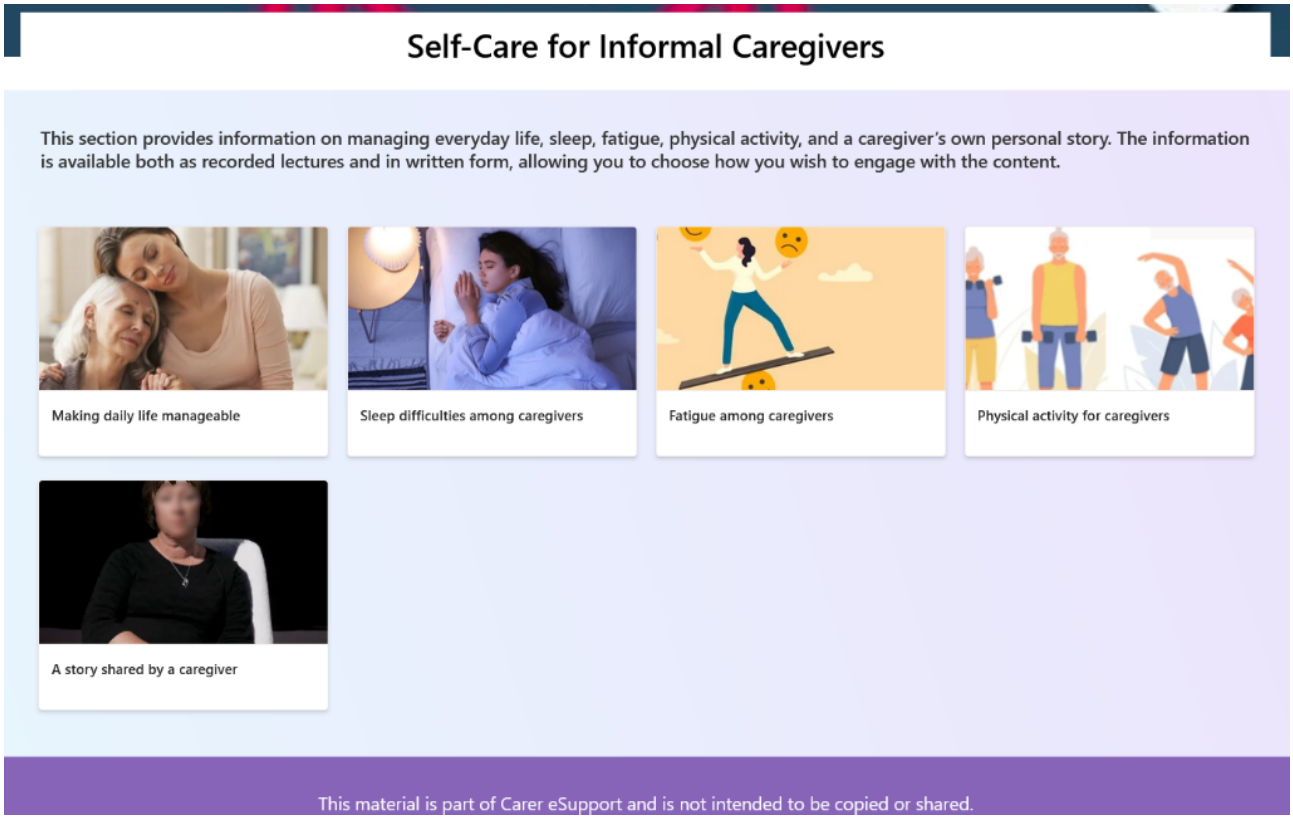
Managing Symptoms of HNC and Side Effects of Treatments

This module is designed to better prepare ICs for the challenges of HNC by providing detailed guidance on managing the symptoms and side effects commonly experienced by patients (as presented in Figure 3). Structured into 8 sections, the module addresses key areas such as oral hygiene, providing detailed recommendations for maintaining oral health, especially after reconstructive surgery and radiotherapy. It includes guidance on nutrition, with a focus on dietary adjustments during treatment, along with resources like a recipe bank and information on feeding tubes.

Support is also offered for issues related to swallowing, speech, and voice, presenting practical strategies to manage these difficulties. The module includes targeted advice for pain relief and approaches to managing lymphedema, including recommendations for reducing swelling during or after radiation therapy. Strategies to mitigate skin reactions caused by radiation are outlined as well. Furthermore, it provides tailored approaches to maintain an active lifestyle that supports overall well-being. It offers insights and practical strategies to manage cancer-related fatigue, ensuring that ICs can support patients and themselves throughout treatment.

XSL•FO
RenderX

Figure 3. Module for managing symptoms and side effects.



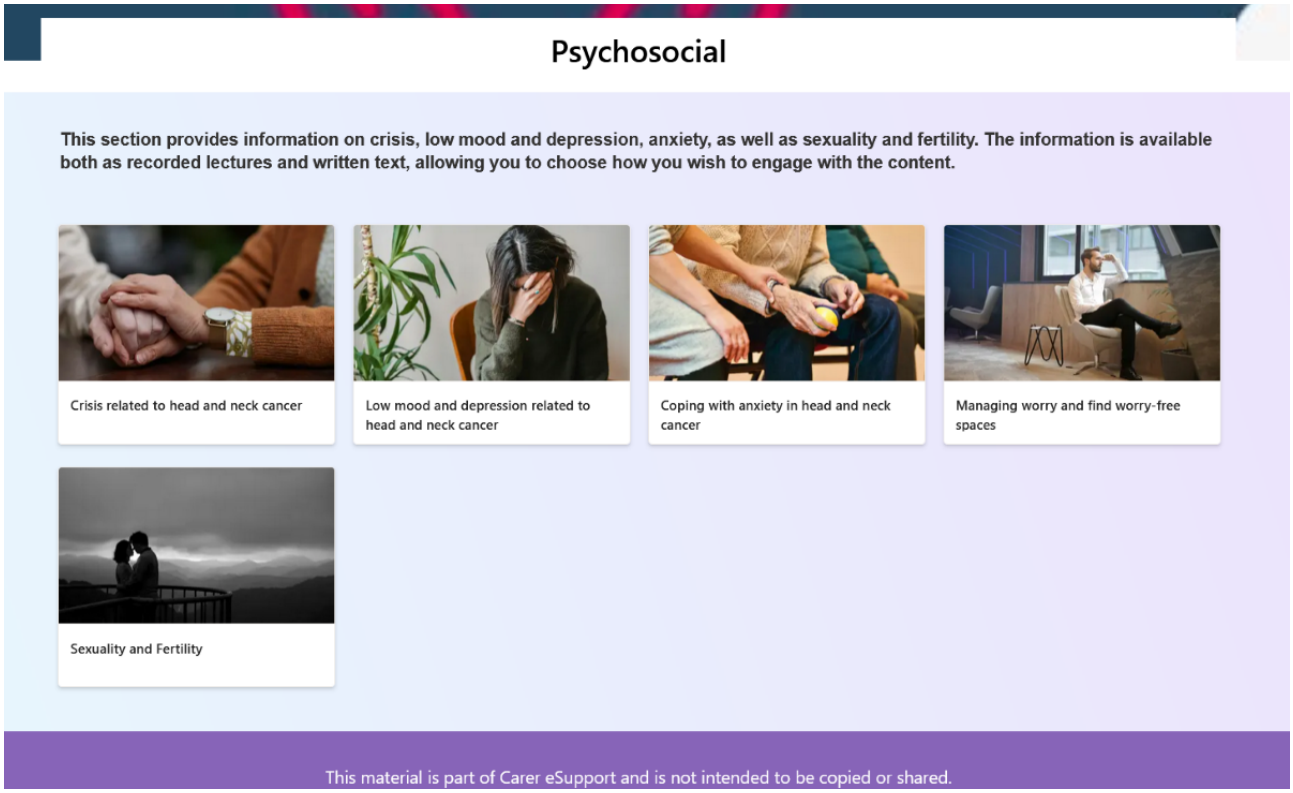
Self-Care for ICs

This module, as shown in Figure 4, supports the physical and psychological well-being of ICs by addressing everyday challenges such as managing routine tasks, sleep difficulties, fatigue, and the need for physical activity. The module is divided into 4 sections. It first provides strategies for adapting to life changes following an HNC diagnosis and then offers recommendations for overcoming common sleep issues. It also tackles exhaustion by introducing practical tools like a diary and a daily activity log to help balance responsibilities and self-care. It also emphasizes the benefits of maintaining an active lifestyle through regular physical activity.

Additionally, a personal story from an IC offers valuable insight into the emotional and physical challenges of caregiving, which may create empathy and a more profound understanding among ICs. The module promotes a eudaimonic perspective by strengthening ICs' sense of competence and personal growth. Providing ICs with practical knowledge and strategies helps them feel more confident and capable, which may contribute to their well-being and resilience.

XSL•FO
RenderX

Figure 4. Module for informal caregivers' self-care.



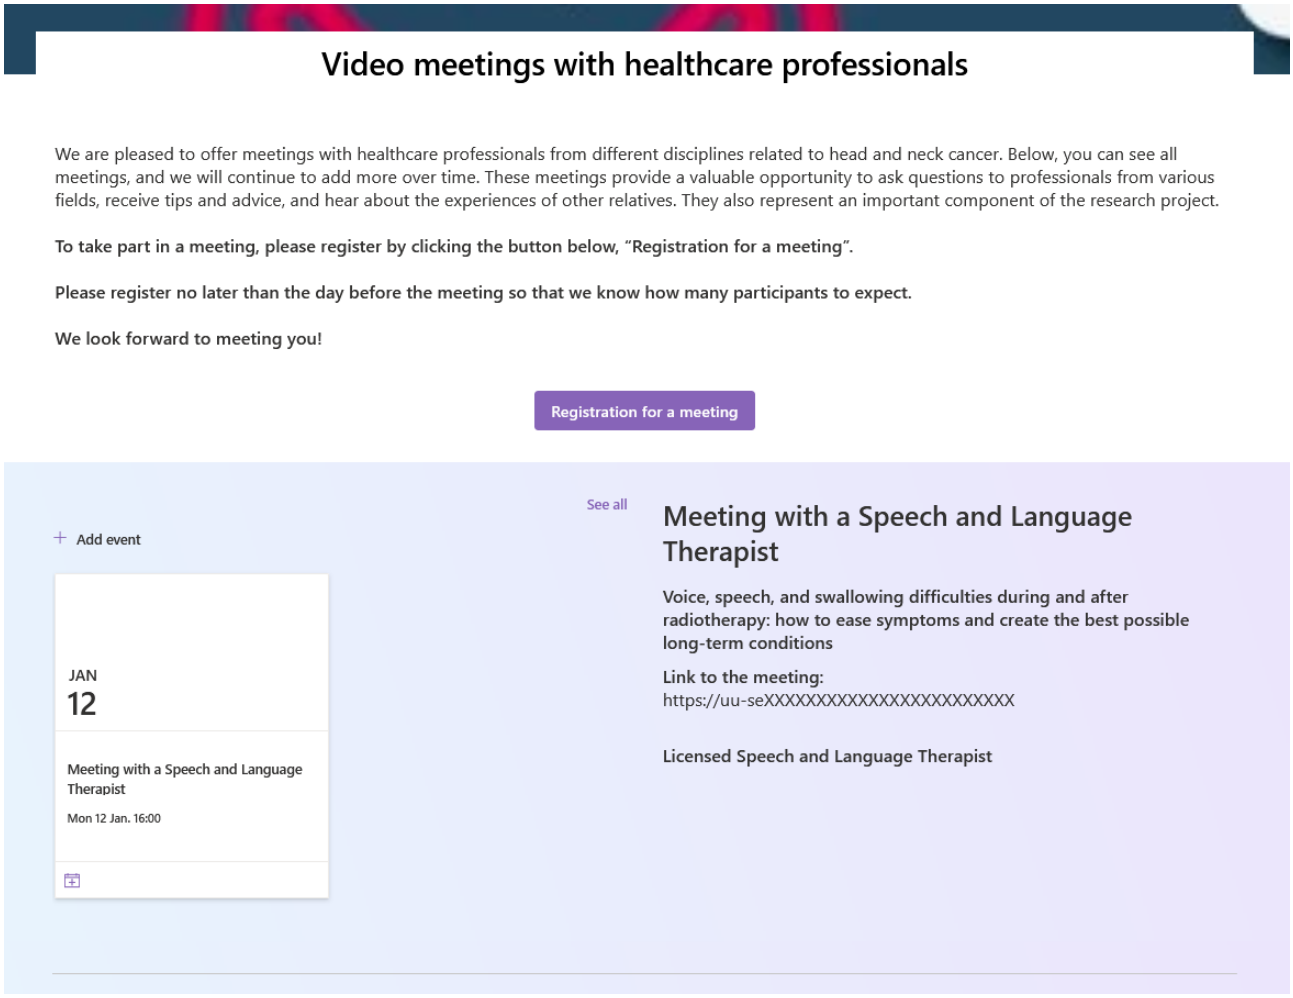
Psychosocial Support

The Psychosocial Support module, shown in Figure 5, is designed to enhance the emotional and psychological well-being of both ICs and patients by offering practical strategies for managing emotional health. This module is divided into 5 sections. It first addresses crisis reactions by providing coping strategies for the immediate psychological challenges during diagnosis and treatment. It then explores sadness and depression, offering guidance on recognizing and managing these emotions effectively. The following sections focus on anxiety, presenting practical strategies for managing worry and stress while also offering advice to create calm environments and concluding with an examination of the impact of cancer on sexuality and fertility, providing support for those affected by these issues.

From a eudaimonic perspective, each section is intentionally crafted to promote personal growth and to effectively prepare ICs to navigate the psychological challenges that accompany significant life changes. Beyond aiding emotional regulation, the module aims to empower ICs with a deeper sense of meaning and control in their roles. By reframing their experiences as opportunities for personal development, this approach may enhance resilience and improve their ability to cope with the demands of caregiving.

XSL•FO
RenderX

Figure 5. Module for psychosocial support.



Video Meetings With HCPs

This module allows participants to meet with HCPs from various fields related to HNC (Figure 6). These sessions allow ICs to ask questions, receive expert advice, and connect with others facing similar challenges. The module offers flexible participation options by allowing ICs to join meetings with or without video and remain anonymous if preferred, ensuring better accessibility and alignment with a eudaimonic perspective. This flexibility caters to diverse comfort levels with technology and fosters a safe space for open engagement.

Recognizing that meaningful community relationships are central to eudaimonic well-being, the design of these virtual sessions encourages ICs to share their experiences, ask questions, and engage in group discussions. Such interactions provide practical guidance while nurturing deep interpersonal connections that enhance emotional support and validation. Occasionally, sessions include short presentations or lectures, with details provided in advance on the application. ICs are encouraged to attend multiple meetings to reinforce learning and maintain access to relevant information. Additionally, they can email questions to HCPs anytime, receiving responses from nurses or other specialists, further strengthening their support system throughout caregiving.

Result From the Pilot Study

The results from the pilot study were satisfactory and met the established progression criteria with a good margin (Figure 7). Among the 30 participants, 20 (66.7%) ICs and 17 (56.7%) patients provided written consent. A total of 12 ICs were randomized to receive access to the application, and 9 out of these 12 (75%) successfully accessed the application. Additionally, 4 out of 30 (13.3%) participants discontinued their study participation.

Challenges and Suggestions to Improve Usability and Accessibility of Carer eSupport

Overview

One week after sending the login details, we contacted participants who had not yet logged in to determine whether they required assistance. In this section, we summarize feedback from ICs regarding their experiences with Carer eSupport. Key challenges included time constraints due to the demanding nature of caregiving, communication barriers, login and authentication difficulties, limited IT knowledge, and inadequate access to proper IT infrastructure. To address these challenges and improve the application's usability and accessibility, we implemented a range of solutions, as detailed below.

Demanding Nature of Caregiving

Due to their ongoing responsibilities, many ICs struggled to find the time and energy to learn new technology. Some of them noted that when their relatives were recently diagnosed with HNC and undergoing treatment, they had little opportunity to engage with the application. Follow-up contacts acted as gentle reminders, prompting them to log in once their situations stabilized. For example, one participant explained that although they could not access the application initially due to pressing concerns, a subsequent reminder enabled them to log in after their circumstances had calmed.

Communication Problems

Communication barriers with ICs also hindered their engagement with the application. Some ICs reported not receiving the initial email with their login details or finding it in their spam folder, which delayed access. To resolve this, we implemented a multichannel communication strategy by sending login details via email and SMS text messaging, making follow-up phone calls to clarify any issues, and offering real-time troubleshooting. It reduced delays in accessing the application and helped build trust with the users.

Login and Authentication Problems

Several ICs experienced difficulties logging into the application. Since Carer eSupport is built on Microsoft SharePoint, users with existing Microsoft accounts sometimes encounter conflicts, leading to errors when the wrong account is used for authentication. In addition, the 2-factor authentication process proved confusing for many users. To address these challenges, we updated the login instructions and tutorials and produced a video tutorial demonstrating the correct login procedure step by step. These improvements reduced errors to some extent for the users, and more users accessed the application without help from the support team.

Access to IT Infrastructure

Some participants faced challenges due to inadequate access to appropriate devices for using Carer eSupport. A few lacked a private computer and relied on work computers or smartphones, which sometimes imposed restrictions that prevented them from logging in. One participant, who relied solely on a smartphone, repeatedly had difficulty entering their username and password, resulting in failed login attempts and further complicating access. As we were unable to provide additional IT infrastructure during the study, we addressed these challenges through extensive telephone-based support. With this support, ICs were eventually able to access the portal. However, access would likely have been more straightforward if a computer or tablet had been available.

XSL•FO
RenderX

Limited IT Knowledge

The limited IT knowledge of ICs emerged as a barrier, particularly among older ICs or those with minimal technical experience. Navigating a new digital application can be overwhelming for ICs who are not tech-savvy. To mitigate this problem, we provided them with telephone support and developed clear and concise tutorials, demonstrating the login process and easy access to the application.

Discussion

Principal Findings

This study introduced an integrated HCD process that incorporated eudaimonic perspectives to develop the Carer eSupport application to improve ICs' preparedness for caregiving and enhance their well-being. Our findings demonstrate that IT applications like Carer eSupport can be effectively developed through a multidisciplinary approach that integrates health care science and HCI methodologies. As a web-based application, Carer eSupport required complementary insights from HCI, mainly through an iterative HCD process, to ensure usability and user acceptance. This integration bridges conventional health care research with HCI, developing evidence-based and user-centered technologies, as supported by recent research [56]. To our knowledge, the Carer eSupport project is the first to use this strategy to support ICs of individuals with HNC.

A well-known challenge in HCI, and one central to this work, is balancing personalization with generalization [27,57]. Technologies that reflect ICs' own situations are often perceived as more useful and engaging. For this reason, the HCD approach used to develop Carer eSupport focused on understanding ICs' specific needs and caregiving contexts related to HNC. At the same time, practical constraints related to time, resources, and technical feasibility limit the degree of personalization that can be achieved [28,45]. HCI research recognizes that users may differ in their abilities, preferences, values, and life circumstances. HCD processes, therefore, begin with methods such as interviews and focus groups to identify human needs, which are then translated into requirements, personas, and scenarios. However, it is not feasible to design a separate system for each IC. Instead, design efforts focus on groups of ICs that share key characteristics while allowing variation within those groups. This tension was evident during the design of Carer eSupport. ICs preferred content reflecting their own HNC caregiving experiences, while HCPs emphasized the need for practical, sustainable solutions. The final design represents a pragmatic compromise, offering HNC-specific content at the user-group level while remaining relevant to a broad range of caregiving situations.

In this study, we presented the major modules and functions of the Carer eSupport application, explicitly incorporating the factors that may enhance the eudaimonic motivation of ICs. This was a challenging task due to the existing research's broad and often vague definitions of eudaimonia. Previous research also highlighted that eudaimonic well-being is inherently subjective and can vary significantly from one individual to another [49,58]. For future research, it is essential to contextualize eudaimonic perspectives according to the user group and the contexts in which they interact with technology [17,43,49]. Otherwise, as noted in previous studies, eudaimonia risks becoming a buzzword without precise, practical implementation, despite its importance in technology adoption [27,41].

Our pilot study yielded promising results, with a 66.7% consent rate, a 75% successful login rate among randomized participants, and a low attrition rate of 13.3%. These outcomes met established progression criteria and confirmed the application's readiness for a full-scale RCT. The study also provided important insights into usability challenges. ICs reported limited time due to demanding caregiving responsibilities, delays in receiving login details, difficulties with authentication, restricted access to suitable IT infrastructure, and limited digital literacy.

We provided multichannel communication via email, SMS text messaging, and follow-up phone calls to overcome these challenges. We also enhanced login instructions, created video tutorials, and provided additional telephone support. All these measures improved the application's overall usability and accessibility, especially for first-time access to the application. The lessons learned from this study will be valuable in a broader context, contributing to the development and evaluation of complex interventions and to the refinement of RCT procedures for future web-based interventions like Carer eSupport.

As an important first step in the HCD process, understanding the user's context and the use of technology is crucial for the smooth implementation of IT systems [33,59]. During the evaluation phase of an HCD process, real-world challenges often emerge that were not apparent at the start. For example, while assisting two ICs in logging into an application via smartphone, we discovered that they were attempting to juggle multiple tasks on a single device. The ICs were on a phone call and, at the same time, opened their email to look up their username and password. Afterward, they tried to access the application in another tab on the same smartphone. This multitasking led to repeated errors when entering their login credentials. The 2-factor authentication process, which requires ICs to retrieve and enter a code on the same smartphone, further complicates their access. When the support team asked whether they had access to an alternative device, such as a tablet or computer, the ICs said they had no other device available. After several attempts and extensive assistance from the support team, the ICs finally managed to log in to the application; however, it was not an easy process for them. Such cases highlight that while understanding user context is emphasized early in the HCD process, vital insights often emerge during evaluation. Such experiences, as highlighted in previous research, underscore the importance of iterative design improvements to ensure systems are more effectively aligned with users' real-life circumstances [59,60].

Our integration of the HCD process and health care science, enriched by a eudaimonic perspective, offers initial guidelines for creating a framework that can be applied beyond the caregiving context. For technology designers and HCI researchers, especially those focusing on vulnerable groups, this study can inform the design and development of digital

XSL•FO
RenderX

solutions that are both evidence-based and empathetic. However, it is worth noting that the study is limited to the pilot study. A complete evaluation of Carer eSupport can only be concluded once the full-scale RCT is completed. We look forward to exploring the full RCT outcomes, particularly regarding improvements in ICs' preparedness for caregiving and their well-being.

Conclusion

This paper presented the design and development of a web-based application that integrates eudaimonic perspectives within an iterative HCD process to prepare ICs for caregiving and improve their well-being. The pilot study results confirmed the application's viability for an RCT, as evidenced by high consent, login, and retention rates. However, it highlighted significant user challenges, such as time constraints and technology-related barriers. Integrating the eudaimonic perspective into the application design also proved challenging due to the subjective and nuanced nature of the elements of eudaimonic motivation. Given the limited participant pool in this study, a more comprehensive evaluation is necessary to assess the relevance, effectiveness, and usability of Carer eSupport. This evaluation is currently underway in our ongoing RCT. Results from this study indicate that personalized, interactive web-based applications like Carer eSupport hold considerable potential to support ICs of individuals with HNC.

Acknowledgments

We are thankful to the informal caregivers for sharing their valuable perspectives. Their active participation contributed to the design and development of Carer eSupport and the study procedures. We also extend our gratitude to the health care professionals, as their insights and support were of great help in shaping Carer eSupport. All text in this article was originally written by the authors. However, an AI tool (ChatGPT, version 5.2) was used only for language refinement and grammatical editing, without contributing to the content, analysis, or conclusions.

Funding

The entire project is funded by the Swedish Research Council (grant 2019-01231), the Swedish Cancer Society (grant 20 1014 PjF), the Swedish state through the ALF agreement between the Swedish government and the county councils (Uppsala County: ALF-941900), and the Oncology Department Foundation's Research Fund in Uppsala. The funding bodies had no involvement in the study design, data collection, data analysis, interpretation of data, or manuscript preparation.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: High-quality professional development can help teachers build the skills and confidence needed to implement evidence-based practices, such as classroom physical activity breaks. While in-person training is often preferred, virtual asynchronous training offers a flexible alternative for teachers. However, its effectiveness may be limited by design and usability challenges.

Objective: The aim of this study was to conduct a usability assessment of the Interrupting Prolonged Sitting with Activity (InPACT) virtual teacher training modules, using a human-centered design (HCD) approach to align the training with end-user preferences and needs.

Methods: The InPACT professional development program includes nine modules delivered through an online platform (Qualtrics XM). A usability assessment was conducted using (1) structured online surveys with elementary school teachers who had completed the modules, (2) a heuristic evaluation based on the Jakob Nielsen 10 usability heuristics, and (3) a competitive analysis of three learning management systems (Moodle, Teachable, and Thinkific) to identify platform strengths, limitations, and insights. Findings and recommendations were compiled to inform module improvements.

Results: Eleven teachers completed the survey. They reported that the modules were easy to use, the content was informative and relevant, and they valued the interactive and practical components. Areas for improvement included enhancing content engagement and increasing technical flexibility. The heuristic evaluation identified 14 usability issues across nine of the Nielsen heuristics (eg, navigation difficulties and text-heavy pages). The competitive analysis highlighted features that enhance user experience, such as progress tracking, estimated completion times, interactive elements, and feedback on quiz answers.

Conclusions: Usability assessments grounded in an HCD approach can enhance virtual training for educators, improving the uptake and implementation of evidence-based practices, such as classroom physical activity breaks. Five overarching recommendations emerged as follows: (1) removing video time constraints, (2) implementing accurate progress bars, (3) incorporating active learning or retention activities, (4) creating consistent and actionable end pages, and (5) ensuring consistency in titles and references to physical materials. Building on preliminary positive data from revised modules, future research should evaluate the impact of HCD revisions on teacher self-efficacy, training completion, and fidelity of program implementation.

Introduction

Physical activity plays a vital role in promoting child and adolescent health by improving cognition, bone health, fitness, and overall health, while also reducing the risk of anxiety and depression [1]. However, most children and adolescents in the United States do not meet the Physical Activity Guidelines for Americans, which recommend at least 60 minutes of moderate-to-vigorous physical activity daily to attain the greatest health benefits [1]. National surveillance data show that only 42% of children aged 6 to 11 years meet this recommendation [2], with participation declining sharply during adolescence [3] and rates being even lower for youth residing in resource-limited communities [4]. This shortfall increases the risk of obesity and related chronic conditions [5,6], highlighting the need to improve youth physical activity engagement.

Schools offer a critical and equitable setting to help close the physical activity gap among children and adolescents [7,8]. Among school-based strategies, classroom-based physical activity interventions have emerged as effective and feasible

XSL•FO
RenderX

approaches for increasing students' daily activity levels, particularly in resource-limited settings [9,10]. These interventions provide structured opportunities for all children to engage in regular exercise by integrating short bouts of movement into the school day. Compared to physical education and after-school sports programs, they are less resource-intensive and easier to implement, making them well-suited for schools with limited staff, space, or funding [11,12].

Recognized as an evidence-based practice by the Community Preventive Services Task Force in 2021, classroom physical activity interventions typically involve teachers incorporating 1 to 5 activity breaks per day, each lasting 4 to 10 minutes [13]. Core implementation components include dedicated time, adequate classroom space, and access to age-appropriate videos and exercise resources. A systematic review and meta-analysis by the Task Force, which included 22 studies (11 using direct observation), found that physical activity breaks significantly increased students' activity levels during school hours and improved time-on-task by a median of 26.2 minutes [10]. These findings provide strong evidence that classroom physical activity interventions can simultaneously promote physical activity and enhance classroom engagement.

Despite the well-established benefits, national data show that fewer than half of US elementary teachers incorporate these breaks regularly [14,15], underscoring the need to better understand barriers and facilitators to their implementation. While many teachers recognize these benefits—such as increased student focus, enjoyment, and a more positive classroom climate—they often experience a lack of confidence, uncertainty about how to integrate activity without disrupting instruction, and the belief that physical activity is not aligned with academic goals [16-21]. Key individual-level factors that influence implementation include teachers' knowledge, attitudes, self-efficacy, and perceptions of social norms [22-24]. Educators who feel confident in their ability to use physical activity, value its role in learning, and perceive support from peers and administrators are more likely to use activity breaks consistently [25-27]. Strengthening these individual factors is critical to expanding the reach and sustainability of classroom physical activity.

To overcome these barriers—particularly teachers' lack of confidence and uncertainty about how to integrate activity without disrupting learning—high-quality professional development is essential [28]. For physical activity integration to become routine, teachers need concrete, classroom-ready strategies that align with existing instructional practices [29]. The Interrupting Prolonged Sitting with Activity (InPACT) intervention addresses this need by providing a skills-based professional development program designed to support direct translation to classroom practice [30]. Through structured training, InPACT equips educators with the tools and strategies needed to integrate physical activity in ways that are feasible within daily classroom routines.

Grounded in the Guskey [28] model of teacher change, which emphasizes practice as a precursor to belief change, the InPACT approach prioritizes the adoption of new classroom behaviors before targeting shifts in attitudes or perceptions. As teachers observe improvements in student focus, classroom climate, and learning, these practice-based successes reinforce the feasibility and value of integrating movement into the school day, thereby supporting subsequent changes in beliefs and acceptability.

The educational strategies embedded within the InPACT training were intentionally selected to reflect adult learning principles and evidence-based models of effective teacher professional development [31,32]. These strategies include practical, classroom-ready examples, active skill-building, structured reflection, and explicit connections between training content and teachers' daily instructional practices. The training was co-created with the University of Michigan School of Education's Instructional and Program Design Coordinator, ensuring alignment with evidence-based pedagogy and responsiveness to teacher-identified needs [30].

The InPACT professional development program consists of 9 interactive training modules that can be delivered either in-person or asynchronously via an online learning platform (Qualtrics XM). In person, the modules are delivered by a trained InPACT professional using a Microsoft PowerPoint presentation, with interactive opportunities for hands-on activities, modeling of classroom activity breaks, and group discussions. In-person InPACT training sessions typically last 6 to 8 hours. The virtual format consists of asynchronous modules combining text, videos, images, and interactive exercises, with each module taking approximately 45 to 60 minutes to complete. Teachers are encouraged to complete all modules within a 4- to 6-week period to support continuity and application to classroom practice. Participants engage in guided self-reflection activities and complete premodule and postmodule assessments to track learning progress. Table 1 provides a description of each training module.

XSL•FO
RenderX

Table . Summary of the Interrupting Prolonged Sitting with Activity (InPACT) virtual teacher training modules.

Module	Title	Description
1	Evidence base for classroom physical activity	Introduces the evidence supporting classroom physical activity and its benefits for health, well-being, and academic performance.
2	Overview of InPACT	Explains how to incorporate short movement breaks (InPACT) into the school day.
3	Optimizing classroom layouts	Guides teachers in creating safe and functional spaces for movement in the classroom.
4	Classroom management during activity breaks	Focuses on maintaining structure and engagement during physical activity breaks.
5	Integrating physical activity with academic content	Helps teachers align movement with learning goals to support academic achievement.
6	Selecting exercise videos and assessing intensity	Covers selecting appropriate videos and assessing student intensity levels to meet physical activity goals.
7	Motivational techniques and gamification	Introduces strategies like gamification to enhance and sustain student engagement.
8	Inclusive adaptation of physical activity	Provides strategies to adapt activities to ensure accessibility and inclusion for all students.
9	Safety guidelines	Emphasizes safety considerations and offers best practices for injury prevention and safety planning.

After developing this content-rich program, we sought to understand teachers' preferences for how these modules could best be delivered. Findings from a group of general education teachers (n=35, teaching experience ranging from 2 to 27 years; mean 14.8, SD 7.4) highlighted the importance of offering flexible training options for classroom physical activity implementation. While nearly two-thirds of teachers expressed a preference for in-person professional development, a substantial portion—approximately one-third—preferred a virtual, asynchronous training option. These teachers cited competing demands, stress, and logistical challenges (such as preparing substitute teacher plans) as barriers to in-person participation (Friday et al, PhD, unpublished data, 2021). Providing autonomy in training modality—allowing educators to select either virtual or in-person formats—could therefore enhance participation and reduce perceived burden, particularly if training is integrated into existing professional development sessions.

Offering virtual training may increase accessibility for teachers facing time constraints and logistical challenges. However, it also introduces a new set of considerations—particularly regarding the usability of the digital learning environment. Ensuring that these online modules are accessible, understandable, and engaging is essential to addressing the very barriers—such as stress and overload—that teachers have identified.

Teachers' ability to benefit from online modules depends on the usability and design quality of the digital learning environment [33]. Usability is defined as "a quality attribute assessing how easy user interfaces are to use, focusing on 5 core components: learnability, efficiency, memorability, error handling, and satisfaction" [34]. Research shows that poorly designed websites can hinder engagement, leading to frustration and high dropout rates [35]. Conversely, user-friendly platforms can promote greater interaction and retention [33]. To address this, we conducted a usability assessment of the InPACT virtual teacher training modules to evaluate how accessible, understandable, and engaging they are for classroom educators. Ultimately, improving the usability of the InPACT virtual modules can empower more educators to confidently and sustainably implement physical activity breaks, regardless of the training format they choose.

Methods

Overview

This study used a mixed methods approach grounded in a human-centered design (HCD) framework to evaluate the usability and delivery of the InPACT virtual teacher training modules, with an emphasis on understanding the end-user needs, constraints, and contexts prior to large-scale implementation, consistent with established HCD models for digital health interventions [36]. Within the HCD lifecycle, this study focused on formative inspiration and ideation stages to inform iterative refinement of the training modules, operationalized through complementary methods, including a structured online survey of teachers, a heuristic usability evaluation, and a competitive analysis of learning management systems (LMSs). HCD served as the overarching, iterative, and participatory framework, integrating principles from user-centered design, which prioritizes usability and functionality from the end-user perspective, and user experience (UX) design, which focuses on optimizing the quality of users' interactions with a system. Together, these principles informed design decisions related to the structure, usability, and delivery of the virtual modules.

XSL•FO
RenderX

Later stages of HCD, including implementation and outcome evaluation, were beyond the scope of this study and are the focus of ongoing and future work.

Recruitment

Elementary school teachers who had completed at least one InPACT virtual module were recruited for this study. Principals in Michigan schools currently implementing InPACT provided the contact information of teachers who participated in the training. Eligibility was determined through these principal-provided contact lists. Eligible teachers were invited via email to participate in the research, with a link to a structured online survey. Participants could opt out at any time.

Structured Online Survey

A structured online survey was administered to evaluate teachers' experiences with the InPACT intervention. Developed by the research team, the survey included both closed-ended and open-ended items to capture quantitative indicators of module use and qualitative feedback on UX. The first section gathered demographic information, such as the grade level taught and years of teaching experience. The second section assessed teachers' experiences with the InPACT modules, including challenges encountered, clarity of module content, perceived strengths and weaknesses, preferred format of the program guide (ie, the written version of the modules; physical book vs digital pdf), use of supplementary links, suggested improvements, and frequency of classroom activity implementation following training.

All participants completed the same set of structured questions, designed to take approximately 15 to 20 minutes. Responses were collected anonymously and analyzed by the research team. Participants were offered the chance to enter a US $25 gift card raffle as an incentive for completing the survey. The full survey instrument, including all closed-ended and open-ended items, is provided in Multimedia Appendix 1.

Heuristic Evaluation

A heuristic evaluation was conducted to assess the usability of the InPACT virtual teacher training modules. The evaluation team consisted of 5 evaluators with diverse academic backgrounds and varying levels of expertise in UX design. UX design is defined as "the process of designing digital or physical products with a focus on optimizing users' overall experience, including usability, accessibility, and satisfaction" [37]. Some evaluators had completed formal coursework in UX design, while others contributed complementary perspectives, including spatial and visual design and applied analytics. All evaluators had prior hands-on experience conducting usability evaluations through Michigan Open UX, the University of Michigan's student organization focused on applied UX research and practice.

Heuristic evaluation is a cost-effective usability inspection method in which evaluators assess an interface against established usability principles, or heuristics, to identify potential design issues [38,39]. This evaluation was guided by the Jakob Nielsen 10 usability heuristics [40], which are grounded in cognitive psychology and human-computer interaction principles. Each evaluator independently completed the virtual training modules and documented any usability issues encountered. Identified issues were mapped to the relevant heuristic and assigned a severity rating ranging from 0 ("no usability problem") to 4 ("usability catastrophe").

Competitive Analysis

A competitive analysis was conducted using a FigJam board (Figma, Inc) to generate strategic insights into potential alternative LMS platforms that could support the scalability and long-term delivery of the InPACT training program. As the program continues to expand, evaluating LMS options beyond its current Qualtrics-based delivery is essential for optimizing UX and infrastructure sustainability.

Three LMS platforms were selected for evaluation: Moodle (version 5.0), Teachable (version 3.3.0), and Thinkific (version 1.17). These platforms were selected based on their relevance to professional education delivery, scalability potential, and cost considerations. Each platform was evaluated through hands-on exploration from both the lecturer and learner perspectives. From the lecturer's perspective, evaluators examined features related to course creation, content uploading, learner analytics, and collaboration among multiple contributors. From the learner's perspective, the evaluation focused on progress tracking, feedback mechanisms, navigation, and alignment with usability heuristics such as visibility of system status (eg, progress bars and activity feedback) and user control and freedom (eg, back and exit buttons). Additional features relevant to both perspectives—including media integration, retention activities, and search or filtering capabilities—were also assessed.

The competitive analysis aimed to (1) identify LMS platforms that may better support InPACT's future delivery needs and (2) inform potential enhancements to the current system by identifying effective design features used in other platforms. The analysis was conducted iteratively, recognizing the evolving nature of LMS technologies and prioritizing transferable insights over the selection of a single replacement platform.

Data Analysis

Closed-ended survey items on the online survey (eg, yes or no responses and categorical frequency ratings) were summarized using descriptive statistics to characterize teacher demographics, module use, and perceived frequency of classroom activity implementation. Open-ended survey responses (eg, "What are some positives of the modules? Negatives?", "If there is something you could change about the modules, what would it be?", and "Is there anything else you'd like to add?") generated free-text responses that were treated as qualitative data and analyzed using thematic analysis. All free-text responses were independently reviewed by members of the evaluation team to identify recurring patterns related to usability, content clarity, engagement, and technical functionality. An iterative process was used to group similar responses, refine theme definitions, and reach consensus on final themes. Representative quotes were selected to illustrate each theme and provide contextual depth to the findings. To protect participant confidentiality, pseudonyms were used for all quotes presented.

XSL•FO
RenderX

Data from the heuristic evaluation were analyzed by compiling all usability issues identified by individual evaluators and categorizing them according to the Jakob Nielsen 10 usability heuristics. Severity scores were determined through group discussion and consensus and were used to prioritize design recommendations.

Competitive analysis data were analyzed through a structured cross-platform comparison of LMS features relevant to usability and instructional design, including course creation, UX, and interactivity. Cross-platform patterns were synthesized to identify design features that could inform the optimization of the InPACT teacher training modules.

Overall, data analysis integrated descriptive quantitative summaries with qualitative thematic analysis and usability-focused evaluative techniques.

Ethical Considerations

This study was approved by the institutional review board of the University of Michigan (HUM00192745). Prior to each interview, all participants provided verbal informed consent. Each participant was assigned a unique numerical identifier, and pseudonymized transcripts and personal data were stored separately on a secure Childhood Disparities Research Laboratory U-Drive, accessible only to authorized research team members. Participants received a US $25 gift card as compensation for their time.

Results

Structured Online Survey

A convenience sample of 11 schoolteachers (grade levels: kindergarten through 5th grade; teaching experience range: 3 - 28 years; mean 18.0, SD 8.9) completed the structured online survey. Overall, teachers reported minimal technical or content-related barriers when completing the InPACT teacher training modules. Only 1 teacher reported experiencing technical issues, and no teachers reported confusion with the module content.

Use of supplemental materials varied across respondents. Approximately half of the teachers reported using a written program guide (PDF or physical version of the modules) alongside the online training, whereas the remaining teachers relied exclusively on the digital modules. Engagement with embedded supplementary links was mixed: 4 teachers reported frequent use, while others reported occasional use (n=5) or no use (n=2), often noting that the core module content was sufficient without additional resources.

Following the completion of the training, all teachers reported incorporating activity breaks into their classrooms, with most reporting doing so very often (n=8) and others somewhat often (n=3). Taken together, these findings indicate that the InPACT teacher training modules were clear, functional, and feasible to implement, with few reported barriers and flexible options for engaging with written materials and supplemental content.

Textbox 1 presents the themes derived from teachers' open-ended survey responses, along with illustrative quotes drawn directly from participants' free-text comments. Five major themes emerged from the thematic analysis of open-ended survey responses. The first theme concerned ease of use and accessibility. Most teachers reported that the modules were easy to navigate and understand, both in terms of the platform interface and the clarity of the content. The flexibility to complete the modules at one's own pace was particularly appreciated, as many teachers noted they were unable to finish a module in a single sitting.

XSL•FO
RenderX

Textbox 1. Themes emerging from thematic analysis of open-ended responses in the structured online survey. Pseudonyms are used for all quotes presented.

Theme 1: ease of use and accessibility

- "I thought they were very easy and useful." [P5, Janice Marquez]
- "Easy access." [P7, Jose Jackson]
- "They were easy to follow and understand." [P11, Lucy Johnson]

Theme 2: content utility

- "I've been using what I learned for years now." [P12, Lauren Smith]
- "It had a lot of useful information." [P3, Isabel Kim]
- "I have been using many activity breaks throughout my day and noticing significant improvement in student's engagement, focus, but mostly happiness." [P12, Lauren Smith]

Theme 3: interactive and applied learning

- "Examples that got us up and moving as we completed the modules." [P4, Farrah Bandow]
- "More interactive activities/links." [P3, Isabel Kim]

Theme 4: engagement and presentation

- "It was not presented in a very engaging way." [P3, Isabel Kim]
- "I would be more concise and shorten them up." [P13, Rhonda Barrales]
- "The video was hard to read." [P2, Emily Canton]

Theme 5: technical flexibility

- "You had to wait before the module let you move forward." [P11, Lucy Johnson]
- "The delay for the videos was sometimes longer than necessary so you had to wait before the module let you move forward." [P10, Sarah Lee]

The second theme focused on the perceived utility of the content. Content utility is defined as how effectively content fulfills a user's specific need, goal, or task, resulting in user satisfaction [41]. Participants described the modules as informative and relevant, highlighting their value as a resource for both learning new strategies and reinforcing prior knowledge. Specific content areas, such as classroom management techniques and safety considerations, were frequently cited as especially useful.

The third theme pertained to the interactive and applied nature of the learning experience. Teachers expressed appreciation for the modules' interactive components and noted the practical application of the material in their classroom settings. They valued being able to convey information to students and implement the strategies directly in their teaching practice.

The fourth theme addressed engagement and presentation. While participants acknowledged the usefulness of the content, some indicated that the modules were overly dense and lacked engaging delivery. Suggestions for improvement included making the modules more concise and enhancing the presentation style to increase user engagement.

Finally, the fifth theme related to technical flexibility. A few participants reported technical issues, such as difficulties with video readability and excessive delays during video progression. To improve the overall UX, teachers recommended shortening the content and providing greater control over video playback, including options to skip or speed up sections as needed.

Heuristic Evaluation

Table 2 presents the results of the heuristic evaluation conducted on the InPACT teacher training modules. A total of 14 usability issues across 9 of the Nielsen 10 heuristics were identified. For the heuristic of help and documentation, the training received a score of 2, indicating minor usability problems. For 6 heuristics—visibility of system status, match between the system and the real world, consistency and standards, recognition rather than recall, aesthetic and minimalist design, and help users recognize, diagnose, and recover from errors—the training received a score of 3, indicating major usability problems. Finally, the heuristics of user control and freedom and error prevention were rated with a severity score of 4, representing usability catastrophes. The heuristic of flexibility and efficiency of use—which emphasizes allowing both novice and expert users to interact effectively with a system, for example, by providing shortcuts or customizable features that make frequent actions faster—was not evaluated, as novice end users were not included in this evaluation.

XSL•FO
RenderX

Table . Heuristic evaluation conducted on Interrupting Prolonged Sitting with Activity (InPACT) modules.

Heuristic	Violation	Recommendation	Severity
1. Visibility of system status	• The survey completion bar does not reflect the user's progress, and there is no indication that progress is automatically saved.	• Add a clear message that progress is autosaved and improve the survey bar accuracy.	3
2. Match between the system and the real world	• The training modules can be seen to be more of a self-evaluation, rather than a training module, as there are "level of agreement" questions premodule and postmodule. • Users would expect assessments, interactive elements, resources, and so on, when completing training modules.	• Introduce interactive case studies that allow users to apply what they learned to a specific scenario. • Add interactive assessments and resources for users to complete and/or learn more about as they complete the modules.	3
3. User control and freedom	• Users cannot go back to previous screens without rewatching the entire video. • No exit button for users to leave the module or return to a main menu (constraint with Qualtrics XM).	• Allow users to navigate back without forcing them to rewatch completed videos. • Add a clear exit or home button for better navigation.	4
4. Consistency and standards	• Inconsistency in page titles (eg, "Do" and "Read" appear on some pages but not others).	• Standardize headings across all modules for clarity.	3
5. Error prevention	• No clear instruction that videos have a time Boolean, leading to confusion. Additionally, even if users fully watch the videos on a different video speed, they cannot advance to the next page.	• Remove the time Boolean. • Incorporate JavaScript to reflect the completion of videos. • Inform users that they cannot go back without having to watch the video again.	4
6. Recognition rather than recall	• Some pages contain large blocks of text without clear sectioning, making content hard to recall.	• Break up text with headings, bullet points, and images.	3
7. Flexibility and efficiency of use	• N/A[a]	• N/A	N/A
8. Aesthetic and minimalist design	• Some pages are very text-heavy, making content overwhelming. • The final page is labeled as a "Summary of Responses" but does not clearly indicate next steps.	• Incorporate images, videos, and better spacing to improve readability. • Reword the title and include a clear call to action on what to do next.	3
9. Help users recognize, diagnose, and recover from errors	• The form for entering an email address does not specify what a "valid email" format is. • Users do not receive feedback if they have not completed a necessary step (eg, watching a video fully).	• Provide clear instructions on acceptable email formats. • Display an error message explaining why the next button is disabled.	3

XSL•FO
RenderX

Heuristic	Violation	Recommendation	Severity
10. Help and documentation	• It is unclear if teachers need the program guidebook to complete the training. • Check-in does not provide contact links for additional help.	• Clearly state whether the book is required or optional. • Include links to resources and a contact person for support.	2

[a]N/A: not applicable.

Competitive Analysis

Table 3 highlights the strengths and limitations across the three evaluated LMS platforms. Moodle demonstrated strong capabilities for course creation and content organization, including support for multimedia integration, multiple courses per module, and clear navigation features, though it lacked consistent progress indicators, time estimates, and a dedicated "next" button. Teachable offered a responsive design across devices, collaborative course-building features, analytics, and interactive activities, but some aspects of content presentation were confusing, and students could bypass quizzes. Thinkific provided intuitive course creation, clear progress tracking, interactive quizzes with feedback, and helpful media labeling, but the course title occupied excessive screen space, limiting navigation efficiency. Collectively, these findings highlight the relative advantages and trade-offs of each platform, offering guidance for selecting or refining LMS solutions to optimize usability, learner engagement, and module scalability for the InPACT teacher training program.

XSL•FO
RenderX

Table . Competitive analysis, where course creation reflects how easily content can be developed and adapted; user experience captures usability, navigation, and accessibility; and interactivity reflects opportunities for engagement, practice, and feedback that support learning and implementation.

LMS[a] name	Course creation	User experience	Interactivity
Moodle	• (+[b]) Allows for the inclusion of slideshows, images, and videos within course content. • (+) Ability to create multiple courses for each training module for less information overload.	• (+) The user can filter and search through courses. • (+) Tracking progress bar shows the user how far into the module they are. • (+) There are organization and categorization of lessons (dropdowns for sublessons). • (+) Indication of completed section (green dot). • (+) There can be multiple pages within main sections to have less information presented all at once. • (+) Clearly marked "back" and "exit" buttons, able to send the user back very easily and without confusion. • (–[c]) Difficult to see progress on course, for some modules, no indications if a section is "completed" or not. • (–) No time estimates. • (–) No "next" button, user must navigate on their own with little to no information. • (–) No progress on how many subsections are in each module, only using a percentage for progress.	• (+) Moodle has learning retention activities, such as quizzes.
Teachable	• (+) Similar process to Qualtrics XM, where the platform allows for blocks to add or remove items. • (+) Ability to see users (students) and other analytics. • (+) Collaborative features; multiple people can work on a Teachable course at once. • (+) Option to bulk upload files (resources), videos, documents, and audio to create a lesson. • (+) AI[d] tools to include a section summary.	• (+) Responsive design, so users can complete the modules on their laptop, tablet, and phones. • (+) Students can see their progress and sections in the course. • (–) Content section is a bit confusing with the circle icon.	• (+) Interactive activities, such as quizzes and clicking on resources. • (–) Students can complete a section without taking the quiz.
Thinkific	• (+) Can easily select categories to create modules. • (+) Ability to change settings on quiz. For example, requiring a passing grade or importing questions. • (+) Easy to navigate course creation.	• (+) Search bar within course allows easy navigation for the user. • (+) Progress bar with numbers with the option to expand on sections. • (+) Informs users about the type of media in each section (eg, video and quiz) and provides an estimated time to complete it. • (+) Provides feedback on quiz when a user answers (correct or incorrect). • (–) The title of the course takes up approximately 1/3 of the navigation section, and there is no way to minimize it.	• (+) Interactive activities, such as quizzes and videos.

[d]AI: artificial intelligence.

Discussion

Principal Results

Given the barriers teachers face in integrating physical activity into classroom routines—particularly related to confidence, stress, and limited time—the purpose of this study was to apply a HCD approach to evaluate and enhance the usability of the InPACT virtual teacher training modules. Using mixed methods—including a structured online survey, heuristic evaluation, and competitive analysis—we assessed teachers' training experiences and identified key usability challenges and opportunities for improvement. Results from the structured survey revealed strong support for the modules' content and structure, including perceived usefulness, flexibility, and applicability. However, teachers also noted that the modules could benefit from improved pacing, greater interactivity, and enhanced video controls. The heuristic evaluation uncovered 14 usability issues across 9 of the Nielsen 10 heuristics, including multiple major usability problems and a severity score of 4 ("usability catastrophe") for user control and freedom. These findings pointed to critical design flaws that may hinder user engagement and reduce the likelihood of training completion. The competitive analysis compared three LMS platforms (Moodle, Teachable, and Thinkific) and highlighted key platform features—such as course creation flexibility, learner feedback mechanisms, and collaborative design tools—that could inform future iterations of the InPACT platform. Taken together, these results suggest that while the InPACT training modules are content-rich and well-aligned with teacher needs, several design and delivery improvements are needed to enhance usability, improve training uptake, and support the sustainable adoption of classroom physical activity practices.

Although this study focused primarily on individual-level factors related to teacher engagement with the training modules, the implementation of classroom-based physical activity interventions is influenced by multiple, interacting levels of context. At the inner setting level, factors such as administrative support, school culture, time constraints, and competing instructional priorities can directly shape teachers' ability to apply training content in daily practice [23,42]. At the outer setting level, district policies, professional development requirements, and broader accountability pressures may further enable or constrain implementation [43,44]. Prior work in low-resource school settings has shown that even well-designed, evidence-based interventions may experience reduced fidelity or sustainment when organizational and system-level conditions are not aligned with implementation demands [44-46]. As demonstrated by Hasson et al [47], addressing these multilevel influences through leadership engagement, district partnerships, and adaptive implementation strategies is critical for translating individual-level training gains into sustained practice. Future efforts to scale teacher training modules should therefore incorporate complementary strategies that target school- and district-level barriers alongside individual professional development.

Comparison With Prior Work

Prior research underscores the critical role of professional development in the successful implementation of school-based health programs [48]. Teachers are more likely to adopt and sustain new interventions when they receive training that is accessible, practical, and tailored to their classroom needs [49]. In the context of physical activity programming, effective professional development has been linked to improvements in teacher confidence, fidelity of program delivery, and student engagement [42,50,51]. Accordingly, the InPACT virtual teacher training modules were designed to serve as a central implementation strategy [52].

However, usability challenges identified in this evaluation suggest that the training modules fell short of best practices for online professional development. Using the Nielsen usability heuristic framework, the evaluation revealed 3 primary issues: lack of user control and freedom, inconsistency and lack of standards, and insufficient recognition rather than recall. Teachers described frustration with not being able to pause or skip segments of the training videos, which reflects poor user control and freedom. This limitation is especially problematic for time-constrained educators [47], who may prefer to pace their training across multiple sittings. Inconsistencies in video labeling and navigation—such as unclear module titles and nonuniform layouts—violated established design standards, making it harder for users to locate content, which can contribute to cognitive overload [53]. Finally, the training platform required users to remember previously viewed content with limited visual cues to support recall. This reflects insufficient recognition rather than recall, a heuristic that emphasizes reducing memory load by making options, actions, and information visible so that users can recognize what to do instead of relying on memory. Without visual scaffolding, such as clear navigation menus or progress indicators, the cognitive burden increases, and learnability suffers [54].

These usability shortcomings contrast with best practices from prior studies, which demonstrate that professional development resources should be easy to navigate, chunked into digestible segments, and provide clear cues to help users orient themselves within the training [40]. Addressing these issues is critical to improving the training experience for teachers and, in turn, increasing the implementation fidelity of classroom physical activity programming in schools.

Recommendations for Enhancement of the InPACT Virtual Teacher Training Modules

A major usability barrier identified during the evaluation was teacher frustration with video replay requirements, particularly when navigating backward in a module. To address this issue,

XSL•FO
RenderX

the evaluation team recommended removing the time-based Boolean constraint on embedded videos. Specifically, they proposed using JavaScript event listeners integrated with the YouTube application programming interface to track video play or pause actions and determine when a sufficient portion of the video has been viewed. This would allow users to resume or advance through content without having to rewatch full segments. In cases where this solution was not feasible within the current Qualtrics platform, the team recommended displaying clear notifications indicating that videos must be viewed in full before proceeding.

Additional enhancements were proposed to improve time management and overall UX. Teachers noted that the existing page-based progress bar was misleading, making it difficult to anticipate the time commitment. To improve clarity, the evaluation team proposed a content-based progress bar with labeled topic nodes, or alternatively, the inclusion of manual page indicators and estimated completion times.

To promote engagement and retention, the team suggested reducing dense text and incorporating visual aids and interactive components such as collapsible content sections, quizzes with feedback, real-world case studies, and downloadable action plans. These enhancements were aimed at strengthening active learning and implementation fidelity. Navigation improvements were also prioritized. Teachers expressed difficulty tracking progress across modules, so a standardized end-of-module message with clear next steps (eg, “To continue to the next module, click here”) was recommended. Inconsistencies in how modules referenced the companion program guide led to confusion, prompting a recommendation to standardize these references and clearly indicate when guide components are optional.

To implement these enhancements and support scalability, we partnered with Michigan Virtual, a statewide leader in accessible professional learning [54]. Michigan Virtual committed to redesigning and developing the revised modules using their Brightspace LMS, ensuring compliance with Web Content Accessibility Guidelines and Americans with Disabilities Act standards. Their instructional designers identified necessary content updates, helped revise training materials, and provided technical support. Michigan Virtual also offered to host the updated modules on its Professional Learning Portal, manage State Continuing Education Clock Hours processing, and share educator completion data with the InPACT team. This partnership is expected to ensure a high-quality, accessible, and scalable professional development experience for educators statewide.

Preliminary data from the revised InPACT teacher training modules hosted on Michigan Virtual indicate strong early uptake, engagement, and performance during the first eight months following release. As of April 7, 2026, 2061 educators have enrolled in the training with 1138 participants earning certificates of completion, reflecting substantially greater reach and completion volume than the prior Qualtrics-hosted training (35 teachers over a 3-year period). Knowledge acquisition was assessed using standardized postmodule quizzes embedded within each training module. Across these module quizzes, participants demonstrated high mastery of content, with an average score of 90.6% (SD 2.7%), and required relatively few attempts to achieve passing scores (mean 1.5, SD 0.2 attempts per module). Collectively, these preliminary findings suggest that the revised training—coupled with a more accessible delivery platform—has markedly improved scalability, engagement, and learning outcomes.

Partnerships played a central role in guiding the enhancements to the InPACT teacher training modules. Engaging a diverse set of collaborators—including classroom teachers, instructional designers, accessibility specialists, and statewide professional learning organizations—was essential for identifying usability challenges, prioritizing improvements, and ensuring that module revisions were both practical and scalable. These partnerships enabled the co-development of solutions that enhanced navigation, interactivity, and accessibility, while ensuring alignment with accessibility and disability standards. For teams with limited budgets, leveraging existing relationships, focusing on high-impact usability improvements, and incorporating low-cost accessibility strategies—such as consistent page structure, clear labeling, and visual scaffolding—can help maximize impact. Additionally, integrating clear data visualization and feedback mechanisms, alongside ongoing communication and iterative feedback with end users, is recommended to promote engagement, learning retention, and sustainable implementation of virtual professional development programs.

Strengths and Limitations

This study has several notable strengths. First, we used a mixed methods usability evaluation that incorporated both end-user feedback and expert recommendations to guide improvements to the InPACT teacher training modules. Second, the evaluation was conducted by a multidisciplinary team with expertise in instructional design, educational technology, and human-computer interaction. Finally, our collaborative and HCD approach fostered partnerships between teachers, evaluators, and implementation support organizations, enabling the co-development of a more accessible, engaging, and scalable professional learning experience for educators across Michigan.

Limitations of this study also warrant consideration. First, teacher feedback was based on self-report and retrospective recall, which may be subject to recall bias or social desirability bias and may not fully capture real-time usability challenges encountered during module completion. Although self-report data are commonly used in early-stage usability and implementation research to efficiently gather end-user perspectives, these methods may overlook nuanced interaction patterns, moment-to-moment frustration points, or navigation errors that occur during actual use [55]. Future usability evaluations that integrate observational and system-level data with teacher self-reports will be critical for identifying real-time barriers and optimizing training engagement and completion.

Second, the participant sample consisted primarily of teachers who were already implementing the InPACT program. While this was appropriate for the study’s aim of evaluating the usability of existing training modules, these participants may have had greater familiarity with the program content and

XSL•FO
RenderX

underlying concepts than educators new to InPACT. Future evaluations should include educators unfamiliar with InPACT to examine initial usability, onboarding experiences, and barriers faced by first-time users.

Third, this study did not assess whether the usability improvements applied in the revised modules translated into changes in teacher self-efficacy, adoption of classroom activities, or fidelity of implementation. Future research is needed to determine whether usability-informed redesigns of the InPACT teacher training modules lead to measurable improvements in teacher self-efficacy, training completion, adoption, and implementation fidelity.

Conclusions

Most teachers in the United States do not implement classroom physical activity breaks with the frequency or fidelity recommended to improve student health and academic outcomes [14,15]. Virtual training modules offer a scalable approach to build teacher capacity, but their effectiveness depends not only on high-quality content but also on user-centered design and usability. In this study, a combination of heuristic evaluation, competitive analysis, and end-user surveys was used to identify and address barriers to teacher engagement with the InPACT virtual teacher training modules. Key recommendations focused on improving navigation, video accessibility, and visual appeal to reduce user frustration and enhance the learning experience. Applying an HCD approach enabled collaboration between evaluators, developers, and end users to optimize virtual training for broader adoption. Future work should examine whether these HCD-informed revisions lead to measurable improvements in teacher self-efficacy, training completion, classroom physical activity program adoption, implementation fidelity, and student outcomes.

Acknowledgments

The authors would like to thank Rongyu Shen, Sanvika Inturi, Shannon Lee, and the University of Michigan School of Information client engagement team for their helpful assistance throughout the research process. The authors are also grateful to the study participants for their involvement. Finally, the authors appreciate the Michigan Virtual team for making subsequent improvements. ChatGPT (GPT-3.5/4.0) was used to edit the grammar and sentence structure of the manuscript. The results are presented clearly, honestly, and without fabrication, falsification, or inappropriate data manipulation.

Funding

The Michigan Health Endowment Fund provided funding for this study (grant G-2404-154026).

Data Availability

Data are available upon request by sending an email to the corresponding author.

Authors' Contributions

REH wrote the manuscript and oversaw data collection for the project. AS and AL developed the Qualtrics virtual training modules and implemented updates. TT and LM conducted the teacher interviews, heuristic evaluation, and competitive analysis. All authors reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Mobile health (mHealth) apps are increasingly used to support healthy lifestyle behaviors through features such as health tracking and personalized reminders. Personalized messaging, tailored to users' profiles, has been shown to improve engagement and retention in health-related contexts. Prior research has linked personality traits, based on the Big Five model, to preferences for specific app mechanisms, leading to the development of a preference matrix for personalizing mHealth apps. This matrix comprises 15 mechanisms derived from behavior change techniques and gamification elements, intended to guide developers in optimizing engagement according to user profiles.

Objective: This study aimed to validate this preference matrix by examining whether the associations between mechanisms and Big Five personality traits reported in the literature align with user preferences observed in an experimental setting.

Methods: A cross-sectional study was conducted using an online survey that collected demographic data, mHealth app usage, and personality traits. Participants were presented with mockups illustrating 15 mechanisms and were asked to select their preferred options. Logistic regression and ordinal logistic regression analyses were performed to examine associations between personality traits, mechanism selection, and motivation scores. All analyses were adjusted using the Bonferroni correction to account for multiple comparisons.

Results: A total of 214 participants completed the survey (mean age 29.42, SD 10.41 y; n=118, 55.1% women; n=89, 41.6% men; n=5, 2% identifying as other; and n=2, 1% nonrespondents). Higher conscientiousness significantly increased the likelihood of selecting the collection mechanism (eg, collecting badges or points; odds ratio [OR] 1.87, 95% CI 1.27-2.75). For competition (eg, competing with other users), conscientiousness (OR 3.22, 95% CI 1.73-6.00) and agreeableness (OR 1.93, 95% CI 1.08-3.45) were significant predictors. Preferences for rewards (eg, virtual incentives such as points or virtual currency) were associated with conscientiousness (OR 2.36, 95% CI 1.53-3.63) and neuroticism (OR 1.97, 95% CI 1.36-2.86). Additionally, 4 mechanisms—self-monitoring, progression, challenge, and quest—were selected by more than half of the participants, independent of personality traits.

Conclusions: The findings partially validate the proposed preference matrix. Conscientiousness consistently emerged as a key predictor of preference across multiple mechanisms, highlighting its central role in engagement with gamified mHealth features. While some mechanisms appear to have universal appeal, others show personality-specific preferences, underscoring the value of combining baseline mechanisms with targeted personalization strategies in mHealth app design.

Introduction

Background

Many studies have demonstrated the role of healthy lifestyle behaviors in increasing life expectancy. Specifically, the adoption of a healthy diet, maintenance of a healthy weight, cessation of smoking, consumption of alcohol in moderation, and regular exercise are associated with significant reductions in mortality. The researchers discovered that the adoption of each healthy lifestyle behavior contributes to an improved quality of life and enhanced longevity [1].

The number of health apps designed to assist individuals in adopting healthier behaviors has continued to grow steadily, with new apps reaching the market every year. In 2018, there were over 35,000 health apps available for download [2]. The advent of smartphone apps has created new opportunities for engaging in health-promoting behaviors. These apps offer immediate access to health-related information, medication reminders, and tools for monitoring progress, which can collectively support healthier lifestyle adoption [3].

Several scales have been developed to assess the quality of mobile health (mHealth) apps, such as the Mobile App Rating Scale [4] and the App Behavior Change Scale [5]. A key feature shared across these frameworks is the inclusion of personalization as a critical quality dimension. Personalization is widely acknowledged as essential in the design of behavioral interventions. For example, 1 study has demonstrated that messages tailored to the user's specific characteristics are more likely to be read, recalled, and retained in memory, and are perceived as more personally relevant than untailored messages. Tailored messages also attract greater attention, stimulate more discussion, and are shared more frequently compared to nontailored messages [6].

The Preference Matrix

Personalization of mobile apps can be done according to the user's profile. In previous studies [7], we identified preference relations between personality traits and specific mechanisms (components that can be integrated into an mHealth app) based on a scoping review of the literature. These findings led to the development of a preference matrix indicating the types of mechanisms preferred according to a user profile. The preference matrix can be used as a framework for the personalization of mobile apps with the aim of encouraging behavioral change. When designing a mobile app intended to support health-related behavior change, designers can draw on this preference matrix to identify the mechanisms most likely to be effective for their target users. For instance, if an individual is classified as extraverted according to the Big Five personality traits, mechanisms that facilitate social comparison or collaboration between users may be particularly relevant [8].

The preference matrix includes 15 mechanisms associated with the Big Five personality traits, which are presented in detail in the table found in Multimedia Appendix 1. For personality profiling, we used one of the most widely applied classification systems, namely the Big Five personality model [8-16].

Personality Measure: The Big Five

One of the most widely used instruments for the assessment of personality is the Big Five model. The Big Five model describes an individual's personality based on 5 distinct traits, as summarized in Table 1.

This model has the advantage of being widely adopted in academic research. Between 1990 and 1994, the number of publications on this topic was approximately 400, while between 2005 and 2009, this figure rose to approximately 1600 [17].

The other advantage of this model is its cross-cultural universality. The Big Five model has been shown to be universal across human populations [18]. Indeed, the authors translated their personality questionnaire, the Revised NEO Personality Inventory (NEO-PI-R), into 6 languages belonging to the same language family as English (German, Portuguese, Hebrew, Chinese, Korean, and Japanese), and the Big Five factors consistently emerged across these versions.

In a subsequent study, researchers examined whether the Big Five personality dimensions, as measured by the NEO-PI-R, were universal across 50 cultures spanning American, European, Arabic, Asian, and African regions [19]. The NEO-PI-R was translated into the local language of each participating country. The participants were primarily students from the country in which the test was administered. Factor analysis demonstrated that the American structure of the NEO-PI-R self-report questionnaire (Form S) could be replicated in all cultures, with 94.4% of factors replicated. Moreover, the general factor structure remained recognizable across all cultural contexts included in the study.

Table . Definition of the Big Five factors of personality.

Traits	The 5 traits represent the tendency to... [20]
Neuroticism	Worried, nervous, emotional, anxious, maladjusted, and hypochondriac
Extraversion	Sociable, active, talkative, open to others, optimistic, fun-loving, and affectionate
Openness	Curious, eclectic, creative, original, imaginative, and nonconformist
Agreeableness	Compassionate, easy-going, trusting, helpful, indulgent, credulous, and honest
Conscientiousness	Organized, reliable, hard-working, disciplined, punctual, meticulous, careful, ambitious, and persevering

Selection of the 15 Mechanisms

Based on the hypothesis that individuals with different profiles exhibit distinct preferences regarding components of mHealth apps designed to facilitate behavior change, a review of the literature identified 15 mechanisms associated with user profiles [21]. In our context, the term "mechanism" is used to denote the entirety of components that can be incorporated within an mHealth app with the objective of promoting behavioral change. We classified the mechanisms into 2 categories: the mechanisms linked to behavior change techniques and the mechanisms linked to game elements. For further details and definition of mechanisms, see Table 2.

Table . List of mechanisms with their definitions.

Mechanism	Definition
Behavior changes techniques	
Prompt and cues	Usually, a message delivered to the user to prompt or recall a behavior at a specified time, with the app or user defining when the message should be sent [22]
Demonstration of the behavior	Enables users to observe the cause-and-effect linkage of their behavior, such as seeing a simulation of their bodies after a diet [23]
Self-monitoring	Users can track their behaviors, providing information on both past and current activities [23]
Punishment	Virtually penalizes the user for not performing the desired behavior or reaching their goal [10]
Social comparison	An individual's perceptions of the prevailing beliefs and behaviors within a social group
Social support	Enables communication between users, such as through chat or sharing activities with other users [24]
Game elements	
Progression	Users can track their progression with steps through the system's purpose over time, visualized with mechanisms like stars or flags along a path [23]
Competition	Users can compete to accomplish the desired behavior [23]
Cooperation	Users collaborate to achieve a shared objective [23]
Collection	Allows users to gather virtual objects
Rewards	Virtual rewards offered to users for engaging in the target behavior [23]
Quest	Users can enter or define the objectives targeted for the activity they will perform [22]
Challenge	Presents various situations that require effort from the user to be completed [24] (eg, accomplishing 3 hours of physical activity per week)
Avatar	Allows users to share their data in the system without revealing their name [24]
App mechanism	
Customization	In contrast to personalization—which involves adjusting automatically the system to the user—customization refers to the user's ability to modify the content or functionalities of the mobile app according to their own preferences [23]. This approach enables users to actively tailor the system based on users' choices.

Preferences Relations Between Big Five Traits and Mechanisms

The preference relations between the mechanisms and the Big Five traits identified in the literature enable us to construct a preference matrix summarized in Multimedia Appendix 1. Each cell of the matrix indicates the number of studies in the review reporting a preference relation between a given user profile and a specific mechanism [21]. Most of the preference relations were positive (53/75, 71%), indicating that a particular personality profile tends to prefer a given mechanism (represented by a plus sign in Multimedia Appendix 1). Negative relations, representing an aversion toward a mechanism (represented by a minus sign in Multimedia Appendix 1), accounted for 12% (9/75) of all potential relations. It is important to note that the relation matrix remains incomplete, as only 73% (55/75) of all potential relations were identified in the literature review.

This study aims to corroborate or enrich this preference matrix by experimentally identifying new preference or nonpreference relations between mechanisms and personality traits.

Methods

Ethical Considerations

This study was approved by the University of Geneva Research Ethics Committee (CUREG_2021-04-38). This section is based on our previously published protocol study [25]. Participants were required to complete a consent form that detailed the purpose of the study, the procedure to be followed, and their right to withdraw from the study at any time. Confirmation that they had read, understood, and agreed to the terms of the consent form was mandatory before accessing the questionnaire and was required for the investigators to use the submitted data for research purposes. Participation was voluntary, responses were collected anonymously, and only deidentified data were used for research purposes in accordance with applicable data protection regulations. Participants did not receive any financial compensation for their participation.

Study Design

We conducted a cross-sectional study to address our research objectives. Participants completed an online questionnaire following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines (Checklist 1) [26].

Outcomes

The primary outcome was the identification of preferred mechanisms according to the user profile.

Study Population

The study targeted French-speaking adults aged 18 years and older. Recruitment was conducted both within the University of Geneva community and through social media platforms (eg, Facebook and Twitter, subsequently rebranded X), enabling participation from a broader population beyond university affiliates. The survey was open to anyone meeting the language and age criteria.

Sample Size Calculation

We calculated the required sample size using a multiple regression power analysis in R (R Foundation for Statistical Computing). The parameters used were the number of predictors (u=3), effect size (f^2=0.07), significance level (α=.05), power of 0.9, and estimated variance of 202.403. These estimates were based on the hypothesis that individuals with higher levels of agreeableness, as measured by the Big Five personality traits, show a preference for social networks [11,24].

To approximate the variance, we used data from a previous study [27] that assessed Big Five personality traits in relation to user preferences for social network posters. Specifically, we relied on the variance in Big Five trait ratings for altruistic participants (n=46) based on their average scores for a blood donation poster, which was evaluated on a 0-to-100 scale. Based on these parameters, we determined that a minimum sample size of 206 participants was required.

Procedure

Participants completed an online questionnaire developed by the investigators using Qualtrics software (Qualtrics; Multimedia Appendix 2). First, participants were required to complete a consent form that detailed the purpose of the study, the procedure to be followed, and their right to withdraw from the study at any time. Participants were then asked to provide demographic information. To proceed to the remainder of the survey, they were required to confirm that they were aged 18 years or older. Eligible participants subsequently completed two main components of the questionnaire: (1) a standardized personality assessment measuring their Big Five profile, and (2) a task in which they reviewed 15 mechanisms, selected their 5 preferred ones, and rated the extent to which each selected mechanism would motivate them to engage in physical activity on a scale from 0 to 100.

Measures and Measurement

Demographic Questions

The participants were asked to provide information regarding their gender, age, occupation, and level of education.

Profile Assessment

To assess the personality of the participants, we used the French version of the Big Five Inventory-10 (BFI-10-Fr) scale, translated and validated by Courtois [26]. The internal reliability of the Big Five Inventory-10 (BFI-10) is reported to be relatively low, with Cronbach α coefficients ranging from 0.37 to 0.83. However, this limitation is expected, as Cronbach α is not well-suited for very short scales, particularly those with only 2 items per dimension [26]. The instrument consists of 10 items, with 2 items pertaining to each of the 5 Big Five dimensions. Participants were requested to indicate on a 5-point Likert scale whether they approve or disapprove of the statements pertaining to themselves. For instance, respondents indicated whether they perceived themselves as reserved or as someone who is easily anxious. Scores for each personality dimension were computed by summing the two relevant items, with reverse scoring applied where appropriate.

This scale was selected because its factorial structure mirrors that of the full BFI-10-Fr, providing a valid measure of personality while minimizing participant burden [26]. Given the number of instruments included in the overall protocol, using a short, validated scale was deemed necessary to reduce fatigue and prevent attrition associated with excessively long questionnaires.

Choice of Mechanisms

Each of the 15 gamification mechanisms was represented by a mockup accompanied by a short textual description (Multimedia Appendix 2). To minimize potential bias related to visual design preferences, all mockups were created using a deliberately simple and neutral layout. The interface used only black-and-white tones and standardized icons to ensure clarity and comparability across mechanisms (Multimedia Appendix 2). The 15 mockups were displayed in a randomized order to control for possible primacy or recency effects. Participants were instructed to carefully review each screen and its corresponding description before making their choices. After viewing all 15 mechanisms, they were asked to select the five they personally found most motivating.

XSL•FO
RenderX

Explanation of Choice

For each of the 5 mechanisms selected in the previous step, participants were asked to indicate the degree to which that specific mechanism would motivate them to adopt healthier behaviors, using a continuous scale ranging from 0 (not at all motivating) to 100 (extremely motivating). After rating each of their 5 chosen mechanisms, participants were also invited to provide an open-ended written explanation describing the reasons behind their selections. All mechanisms that were not included among the participants' 5 preferred choices were automatically assigned a score of zero.

Analysis

Preference Matrix Validation

To compare the experimental results with the preference patterns reported in the literature, three matrices were generated.

The first matrix (M1) summarizes the preference relationships identified in the scoping review previously conducted [21]. Each cell represents the strength of evidence supporting a link between a Big Five personality trait and a gamification mechanism. The numerical value indicates the number of studies reporting a positive association (eg, 1=one study, 2=two studies, 3=three studies, and so on). A value of –1 denotes an aversion relationship, 0 indicates that both preference and aversion were observed, and null corresponds to an absence of a reported relationship.

The second matrix (M2) was derived from the empirical data collected in this study. Each cell represents a discriminative value computed for the combination of a Big Five trait (column) and a gamification mechanism (row). This value reflects the difference between the average personality scores of participants who selected a given mechanism and those who did not, as calculated using the following formula: $C_{m,b}=round(\sum_{p=1}^{n}1_{p,m}\cdot S_{p,b}\sum_{p=1}^{n}1_{p,m}-\sum_{p=1}^{n}0_{p,m}\cdot S_{p,b}\sum_{p=1}^{n}0_{p,m})$ (1)

where $1_{p,m}=1$ if participant p selected mechanism m, $0_{p,m}=1$ if participant p did not select mechanism m, $S_{p,\beta}$ is the score of participant p on the Big Five dimension $_{\beta}$, and n is the total number of participants.

To facilitate interpretation, discriminative values were categorized based on their magnitude: 0 - 1 (minimal selection of the mechanism by that trait), 2 (moderate selection), 3 (high selection), and 4+ (very high selection).

The third matrix (M3) represents the difference between M1 and M2, allowing direct visual and quantitative comparison between literature-based expectations and experimental results. Positive values indicate stronger associations in the current data than previously reported, whereas negative values indicate weaker or opposing trends. Cells with "null" values in M1 were excluded from the difference calculations.

Statistical Analysis

A logistic regression analysis was conducted to examine the relationship between the mechanisms and the Big Five personality dimensions. The purpose of this analysis was to determine whether participants' scores on the BFI-10-Fr significantly predicted the likelihood of selecting a given mechanism. Accordingly, logistic regression analysis was conducted for each mechanism to ascertain whether the BFI-10-Fr scores were predictive of the mechanism selection.

In addition, an ordinal logistic regression analysis was performed using the motivation scores assigned to the selected mechanisms as dependent variables and the BFI-10-Fr scores as predictors. A distinct model was computed for each mechanism to evaluate whether personality scores predicted the level of motivation attributed to that mechanism.

To reduce the risk of type I errors, the Bonferroni correction was applied across all regression analyses. This adjustment was implemented to account for the multiple comparisons conducted across mechanisms and personality dimensions, thereby minimizing the likelihood of false positive results.

Results

Demographics Data

A total of 214 participants completed the questionnaire, including 118 (55.1%) women, 89 (41.6%) men, 5 (2%) individuals identified as "other," and 2 (1%) participants who did not report their gender. The mean age of the sample was 29.42 (SD 10.41) years. Additional demographic characteristics are presented in Table 3.

XSL•FO
RenderX

Table . Demographics data. Participants were recruited both within the University of Geneva community and through social media platforms, allowing for the inclusion of individuals beyond the academic environment (N=214).

Characteristics	Values
Age (y), mean (SD)	29.42 (10.41)
Gender (N=214), n (%)	
Women	89 (41.6)
Men	118 (55.1)
Others	7 (3.3)
Education level (n=211[a]), n (%)	
Mandatory education	53 (24.8)

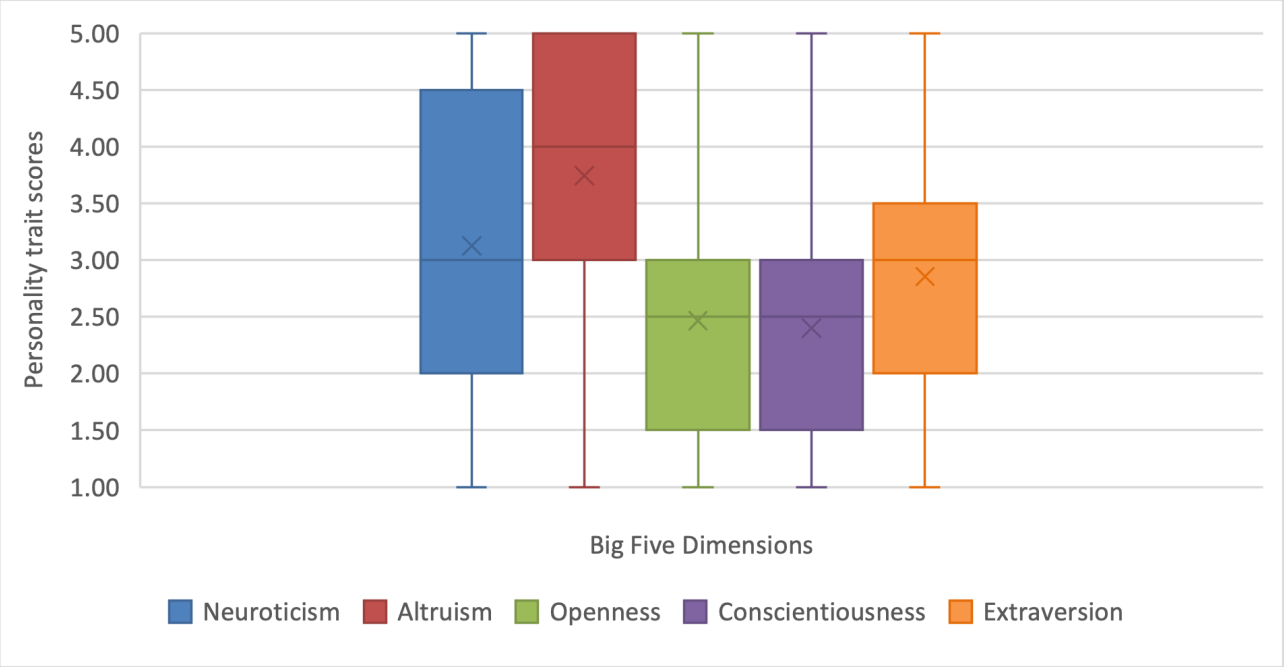
Already used mHealth[b], n (%)	135 (63.1)

[a]Education level: 3 missing responses (n=211).



[b]mHealth: mobile health.

Characteristics of the Participants on the Big Five

Personality trait scores were measured on a 1 to 5 scale. The distribution of the sample across the Big Five dimensions is presented in Figure 1, where the line depicts the median and the cross indicates the mean.

Overall, participants in this study tended to score higher on agreeableness (mean 3.71, SD 1.31), followed by neuroticism (mean 3.12, SD 1.23) and extraversion (mean 2.86, SD 1.17).

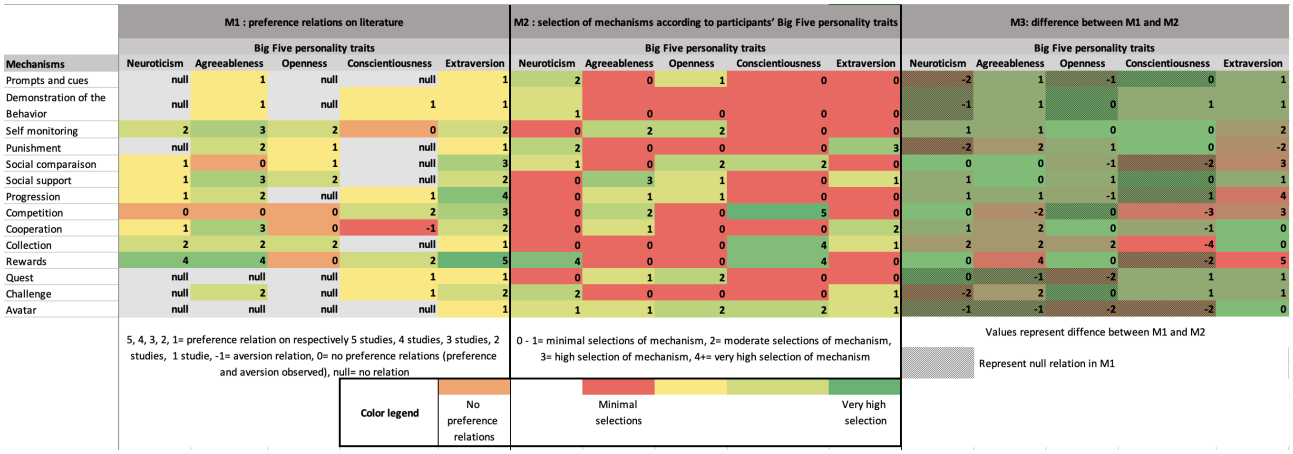
Punition	8 (3.7)	3.3 (1.5)	3.5 (1.3)	2.2 (0.7)	2.3 (1.0)	3.1 (1.2)

Comparison Between This Study's Results and the Preference Matrix



The initial matrix (M1) summarizes the preference relations identified in the literature between personality traits and mechanisms. A positive relation indicates that individuals with a given Big Five profile tend to prefer a particular mechanism, whereas a negative relation (aversion) reflects a lower interest or dislike for that mechanism among individuals with that profile. Mixed relations correspond to cases where both preference and aversion were reported across studies, while missing relations denote the absence of evidence. Overall, M1 presents 60% (42/70) positive preference relations, 1% (1/70) aversion relations, 10% (7/70) mixed relations, and 29% (20/70) missing relations (see M1 in Figure 2).

The second matrix (M2) represents the empirical data collected in this study. For each selection mechanism (eg, collection, challenge, or reward), a discriminative score was calculated. This score indicates how strongly a given personality trait differentiates between participants who selected a mechanism and those who did not. M2 shows that 5% (4/70) of mechanisms had a very high discriminative score (>4), 3% (2/70) high (3), 17% (12/70) moderate (2), and 74% (52/70) low (0 - 1; see M2 in Figure 2).

The second matrix (M2) represents the empirical data collected in this study. For each selection mechanism—defined as one of the gamified motivational strategies participants could choose (eg, collection, challenge, or reward)—a discriminative score was calculated. This score indicates how strongly a given personality trait differentiates between participants who selected a mechanism and those who did not. M2 shows that 5% (4/70) of mechanisms had a very high discriminative score (>4), 3% (2/70) high (3), 17% (12/70) moderate (2), and 74% (52/70) low (0 - 1; see M2 in Figure 2).

Preferred Mechanisms and Big Five: Statistical Analysis

A separate logistic regression analysis was performed for each mechanism to determine whether the personality scores predicted the likelihood of selecting that mechanism. In addition, an ordinal logistic regression was conducted using the motivation ratings assigned to the selected mechanisms as the dependent variables and the BFI-10-Fr scores as the predictors. Across analyses, 3 mechanisms yielded statistically significant models.

Collection Mechanism

For the collection mechanism, defined as a feature that allows users to gather virtual objects, the regression model was statistically significant (χ^2_5=13.07; n=207; P<.05), indicating that the model successfully distinguished between participants who selected the collection mechanism and those who did not. The model explained between 6% (Cox and Snell R^2) and 10% (Nagelkerke R^2) of the variance in mechanism selection and correctly classified 83.1% of cases. As shown in Table 5, only 1 predictor made a unique statistically significant contribution: conscientiousness with an odds ratio (OR) of 1.87 (95% CI 1.27-2.75). This indicates that participants scoring higher on conscientiousness were over 1.87 times more likely to select the collection mechanism compared with those scoring lower on this trait, after controlling for all other predictors in the model.

Table . Logistic regression predicting the likelihood of selecting the collection mechanism.

Personality trait	B	SE	Wald chi-square (*df*)	*P* value	OR[a] (95% CI)
Openness	–0.019	0.193	0.010 (1)	.92	0.981 (0.672-1.432)

Neuroticism	–0.191	0.163	1.376 (1)	.24	0.826 (0.600-1.137)
Constant	–2.089	1.093	3.654 (1)	.06	0.124 (0.015-1.054)

[a]OR: odds ratio.

Competition Mechanism

The logistic regression for the competition mechanism, a feature emphasizing performance comparison or rivalry between users, was statistically significant (χ^2_5=31.49; n=200; P<.01). This result indicates that the model successfully distinguished between participants who selected this mechanism and those who did not, based on their Big Five personality scores. The regression explained between 15% (Cox and Snell R^2) and 33% (Nagelkerke R^2) of the variance in the selection of the competition mechanism and correctly classified 91.5% of cases. As shown in Table 6, 4 personality dimensions made a unique statistically significant contribution to the model: neuroticism, conscientiousness, extraversion, and agreeableness. Conscientiousness emerged as the strongest positive predictor (OR 3.22, 95% CI 1.73-6.00), followed by agreeableness (OR 1.93, 95% CI 1.08-3.45). In contrast, neuroticism (OR 0.43, 95% CI 0.25-0.74) and extraversion (OR 0.52, 95% CI 0.30-0.89) were negatively associated with selecting the competition mechanism, indicating that individuals with higher levels of these traits were substantially less likely to choose this feature.

[a]OR: odds ratio.

An ordinal logistic regression was conducted for each mechanism to determine whether participants' Big Five personality scores predicted their motivation ratings for the competition mechanism. The model for the competition mechanism was statistically significant (χ^2_5=11.16; N=214; *P*=.05), indicating that the predictors reliably differentiated participants' motivation levels for engaging in mHealth apps through competition-based features. The model explained between 5% (Cox and Snell R^2) and 8% (Nagelkerke R^2) of the variance in the motivation scores. As shown in Table 7, 2 personality traits made unique and statistically significant contributions to the model: conscientiousness and neuroticism. Higher conscientiousness was associated with greater motivation to use competition-based features (OR 1.63, 95% CI 0.08-0.89), whereas higher neuroticism was associated with lower motivation (OR 0.71, 95% CI 0.70-0.01).

Table . Logistic regression predicting the likelihood of the score of the competition mechanism.

Personality trait	B	SE	Wald chi-square (*df*)	*P* value	OR[a] (95% CI)
Openness	–0.072	0.207	0.121 (1)	.73	0.931 (–0.478 to 0.553)

[a]OR: odds ratio.

Reward Mechanism

The logistic regression for the reward mechanism, a feature offering virtual incentives for engaging in the target behavior, was statistically significant (χ^2_5=35.29; n=204; *P*<.001). This indicates that the model successfully distinguished participants who selected this mechanism from those who did not, based on their Big Five personality traits. The model explained between 16% (Cox and Snell R^2) and 27% (Nagelkerke R^2) of the variance and correctly classified 81.4% of cases. As shown in Table 8, 2 personality traits made unique statistically significant contributions to the model: conscientiousness and neuroticism. Participants scoring higher on conscientiousness were 2.36 times more likely to select the reward mechanism, while those scoring higher on neuroticism were 1.97 times more likely to choose it, controlling for all other predictors.

Table . Logistic regression predicting likelihood of selecting the reward mechanism.

Personality trait	B	SE	Wald chi-square (*df*)	*P* value	OR[a] (95% CI)

Discussion

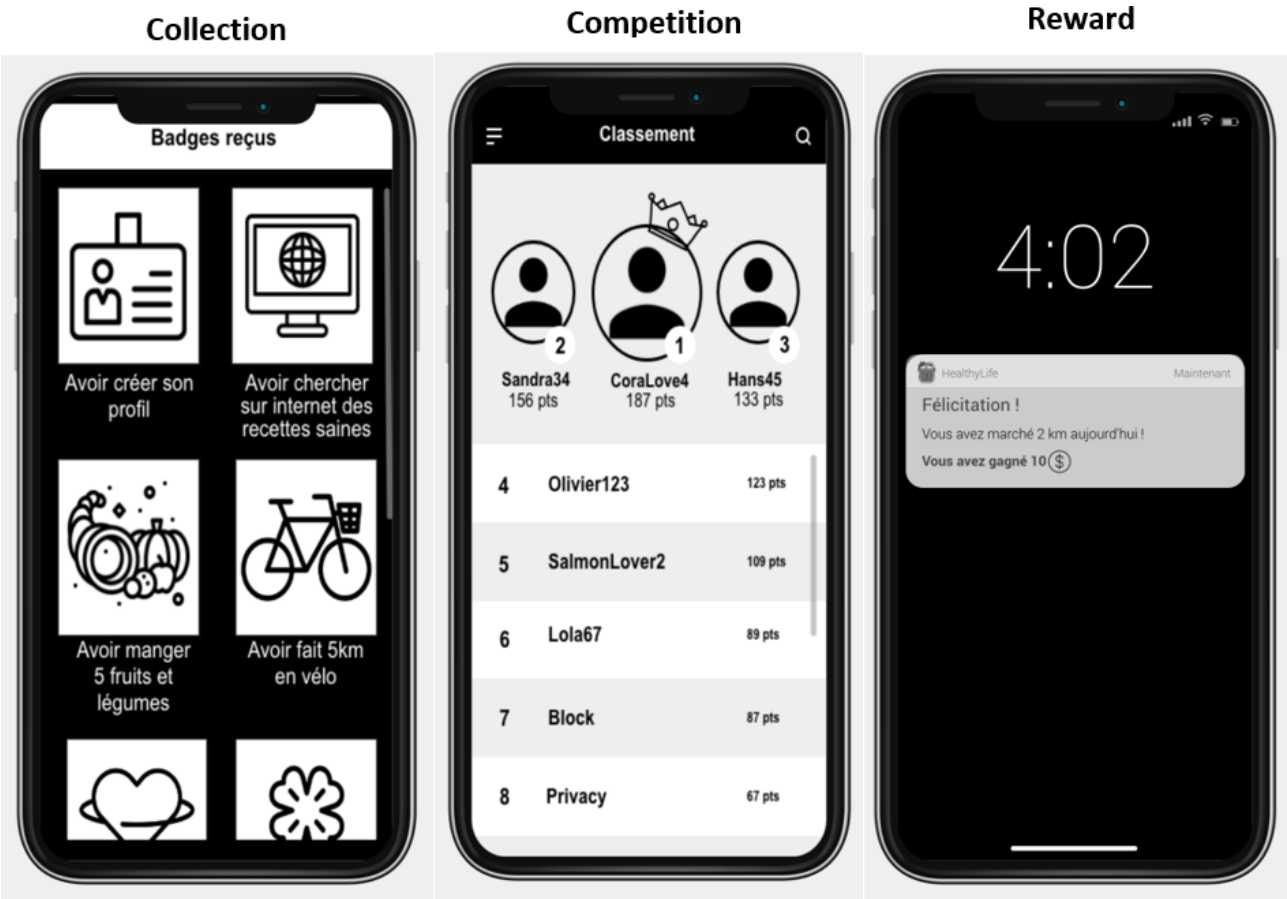
Principal Findings

The objective of this study was to validate the preference matrix derived from a previous literature review by examining whether similar relations could be observed empirically in our sample.

Four mechanisms were selected by more than half of the participants: self-monitoring (n=149), progression (n=127), challenge (n=112), and quest (n=111). No significant associations were found between these mechanisms and the Big Five personality dimensions. However, when comparing these findings with the validated preference matrix (M1), a more nuanced interpretation emerges. According to the matrix (M1), self-monitoring is generally appreciated across all Big Five profiles, with the exception of one study reporting lower preference among highly conscientious individuals. The progression mechanism also appears to be universally preferred, reinforcing its broad motivational relevance. By contrast, the preference matrix (M1) suggests that the quest mechanism is predominantly preferred by conscientious and extraverted individuals, whereas the challenge mechanism tends to be favored by users scoring high in agreeableness, conscientiousness, and extraversion. Taken together, these results indicate that certain gamification mechanisms, particularly self-monitoring and progression, possess strong, cross-profile motivational appeal. These mechanisms should, therefore, be considered foundational elements in the design of mHealth apps, providing a core layer of user engagement upon which more personalized, profile-specific interventions may be developed.

Comparison Between M1 and M2

The comparison between matrices M1 and M2 highlights several developments in the identification of potential relationships between mechanisms and Big Five personality traits. In M2, new associations emerge that were not identified in M1, particularly between neuroticism and mechanisms such as prompts and cues, demonstration of behavior, punishment, quest, challenge, and avatar. Similarly, openness shows newly emerging association with prompts and cues, progression, quest, and challenge, while conscientiousness displays novel relations with social comparison and avatar, as well as a particularly strong association with the collection mechanism in M2. These findings reflect a refined and evolving understanding of how specific personality traits may align with distinct mechanisms when examined in an experimental context.



In addition, whereas M1 did not show a clear consensus regarding the relationships involving agreeableness and openness, M2 reveals emerging associations, notably between agreeableness and competition, and between openness and rewards. Conversely, several relationships previously identified in M1 do not reappear in M2. For example, extraversion was associated in M1 with a wide range of mechanisms, including prompts and cues, demonstration of behavior, self-monitoring, punishment, social comparison, social support, progression, competition, cooperation, collection, rewards, and quest, but these associations were not observed in M2. A similar reduction in associations is observed for agreeableness, which in M1 was linked to prompts and cues, demonstration of behavior, punishment, collection, challenge, and especially rewards. Despite these discrepancies, statistically significant results in this study were identified for only 3 mechanisms: collection, competition, and rewards. Of the 5 significant relationships observed, 3 were already present in the preference matrix M1 (conscientiousness-competition, conscientiousness-rewards, and neuroticism-rewards). Two relationships, those involving neuroticism-competition and agreeableness-competition, had shown inconsistent evidence in M1, with both preference and nonpreference relations reported in the literature.

This study contributes to refining the preference matrix in two ways. First, it enriches the matrix by identifying a new significant preference relation between conscientiousness and the collection mechanism. Second, in cases where the literature reports incongruent findings, our results help clarify these relationships by supporting a nonpreference relation for neuroticism and agreeableness with competition.

In the following sections, we examine in greater detail the 3 mechanisms for which significant regressions were obtained. Figure 3 presents the mockups used in the online survey to illustrate the 3 mechanisms preferred by participants according to their personality traits. These visual representations supported participants' understanding of each mechanism and facilitated more reliable self-selection during the experimental procedure.

XSL•FO
RenderX

Figure 3. Preferred mechanisms according to personality profiles.

Collection

In this study, the collection mechanism refers to the accumulation of virtual items or badges over time. Collecting has been identified as a motivational strategy that can support engagement in health-related behaviors, such as maintaining physical activity [28]. Our results show that participants scoring higher on conscientiousness were 1.87 times more likely to select the collection mechanism than those with lower levels of this trait.

These findings are largely consistent with the existing literature, which reports a general preference for collection-based mechanisms across most Big Five personality traits in the preference matrix M1 [9,24,29-31]. Notably, however, none of the previously reviewed studies identified a specific preference for collection among highly conscientious individuals. As such, the present result constitutes a novel contribution to the preference matrix by establishing a new, trait-specific association between conscientiousness and the collection mechanism.

Competition

In this study, the competition mechanism is defined as enabling users to engage in competitive interaction with others in order to encourage the target behavior [23].

According to the preference matrix M1, competition is associated with all 5 Big Five personality traits. However, our results reveal a more differentiated pattern. Individuals scoring high in conscientiousness (OR 3.22, 95% CI 1.73-6.00) and agreeableness (OR 1.93, 95% CI 1.08-3.45) were significantly more likely to select competition as a motivating mechanism for maintaining their health compared with participants scoring lower on these traits. In contrast, participants with higher levels of extraversion (OR 0.43, 95% CI 0.25-0.74) and neuroticism (OR 0.52, 95% CI 0.30-0.89) were significantly less likely to select this mechanism.

Consistent with these findings, the ordinal regression analysis showed that participants with higher conscientiousness scores rated the competition mechanism as more motivating (OR 1.63, 95% CI 0.08-0.89), whereas those with higher neuroticism scores assigned lower motivation ratings (OR 0.71, 95% CI 0.70-0.01).

These divergent results suggest a controversial or polarized preference for competitive mechanisms. Qualitative feedback indicated that some participants favored individual-based mechanisms that emphasize personal effort rather than social comparison or rivalry. This interpretation aligns with previous research, which reports similar reservations toward competitive features in health-related apps, particularly when users prefer self-directed rather than socially driven motivation [10].

> *No comparison with others because it stresses me out if I don't win. I'm more motivated by the idea of doing myself good.* [P14]

> *I choose for myself, not for others, so there's no competition or comparison with others.* [P39]

XSL•FO
RenderX

> *I've excluded those that involve other people because I prefer autonomy.* [P129]
>
> *I no longer have anything to prove to anyone but myself.* [P134]
>
> *The individuality aspect. In my opinion, when you do something, you do it for yourself and not for others.* [P112]
>
> *I think the principle of fitness should be personal and not a competition with others.* [P140]

While other participants said they found competition more motivating:

> *I find competition very enjoyable, it pushes me to excel*. [P44]
>
> *Comparing myself to others pushes me to do better.* [P176]
>
> *I'm very competitive and I like it when people show me that I've made progress. It encourages me to keep going.* [P192]

The preference matrix (M1) further indicates that individuals scoring high in agreeableness and conscientiousness tend to prefer competition [8,10,32]. However, it also reports a preference relation with extraversion [9,10,24] and neuroticism [33], whereas our results show that individuals high in these 2 traits selected the competition mechanism less frequently. This discrepancy is noteworthy, as the preference matrix (M1) is based on evidence from three studies reporting a positive association between extraversion and competition, which contrasts with the nonpreference pattern observed in our data. In addition, several studies examining competitiveness more broadly have documented a general attraction to competitive contexts among extraverted individuals, further emphasizing the unexpected nature of our findings [34,35]. One possible explanation lies in the heterogeneity of the extraversion construct itself: preferences for competitive environments appear to vary depending on specific subfacets of extraversion [36]. Individuals scoring higher on friendliness ("make friends easily" and "often feel uncomfortable around others") or cheerfulness ("have a lot of fun" and "am not easily amused") tend to show reduced interest in competitive dynamics. In contrast, those characterized by higher assertiveness ("take control of things" and "wait for others to lead the way") or excitement-seeking ("love action" and "dislike loud music") display stronger preferences for competition and achievement-oriented contexts [36]. These nuances suggest that the link between extraversion and preference for competitive mechanisms is not uniform and may be facet-dependent, an aspect that warrants deeper investigation in future research.

By contrast, the preference matrix (M1) also reports a nonpreference relation for individuals with higher levels of neuroticism profiles [32], a pattern that is corroborated by the results of our experiment.

Rewards

The reward mechanism involves the provision of virtual incentives to users for completing a target behavior [23]. It differs from the collection mechanism in that rewards are not necessarily accumulated as part of a predefined or structured set of items.

In our study, individuals with higher levels of neuroticism (OR 1.97, 95% CI 1.36-2.86) and conscientiousness (OR 2.36, 95% CI 1.53-3.63) were significantly more likely to select the reward mechanism. In addition, these participants assigned higher motivation scores to this mechanism ($OR_{Conscientiousness}$1.66, 95% CI 0.16-0.85; $OR_{Neuroticism}$1.38, 95% CI 0.03-0.61).

These findings are consistent with the preference matrix (M1), which reports established preference relations between the reward mechanisms and both conscientiousness and neuroticism across multiple studies [24,30,32,33,37,38].

Big Five Dimensions

Notably, conscientiousness emerged as a significant predictor across all 3 mechanisms identified in this study. In contrast, no significant associations were observed for openness, despite prior literature suggesting preferences for certain mechanisms, such as collection and competition, among individuals high in this trait.

Similarly, no significant preference results were identified for extraversion, even though the preference matrix derived from the literature (M1) reports associations between extraversion and multiple mechanisms. A comprehensive summary of the experimental findings alongside the preference matrix is presented in Table 10.

XSL•FO

[c]*Italicized text* indicates findings inconsistent with the literature.

Applying the Preference Matrix in Practice

Implementing the preference matrix involves 2 main steps: identifying the user profile and tailoring the app content accordingly. User profiling traditionally relies on validated personality questionnaires (eg, BFI-10 and NEO-PI-R); however, these instruments can be time-consuming and may discourage user participation. As an alternative, automated profiling approaches based on smartphone usage patterns [39,40] or social media data [41-43] have shown promising results, although privacy concerns remain a major limitation. Such approaches require access to personal data, sometimes including sensitive inputs such as audio or video, which many users are reluctant to share [44]. Moreover, extensive data collection may increase perceptions of intrusiveness or manipulation, potentially undermining user trust and the perceived validity of behavior-based personalization [44]. To address these concerns, we recommend making personalization optional, offering users the choice to complete a brief, validated personality questionnaire if they opt in, and implementing strict ethical safeguards to ensure responsible data use. In particular, personality-related data should be collected solely for the purpose of enabling individualized personalization within the app, should not be repurposed for any secondary uses or shared with third parties, and should be handled with full transparency. Users must be clearly informed about what information is being collected, how it will be processed, and for what specific purpose (to tailor the app's features to their personality profile), thereby promoting informed consent, user autonomy, and trust.

Once the profile is established, app content can be adapted by selecting mechanisms aligned with the user's dominant personality traits, as defined by the preference matrix. For example, a user scoring high in conscientiousness might be shown mechanisms emphasizing rewards, competition, and collection, while competitive features could be intentionally avoided for a more extraverted user. This automated adaptation enhances user engagement by aligning motivational strategies with intrinsic preferences derived from psychological profiling.

However, to ensure that personalization remains user-centered and flexible, the system should also allow users to manually adjust or refine these automatically suggested mechanisms. After reviewing the proposed configuration, users can confirm, modify, or reject specific mechanisms based on their subjective preferences or contextual needs. This hybrid approach, combining data-driven profiling with user autonomy, maximizes

XSL•FO
RenderX

both the accuracy and acceptability of personalization. It also mitigates potential mismatches between predicted and actual motivation, ensuring that the final app configuration genuinely reflects the user's individual preferences.

Limitations

The requirement for participants to select exactly 5 mechanisms out of 15 constitutes a methodological limitation. Some participants may have selected mechanisms they did not find particularly motivating to reach the required number, while others may have wished to select more than 5 mechanisms but were constrained by the study design. This forced-choice approach may, therefore, have influenced the distribution of selected mechanisms and attenuated individual preference differences.

In addition, our study sample was not fully representative of the general population, as it included a high proportion of university students, who are typically younger ($mean_{age}$ 29.42, SD_{age} 10.41). Such demographic homogeneity may restrict the extent to which these findings can be generalized to other age groups or populations. Nevertheless, prior research on digital behavior changes and web-based health interventions suggests that age does not substantially moderate the effects of these interventions on health-related behaviors [45,46]. Systematic reviews have similarly reported that demographic variables such as age, sex, and education tend to have weak or inconsistent moderating influences on the effectiveness of these techniques [45]. Moreover, individuals most inclined to engage with health apps are generally younger and possess higher levels of education and income [47], which aligns closely with the characteristics of our sample and supports the external validity of our findings. Future research should, however, aim to include older adults and individuals less familiar with digital technologies to examine whether similar patterns of preference and engagement are observed in these groups. This population is particularly relevant to investigate, as older adults also represent an active and growing user base of mHealth apps, often using them for health monitoring, disease prevention, or physical activity tracking. Recent evidence from a comprehensive scoping review underscores the growing importance of this demographic and highlights that addressing key barriers, such as evolving capability requirements, cost, privacy concerns, and age-related design assumptions, can substantially enhance meaningful engagement. It also emphasized the importance of empowering older adults through learner-centered, need-based digital education [48]. Building on these insights, future studies should explore how mHealth apps can be designed to support sustained digital engagement among older adults and to better capture the diversity of their experiences and values in technology use.

Another limitation concerns the personality assessment instrument used in this study. We used the BFI-10-Fr, an ultra-short version of the Big Five Inventory, to minimize participant burden given the overall length of the online questionnaire. Although the BFI-10-Fr provides a practical and time-efficient measure, previous research has noted that its internal reliability can be relatively low due to the limited number of items per trait [49]. Nevertheless, according to the original validation study by Rammstedt and John [49], the BFI-10 demonstrates satisfactory test–retest stability and acceptable construct validity, supporting its suitability for large-scale or time-constrained surveys. Future studies should, however, consider replicating these analyses using a more comprehensive personality inventory, such as the Big Five Inventory-44 or NEO-PI-R, to ensure higher internal consistency and further validate the robustness of the associations observed.

We also observe that, despite our sample size calculation, it appears that it did not allow for proper discrimination, as we obtained significant results for only 3 out of 14 mechanisms. Therefore, this calculation should be reconsidered.

It was not feasible to assess the customization mechanism, given its expansive scope and the consequent challenges in representing it in the format of a conventional mockup screen.

Although the regression analyses yielded statistically significant results for several mechanisms, the explanatory power of the models remained relatively modest. For instance, the proportion of variance explained ranged from 6% to 10% for the collection mechanism, and from 5% to 9% for the ordinal regressions predicting motivation scores. Even for the most predictive models, such as competition (15% - 33%) and Rewards (16% - 27%), a substantial portion of the variance remained unexplained. This indicates that while personality traits, particularly conscientiousness and neuroticism, appear to play a meaningful role in the selection of gamification mechanisms, other unmeasured variables likely contribute to these motivational choices. Therefore, the practical significance of these findings should be interpreted with caution: the Big Five dimensions alone may not fully account for users' preferences, which are likely shaped by situational, contextual, or motivational factors beyond personality. Future studies could aim to include such variables, or use alternative modeling approaches (eg, interaction terms or structural models) to capture more of the underlying variance in mechanism selection.

Conclusions

The entire preference matrix could not be validated with experimental data. Significant relations were identified for three mechanisms only: collection, competition, and rewards. Most of these preference relations are consistent with those reported in the literature-based preference matrix (M1), apart from the preference relation for the collection mechanism and conscientiousness and the nonpreference relation for competition regarding the extraversion trait, which is significant in this study but, according to the preference matrix M1, is a preference relation. The neuroticism trait is significant for competition as nonpreferred, yet the preference matrix studies demonstrated both a preference and a nonpreference relation for this trait. Considering these findings, it can be concluded that a nonpreference relation is corroborated. It would be interesting to replicate this study with a larger, less student-dominated panel to achieve better representation and more significant results on mechanism preference relations by Big Five traits.

Abstract

Background: Hearing loss is a global health issue affecting millions and creating significant communication barriers, particularly in accessing health care services. These barriers can lead to complications and iatrogenic events, emphasizing the need for assistive technologies that enhance communication efficiency.

Objective: This study aimed to develop a corpus of medical terms for the "Captar-Libras" project, designed to improve communication between health care professionals and deaf patients through a bidirectional sign language system.

Methods: This study used the Delphi method to obtain consensus on key terms for a sign language translation system in health care emergency consultations. Initially, a questionnaire with common emergency questions was developed and distributed to health care professionals. The collected data were analyzed by a team of experts and adapted to Brazilian Sign Language (Língua Brasileira de Sinais [Libras]). Simulated clinical scenarios were then created to validate the system and ensure the accuracy of the vocabulary in the medical context.

Results: Among the 16 participants, most were physicians (n=14, 87.5%) with experience in emergency care, and half had previously treated patients with hearing loss in emergency settings. The questions evaluated received high average importance scores, particularly those related to initial symptoms and pain intensity. Some suggestions for adjustments were made, with two wording modifications significantly improving clarity regarding smoking and alcohol use. Additional suggestions to enhance the medical interview were also proposed. This study aimed to identify essential questions for emergency consultations with deaf patients, focusing on developing a corpus for Libras recognition system. The findings emphasize the importance of effective communication and highlight the challenges of translating medical terms into Libras. To address these complexities, a multidisciplinary team used the Delphi method to ensure linguistic and cultural accuracy. Additionally, the study reinforces the need for clear, structured medical queries to improve accessibility in emergency care. As a next step, system validation through simulated scenarios will be conducted. Despite certain limitations, this research lays a solid foundation for advancing sign language recognition in medical settings.

Conclusions: This study represents a significant methodological step toward improving communication between health care professionals and deaf individuals in emergency medical settings. Rather than proposing a universal solution, the study presents a structured and participatory approach for developing a corpus of medical terms in Libras, with interdisciplinary validation. The process included the involvement of deaf sign language experts during the translation and linguistic adaptation phase, ensuring that the corpus reflects authentic usage and articulation in Libras.

KEYWORDS

deafness; sign language; assistive technology; emergency health services; Delphi technique

Introduction

Hearing loss is a significant global health issue, affecting millions worldwide. According to the World Health Organization (WHO), more than 430 million people globally experience some degree of disabling hearing loss, a number projected to rise to 700 million by 2050 [1]. Approximately 10 million people in Brazil are deaf, 2.6 million of whom have

XSL•FO
RenderX

severe functional difficulties [2]. For these individuals, sign language is not just a communication tool but a vital aspect of their cultural identity, enabling interactions based on gestures and facial expressions.

Despite the critical role of sign language in the lives of deaf individuals, significant communication barriers persist, particularly in accessing health care. These barriers are a reflection of the broader challenges faced by people with disabilities, who often encounter services that are not equipped to meet their specific needs [3]. In the context of health care, these challenges can have profound implications. The lack of effective communication between health care providers and deaf patients can lead to misdiagnosis, inappropriate treatments, and overall poorer health outcomes [4].

The situation is even more challenging in emergency settings, where the inability to establish timely and effective communication can directly impact the health and safety of deaf individuals. Delays in diagnosis, treatment, and even basic information exchange can result in worse prognosis, higher incidence of complications, and iatrogenic events [4,5]. This underscores the urgent need for improved accessibility and preparedness within health care systems to address the needs of deaf individuals.

To address some of these challenges, the project "Captar-Libras: Video Communication System for the deaf applied to medical pre-care" from the Universidade Federal de Minas Gerais (UFMG) aims to overcome this obstacle by developing a prototype for the recognition and synthesis system for Brazilian Sign Language (Língua brasileira de sinais [Libras]), with the recognition of signs and generation of gestures and expressions with a photo-realistic avatar.

For successful implementation and future applicability, it was first necessary to select the most relevant terms and questions most commonly used in medical consultations. Freitas [6] defines "corpus" as a collection of text documents compiled according to a specific objective that can be processed by machines. Thus, Corpus Linguistics plays an important role in enabling the development of new assistive technologies, especially in the construction of databases for the study of languages [7].

However, in a systematic review conducted by our group, we found that no studies have been published regarding the development of such a corpus of questions and possible answers to be used in translation systems [8]. Therefore, this study aims to construct a linguistic corpus specifically tailored for emergency medical care, serving as the foundational resource for the development of real-time sign language translation technologies to improve health care accessibility for the deaf community. We hypothesize that the development of a medical corpus based on commonly used terms and questions in emergency consultations will provide the necessary linguistic foundation for effective and accurate sign language translation systems.

Methods

Study Design

This study used a qualitative, exploratory, and consensus-based Delphi method within a mixed methods framework. It constitutes a subanalysis of the "Captar-Libras Project"—a multidisciplinary initiative focused on developing a bidirectional sign language recognition and translation system for primary medical consultations. Recognizing the paucity of literature on sign language translation systems in health care, the Delphi method was selected for term selection. Initially conceptualized in the 1950s, this research strategy effectively elicits expert consensus on subjects where scientific evidence is insufficient or divergent [9].

Step 1: Initial Question Formulation

The process began by identifying the most frequent questions encountered in emergency care settings. This was based on the extensive experience of the lead researcher (MSM), who had more than 12 years of experience in emergency care. Drawing from this expertise, a preliminary set of questions was developed to reflect the most common and critical inquiries health care professionals need to communicate with patients during emergencies.

Step 2: Questionnaire Development

Using the initial set of questions devised in Step 1 as a foundation, a detailed questionnaire was created. The questionnaire included items developed through a Delphi approach to identify and reach consensus on the most relevant medical terms and questions for emergency care interactions with deaf patients, using Likert scale items. It also included open-ended questions to gather qualitative feedback. This mixed methods approach ensured that the final selection of terms and questions would meet the practical needs of a consultation at the emergency care service. Then, the questions were organized and clustered to provide the respondents with a natural flow and facilitate the data collection process, which was carefully planned to minimize the time and burden of answering the questions and to optimize communication between our team and the participants.

Step 3: Questionnaire Content

The questionnaire consisted of 6 questions regarding the professional profile, 21 Likert scale questions, and 2 open-ended questions. Besides the questions defined and established in Step 1, there were also questions designed to evaluate the participants' experience with emergency care and interacting with deaf patients (Multimedia Appendix 1). One of the questions assessed the professionals' workplace, with options: "hospital"—large health establishments with an organized flow of care, "emergency care unit"—medium-complexity services with open access whose objective is to provide initial assistance in urgencies or emergencies, and "pre-hospital care"—which involves the first care and transportation to hospitals.

Step 4: Data Collection

The questionnaire was created in Google Forms (Google LLC) for easy access and availability, and the link was sent via

XSL•FO
RenderX

WhatsApp (Meta Platforms, Inc), a widely popular instant messaging app in Brazil. Before answering, the participants received a brief overview of the "Captar-Libras Project" and an informed consent form.

Expert Selection

Experts were recruited among physicians and nurses currently working or with prior professional experience in emergency care services. This criterion was adopted because familiarity with emergency consultations is essential for identifying the most relevant questions and medical terms to be included in the corpus.

Step 5: Data Analysis

After the data collection period ended, responses were analyzed to identify consensus on the most critical terms and the need to include additional questions for the sign language recognition corpus. Consensus was defined a priori as at least 80% of participants rating an item as 4 or 5 on the 5-point Likert scale. Nevertheless, all qualitative suggestions provided in the open-ended questions were also considered. The team of linguists and Libras specialists evaluated these contributions to determine their applicability to sign language translation, ensuring linguistic and cultural adequacy. Once the final corpus was consolidated in Brazilian Portuguese, adjustments were carried out for translation and adaptation into Libras.

Quantitative data from the Likert scale questions were analyzed using descriptive statistics. Specifically, the proportion of participants selecting each response option was calculated for each question. No inferential statistical tests were conducted, as the primary aim was to identify consensus and assess the relative importance of terms for inclusion in the sign language corpus.

While the Delphi process established the selection and prioritization of questions, the response options were constructed based on the expertise of the lead author (MSM) to reflect realistic scenarios and ensure practical applicability. This approach allowed the incorporation of clinically accurate and contextually appropriate responses, which were subsequently adapted into Libras during the translation and validation process.

Step 6: Adaptation Process for Sign Language

The sign language team carefully analyzed the corpus in Portuguese for translation and cultural and linguistic adaptation. A direct word-for-word translation was not feasible due to the structural and semantic specificities of sign languages. Therefore, it was essential to make adaptations and adjustments in the corpus to ensure that the corpus reflected how deaf users articulated specific medical terms. The initial adaptation team included 2 deaf individuals, a sign language linguist (university professor), and a graduate student with health-related experience, and 2 hearing professionals (a sign language linguist fluent in Libras and a sign language interpreter). The team worked collaboratively to identify terminological discrepancies between spoken Portuguese and Libras, considering both linguistic and contextual aspects.

The adaptation process followed an iterative cycle:

1. Initial translation and restructuring: the team identified questions that were too complex for direct translation and restructured them into shorter, sequential items (eg, the cluster "If the complaint is pain: Where is the pain? What is the pain like? Does it feel like a tightness or weight, or burning, or stabbing, or a shock?" was expanded into multiple questions regarding location, type, and sensation). Some concepts required additional explanation or modification; for example, (1) "Pain in the middle of the belly" was clarified by medical staff for accurate articulation. (2) The term "trauma" lacks a direct sign, so translations were elaborated to convey "physical trauma" or "psychological trauma" depending on context. (3) "Penetrating trauma" was translated into a descriptive sign sequence ("material group cut also long thin object stick") to ensure comprehension. (4) Aggression was translated using the most comprehensive and contextually appropriate signs, reflecting various scenarios of physical aggression. Decisions were guided by the principle that the translated signs should reflect the intended meaning, be understandable by deaf informants, and align with authentic Libras usage. This approach is consistent with previous work highlighting that effective communication in health care requires corpora that are functionally and contextually realistic, thereby improving the accuracy and usability of sign language recognition systems [10].
2. Peer validation: each item was translated to Libras by a deaf undergraduate student and recorded as individual videos. To validate comprehension, the videos were presented to a small group of deaf graduates and to a deaf university professor who had not seen the questionnaire in Portuguese. Their feedback focused on clarity, naturalness, and cultural adequacy.
3. Revisions: terms or expressions flagged as unclear were reformulated. For example, grammatical suggestions that had no functional equivalent in Libras were discarded, while ambiguous medical terms were replaced with more visually descriptive alternatives.
4. Final validation: this cycle of translation, feedback, and revision was repeated until mutual comprehension was reached across both deaf linguists and health professionals.

During the project, team composition evolved (the deaf professor left for personal reasons and was replaced by another deaf linguistics professor, while new members, including a physiotherapist and 2 undergraduate students, joined), but the iterative approach remained constant. Throughout the adaptation process, all feedback from deaf linguists, health professionals, and volunteer reviewers was carefully considered. Suggestions that enhanced clarity, comprehension, or cultural accuracy were incorporated directly into the corpus, while minor issues irrelevant to sign language translation (eg, Portuguese punctuation) were documented but not applied. This iterative approach ensured that each input led to specific refinements, resulting in a final corpus that accurately reflected the intended medical terminology in Libras and was understandable by the target population. Overall, the adaptation phase spanned approximately 3 months, encompassing reevaluation, translation, and video recording, culminating in the production of a definitive video corpus. The final version served as a

XSL•FO
RenderX

"teleprompter" guide for deaf volunteers, who reproduced the validated signs in a controlled setup composed of multiple cameras, chromakey background, and illumination. The data collection started in January 2024 and was finalized in May 2025.

Step 7: Development of Hypothetical Medical Care Situations

Hypothetical clinical scenarios were developed by the aforementioned researcher (MSM), who has clinical expertise in emergency care, based on common situations encountered in emergency settings. Each scenario was designed to simulate realistic interactions between health care professionals and deaf patients, including typical questions about symptoms, pain, and treatment history. This step was fundamental to ensure adequate understanding by the systems team, enabling the translation into sign language process to be carried out without losing critical information or meaning.

The evaluation of the sign language recognition system, which is being developed, will focus on three aspects:

1. Comprehension by the target users: deaf volunteers will assess whether the terms and questions are clearly understood and reflect realistic emergency situations.
2. Accuracy of translation: the system's ability to correctly interpret and reproduce the intended medical terms in Libras will be checked against the original Portuguese questionnaire.
3. User experience and system performance: participants will provide feedback on ease of use, clarity of interaction, and any technical issues such as system crashes or delays, which will inform iterative improvements to the interface and functionality.

Feedback from participants will be systematically recorded, and necessary adjustments will be made iteratively to ensure the clarity, accuracy, and usability of the system in emergency care contexts.

Ethical Considerations

This study was approved by the UFMG Ethics Review Board, under protocol number CAAE 71623323.8.0000.5149, in accordance with national and international research ethics guidelines. All participants, including health care professionals and sign language experts, provided informed consent prior to participation in the Delphi process, translation, and validation activities. In addition to obtaining informed consent, all procedures were designed to respect cultural and linguistic nuances within the deaf community. The participants' autonomy, comfort, and comprehension were prioritized during data collection. Data collected through questionnaires were anonymized to ensure confidentiality. Video recordings were securely stored, accessible only to the research team, and were used exclusively for the purposes of corpus development. Participants and the team members who appeared in video recordings of sign language production signed specific consent forms authorizing the use of their images for research purposes and for inclusion as multimedia material accompanying this publication. No other personally identifiable information is disclosed in this paper or in the supplementary material. Participants who were deaf and took part in the video recordings received financial compensation to cover transportation costs to the UFMG, where the recordings took place.

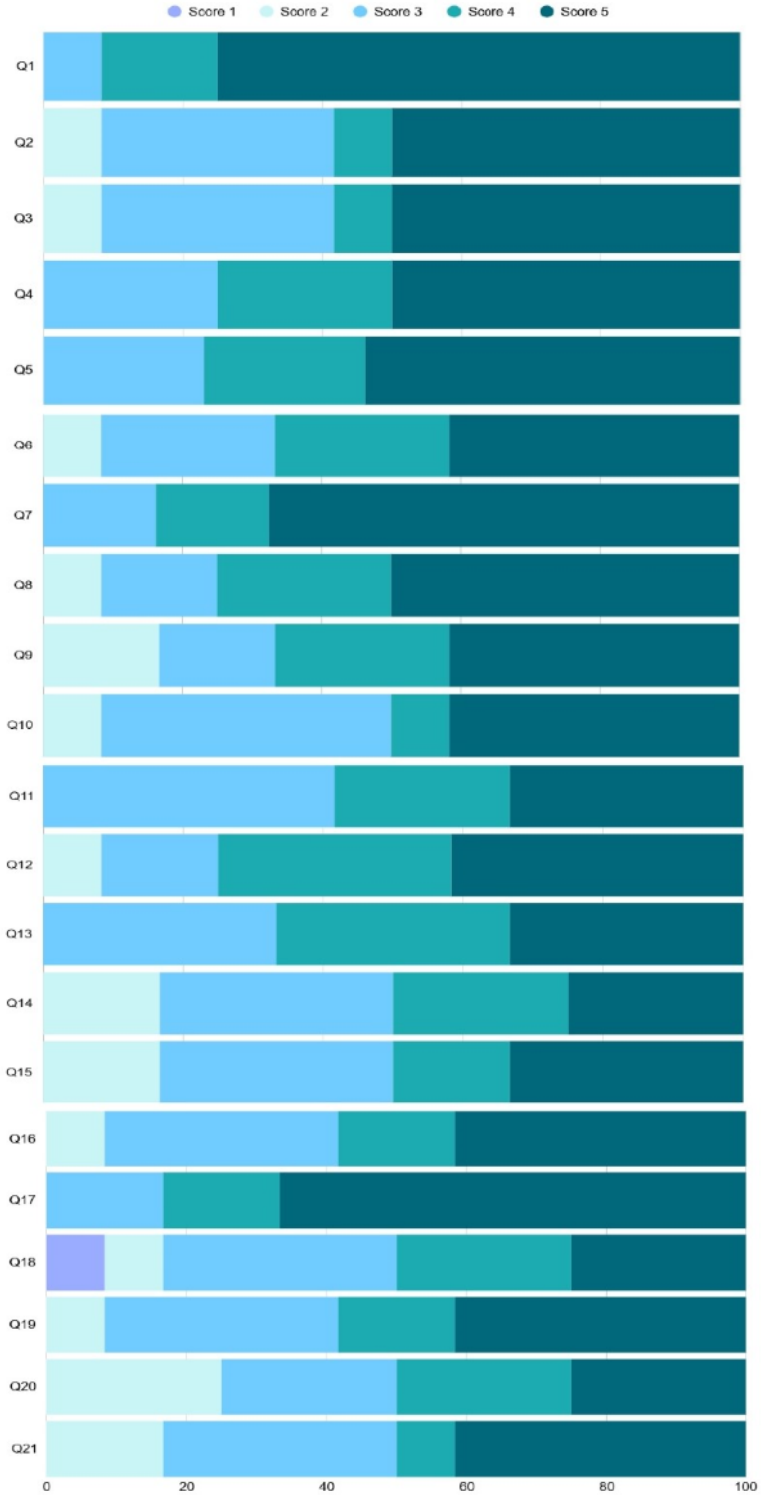
Results

Profession and Field of Activity

Among the 16 participants who answered the questionnaire, 12/16 (75%) were currently working in emergency and urgent care services, which aligns with the focus of this study. Among these 12 participants, 11/12 (91.67%) were physicians and 1/12 (8.33%) was a nurse. Considering all participants (N=16), 3/16 (18.75%) participants had worked in the area for less than 5 years, 4/16 (25%) for 5 to 10 years, and 5/16 (31.25%) for more than 10 years. Regarding the workplace, 7/16 (43.75%) participants reported working in hospitals, 2/16 (12.5%) in emergency care units, 1/16 (6.25%) in prehospital care, and 2/16 (12.5%) worked simultaneously in hospitals and emergency care units.

Experience in Treating a Hearing-Impaired Patient in an Emergency

Among the 12 participants working in emergency and urgent care services, 8 (66.66%) had already treated hearing-impaired patients in emergencies. Regarding the frequency of these occurrences, 2/12 (16.67%) professionals had treated 2 patients in this scenario, 4/12 (33.33%) had treated between 2 and 5, and 2/12 (16.67%) had treated more than 5.



Level of Relevance of the Proposed Questions

Figure 1 and Multimedia Appendix 2 summarize the general results. Most questions were considered important, with medians predominantly between 4 and 5. Notably, questions addressing the primary complaint (eg, "What are you feeling that made you seek the hospital?") and the patient's medical history (eg, "Are you allergic to any medication?") were consistently rated as highly relevant.

A Likert scale ranging from 1 to 5 was used, with the following correspondence: 1=not important at all; 2=of little importance; 3=of average importance; 4=very important; 5=absolutely essential.

XSL•FO
RenderX

Figure 1. Graphical representation of the importance score assigned to each question by health professionals with emergency care experience.

Opinion on the Wording of the Questions and Contact Availability

Six participants suggested 10 recommendations for improvement of the already proposed questions (Textbox 1). Most suggestions involved minor grammatical adjustments, which were deemed nonrelevant for sign language translation by the team of linguistics specialists. Questions regarding smoking and alcohol consumption were revised to better capture the patients' habits, reflecting these contributions. The other 6 participants indicated no need for changes.

XSL•FO
RenderX

Textbox 1. Questions included in the final version for the corpus development.

1. If the complaint is pain: was it 1 episode of pain, or more episodes? If more episodes, when was the first episode? How did the pain evolve? Did it increase in intensity? Did it increase in duration?
2. Are you feeling nauseous or vomiting? Do you have diarrhea? If so, what is it like? Is there blood, mucus, or pus? Do you have stomach pain?
3. Have you had any surgery? If so, which one?

General Suggestions and Proposals for New Questions

Five participants provided other general suggestions or proposed new questions:

1. Incorporating the Manchester Protocol for prioritizing patient care
2. Organizing the assessment in a flowchart format, based on the main complaint and the Manchester protocol
3. Inserting a question regarding the duration of the pain and its evolution (whether it has improved or worsened over time)
4. Inserting a question regarding other known allergies and surgical history
5. Inserting questions regarding gastrointestinal complaints (“Are you feeling nauseous or vomiting? Do you have diarrhea? Do you have stomach pain?”)

Although the inclusion of the Manchester Protocol and organizing in a flowchart assessment would be enriching, these suggestions exceeded the scope of this study. In the case of the Manchester Protocol, information about waiting time depending on the severity of the patient’s pain is relevant for health care professionals. For patients, this is not a piece of information that needs to be translated into sign language. Regarding the other suggestions to insert new questions, the changes were made (Table 1).

Hypothetical Medical Care Situations

Fourteen hypothetical scenarios were developed as a corpus enhancement tool in order to test its applicability and comprehensiveness (Multimedia Appendix 4). The medical conditions were selected according to their prevalence in emergency services, in a way that the main diagnosis involved could be broadly represented. Therefore, the scenarios included common infections, inflammatory conditions such as acute abdomen, migraine, respiratory decompensation, cardiovascular, and thromboembolic events. In each of them, a clinical description of the patient's probable complaints and expected physical examination data was made. This stage was essential for the corpus's validation process.

Discussion

Main Findings

This study demonstrated the feasibility and methodological value of using a Delphi technique to develop a clinically relevant corpus of medical terms. In this analysis, the process focused on emergency care and involved health care professionals to identify and refine expressions considered essential for patient-provider communication. The subsequent linguistic adaptation phase engaged deaf and hearing sign language experts to ensure that the selected content was accurate, natural, and culturally appropriate in Libras. The final corpus includes questions and expressions organized to reflect the logical sequence of emergency medical anamnesis, thus bridging clinical communication needs with the linguistic and cultural norms of the deaf community. These findings highlight the potential of interdisciplinary, consensus-based approaches to improve accessibility and guide the development of sign language resources and technologies in health care. They also underscore the complexities involved in developing a bidirectional translation system that takes into account the linguistic and cultural specificities of the deaf community.

The need for this study arose from a larger project, whose objective is to develop a prototype for recognizing Brazilian sign language in the context of medical settings [11]. This area is still largely underexplored, with a growing demand for development based on emerging technological innovations and the use of novel artificial intelligence models.

Comparison With Prior Work

While the development of translation systems for sign languages has been explored in prior research, and some studies have described the creation of sign language corpora for health care–related applications, none have used a structured consensus method such as the Delphi technique. For example, Camgöz et al [12] developed a Turkish Sign Language Recognition Corpus that included content from health, finance, and daily life domains. Although the authors consulted linguists, members of the deaf community, and domain specialists, they did not report how the final corpus content was selected. Similarly, Wille et al [13] described the development of a Flemish Sign Language corpus based on descriptive grammatical research, including elicited and spontaneous narratives, conversations, and on-topic interviews. However, these corpora were primarily linguistically oriented, with no focus on health care, and did not involve systematic validation by health care professionals. Roelofsen et al [14] reported collecting a set of phrases commonly used during the diagnosis and treatment of COVID-19, based on consultations with health care professionals at the Amsterdam University Medical Center as well as on direct experience (one of the authors is a medical doctor). They also referenced phrases from the SignTranslate system. However, the authors were not transparent about how the most important sentences were selected or ranked for inclusion in the corpus [14].

In a previous systematic review of sign language translation systems, the corpus development process was not even mentioned [15]. Our recent systematic review identified 23 studies involving sign language recognition systems developed and tested to be applied in health care settings [8]. These studies often emphasize technical aspects, such as gesture recognition, but provide little detail on how the linguistic content, particularly in specialized domains such as health care, is selected or validated. The vast majority were in the development or testing stage and used corpora based on isolated terms, often defined by researchers or adapted from dictionaries, with minimal contextual adaptation. Very few studies involved health care professionals or sign language experts in corpus development, and none used structured consensus methods such as the Delphi technique. Furthermore, most systems lacked integration of key communicative features such as facial expressions and bidirectionality, both essential for health care communication. To our knowledge, no prior study has detailed a participatory, interdisciplinary approach to constructing a medically oriented sign language corpus using both clinical and linguistic validation. Our study addresses this gap, contributing a novel methodology tailored to emergency health care settings in Libras.

The lack of literature on this specific process led us to create approaches that seemed to be most adequate. After much investigation and planning, the Delphi method was selected [9], since it could assist in directing and supporting the process of choosing terms, thus ensuring its reproducibility. With the collection and analysis of the responses, the process of adaptation to sign language was carried out in collaboration with the linguistics team.

Relevance of Proposed Questions

The high relevance ratings for most of the proposed questions (with medians predominantly between 4 and 5 on the Likert scale) reflect the importance of accurate, detailed, and efficient communication in emergency care. Specifically, questions related to the patient's primary complaint (eg, "What are you feeling that made you seek the hospital?") and medical history (eg, "Are you allergic to any medication?") were consistently rated as critical. This aligns with the standard practices in emergency medical care, where understanding the nature and timeline of symptoms is essential for accurate diagnosis and appropriate treatment [16].

The consistency in the importance assigned to these questions indicates that health care professionals value information that directly impacts clinical decision-making. This also reinforces the necessity for such questions to be clearly and accurately

XSL•FO
RenderX

translatable into sign language, ensuring that deaf patients can provide this vital information without delay or confusion.

Challenges in Sign Language Translation

One of the main challenges identified in this study was the translation of medical terms and questions into Libras. As sign languages are linguistically distinct from spoken languages, direct translation of phrases often leads to ambiguities or misinterpretations [17]. The need for careful adaptation, particularly for complex medical queries (eg, questions regarding the nature of pain or its progression), was emphasized by the research team. In many cases, questions had to be broken down into simpler, shorter queries, a process that aligns with previous findings in the literature regarding the importance of adapting questions for clarity in sign language. This process, while time-consuming, is crucial to ensure that the information exchanged during an emergency consultation is accurate and comprehensive.

When translating into Libras, 2 questions were more challenging, for different reasons. The first of them, question 9, "On a scale of 1 to 10, with 1 being very weak pain and 10 being unbearable pain, what is the intensity of the pain?" It has a more complex grammatical structure, and it was not possible to break it into 2 or more distinct questions, as we did with question 8, for example. As a translation strategy, we transformed the question into a comment topic. In other words, we start the sentence with the topic "pain," followed by the question-comment "on a scale from 1 to 10, with intensity 1 being a weak pain, intensity 5 being a medium pain, and 10 being a very strong pain, what is the intensity of the pain?" The addition of "average pain" gave the question a better idea of the intended gradation.

In the second question 10, "Does it stay in one fixed place, or does it spread to another location?," the challenge was to define a pain location without interfering with the original question. This is because "[to] stay in one fixed place" makes no sense in Libras if it is not defined in the signer's body what that place is. The translation choice of the deaf woman who recorded the question was "pain, for example [points to a place on her own body], stays in the same place or spreads [performs the sign [to spread] starting from the chosen location on her body for the pain and spreading to adjacent places]."

These translation strategies were discussed with the translation team, tested, and evaluated until we reached a consensus on what would be the best way to translate them without interfering with the desired meaning, but taking into account how the deaf person would clearly understand.

Additionally, it became evident that translation is not merely a matter of substituting words; it involves a deep understanding of both the linguistic structure of sign language and the cultural context in which it is used [17].

The involvement of a multidisciplinary team, including deaf linguists, health professionals, and sign language interpreters, was essential to ensure the validity and appropriateness of the translations. The medical professionals on the team were essential in the initial process of suggesting sentences, which, after evaluation by the group of health professional experts, were submitted to the linguistics team for careful evaluation. This framework ensured that all necessary adjustments were made to guarantee that the final product was scientifically and grammatically correct, both in the written and signed versions.

Surely much can be learned from the advances in natural language processing; however, there are many new dimensions yet to be explored when it comes to sign language understanding and synthesis. If, on the one hand, spoken languages embed significant information such as rhythm, tone, and pauses, on the other hand, it does not require delving into finer details such as facial expressions, as is the case with sign languages. When describing the creation of a text-to-sign translation method, Bertin-Lemée et al [18] mention the need to preserve the linguistic structures of sign language during the translation process and point it out as an inherent challenge to the process.

This stage involved making the necessary adjustments to the sentences to ensure their correct meaning in both written and signed forms. All suggestions were carefully analyzed, with several related to the positioning of commas and grammatical structure, without significantly interfering with the message conveyed or the intent of the questions. It is important to note that those unfamiliar with sign language may not realize that punctuation, such as commas, does not hold the same relevance in this context. The structure of sign language differs significantly from spoken languages, and such differences are often overlooked by society at large [17]. Only 2 suggestions were deemed significant, leading to adjustments in questions 20 and 21. This highlights the importance of having knowledgeable researchers with extensive technical expertise to ensure a proper critical analysis and adaptation of the content.

Implications for Practice

This project has significant implications for improving health care accessibility for deaf individuals, especially in emergency care settings. By developing a system that enables real-time communication in Libras, the "Captar-Libras" Project aims to reduce the critical communication barriers that deaf patients face when seeking urgent medical care. It also contributes to the broader movement toward greater inclusion and accessibility in health care systems.

One of the key outcomes of this study is the development of a clear, structured corpus of terms that can be directly applied not only in the sign language recognition system developed by our group but also in systems created by other research teams. By contributing to the existing body of literature, this work aims to contribute to the development of future systems for medical communication in sign language. The next steps will focus on validating the system through hypothetical medical care scenarios, ensuring that the signs synthesized by the system are accurate and comprehensible for deaf users.

Limitations

Similar to spoken languages, sign languages are inherently regional and culturally specific. Our work focused on Brazilian Sign Language (Libras), which limits the generalizability of the corpus to sign languages of other countries. While this limitation is intrinsic to any language-based system, future adaptations will require cultural and linguistic tailoring to adapt it to other

XSL•FO
RenderX

contexts, thus ensuring broader applicability. However, the primary contribution of this study lies in the methodological approach: a structured, interdisciplinary process for corpus development tailored to health care contexts, rather than in proposing an unabridged compendium of signs.

Second, the number of health care professionals participating in the Delphi process was relatively small. Although their responses were consistent and included a range of clinical experiences, a larger and more diverse sample, including professionals from different regions, more sign language users, and a broader range of professional roles and experiences, could further strengthen the representativeness and validity of the selected terms. Future iterations should aim to broaden participation, possibly involving deaf health care users as well.

Third, the list of terms and questions was based on hypothetical medical emergencies and predefined scenarios. While this approach provided structure and facilitated consensus, it may not fully capture the emotional complexity and spontaneity of real-life interactions in emergency care. Future studies should validate the corpus using real-world consultations or simulations, allowing for refinement based on authentic communication dynamics.

Despite these limitations, we believe that this study proposes a solid foundation for future corpus development efforts. The use of a transparent, interdisciplinary, and consensus-based approach represents a significant methodological advancement in the field of sign language translation systems for health care.

Potential Scalability and Future Directions

Although this study focused on developing a Brazilian Sign Language (Libras) corpus for emergency care, the methodology and participatory approach used may provide a model for adaptation to other sign languages and cultural contexts. Key elements such as expert consensus on terminology, iterative translation with linguistic validation, and the incorporation of hypothetical clinical scenarios could be applied in different health care settings, allowing for the creation of contextually and culturally appropriate corpora.

Building on this initial effort, future research should focus on validating the proposed corpus in real or simulated health care interactions to assess its communicative adequacy in practice. Further expansions may include broadening the development of corpora for other care contexts, such as primary care or mental health. Additional Delphi rounds involving deaf patients themselves could enrich the corpus with user-centered insights. Moreover, adapting the proposed methodology to other sign languages and national health systems may support the development of culturally relevant corpora worldwide. Finally, the integration of this corpus into translation tools and health professional training programs could enhance accessibility and equity in health care communication.

Conclusions

This study represents a significant methodological step toward improving communication between health care professionals and deaf individuals in emergency medical settings. Rather than proposing a universal solution, the study presents a structured and participatory approach for developing a corpus of medical terms in Libras, with interdisciplinary validation. The process included the involvement of deaf sign language experts during the translation and linguistic adaptation phase, ensuring that the corpus reflects authentic usage and articulation in Libras.

The findings underscore the complexity of translating medical terminology into sign language and highlight the importance of integrating both health care and linguistic expertise. While this corpus provides a solid foundation, future validation in real-world or simulated scenarios remains essential to assess its practical utility.

Acknowledgments

The authors thank the researchers Raniere Cordeiro, Raiane Barros, Felipe Barros, Isabel Franco de Carvalho, Natália Afonso, and Michelle Murta, who are deaf Libras signers, and who helped in the corpus discussion and adaptation.

Funding

This study was funded in part by Financiadora de Estudos e Projetos (FINEP, grant 01.21.0097.00) and SignumWeb Comunicação Inclusiva Ltda, as part of the Project “Captar-Libras: Sistema de Comunicação por vídeos para surdos aplicado ao pré-atendimento médico." MSM was supported in part by the Institute for Health Assessment and Translation for Chronic and Neglected Diseases of High Relevance (Instituto para Avaliação e Translação em Saúde para Doenças Crônicas e Negligenciadas de Alta RElevância [IATS CARE])/National Council for Scientific and Technological Development (Conselho Nacional de Desenvolvimento Científico e Tecnológico - CNPq; grant number 408659/2024-6) and CNPq (Bolsa de Produtividade em Pesquisa 311742/2025-4). MFMC was supported in part by CNPq (Bolsa de Produtividade em Pesquisa 316841/2021-8). Abstract

Background: Rare diseases affect approximately 20 million Europeans, presenting unique challenges such as delayed diagnoses, limited therapies, and significant personal and financial burden. While resilience-supporting factors such as peer support are available and artificial intelligence–based diagnostic tools are being developed further, there is a lack of a dedicated online social network connecting patients, caregivers, relatives, and experts. This study presents the development and preliminary findings of Unrare.me, a novel social network designed to provide a secure space for experts and individuals affected by rare and chronic diseases (diagnosed and undiagnosed).

Objective: This study aimed to design, develop, and evaluate a social networking platform tailored to the needs of different stakeholders of the rare disease community, facilitating interaction, knowledge exchange, and emotional support while prioritizing data security.

Methods: This multidisciplinary, multicenter initiative brought together patient groups, health care professionals, psychologists, and web design experts. A literature review assessed existing networking approaches in the rare disease community. Structured interviews and user journey mapping defined user needs and essential app features. Iterative prototyping and stakeholder discussions informed the final design, which was developed into a functional app launched in December 2023 on major platforms. A survey conducted four months post-launch evaluated user feedback. Data security was prioritized throughout development.

Results: A total of 270 users (approximately 1 in 7 users at the time) participated in the evaluation. Most of them (n=221, 81.9%) registered to connect with others in similar situations, whereas 56.7% (n=153) sought expert input and 44.4% (n=120) looked for disease-related information. The app received positive ratings for usability (mean 6.12, SD 1.03; out of 7), accessibility (mean 5.59, SD 1.22), and design (mean 5.84, SD 1.12), as well as overall impression (mean grade of 2.24, SD 0.90 on a scale from 1-6, with 1 being the best score). Data security was highly rated (mean 5.58, SD 1.15). The app's ontology was suitable for 77% (n=208) of the participants, enabling them to find their diagnosis, and 60.7% (n=164) of users found at least one match. Matching preferences centered on shared diagnosis (mean 82.5, SD 25.1 on a visual analog scale from 0 to 100), symptoms (mean 74.2, SD 25.8), and everyday experiences (mean 69.6, SD 29.5). Overall, users welcomed the opportunity to network with each other securely and highlighted areas for further improvement, such as enhanced matching features and group chat options.

Conclusions: Unrare.me has generated significant interest and engagement within the German rare disease community, serving as a valuable tool for peer support, knowledge sharing, and expert identification. Current challenges include optimizing user acquisition and refining matching algorithms. Planned features include group chats, expert interaction, and gamification elements. Unrare.me illustrates the potential of tailored digital solutions to address unmet needs in the rare disease community.

Introduction

Rare and chronic diseases pose unique challenges for those affected in terms of both health care and social well-being. Rare diseases are defined as conditions affecting fewer than 1 in 2000 individuals; worldwide, over 300 million people live with one of the 6000 to 8000 known rare diseases. In the European Union alone, these diseases impact approximately 20 million individuals along with their caregivers [1].

One of the first challenges for people with rare diseases is receiving an accurate diagnosis. Due to the low prevalence of these conditions, health care professionals often lack the resources to recognize and diagnose them efficiently. On average, a time frame of 5 years from the first symptom to diagnosis is accepted as typical for rare diseases [2]. During this period, patients may undergo misdiagnoses, unnecessary treatments, and worsening symptoms [3]. This diagnostic delay increases the emotional and psychological burden on patients and their families and caregivers, leading to higher rates of anxiety and depression, feelings of isolation, and helplessness. This is particularly pronounced in children, placing even greater demands on caregivers to balance emotional and practical responsibilities [4]. Compounding these emotional challenges is the financial strain on both individuals and health care systems as the complexity of diagnosis and treatment leads to much higher health care costs than those for common diseases. This burden is exacerbated by the excessive cost of orphan drugs and indirect costs such as lost productivity due to illness or caregiving responsibilities [5].

Beyond those challenges, people with rare diseases and their caregivers also struggle with a lack of access to information and support and connecting with others who share similar experiences [6]. Traditionally, health care systems are ill-equipped to provide specialized knowledge or resources, and patients frequently report difficulties in finding experts or communities who understand their condition. The scarcity of research and information contributes to this challenge, leaving patients and caregivers to rely on fragmented information from various sources. The rarity of their conditions means that opportunities for peer support are limited, whether through local health care providers, community groups, or even large-scale social networks. As a result, many patients turn to online communities and digital platforms as a means of finding solidarity, sharing experiences, and accessing critical information. Studies have shown that such online communities can be powerful tools for providing emotional and social support, helping patients manage both the physical and psychological aspects of their condition [7]. The mutual benefit of networking is illustrated by European activities such as Share4Rare to connect experts to improve knowledge and foster therapy [8-11]. Similarly, the necessity of including a community-based stakeholder group of those affected by rare pediatric diseases was recently illustrated by Berrios et al [12].

Many individuals with rare diseases are organized within common online social networks such as Facebook or WhatsApp, whereas individuals might also use Instagram and TikTok for engagement and information exchange. Individuals actively seek emotional support, disease-related information, and peer connection in the online world [13].

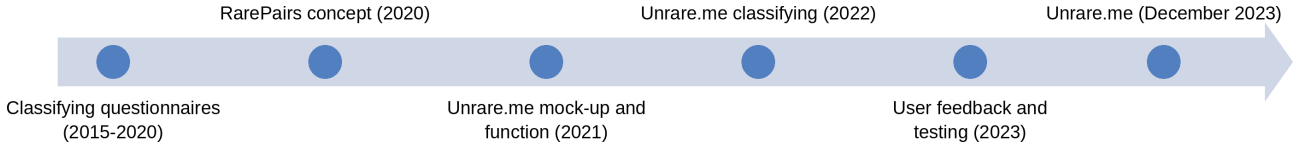
However, common online social networks are rarely designed to meet the needs of this population. General platforms may lack the privacy, specialized and trustworthy information, and support structures required for navigating rare and chronic diseases [14,15]. In addition, these social networks are less beneficial for those who do not know their diagnosis as they lack specific questionnaires or search methods for this population.

In the past years, the work on diagnostic support systems demonstrated the potential of computational matching approaches. Shen et al [16,17] demonstrated that undiagnosed individuals benefit from symptom-based matching, particularly in clinical decision support settings. Yates et al [18] showed that matching patient symptoms with the Human Phenotype Ontology allowed for the ranking of diagnoses. The open-source tool PatientMatcher also allows for phenotype-driven matching of undiagnosed individuals [19]. These previous works focus on diagnostic help for medical professionals but do not directly address affected people and their needs.

Given the unmet needs of individuals with rare and chronic diseases and their relatives and our experiences in mathematical classifying processes, we first prototyped a platform (called RarePairs) for individuals with rare diseases [20]. This prototype evaluated the hypothesis that a detailed questionnaire (focusing on daily activities and past medical history) could assist in matching individuals with different rare diseases. In the pilot project, a dataset of 700 anonymized questionnaires collected among individuals with different rare diseases was used; nearest neighbor was used for the classifying procedures. Briefly, the results indicated that a set of 53 questions might suit to “match” individuals with selected diseases according to their answer pattern [20]. This prototype was designed only to demonstrate the feasibility of questionnaire-based matching and did not include a publicly available platform, real-time user interaction, data security concepts, or real-world evaluation. This manuscript details the evolution of the prototypical idea (RarePairs) into a fully operational and secure app designed for diverse user groups (eg, patients, caregivers, experts, and health networkers) with ontology-based and machine learning (ML)–supported matching and real-world use and evaluation.

Specifically, this work contributes (1) a user-centered requirement analysis involving patients, caregivers, and professionals; (2) the development and iterative validation of an ontology-based and ML-supported matching logic for real-world use; (3) the establishment of a robust data security and privacy framework tailored to sensitive health data; and (4) an implementation approach designed to be feasible, scalable, and appropriate for health care–related applications.

XSL•FO
RenderX



In essence, Unrare.me should function as a specialized networking platform for experts in and individuals with rare or undiagnosed health conditions, providing a vital digital space for support and information sharing.

Methods

Study Overview

The development of Unrare.me followed a multicenter, mixed methods approach. The process was led by a multiprofessional team comprising medical doctors from diverse specialties, including a focus on rare diseases; psychologists; representatives from patient advocacy groups; gaming experts; programmers; data analysts; and designers. The timeline is shown in Figure 1.

Figure 1. Timeline of the Unrare.me development process.

User Needs and Requirements

To assess the needs and preferences of potential users, we conducted 15 semistructured interviews targeting individuals impacted by rare diseases and their caregivers early after launching Unrare.me. The interviews served as initial orientation and gathered information in this new thematic field. The aim was to identify commonalities and typical features. Data analysis was based on the approach by Meuser and Nagel [21], consisting of paraphrasing important passages, creating headings for paraphrased text, and conducting thematic comparison.

App Development

Through a series of workshops using collaborative tools (eg, Miro boards), the interview findings were discussed and assessed for their relevance to the app's functional design. It became evident that there is no singular "need" for individuals with rare diseases; rather, needs vary over time, following the trajectory of the disease. For instance, immediately following diagnosis, users have a strong demand for information, whereas as the condition progresses, needs shift toward disease-specific support, such as finding experts for managing particular complications. To illustrate user needs, we employed the persona method and developed corresponding screen mock-ups (Figures 2-4).

XSL•FO
RenderX

Figure 2. User journey illustrated in mock-ups during app development. This mock-up user, alisa192, has been searching for a diagnosis for 4 years. She is 35 years old and female. In her short profile, she states that she has experienced persistent dizziness for 5 years, accompanied by numbness in her hands and other symptoms. She has gone through an odyssey of consultations with various specialists—unfortunately still without a clear diagnosis.

XSL•FO
RenderX

Figure 3. User journey illustrated in mock-ups during app development. In this screen, we see the dashboard of peterpiper62. He can see that his profile is 40% complete and that another user, yana21, has asked him a question (“Did your doctor run a full blood panel back then?”). He also has 5 additional unanswered questions. At the bottom of the screen, new relevant matches are displayed for him. At the very bottom, he can navigate between different app functions (eg, chat and matches).

XSL•FO
RenderX

Figure 4. User journey illustrated in mock-ups during app development. Here, the user can see a list of items in their profile that have already been completed and where additional information can or should be added. This user has already filled in the basics (eg, age and gender) and has written their short profile. However, they have not yet fully entered their symptoms. To integrate these diverse and shifting user needs into the app and its mock-ups, we used various user stories (persona method) at an early stage. This approach involved brainstorming based on fictional app users (persona concept) to understand how they might interact with the app, their potential expectations, and ways to address these in the app's design.

Matching Logic

To enable user-to-user connections ("matching"), it was necessary to collect essential information regarding participants' medical and personal histories. To ensure the compatibility of these data with the matching algorithm, a structured approach to organizing users' medical information was required. Therefore, suitable medical ontologies that would support standardized data representation were analyzed [22,23]. The review identified several relevant resources, including the Orphanet database and its derived ontology Orphanet Rare Disease Ontology, the Human Phenotype Ontology, Online

XSL•FO
RenderX

Mendelian Inheritance in Man, the International Classification of Inherited Metabolic Disorders, and Mondo Disease Ontology, as well as 2 classification systems specifically addressing autoinflammatory disorders and immunodeficiencies [24,25].

The matching logic underwent comprehensive discussion in the context of user stories, as well as considering the medical and patient group expertise present within the team. A particular focus was placed on defining the characteristics that would constitute optimal matching. This included exploring parameters such as shared diagnoses, symptomatology, disease progression stages, and lifestyle factors that might impact mutual support or therapeutic benefit.

Concurrently, the structure of the databases was assessed based on the merged ontologies to ensure that they could accommodate the complexity of matching criteria relevant to individuals with rare diseases and chronic conditions. This assessment involved a rigorous validation process in which potential matching algorithms were tested against automatically generated datasets to simulate real-world user scenarios. This testing aimed to refine the algorithms by evaluating their performance in achieving accurate and meaningful matches, ensuring that users relate to others who have comparable experiences, informational needs, or therapeutic requirements.

The integration of these steps provided a robust foundation for creating a responsive matching system that adapts to the varied and evolving needs of users grounded in both clinical insights and practical patient experiences. Beyond ontology-based similarity, user feedback was used to iteratively refine matching. The underlying ML-based optimization is described in detail elsewhere [26,27].

Evaluation Methods

Every user was offered to take part in a feedback survey through a banner on the start page of the app four month after launch. We used SoSci Survey (SoSci Survey GmbH), a secure cloud service for conducting online surveys, to collect data between December 11, 2023, and March 12, 2024.

In addition to demographic data, we collected feedback concerning usability, design, content, use, expectations, and overall impression. The survey used validated questionnaires for evaluating websites, which were slightly adapted for evaluating the app. It comprised 7 usability items from the Usability Metric for User Experience Lite [28] and the Perceived Website Usability–German [29]; 4 items on design from the Visual Aesthetics of Websites Inventory–Short Form [30]; 10 items from the Website–Clarity, Likeability, Informativeness, and Credibility [31]; 2 items measuring intention to revisit the website [32]; and 3 self-constructed items measuring fulfillment of expectations (1="Not at all"; 7="Absolutely"), trust in data security (1="Not at all"; 7="Absolutely"), and an overall rating (1="Very good"; 6="Very bad"). In addition, users were able to provide open feedback.

Participants were also asked whether they had found a match and, if so, to rate it on a visual analog scale from 0 to 100. In addition, they should rate the importance of 5 criteria for matching: same diagnosis, same symptoms, same everyday experiences, reason for app registration, age, and gender. Multiple selection was possible.

User statistics such as number of users, user group, and behavior of these user groups were analyzed separately and are not part of this paper. This evaluation was designed as a formative pilot implementation study to gather early user feedback on usability, perceived value, and initial matching experience. The survey was not powered for inferential group comparisons and, therefore, focuses on descriptive results.

Ethical Considerations

To take data privacy and ethical considerations into account, the app was developed in close collaboration with the senior data protection officer at University Hospital Bonn and in consultation with the local ethics committee. Due to the specific nature and purpose of the project—focused on app development—a formal ethics vote was deemed unnecessary.

All individuals who participated in the semistructured interviews were informed in advance about the purpose and use of the findings and provided explicit informed consent. All app users were informed about the data privacy terms, and participation in the user survey was voluntary and anonymous. According to § 2 (1) of the Statutes of the Ethics Committee of the Medical Faculty of the University of Bonn [33] and § 15 (1) of the Professional Code of Conduct for Physicians of the North Rhine Medical Association [34], no ethics committee approval was required for this study, as it did not constitute a clinical trial of a medicinal product or a clinical investigation of a medical device.

Results

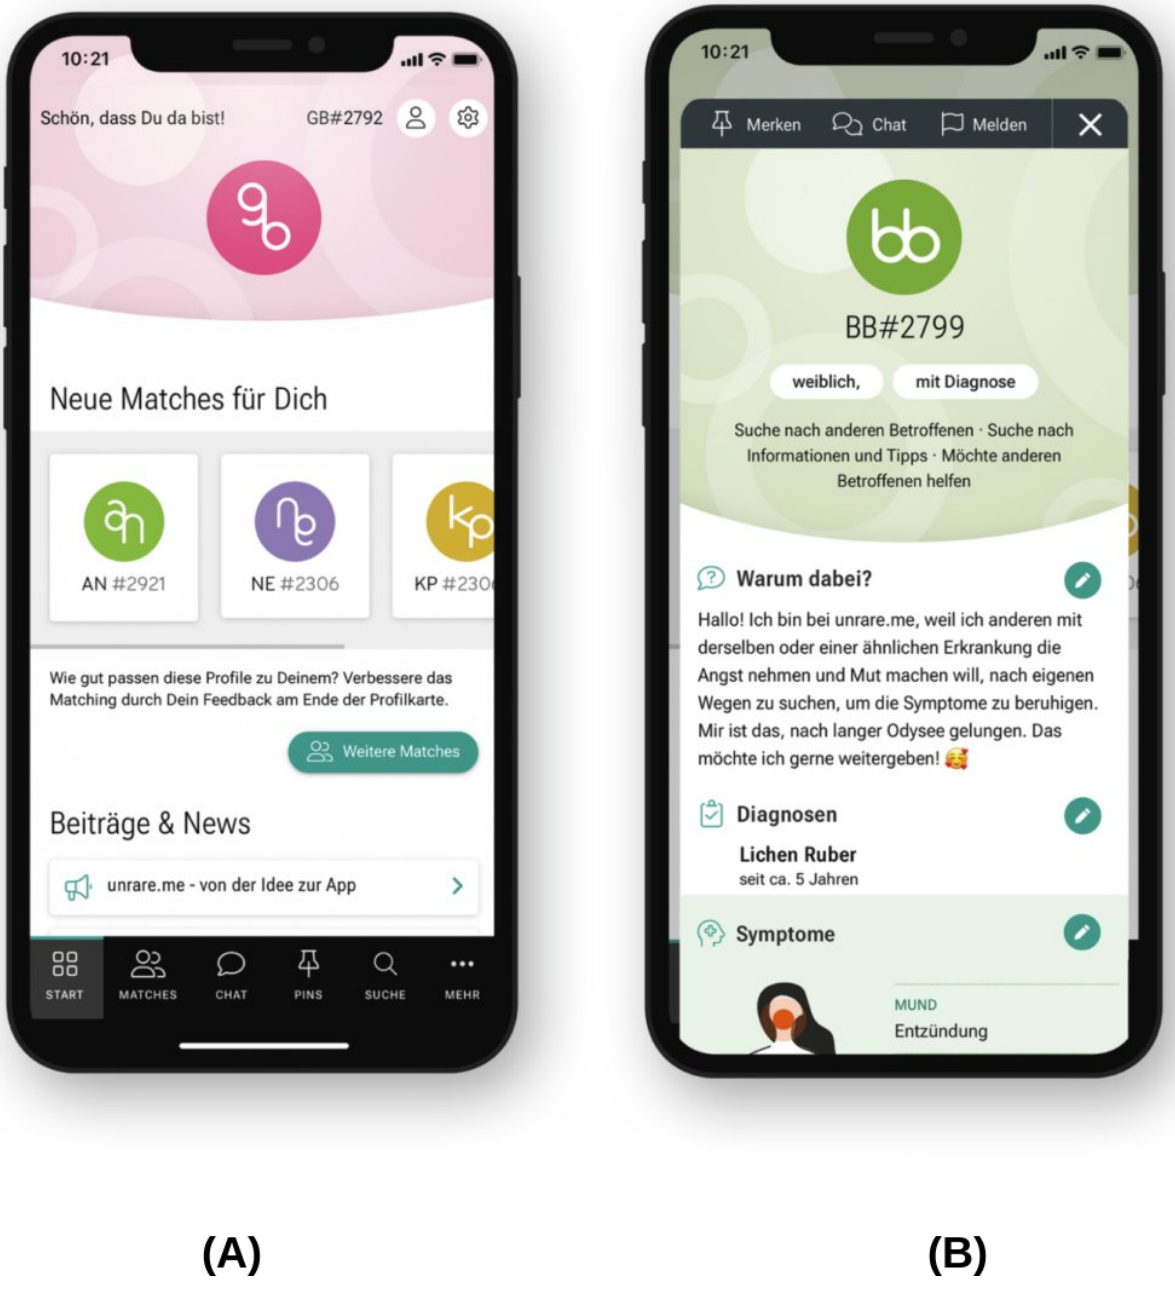
User Needs and Requirements

Participants for the semistructured interviews included representatives from patient organizations (n=3), health care professionals (n=4), patients (n=4), and relatives (n=4). The ages of the participants ranged from 20 to 62 years, and their self-reported technical proficiency was rated as "average."

All participants reported currently using platforms such as Facebook and/or WhatsApp for peer communication, often focusing on specific aspects of their condition (eg, transplantation or augmentative and alternative communication). All participants also emphasized the importance of credibility and professionalism in the desired platform. Both were associated with the design and easy and failure-free management of the app. Data safety was not a predominant concern among participants. Participants expressed clear nonnegotiable features of the new platform. These included avoidance of commercial content (3/15, 20%); prevention of fake profiles and trolls (6/15, 40%); and minimal collection of personal data, limited strictly to essential information (5/15, 33%).

Concerns were also raised about unreliable information, populist influencers, the influence of the "Pharma industry," and negative interactions that might exacerbate psychological distress. To mitigate this, one-third of the participants (5/15, 33%) expressed a desire for active moderation to ensure a supportive environment. Additionally, participants highlighted the

XSL•FO
RenderX



importance of encouraging positivity and sharing uplifting news to foster a sense of hope and encouragement.

Regarding platform functionality, participants expressed concerns about low user numbers potentially hindering fast and meaningful interactions. As a result, they emphasized the importance of customizable settings for profiles, visibility, and chat search functions. The opportunity to interact with researchers and experts was universally welcomed; however, health care professionals voiced apprehensions about potential overextension of their responsibilities beyond working hours. They suggested implementing "offline" modes to ensure boundaries between professional and personal time.

App Development

On the basis of the mock-ups shown in the methods section, we developed a preliminary data structure and designed the core screens of the app (Figures 5 and 6) and the brand design (Figure 7).

Figure 5. (A) The dashboard of user GB#2792. New matches are displayed here, along with new posts and news items relevant to the user. (B) The profile of BB#2799, a female patient with a diagnosis. Her profile states that she is looking for others affected by the condition as well as information and advice. She also wishes to support other patients. In her short profile, she explains that she joined Unrare.me to encourage others living with the disease and share her experiences. Under "Diagnoses," it is noted that she has been living with lichen ruber moniliformis for 5 years. At the bottom, partially visible, is the symptom body map, where she has indicated inflammation in the mouth.

XSL•FO
RenderX

Figure 6. The final app interface as displayed to a user registered in the patient role. It provides an overview of the different screens: the dashboard, the post page, the symptom map, an example of another user's profile, and feedback on the user's own profile completeness.

Figure 7. Brand design of the app: colors and typeface.

During the development of Unrare.me, the primary goal was to balance performance, stability, and cost efficiency. The back end needed to be lightweight, reliable, and inexpensive to operate while remaining easy to maintain—both by the Unrare.me team and potential external contributors.

We implemented a cost-efficient, maintainable cross-platform architecture to support iOS and Android users from a shared codebase and enable iterative updates. The technical stack was selected to ensure scalability, stability, and low operational overhead.

A robust data security framework was developed in collaboration with local data security experts. Key components of this framework included the hosting of servers in Germany to ensure compliance with local data protection regulations and

XSL•FO
RenderX

implementing an Alphatar concept to avoid collecting personal information of patients and their relatives. We also identified the most important data protection issues to be addressed:

- Using (end-to-end) encryption technologies for data safety
- Following the principle of data minimization (eg, Alphatar concept, refer to Figure 8)
- Establishing a secure end-to-end encrypted chat function
- Promoting transparency through data minimization and clear explanations of data collection purposes
- Providing detailed adjustment possibilities for personal and medical data (Figures 9 and 10), permanently and irrecoverably deleting all user data upon account deletion.

The app became available in popular app stores for Apple and Android in December 2023. During the first 6 months of operation of the online platform, no major technical issues were recorded. Users had the possibility to provide feedback on technical issues via email and specific support buttons inside the app. An increasing number of users necessitated technical adjustments: computational power and server capacities had to be optimized to ensure fast matching and the stable functionality of the app.

XSL•FO
RenderX

Figure 8. The Alphatar concept of Unrare.me. Users are anonymous using a 2-letter chiffre and a color during private chats. In this screen, the user is encouraged to enter their initials and choose a color for the avatar.

XSL•FO

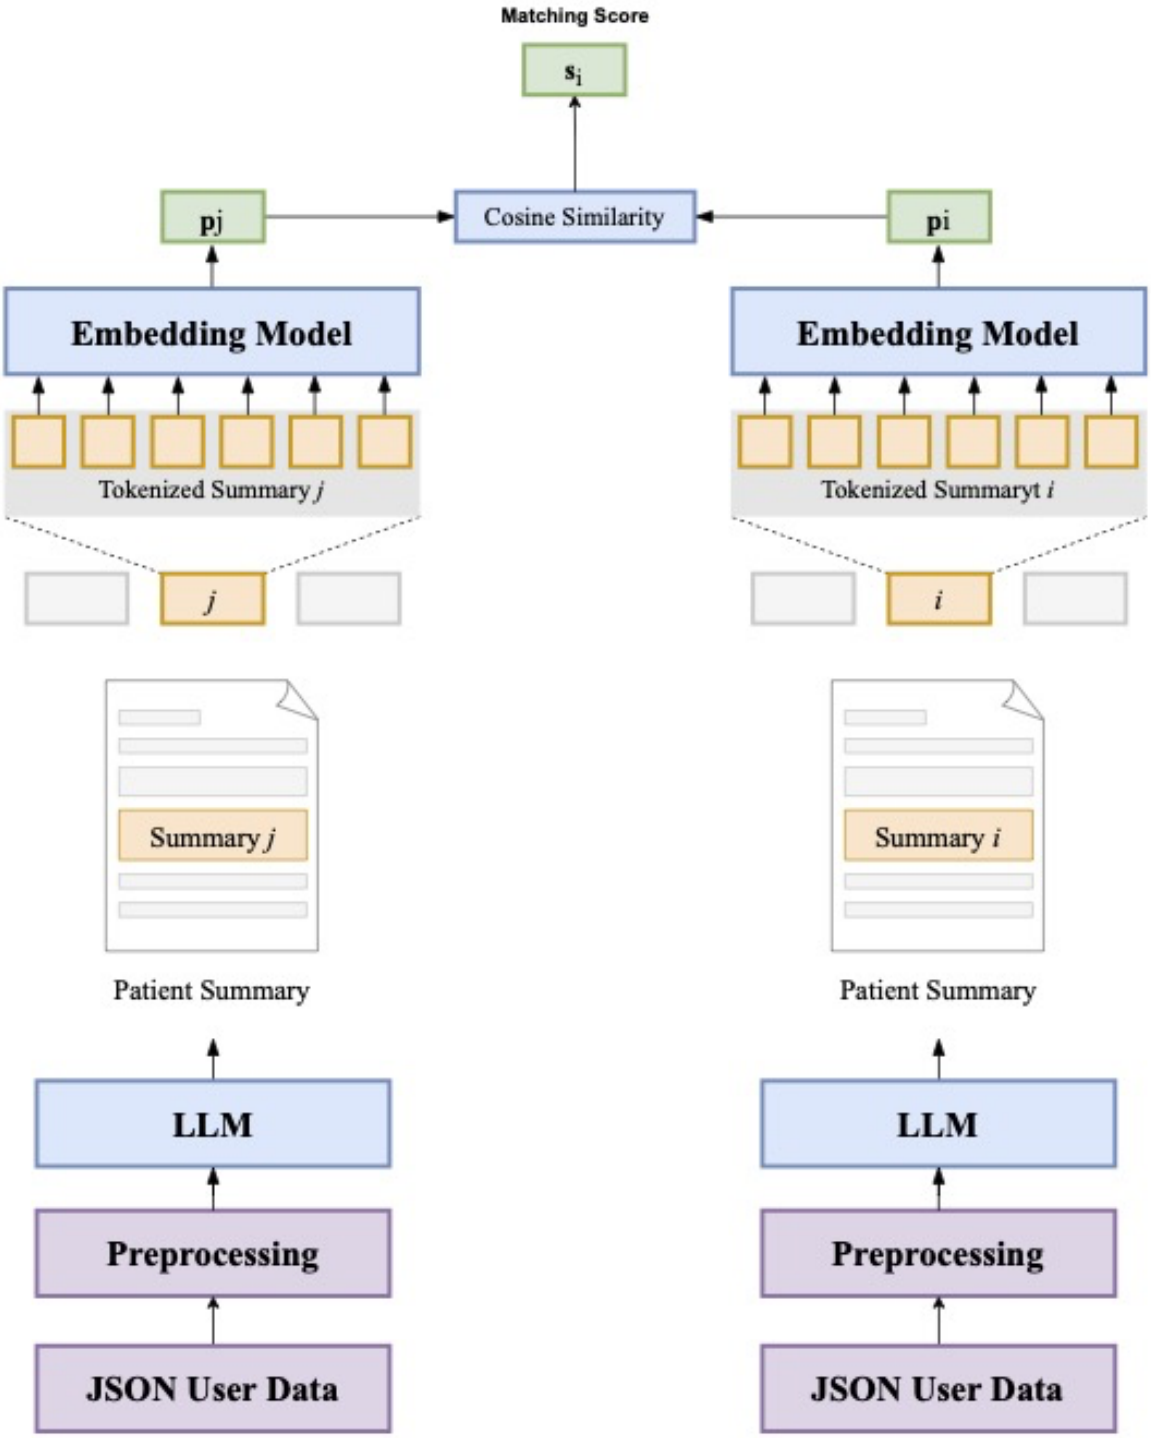
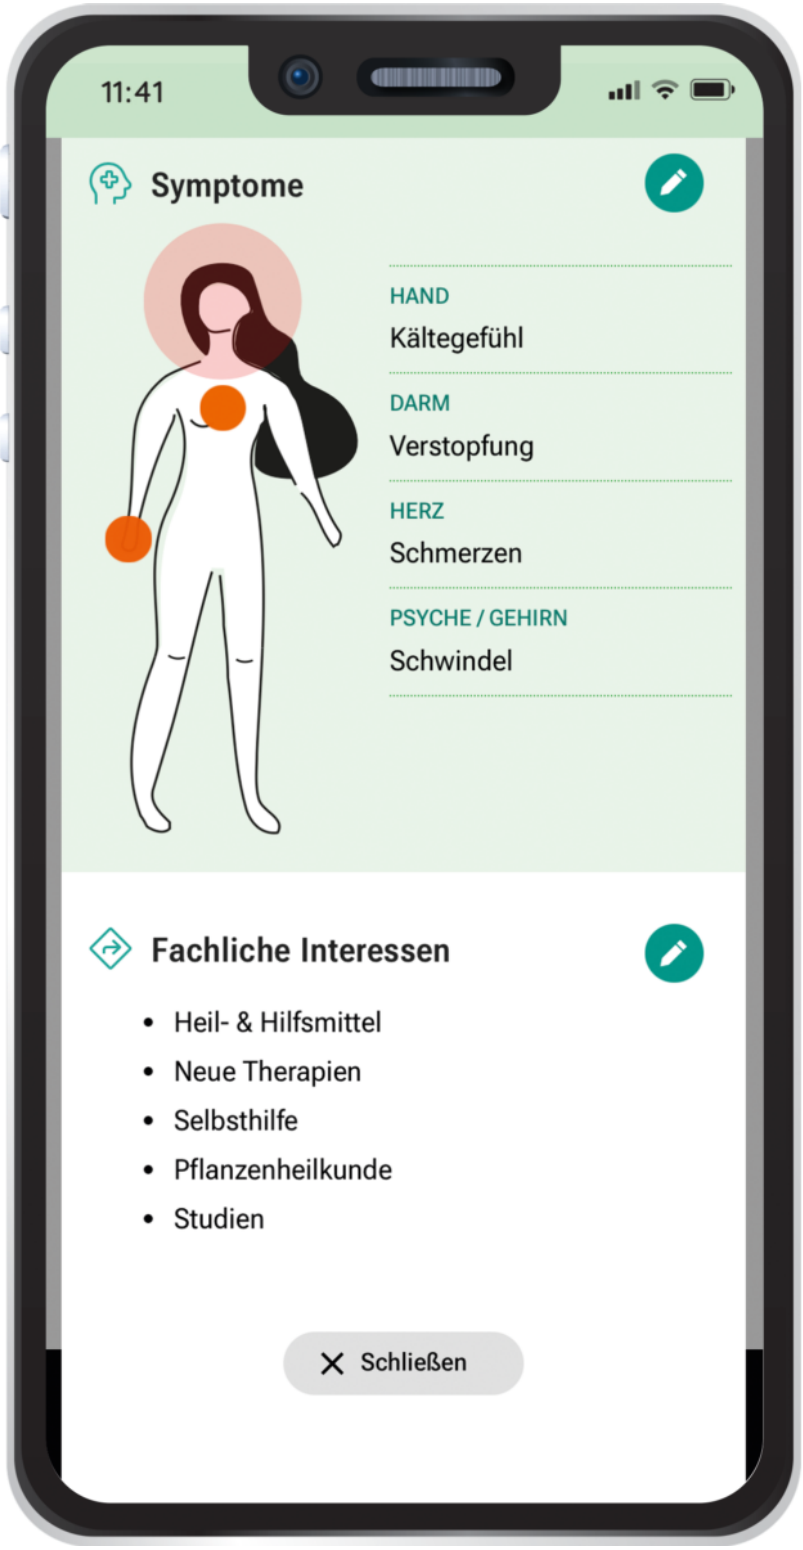
Figure 10. On this screen, users can choose whether other users may contact them and, if so, which user groups (eg, other patients, physicians, and research centers).



XSL•FO
RenderX

Matching Approach

For the Unrare.me matching architecture, the different open-source ontologies evaluated were translated, merged, weighted, and integrated into the back-end structure. The matching algorithm was primarily based on the similarity of diagnoses but also considered symptoms, age, and gender. A user feedback system enabled users to rate each matching suggestion. This information was then used by the algorithm (Figure 11) to further refine the matching process beyond ontology-based criteria [35].



Therefore, we fully designed and implemented a symptom finder that can be used by laypeople (Figure 12).

Figure 11. Schematic visualization of the user data augmentation approach. LLM: large language model.

XSL•FO
RenderX

Figure 12. A body compass and a symptom checker enable users to enter relevant clinical information themselves. On this screen, the user has entered symptoms such as feeling cold, constipation, pain, and dizziness, as well as topics of interest such as assistive devices, new therapies, self-help, herbal medicine, and clinical studies. The technical algorithm approach is described by Berger et al [26,27].

Evaluation Study

Overview

To obtain user feedback on the first version of the app, a feedback questionnaire was made available to users during the first 3 months after the launch. More detailed information about user groups and their behavior will be published in a separate paper.

Accordingly, the findings (Table 1) should be interpreted as early implementation insights rather than evidence of effectiveness.

XSL•FO
RenderX

Table . Results of the user experience evaluation measured using the Usability Metric for User Experience Lite; Perceived Website Usability–German; Visual Aesthetics of Websites Inventory–Short Form; and Website–Clarity, Likeability, Informativeness, and Credibility. Items translated from German.

Questionnaire and items	Score (1-7), mean (SD)
Usability (in general)	5.81 (0.29)
The app's capabilities meet my requirements.	5.45 (1.42)
The app is easy to use.	6.12 (1.03)
The way of function of the app is easy to understand.	6.13 (1.03)
I can easily understand the structure of the app.	5.93 (1.17)
It is easy to navigate the app.	5.91 (1.16)
I can quickly access the content I was looking for.	5.53 (1.29)
The app meets accessibility standards.	5.59 (1.22)
Content (total)	5.51 (1.23)
The app sparks my interest.	6.23 (1.01)
The content is of high quality.	5.27 (1.28)
The text provides the most important information concisely.	5.45 (1.25)
The app's content is engaging.	5.17 (1.29)
The language used is common and easy to understand.	5.99 (1.11)
The content is presented in a clear and illustrative manner.	5.63 (2.24)
The app is useful.	5.50 (1.35)
I can trust the app.	5.46 (1.21)
The app is informative.	5.24 (1.28)
I enjoy using this app.	5.11 (1.33)
Design (total)	5.59 (1.20)
Everything in the app fits together cohesively.	5.36 (1.29)
The design is pleasantly varied.	5.51 (1.24)
The color scheme is attractive.	5.67 (1.16)
The design is professional.	5.84 (1.12)

Sample

A total of 15.8% (270/1708) of the app's user base at the time took part in the survey. Most participants (240/270, 88.9%) were female. Patients constituted 65.2% (176/270) of the sample, followed by relatives (79/270, 29.3%), health care professionals (13/270, 4.8%), and health network professionals (2/270, 0.7%). Most of the respondents (221/270, 81.9%) stated that they had registered on the app to find other people in the same situation, and 56.7% (153/270) of the users were looking for experts on their diagnosis or symptoms. Another 44.4% (120/270) were looking for information on their condition. Furthermore, 32.2% (87/270) registered out of curiosity, and 23% (62/270) stated that they wanted to find the correct diagnosis. This pattern suggests that Unrare.me was primarily used as a peer support tool, while expert access and information seeking represented important secondary motivations.

Usability, Design, Content, and Satisfaction of User Demands

Overall, the self-constructed items "I will use the app again" and "I would recommend the app to others" received high levels of agreement, with mean scores of 6.05 (SD 1.08) and 5.99 (SD 1.18), respectively. The item "The app met my expectations and requirements" showed an average level of agreement (mean 4.74, SD 1.37). Participants also rated the question about perceived data security on the app with an average score of 5.58 (SD 1.15).

In addition, the item asking users to give an overall rating for the app (1=highest rating; 6=lowest rating) yielded an average of 2.24 (SD 0.90).

High usability and trust ratings indicate that privacy-oriented design does not necessarily compromise user experience in rare disease communities.

In general, the participants' open-text responses reflected both positive feedback and suggestions for improvement. On the one hand, the app was described as "a great idea," with users valuing the possibility to connect with others "sharing the same destiny." On the other hand, participants requested enhanced matching features (eg, regional search) and the addition of group chats.

During registration, 77% (208/270) of the participants found their diagnosis on the app. However, 17% (46/270) only found

XSL•FO
RenderX

their diagnosis partially, and others (22/270, 8.1%) only found it under a different name.

The main goal of obtaining at least one match in the first 3 months was achieved by 60.7% (164/270) of the participants. On a visual analog scale from 0 to 100, the mean satisfaction with this match was 42.9 (SD 28.2; 1=worst match; 100=best match). According to the participants, the most relevant factors for matching were having the same diagnosis (mean 82.5, SD 25.1), symptoms (mean 74.2, SD 25.8), and everyday experiences (mean 69.6, SD 29.5). The age (mean 27.8, SD 31.3) and gender (mean 11.8, SD 23.5) of matching partners were rated as less relevant.

Discussion

Principal Findings

Networking allows people with health issues to learn from others' experiences [36]. This is particularly evident in the widespread success of platforms such as Facebook for patient groups [37]. However, there is a significant lack of appropriate digital networking spaces for health-related topics, especially for individuals with less common diseases [38]. Although there are isolated efforts to establish noncommercial digital networks within the European Union, such as Share4Rare, these initiatives have so far had little visible impact on service provision [12]. As a result, many people turn to commercial social media platforms such as Facebook. This brings with it the danger of information overload and makes it difficult to distinguish between valid personal experiences or scientific information and advertising or hearsay [37].

Recognizing the value of shared experiences as a resource for individuals with chronic and rare diseases, we developed and launched the social network Unrare.me in December 2023. The app provides a platform for networking with other affected individuals and health care professionals, enabling the exchange of information and experiences in a data-secure environment.

The goals of Unrare.me are in line with the analyses by Smith et al [39], who identified these factors as resources for improving health. Similarly, as early as 2010, the World Health Organization promoted the impact of peer support in managing complex health challenges in the context of diabetes, including "horizontal and vertical networking among users," "providing access to relevant information," "promoting self-help and peer support," "alleviating the burden on individuals and their families," and "leveraging the collective knowledge of users (lay expertise and collective intelligence)" [40].

The results of our evaluation underline the successful implementation process of Unrare.me. Overall, users found the app easy to use and interesting, and its design was considered professional. Participants' high rating (mean 5.99, SD 1.18 on a 7-point scale) for the intention to recommend the app indicates strong user motivation to share the app with others, suggesting a generally positive user experience. However, given its innovative approach, the development and implementation of Unrare.me faced several challenges. First, effective marketing is crucial to attract a critical mass of users, yet the resources for marketing in this primarily scientific project were limited. The question of what constitutes a sufficient user base for a rare disease network remains. Due to the diversity of rare diseases, it is still uncertain whether—or to what extent—users can genuinely learn from each other when their conditions or diseases differ significantly. This problem is evident in the evaluation results. The evaluation was conducted at an early stage, before many users had registered. Although three-quarters of users (208/270, 77%) were offered a match, this was not always an ideal fit due to the limited size of the database, as reflected in the slightly negative assessment of the matching. The rating would probably be higher if the evaluation were conducted at this point given the considerable efforts that have been made to improve the app, especially the matching algorithm.

Second, ensuring optimal data privacy is a persistent challenge. Users need assurance that their personal and health information is secure. The balance between providing a useful service and maintaining stringent data privacy standards is delicate and ongoing []. The Unrare.me initiative addressed this issue by using both an extremely transparent information approach and an information-conserving strategy. Another concern is the participation of minors in social networks. Specific measures need to be implemented to protect younger users while allowing them to benefit from the network [41].

Third, it is crucial to ensure the long-term sustainability of Unrare.me. Planned future enhancements to the app include additional interaction features such as group chats, structured feedback mechanisms, bulletin boards, and current news updates. These features aim to foster a more vivid, engaging, and supportive community. However, this also involves exploring viable business models and alternative funding sources so that the platform can be maintained and expanded without relying on a traditional commercial approach.

Finally, reducing barriers to access is essential. This involves enhancing accessibility features, expanding the platform's international reach, and incorporating multilingual support to cater to a diverse user base.

Consequently, the Unrare.me team is currently planning the further development of the platform, including technical aspects, funding, collaboration, matching optimization, and new features for the app. The continuous positive feedback from users serves as positive reinforcement and illustrates the urgent need for a network such as Unrare.me, which is expected to grow with the support of strong stakeholders. Specific next steps include the establishment of an Unrare.me registry structure as well as "meet the expert" offerings within the platform.

Limitations

An evaluation of Unrare.me was carried out alongside app development using a multimodal approach. However, monitoring was only possible for the first 3 months after app launch. Therefore, the results may only be of limited significance. As previously mentioned, the small user pool for matching in this early phase is a limitation. However, technical problems in the early stages may also have distorted the results. Given the many improvements made since then, it can be assumed that the evaluation would be more positive today.

XSL•FO
RenderX

However, on the other hand, only 1 in 7 users took part in the survey. Therefore, distortions caused by particularly committed individuals cannot be ruled out.

The capacity for conducting interviews was also limited at the beginning. A total of 15 qualitative interviews were conducted. To reflect a wide range of needs and concerns, the interviewees were carefully selected based on factors such as age, gender, digital literacy, and migration background. Nevertheless, the interviews did not cover all interests. To take these limitations into account, a re-evaluation of the app is planned.

In conclusion, while Unrare.me addresses a significant gap in the digital networking space for individuals with chronic and rare diseases, several areas require ongoing attention and development. Effective marketing, robust data privacy measures, sustainable funding models, enhanced user interaction, and improved accessibility are key to the platform's success. By continuing to evolve and adapt, Unrare.me has the potential to become a vital resource for the rare disease community, facilitating meaningful connections and support.

Acknowledgments

The authors would like to thank the Kindernetzwerk e.V. and all involved self-help groups for their valuable support that significantly enriched this study. Dr Claudio Cinquemani (CureRare), Dr David Katzer (University Hospital Bonn), and Eric Seitz and his team provided helpful feedback on how to improve the app. Achim Flender is acknowledged for helpful feedback on data safety aspects within Unrare.me. Dr Werner Lechner and Professor Frank Klawonn are gratefully acknowledged for valuable support and fruitful discussions during the early phase of the project. The authors are also grateful to their first real-life testers for their insightful feedback and encouragement. Professor Dr. med. Lars Pape and Dr. med. Metin Cetiner from the NEOCYST initiative are acknowledged for their excellent collaboration. Professor Nadine Scholten provided valuable insights on the perspective of patients with chronic diseases, and Professor Dagmar Wachten and team (Institute of Innate Immunity) connected the Unrare.me initiative to the Bardet-Biedl syndrome community, which was of immense help. The authors used GPT-5.1 (OpenAI) for language and grammar improvement.

Funding

This research was supported by the German Federal Ministry of Health (*Bundesministerium für Gesundheit*) under grant ZMI5-2521SBG004.

Abstract

Background: Deep vein thrombosis (DVT) is a significant global health issue, often associated with a high symptom burden and reduced quality of life, especially after discharge. Traditional symptom management models are typically passive, clinician-centered, and lack real-time monitoring and feedback, which can lead to delayed interventions and poor patient engagement. While mobile health (mHealth) interventions offer a promising alternative, they require rigorous usability testing to ensure both efficacy and adoption.

Objective: This study aimed to design and develop Tpro (developed by the Department of Vascular Surgery, Peking Union Medical College Hospital), a patient-reported outcome (PRO)–based mobile app for patients with DVT. Using an iterative convergent mixed methods design, the app seeks to enable proactive symptom monitoring, health education, clinician-patient interaction, and peer support, thereby optimizing its usability, functionality, and alignment with patient needs.

Methods: The development followed an iterative convergent mixed methods design, comprising predevelopment and iterative optimization phases. Initial functions were informed by qualitative interviews with 14 patients with DVT. Over 4 iterative cycles, qualitative feedback and quantitative usability data (including task completion rates and User Interface Usability Questionnaire [UIUQ] scores) were concurrently collected, analyzed, and integrated via joint displays to guide refinements in content, interface, and system architecture until usability benchmarks were met.

Results: The final Tpro app encompasses 4 core modules, including gamified symptom reporting, multimodal health education, clinician-patient communication, and a peer support community. Iterative testing identified and resolved key usability issues. The final prototype demonstrated high usability, achieving an excellent UIUQ score (mean 89, SD 13) and a task completion rate of 92% (12/13), indicating high user acceptance and operational reliability.

Conclusions: Applying the iterative convergent mixed methods approach enabled the systematic and user-centered development of Tpro. This methodology effectively integrated diverse stakeholder feedback into a functional and engaging patient-reported outcome–based app, ready for subsequent efficacy trials. This approach offers a replicable model for developing digital health tools in complex clinical contexts.

KEYWORDS

deep vein thrombosis; patient-reported outcomes; mobile app; mixed methods research; iterative design

Introduction

Deep vein thrombosis (DVT) has emerged as a significant contributor to cardiovascular disease-related mortality on a global scale [1]. Individuals afflicted with DVT frequently experience a substantial array of acute and chronic symptoms, including persistent pain, swelling, functional impairment, and psychological distress, leading to a diminished quality of life and subsequently escalating the overall economic burden on health care systems worldwide [2].

Effective symptom management is crucial for predicting adverse prognostic events, preventing complications, optimizing

XSL•FO
RenderX

treatment outcomes, improving overall health, and enhancing quality of life in patients with DVT [3]. However, this traditional symptom management model operates on a passive-reactive and clinician-centric framework, predominantly reliant on infrequent routine ward rounds or scheduled in-person hospital consultations [4]. This approach inherently lacks mechanisms for active, real-time monitoring of patients' symptoms, particularly those occurring between visits or in out-of-hospital settings, and fails to adequately incorporate the patient's subjective experience and perspective. Consequently, health care providers are often unable to promptly identify worsening symptoms or address emerging patients' needs, leading to significant delays in intervention and a critical disconnect between the patient's actual clinical status and the health care system's responsiveness.

The integration of patient-reported outcomes (PRO) into symptom management exemplifies a patient-centered approach, fully aligning with core principles of patient-centered medical care. This model empowers patients to autonomously monitor symptoms, alleviate symptom burden, and enhance quality of life [5]. While widely applied in clinical trials, drug approval, and tumor prognosis, this model has yet to be integrated into symptom management for patients with DVT [6,7].

Mobile health (mHealth) apps offer a promising platform to facilitate PRO collection and support self-management, enabling patients to engage in disease management beyond clinical settings [8]. Nevertheless, many mHealth solutions face poor adoption due to insufficient usability and a lack of end-user involvement during development [9]. Currently, there is no mHealth app based on PRO that has been developed with a rigorous user-centered design approach specifically tailored to address the symptom management needs of patients with DVT.

To tackle these obstacles, this study used an iterative convergent mixed methods design [10], a robust methodology that concurrently gathers and evaluates qualitative and quantitative data throughout various development phases, to create Tpro, an mHealth app centered on PRO specifically for individuals with DVT. The app is structured to facilitate proactive symptom monitoring, deliver health education, enhance clinician-patient communication, and provide peer support. In practice, patients are guided through a daily workflow and after receiving a customizable reminder, they complete a symptom report, during which they can message their clinician. Upon submission, tailored health education content is automatically unlocked. A knowledge library and a peer community remain available for self-directed use at any time. By merging the PRO framework with iterative user-centered development, Tpro strives to enhance usability, functional significance, and alignment with patient requirements, thereby promoting a more adaptive and patient-involved approach to managing DVT symptoms.

Methods

Overview of Development Methodology

The development of Tpro used an iterative convergent mixed methods design as formalized by Alwashmi et al [10]. This approach is characterized by the concurrent collection and integration of qualitative and quantitative data across cyclical iterations, continuing until predefined usability endpoints are achieved [10]. In this study, the process was structured across 2 interlinked phases, namely a predevelopment phase, which defined core functions and wireframes based on prior qualitative inquiry and clinical consensus, and an iterative optimization phase consisting of 4 consecutive cycles of prototype testing and refinement. Within each cycle, qualitative feedback and quantitative usability metrics were systematically integrated through joint displays and team interpretation sessions, directly informing real-time design modifications. This evidence-driven, user-centered process continued until design saturation was achieved, that is, until no new critical usability issues emerged and key performance metrics stabilized.

Predevelopment Phase

Defining Core Functions Through Qualitative Inquiry

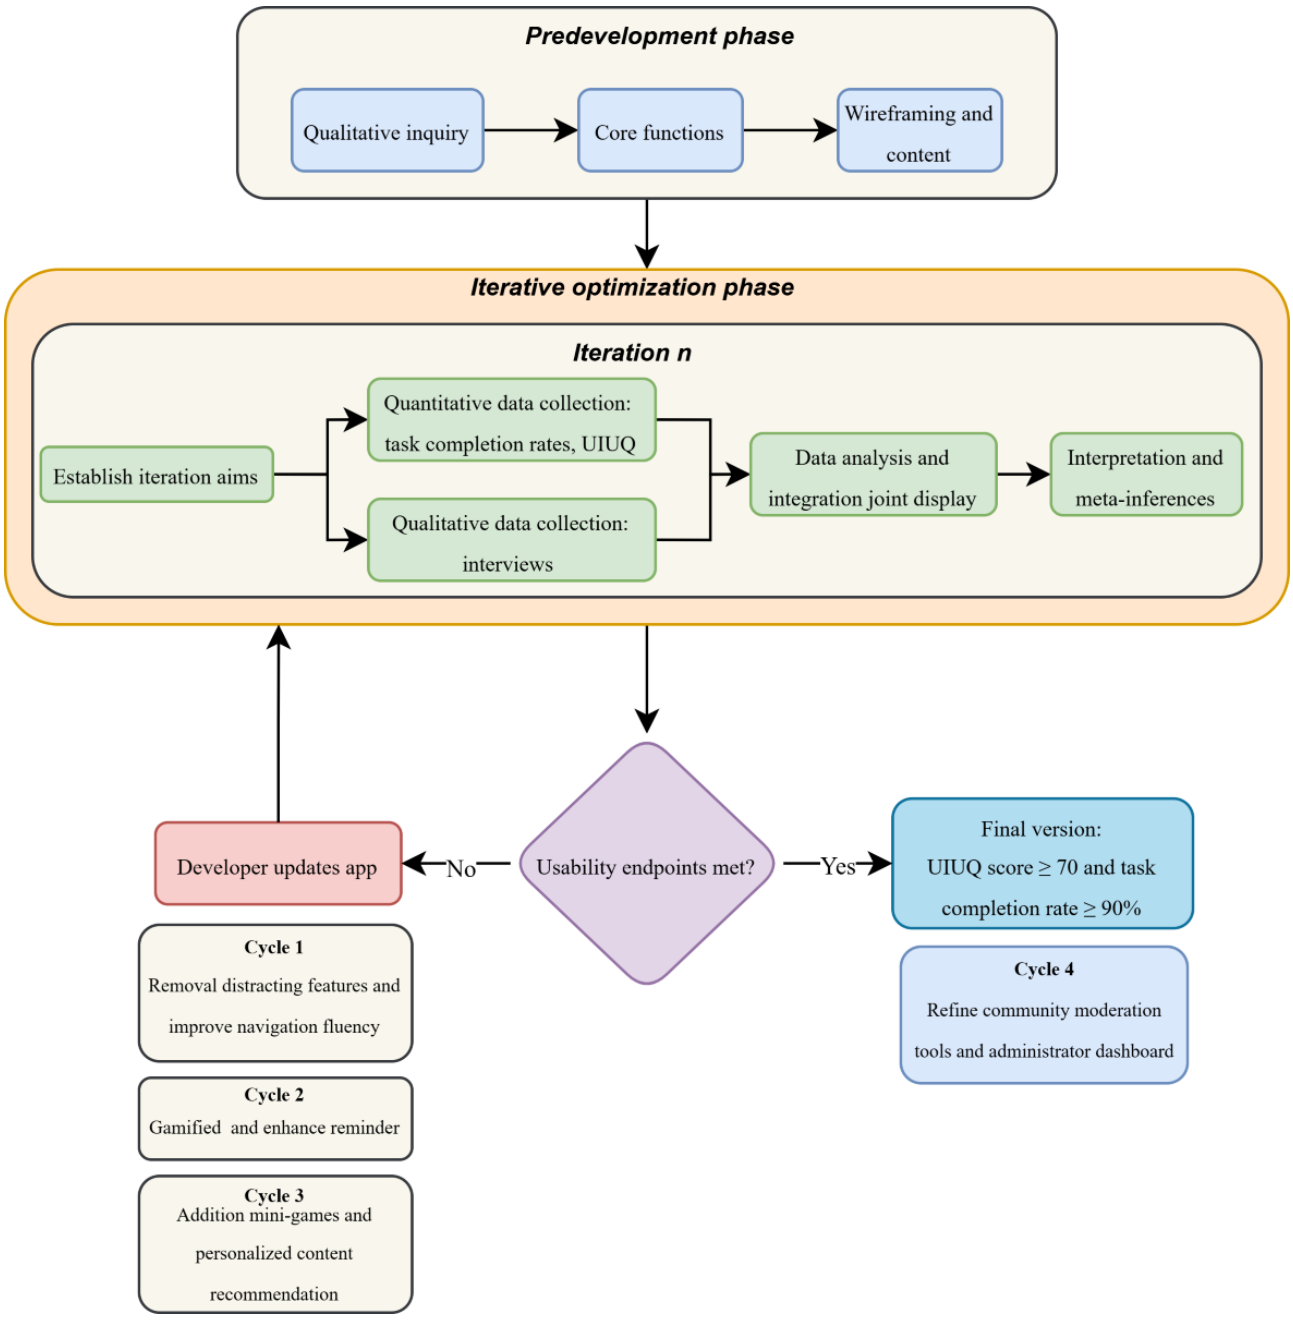
The primary function of Tpro was derived from qualitative interviews conducted in the initial phase of the study with 14 patients with DVT engaged in 6-month out-of-hospital self-management [11]. The findings suggest that enhancing health education can enhance patients' understanding, improve doctor-patient communication, facilitate monitoring, and establish a support system to enhance the quality of out-of-hospital patient with DVT management [11].

Expanding on these results, the researchers, leveraging their substantial clinical expertise in managing patients with DVT (each investigator with at least 5 years of experience), reached a consensus. As a result, the primary roles of Tpro were identified as symptom monitoring, health education, facilitating medical-patient interaction, and fostering peer support among patients.

Wireframing and Content Development

Wireframes, shown as line diagrams and geometric placeholders, define spatial hierarchy, modular component organization, and relationships among interactive elements. They explicitly convey an app's basic architectural topology and provide a visual framework for design and development teams. Wireframes are used for concept communication, user-flow optimization, and the establishment of the structural foundation during the initial development stage [12]. The researchers generated a wireframe diagram of Tpro based on its 4 primary functions. As shown in Multimedia Appendix 1, the wireframe illustrates the initial layout and user flow among the symptom monitoring, education, communication, and community modules.

Following the definition of the app's core functions and structure, the app was named "Tpro," a term derived from combining the target condition ("Thrombosis") with the core methodology ("Patient-Reported Outcomes"). The multimedia content was subsequently developed through a systematic, evidence-based process. This included original anatomical illustrations (eg, diagrams of human vasculature) created by medical illustrators; educational texts and instructional videos, adapted from existing patient education materials and produced in collaboration with vascular nursing specialists, with all materials undergoing health literacy review [13]; a knowledge question bank clinically validated by experts; and gamified



XSL•FO
RenderX

learning scripts, designed based on behavior change theory [14] and integrated with the core text and image materials.

Iterative Optimization Phase

We conducted 4 complete iterative cycles of testing and refinement between November 2024 and March 2025. Each cycle followed the structured process outlined in Figure 1 and incorporated the integration procedures detailed below. Representative screenshots of key interface updates from each cycle (Cycle 1-Cycle 4) are provided in Multimedia Appendix 2.

Figure 1. Flowchart of the 4-cycle iterative convergent mixed methods optimization process for Tpro development. UIUQ: User Interface Usability Questionnaire.

Integration in the Research Questions Dimension

The study used 3 types of research questions that guided each iteration:

(1) Mixed methods aim: to illustrate, explore, and measure how to improve the usability and functionality of Tpro for DVT symptom management

(2) Quantitative research questions: focused on measuring effectiveness (task completion rates) and satisfaction (User Interface Usability Questionnaire [UIUQ] scores) [15]. Task completion rates were defined as the proportion of participants who successfully completed both the symptom reporting process and at least one health education activity (knowledge reading or quiz completion) within the Tpro app. The UIUQ developed by Chinese scholar Liu consists of 20 items scored on a 0 - 5 scale, yielding a total score of 0 - 100 points. Higher scores

XSL•FO
RenderX

indicate better interface usability. Based on the total score: below 50 points represents unacceptable usability, 50 - 70 points indicates marginally acceptable usability, and above 70 points reflects satisfactory usability.

(3) Qualitative research questions: centered on understanding how and why users interacted with Tpro as they did, their experiences with specific features, and suggestions for improvement. Table 1 summarizes the data collection methods and integration timing used in this study.

Table . Data collection methods and integration timing. This table summarizes the mixed methods data collection strategy, specifies the types of data collected, and outlines how they were integrated concurrently to inform real-time design decisions during each development cycle.

Data type	Methods	Collection timing	Integration approach
Quantitative	UIUQ[a], task completion rates	During and immediately after app use	Concurrent with qualitative data collection
Qualitative	Semistructured interviews	During app use and in postuse debriefing	Immediate feedback into quantitative understanding

[a]UIUQ: User Interface Usability Questionnaire.

Integration in the Data Collection Dimension

We implemented 3 integration strategies during data collection: (1) matching: qualitative questions were intentionally matched to quantitative constructs. For example, when low task completion rates were observed quantitatively, we asked, "I noticed you hesitated when completing the task, can you tell me more about what was unclear?" (2) Diffracting: qualitative questions explored aspects beyond quantitative measures, such as emotional responses to the gamified interface, trust in medical recommendations, and preferences for community interaction styles. And (3) expanding: when quantitative and qualitative findings diverged, we expanded questioning to understand both perspectives. For instance, when users reported high satisfaction qualitatively but gave medium UIUQ scores quantitatively, we explored this discrepancy specifically.

Collection of Qualitative Data and Researcher Reflexivity

Qualitative data within each cycle were collected primarily via semistructured interviews, conducted by 2 researchers (MS and YL). Both interviewers held clinical research backgrounds and had completed formal training in qualitative interview techniques. They had no prior clinical or therapeutic relationship with the patient participants, nor had they engaged in any discussions with participants regarding the Tpro app or DVT management prior to the study, which was explicitly explained at the outset to minimize social desirability bias and encourage candid feedback. Researchers maintained reflexive journals to document and bracket their own assumptions prior to and following interviews. Data collection proceeded within each cycle until informational saturation was attained on the usability themes specific to that cycle's prototype, which was determined when subsequent interviews yielded no new insights related to the core evaluation objectives.

Integration in the Data Analysis Dimension

We used a combined independent and interactive analysis strategy:

(1) Interactive analysis: during early iterations (Cycles 1 - 2), researchers analyzed qualitative and quantitative findings in real-time as data were collected, allowing immediate exploration of emerging issues

(2) Independent intramethod analysis: in later iterations (Cycles 3 - 4), qualitative data underwent inductive thematic analysis and quantitative data were analyzed statistically prior to integration. Specifically, for thematic analysis, 2 researchers (QL and LW) independently coded transcripts from initial cycles to develop a preliminary codebook. Discrepancies were resolved through discussion until consensus was reached, thereby enhancing interpretive reliability. The refined codebook was then applied to subsequent cycles, with ongoing peer debriefing within the research team to ensure analytical rigor. Representative quotations illustrating key themes are provided in Multimedia Appendix 3.

(3) Data integration procedures: we used joint displays to visually represent the integration of qualitative and quantitative findings (see Table 2 for example). The fit of the 2 data types was examined for confirmation, complementarity, expansion, or discordance. Discordant findings were resolved through additional data collection or reanalysis.

XSL•FO
RenderX

Table . Joint display from Cycle 1 showing data integration and resulting design decisions. This table provides a concrete example of the convergent mixed methods analysis, showing how specific usability metrics were interpreted alongside direct user feedback to identify root causes and translate them into actionable design modifications.

Quantitative findings	Qualitative findings	Integration insights	Design decisions
Around 52% (11/21) of users failed to complete symptom reporting or knowledge learning first attempt	• "I got distracted by the chat function on main screen and forgot to report symptoms" (Patient 03) • "app is super convenient, but I don't really have time to learn about thrombosis. I just check it out from time to time" (Patient 10) • "The knowledge base still has some room for improvement. There are so many topics I want to learn about! It would be great to have more educational mini-games" (Patient 11, Patient 08)	Core functionality was being undermined by secondary features and cognitive load	• Removed chat function from main screen to dedicated section • Added interactive mini-games and expanded knowledge content • Enhanced personalized reminder system based on usage patterns
UIUQ[a] score for efficiency (86/100)	• "I wasn't sure if my report went through-no confirmation" (Patient 07) • "The navigation feels jumpy between sections" (Patient 05)	Lack of feedback and inconsistent navigation patterns created uncertainty and frustration	• Added clear submission confirmations • Standardized navigation patterns across all modules • Improved transition animations

[a]UIUQ: User Interface Usability Questionnaire.

Integration in the Interpretation Dimension

During each iteration cycle, the research team conducted interpretation sessions where quantitative and qualitative findings were merged to draw metainferences that considered both types of data. These sessions followed a structured process:

(1) Data triangulation: comparing quantitative metrics with qualitative themes

(2) Pattern identification: looking for convergent, complementary, or divergent findings

(3) Priority setting: determining which issues to address in the next iteration based on severity and frequency

(4) Solution generation: brainstorming specific design modifications

Participant Recruitment

Participant recruitment used a combination of convenience and purposive sampling strategies to engage key stakeholder groups. Patient participants were recruited via convenience sampling from the vascular surgery outpatient clinic of Peking Union Medical College Hospital. Inclusion criteria for patients required a confirmed DVT diagnosis, proficiency in smartphone use, and expressed willingness to engage in multiple testing cycles. Exclusion criteria encompassed significant cognitive impairment, visual disabilities preventing effective smartphone interaction, or concurrent participation in other digital health studies. Clinical experts, including vascular surgeons and specialized nurses, were purposively recruited from the Department of Vascular Surgery at Peking Union Medical College Hospital based on their documented clinical expertise and experience in DVT management. Similarly, nonmedical technical evaluators with specialized backgrounds in usability engineering, software development, or human-computer interaction were purposively selected from the collaborating technical team involved in this research project.

Sample Size Justification

The sample size for iterative usability testing was determined a priori based on established principles of user-centered design and the iterative convergent design framework adopted for this study. Foundational usability research indicates that testing with 5-12 users per iteration is sufficient to identify the majority of interface problems [16]. Aligned with this framework [10], the primary endpoint of the iterative process was not statistical power but the achievement of thematic and design saturation, the point at which additional testing cycles yield no new critical usability themes, barriers, or actionable design feedback. Recruitment and iterative testing continued until this saturation criterion was operationally confirmed, which was assessed through the stabilization of quantitative usability metrics (task completion rate and UIUQ score) in consecutive cycles.

Ethical Considerations

The study received approval from the Institutional Review Board of Peking Union Medical College Hospital (approval number: I-24PJ1204). Written informed consent was obtained from all participants prior to their enrollment in the study. We attest that the privacy and confidentiality of all research subjects' data and identities were strictly maintained throughout the study.

Development Technical Specifications

Tpro is constructed using the Flutter (Google LLC) framework, enabling simultaneous app development for Android, iOS, Web, and desktop (Windows, macOS, and Linux), thereby

XSL•FO
RenderX

streamlining code writing across platforms, shortening project timelines, and reducing costs. Embedded pages are built on a Java-based low-code platform. The Tpro app is compatible with Android 5 and higher, as well as iOS 11 and newer versions. Initially developed in Chinese to align with regional preferences, Tpro will be offered in English and other languages in the future.

During the iterative testing cycles, the Tpro package was installed on participants' personal devices via a secure, authenticated download link, or was made accessible on preconfigured study devices where necessary. Access required individual user accounts verified by the clinical research team. This deployment strategy ensured controlled distribution and facilitated rapid iterative updates during the optimization cycles.

Data Security and Privacy Protection

The Tpro system was designed with a multilayered security and privacy architecture. All data transmission was protected by TLS encryption, and sensitive data were encrypted at rest. The app backend was deployed on a secure, internal server to ensure physical and administrative data control. Access to patient information was strictly governed by role-based permissions within the clinician admin portal, and all accesses were logged. In the peer community, user identities were anonymized. These measures were designed to comply with relevant data protection regulations and were reviewed as part of the ethical approval process.

Results

Participant Characteristics and Iterative Testing Process

The iterative development of Tpro was conducted over 4 cycles spanning a 4-month period, engaging a total of 21 participants. The patient cohort consisted of 12 individuals with confirmed DVT (8 males and 4 females), with an age range of 25-72 years, all recruited from the vascular surgery outpatient clinic. Their educational backgrounds ranged from elementary school to master's degree, and they presented with diverse DVT locations (including iliofemoral, calf, and femoral veins) and varying symptom severities. The multidisciplinary evaluation team comprised 6 clinical experts: 2 vascular surgeons (mean 10.5, SD 6.4 years of specialization) and 4 specialized nurses (mean 6, SD 1.4 years of experience). Additionally, the team included 3 nonmedical technical evaluators specializing in usability research and software engineering (mean 8, SD 3.6 years of relevant experience).

Engagement across the iterative cycles was structured to balance depth of longitudinal feedback with the introduction of fresh perspectives, continuing until thematic and data saturation were achieved. All 6 clinical experts and all 3 technical evaluators participated in all 4 cycles, providing consistent expert and technical oversight. Among the 12 patients, 4 completed all 4 cycles, forming a core longitudinal feedback group, while the remaining 8 patients participated in 2-3 cycles, ensuring that new user perspectives were incorporated at each stage. Consequently, a total of 13 participants (4 patients, 6 clinical experts, and 3 technical evaluators) completed all 4 testing cycles, thereby providing the continuous and in-depth feedback necessary to reach this saturation endpoint. The comprehensive demographic, clinical, professional, and cycle-by-cycle participation details for each individual are provided in Multimedia Appendix 4.

Evolution of Usability Metrics

The systematic application of the iterative convergent approach yielded substantial improvements across all usability metrics. The UIUQ score demonstrated progression from an initial score of 86 in the first cycle to a final score of 89 in the fourth cycle. Task completion rates showed consistent improvement, rising from 46% (6/13) in initial testing to 92% (12/13) in the final evaluation (Table 3).

Table . Usability metrics evolution across 4 iterative cycles (n=13). This table presents the progression of key quantitative usability indicators, including the overall User Interface Usability Questionnaire (UIUQ) score and the task completion rate, demonstrating the systematic improvement achieved through the iterative refinement process.

Metric	Cycle 1	Cycle 2	Cycle 3	Cycle 4
Overall UIUQ[a] score, mean (SD)	86 (6)	87 (6)	88 (8)	89 (13)
Task completion rate, n (%)	6 (46)	10 (77)	11 (85)	12 (92)

[a]UIUQ: User Interface Usability Questionnaire.

Key Refinements Through Integrated Data Analysis

The integrated analysis throughout the development cycles revealed a consistent pattern of strong initial usability with progressive optimization in user engagement. From the first cycle, quantitative data showed excellent UIUQ scores (mean 86, SD 6), while qualitative feedback confirmed the interface was perceived as "intuitive and pleasant." However, the convergent analysis uncovered a critical gap between this high usability perception and actual engagement metrics, with only 46% (6/13) task completion rate initially. This paradox was elucidated through user reports of forgetting to complete tasks despite appreciating the design, leading to the insight that excellent usability alone was insufficient to ensure consistent engagement. Consequently, we implemented a gamified task sequence with progressive rewards and streamlined the workflow between symptom reporting and educational content.

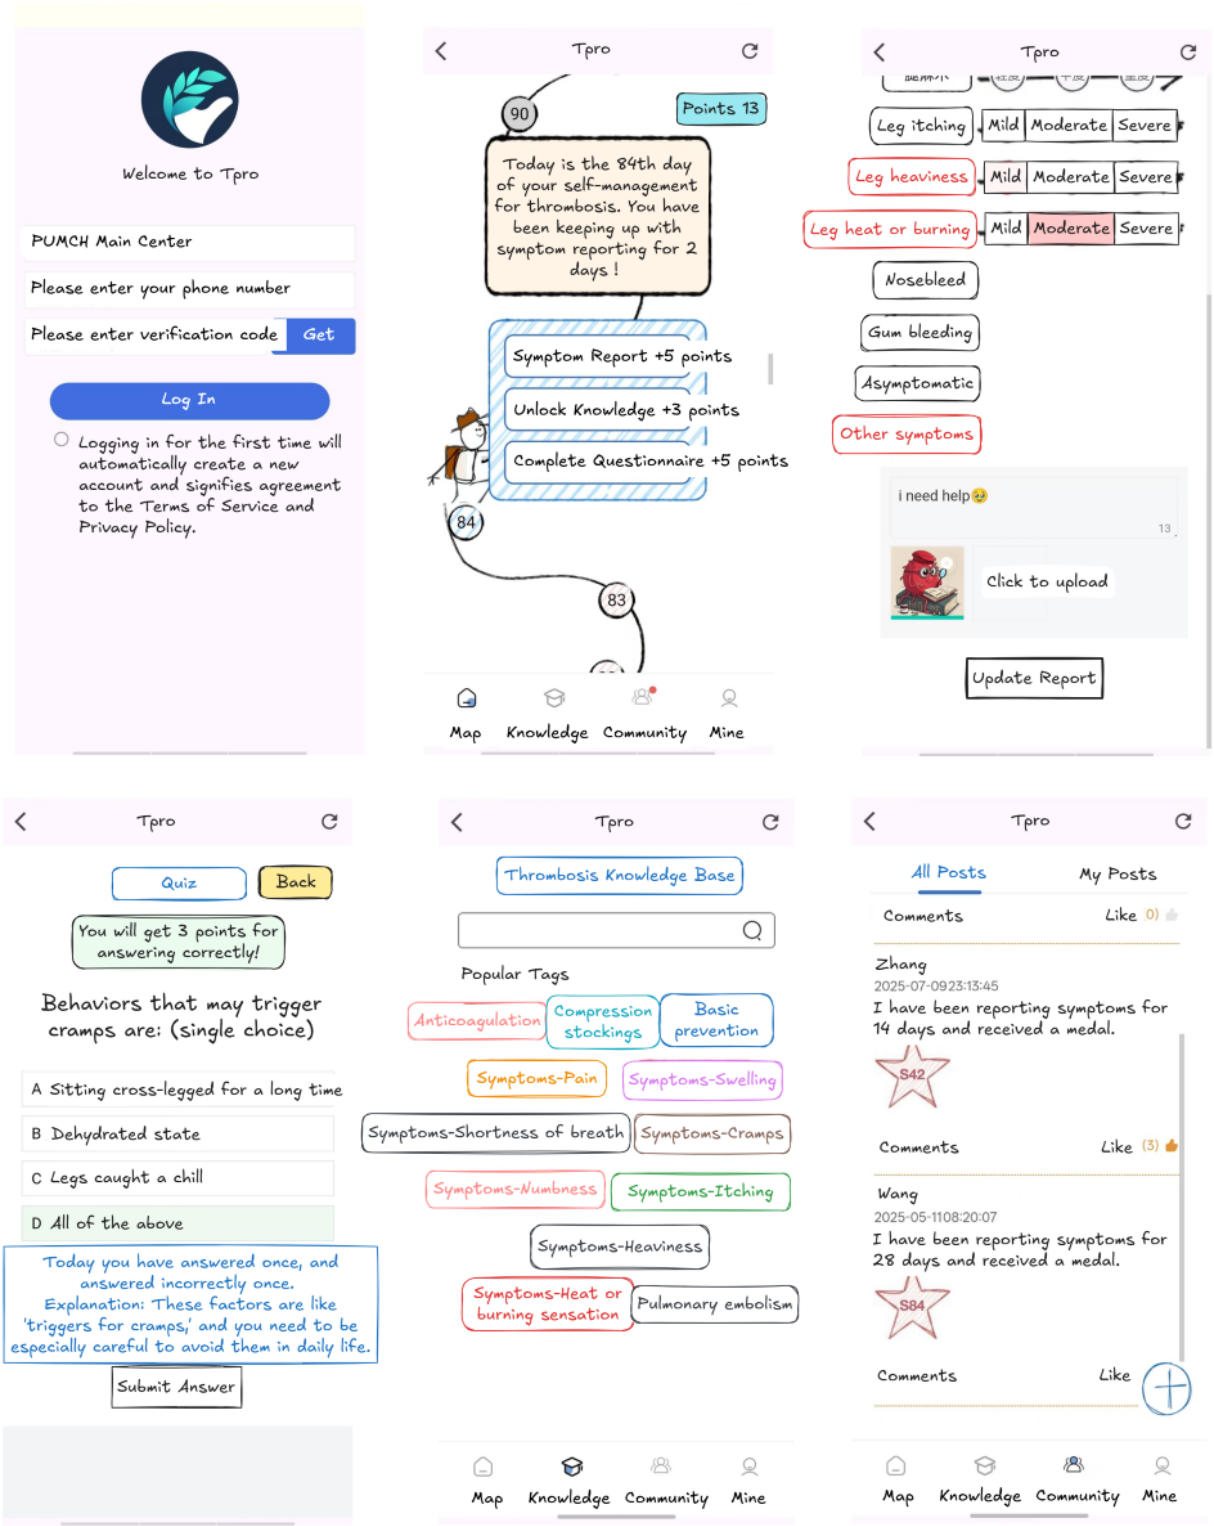
During the second cycle, as task completion rates rose substantially to 77% (10/13) while maintaining high UIUQ scores (mean 87, SD 6), qualitative feedback indicated that the improved task flow made it easier for users to remember subsequent actions. This convergence of metrics confirmed that structural enhancements had successfully translated the strong

XSL•FO
RenderX

usability foundation into improved engagement. Building on this success, we enhanced the reminder system with contextual prompts and personalized notification timing. In the subsequent cycles 3‐4, further improvements in task completion (12/13, 92%) with stable UIUQ scores were reinforced by qualitative reports of increased enjoyment from educational games and anticipation of weekly content discoveries. This integrated understanding highlighted the importance of continuous content innovation, prompting the introduction of rotating educational mini-games and personalized knowledge recommendations based on symptom patterns to sustain long-term engagement.

Final App Architecture

The iterative development process culminated in a refined app comprising well-integrated functional modules that collectively support comprehensive DVT management. Figure 2 shows the final integrated architecture including the user onboarding, gamified reporting map, dynamic education ecosystem, and communication channels. The patient registration system evolved into a streamlined onboarding process where users complete demographic and clinical profiles after administrative verification, capturing essential information including DVT location, existing symptoms, and relevant medical history through an intuitive form-based interface.



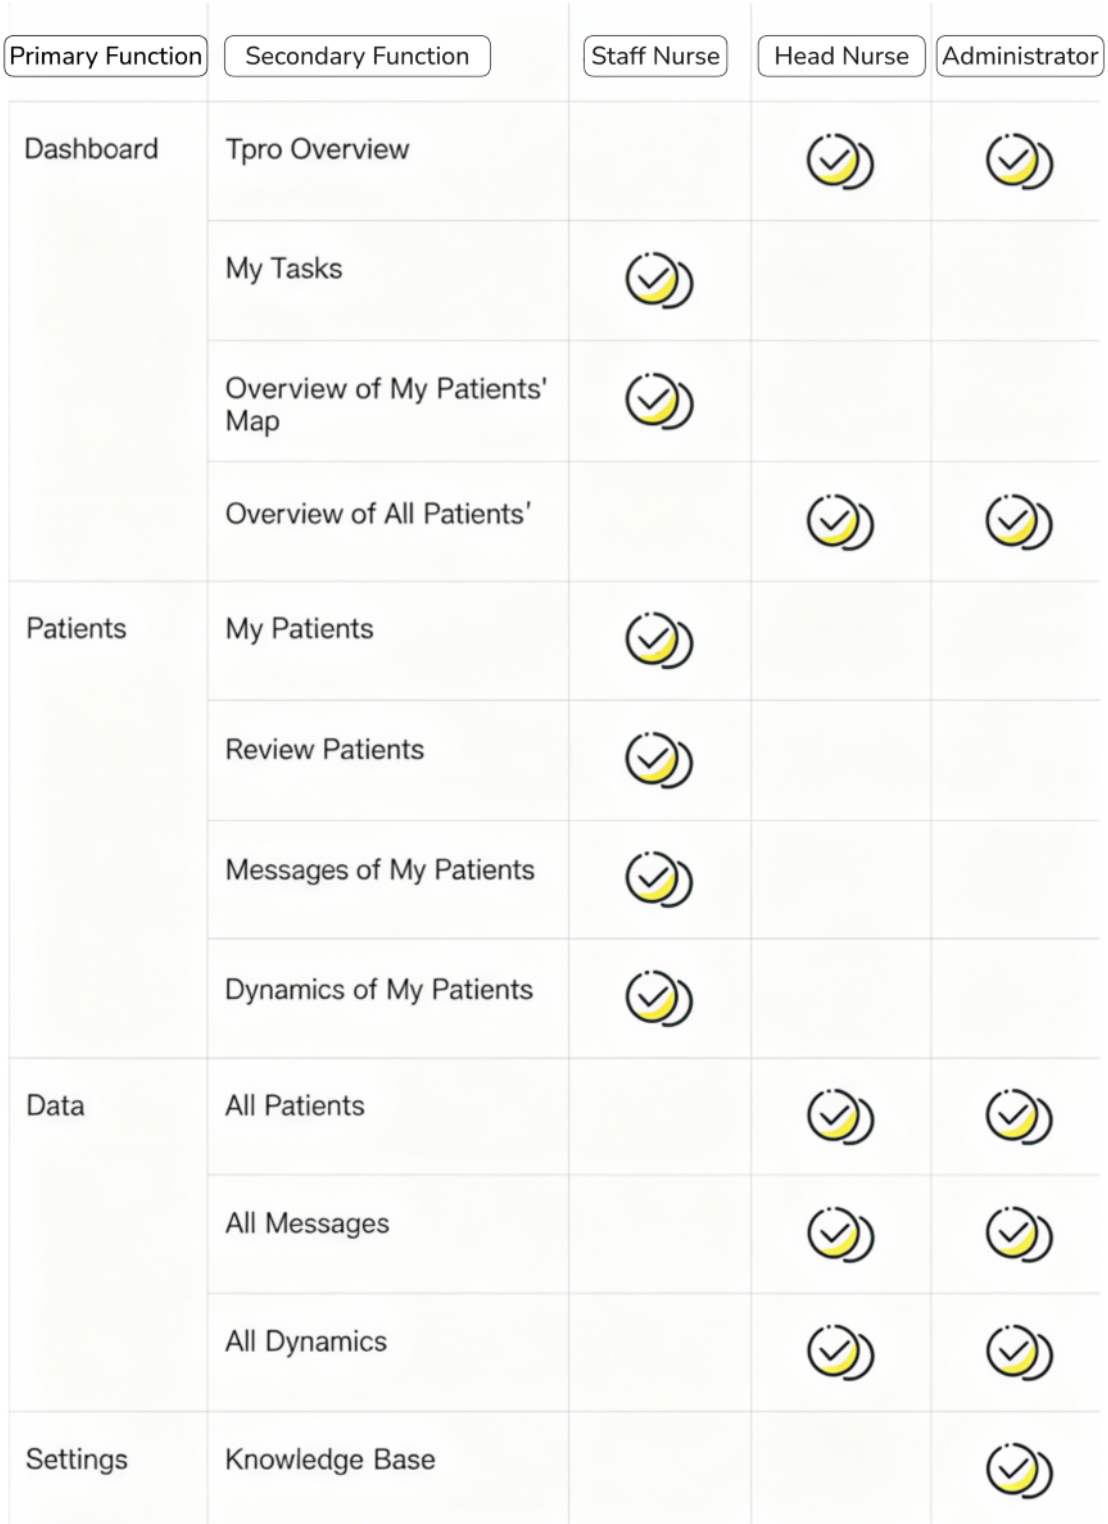
Central to the app is the gamified symptom monitoring module. Patients are guided through a structured daily workflow, initiated by an adaptive reminder system that sends a notification at a default time of 5:00 PM, which can be customized to individual preferences. Upon entering the app, patients complete their symptom report through an “Exploration Map” interface, which transforms daily symptom reporting into an engaging, game-like activity. A carefully designed incentive mechanism awards points for consistent reporting, which accumulate toward priority scheduling for in-person follow-up appointments. For clinical support, the system features an integrated clinician-patient communication channel that enables patients to submit detailed queries with text and photographic evidence directly through the symptom reporting interface. This module operates with a sophisticated triage protocol where acute symptoms such as dyspnea trigger immediate alerts for urgent clinical response, while chronic concerns receive guaranteed feedback within a 48-hour framework.

The educational component underwent significant transformation from static information delivery to a dynamic learning ecosystem. Upon submission of each symptom report, health education content specifically matched to the symptoms reported that day is automatically unlocked and delivered through multiple formats, including illustrated materials, instructional videos, interactive quizzes, and gamified learning activities, with each educational interaction further contributing to the user’s point accumulation. At the final testing stage, the module contained 3 instructional videos, 53 illustrated materials, 292 interactive knowledge quiz items, and 45 gamified learning activities, which together constituted a content library to support rotated delivery. Based on user feedback collected during the testing phase indicating a need for continuously refreshed educational content, the clinical team will review user needs on a monthly basis and develop and add new materials accordingly. This content rotation and expansion strategy is designed to sustain long-term user engagement beyond the testing phase. For patients with a strong interest in learning, the comprehensive knowledge library remains accessible for self-directed exploration at any time, independent of the daily reporting workflow.

Complementing these core functions, the app incorporates a dedicated peer support community where patients share treatment experiences and disease management insights through text and image posts at any time. This social platform fosters mutual support through interactive features including likes and comments, while maintaining a therapeutic environment through active moderation by health care professionals.

XSL•FO
RenderX

Figure 2. Final integrated system architecture of Tpro (English translations). The architecture comprises 4 interconnected modules developed through iterative refinement: a gamified "Exploration Map" for symptom reporting, a dynamic educational ecosystem that unlocks content based on user actions, a tiered clinician-patient communication channel with acute symptom alerts, and a professionally moderated peer support community. This design successfully integrates a high-usability interface with patient-centered functional requirements for comprehensive deep vein thrombosis (DVT) management.



Administrative System Development

The backend administrative portal similarly evolved through the iterative refinement process, developing enhanced role-based permissions with granular access controls, automated flagging systems for urgent patient communications, advanced analytics dashboards for tracking patient engagement patterns, dynamic content management capabilities for educational material updates, and integrated moderation tools for community management. This comprehensive administrative infrastructure supported efficient oversight while maintaining flexibility for institutional customization. Figure 3 presents the admin portal

XSL•FO
RenderX

interface with its analytics dashboard, content management, and moderation tools.

Figure 3. Overview of the backend administrative portal for Tpro. The portal provides role-based access controls, an analytics dashboard for tracking patient engagement, dynamic content management tools, and community moderation features. This comprehensive administrative infrastructure enables efficient patient oversight and supports institutional customization.

Final Usability Outcomes

The final evaluation demonstrated outstanding usability outcomes across all metrics. The system achieved an excellent UIUQ score with a mean of 89 (SD 13) in the fourth cycle, and the task completion rate, defined as completing both symptom reporting and at least one health education activity, reached 92% (12/13), confirming high operational reliability and indicating that nearly all patients proceeded from symptom reporting to the automatically unlocked educational content, which was delivered in randomly presented formats, including illustrated materials, videos, quizzes, and games. Regarding

XSL•FO
RenderX

clinician-patient communication, 12 patients generated a total of 6 inquiries across the testing period, all submitted through the symptom reporting interface. In the peer support community, 4 posts were shared across the 12 patients, while several others browsed content without actively posting. Notably, 83% (10/12) of patient participants expressed willingness to continue using Tpro and recommend it to peers, and clinical doctors and nurses consistently provided highly positive evaluations regarding the system's clinical utility and workflow integration.

These convergent findings from multiple stakeholder perspectives substantiate that Tpro has evolved into a clinically valuable, highly usable, and widely accepted digital health intervention, positioning it as a promising tool for optimizing out-of-hospital management of DVT.

Discussion

Principal Findings

This study successfully demonstrates the application of an iterative convergent mixed methods design in developing Tpro, a comprehensive mHealth solution for DVT symptom management. The systematic integration of quantitative usability metrics with qualitative user feedback across multiple development cycles enabled the transformation of an initial prototype into a refined digital health intervention. The final app not only achieved excellent usability, as evidenced by a high UIUQ score (mean 89, SD 13) and task completion rate (12/13, 92%), but also received endorsement from clinical experts. More importantly, this methodology facilitated a deeper understanding of the complex interplay between technical functionality, user engagement, and clinical utility that would likely remain obscured through traditional single-method approaches.

Comparison With Prior Work

From a design philosophy perspective, the construction of Tpro based on PRO represents an essential reshaping of the medical paradigm. Traditional clinical research has predominantly focused on objective indicators from the medical perspective. For instance, Tritschler et al's [17] scoping review on clinical outcomes of venous thromboembolism interventions in nonpregnant adults identified recurrence, major bleeding, and mortality as the most frequently reported outcome measures. However, these metrics often fail to accurately capture patients' real-life challenges, such as prolonged immobilization, anxiety, and depression induced by anticoagulant therapy, or the inconvenience of daily activities caused by wearing compression stockings [18,19]. In contrast, PRO directly reflects patients' physical, psychological, and social functional experiences [20]. By collecting first-hand information through PRO, Tpro bridges the critical gap in physician-patient communication, precisely identifies patient needs, and enables targeted subsequent interventions.

The design of each core module in Tpro was meticulously informed by this PRO-driven philosophy and the specific needs uncovered in our preliminary research [11]. The symptom monitoring module uses an interactive exploration map format, while the daily reporting feature adopts a gamified approach akin to unlocking new levels. This innovative design strategically leverages game-based mechanics to transform traditionally monotonous health management tasks into engaging daily activities, fostering patient motivation through an integrated incentive system. Underlying this framework is the application of behavior change theory, which posits that patients are significantly more likely to adhere to healthy behaviors when they perceive autonomy, competence, and relatedness [14]. The multimodal health education component incorporates graphics, videos, interactive quizzes, and gamified elements to accommodate diverse learning preferences, thereby translating complex medical knowledge into easy-to-understand and easy-to-use resources [21,22].

Furthermore, Tpro actively fosters social support networks, a critical component often neglected in traditional care. The integrated clinician-patient communication channel provides a "lifeline" for acute concerns and establishes reliable, timely feedback for chronic issues, offering patients psychological security [23]. The peer support community, moderated by health care professionals, facilitates emotional resonance and the sharing of practical lived experiences, which can enhance disease-related resilience and mitigate feelings of isolation [24].

Methodological Contributions

This study advances digital health development methodology by addressing documented limitations in conventional approaches, particularly the high abandonment rates of health apps due to poor usability [9]. Our iterative convergent mixed methods framework enabled proactive identification and resolution of usability barriers through continuous refinement based on rich, contextualized user understanding. The successful translation of user needs into design features, particularly the gamified symptom reporting and tiered communication system, aligns with evidence supporting behaviorally-informed design in digital health [9,25,26]. Beyond confirming what works, our approach systematically leverages quantitative-qualitative integration to reveal why and how features succeed across diverse users.

Strengths

This study boasts several notable strengths. First, the adoption of an iterative convergent mixed methods design represents a rigorous and transparent methodology for mHealth development. This approach allowed for the simultaneous collection and integration of rich qualitative insights with quantitative usability metrics, enabling us to not only identify what usability issues existed but, more importantly, to understand why they occurred and how to effectively address them. Second, the development process was deeply rooted in a patient-centered philosophy, from the initial qualitative inquiry that defined the core functions to the iterative testing with end users (both patients and clinicians). This ensured that the final Tpro app was not only highly usable but also directly addressed the authentic needs and challenges faced by individuals managing DVT in their daily lives. Finally, the study delivers a fully functional and rigorously refined digital health intervention with demonstrated high usability and acceptance, which is now primed for subsequent efficacy testing, thereby providing a tangible and significant contribution to the field.

XSL•FO
RenderX

Limitations and Challenges

Several limitations should be considered when interpreting the findings of this study. First, the generalizability of the results is constrained by the sample characteristics. All participants, including the 12 patient participants, were recruited from a single, high-resource academic medical center. Although the sample size and setting were appropriate for achieving usability saturation within the iterative convergent design framework, which was the primary aim of this development phase, they may limit the direct transferability of the findings to other contexts, such as community hospitals or populations with differing socioeconomic backgrounds, health literacy, or digital access. Second, individuals without smartphones or with significant visual or cognitive impairments were excluded, meaning accessibility barriers for these vulnerable groups remain unaddressed. Third, this version of Tpro is available only in Chinese, which necessitates thorough cultural and linguistic adaptation for broader global implementation. Fourth, engagement with the peer support community was relatively modest during the testing phase, with only 4 posts generated across the 12 patient participants. This may reflect the limited testing duration, the small user group, or the acute nature of DVT, where patients may prioritize symptom management and education over social interaction in the initial phase of self-management. The community was designed as one component of a multifaceted intervention, and the observed pattern of intermittent, need-based use may represent an appropriate level of engagement for this population. Finally, while this study demonstrates high usability and acceptance, the definitive clinical efficacy of Tpro on outcomes such as symptom burden, quality of life, and DVT recurrence requires validation through a future randomized controlled trial (RCT).

Security Considerations

The integration of foundational data security and privacy protections, including end-to-end encryption, internal server deployment, and role-based access controls, was essential for Tpro as an mHealth tool handling sensitive patient information. These safeguards were designed to protect confidentiality, build user trust, and meet core data protection requirements. For future implementations in other settings, such controls must be adapted to local regulatory frameworks. A focus on privacy-by-design addressed a key barrier to patient adoption and supported sustainable clinical integration of digital health tools.

Implications for Practice and Research

This study presents significant implications for both mHealth development and future research. For developers and health care organizations, the iterative convergent mixed methods approach offers a replicable framework for creating evidence-based digital health solutions that effectively balance technical sophistication with user-centered design principles. The specific design strategies developed through this process, particularly the gamification elements and tiered communication system, provide valuable reference models for other chronic disease management apps. For researchers, this methodology demonstrates how rigorous mixed methods can substantially enhance intervention development quality and impact.

Future research should prioritize a multicenter RCT to establish the clinical efficacy of Tpro. A proposed design for such a trial includes the following key components:

(1) Design and participants: a pragmatic, 2-arm, parallel-group RCT comparing Tpro plus usual care versus usual care alone. We plan to recruit approximately 200‐250 patients with confirmed DVT from multiple clinical sites, stratified by factors such as initial clot location and risk profile.

(2) Intervention: the intervention group will receive access to the Tpro app alongside standard clinical management. Usual care will follow current local guidelines without the app.

(3) Primary outcomes: the primary endpoints will focus on patient-centered outcomes, including symptom burden and health-related quality of life, assessed at 3 and 6 months postenrollment.

(4) Secondary outcomes: key secondary outcomes will include objectively confirmed DVT recurrence rates, health care use, adherence to anticoagulant therapy, and sustained engagement metrics within the app.

(5) Analysis: the primary analysis will follow the intention-to-treat principle. This definitive efficacy trial will be essential to translate the demonstrated usability of Tpro into evidence for clinical and patient-centered benefit. Beyond this RCT, subsequent research directions remain important, integrating artificial intelligence for personalized symptom management; validating the system across diverse health care systems and cultural contexts to enhance generalizability; exploring strategies to foster more active peer interaction within the community module; and conducting longitudinal studies to examine the relationship between sustained engagement and long-term health outcomes.

Conclusions

The iterative convergent mixed methods design enabled the successful development of Tpro, a PRO-based mobile app for DVT symptom management, yielding a highly usable and clinically relevant digital health intervention. Through 4 iterative cycles integrating mixed methods research, we resolved critical usability issues while gaining profound insights into patient engagement patterns. The resulting app provides comprehensive symptom monitoring, education, communication, and peer support within an evidence-based framework, now ready for formal efficacy testing. This study validates a rigorous methodology for developing digital health solutions that effectively balance technical sophistication with human-centered design, offering significant potential to enhance out-of-hospital DVT care while establishing a replicable approach for creating meaningful solutions for patients and clinicians.

Abstract

Background: Epilepsy is a serious chronic neurological condition with no permanent cure. Continual self-management is important to mitigate seizure frequency and optimize quality of life in people with epilepsy who have greater disparities in accessing epilepsy care. The Management Information & Decision Support Epilepsy Tool (MINDSET [UTHealth, University of Arizona, and Radiant Digital]) was developed to enhance accessibility to epilepsy self-management (ESM) assessment and treatment. The purpose of this formative usability pilot study was to assess the user experience and functionality of MINDSET 2.0, an enhanced cross-platform online version of MINDSET, among a sample of patients with epilepsy prior to feasibility testing within neurology clinic settings.

Methods: MINDSET 2.0 comprised an updated cross-platform architecture for easier accessibility and added quality of life, cognitive function, and social determinants assessments. User experience and functionality were assessed in January 2022. Six patients with epilepsy in Texas (n=4) and Arizona (n=2) participated in individual online usability sessions, completing a sociodemographic survey, accessing all components of MINDSET, and then completing usability rating scales and an exit interview. Logical inconsistencies in embedded algorithms were examined for the usability sample and in user case challenges to ensure functional fidelity.

Results: Patients reported low adherence to ESM behaviors in each of the management domains. More than 80% of patients agreed that MINDSET 2.0 was acceptable, easy to use, likable, credible, of appropriate duration, and motivationally appealing. Patients agreed that the program helped them think about and manage their epilepsy more carefully, and that it improved decision-making between them and their health care providers (100%). Patients provided lower ratings (≤50%) and reported the greatest number of difficulties with their understanding of how to select goals and strategies, and develop an action plan due to constraints of item response options leading to user confusion. An inconsistency in algorithm branched logic was identified that related to translating depression scores into recommendations for depression self-management programming.

Conclusions: The results replicated usability findings from earlier versions of MINDSET but also catalyzed adjustments to user survey response options and algorithm repair. The value of the formative user experience functionality assessment was demonstrated to ensure a high-fidelity program prior to feasibility testing in neurology clinic settings.

Introduction

Epilepsy is a neurological condition, defined by repeated seizures of varied onset and type that affects more than 50 million people globally [1]. Approximately 2.9 million adults in the United States have active epilepsy [2,3]. People with epilepsy exhibit seizures that can manifest with temporary loss of awareness or consciousness; disturbed movement; altered vision, hearing, and taste; reduced mental function; anxiety and depression; and lower quality of life [4,5]. Epilepsy self-management (ESM) is important to enhance the self-efficacy of people with epilepsy in managing seizures and to optimize their quality of life [6]. ESM comprises a range of behaviors that include (1) medication management (eg, adherence to prescribed medication and clinical visit regimens), (2) seizure management (eg, preparation for, and response to, seizure episodes), (3) lifestyle management (eg, altering behaviors to avoid seizures and/or adverse consequences of seizures), and shared decision-making between the patient and their health care provider (HCP) [7,8]. ESM is associated with increased management self-efficacy and decision-making by people with epilepsy and their families, fewer breakthrough seizures, lower rates of hospitalization, and decreased risk for injury and premature death [8].

The COVID-19 pandemic disrupted traditional in-person clinic visits due to social distancing requirements and promoted digital solutions for patient treatment, such as telemedicine [9]. Digital decision support can assist HCPs to tailor patient care and increase patient awareness, knowledge, skills, and reach [10]. The Management Information & Decision Support Epilepsy Tool (MINDSET) was developed in 2015 to enhance patients with epilepsy and HCP assessment of ESM and has demonstrated improvement in adherence of patients with epilepsy to ESM [11-14]. An enhanced cross-platform web-based version of MINDSET, MINDSET 2.0, has been developed to enable improved function, phone-based accessibility, and added assessment and feedback on patient quality of life, cognitive difficulties, and social determinants of health [15-17]. User experience testing is a necessary antecedent of successful implementation of digital decision support to ensure it meets the specific needs of the priority population prior to deployment in the field [18]. The purpose of this study was to assess the user experience and functionality of MINDSET 2.0 with a sample of patients with epilepsy prior to deployment for feasibility testing within neurology clinic settings.

Methods

The Intervention

MINDSET is a theoretically and empirically based digital ESM program, originally accessible on desktop or tablet computers in the clinic [11,19]. Patients choose their preferred language (English or Spanish) and input data (“My Epilepsy”) about their epilepsy condition (overall subjective health rating, seizure frequency in the last 30 days, seizure symptoms, antiseizure drug [ASD] prescription, and days of missed doses in the last 2 weeks) and their adherence to ESM behaviors within each of the 3 ESM domains (seizure, medication, and lifestyle management) using the Epilepsy Self-management Survey (ESMS) [20-22]. They complete the Neurological Disorders Depression Inventory in Epilepsy (NDDI-E) to assess depression [23] and the Liverpool Adverse Events Scale to assess ASD side effects [24-26] (Table 1). Patients select up to 3 ESM goals (one each for seizure, medication, and lifestyle management) to improve low adherent ESM behaviors (“My Goals”), choose strategies to accomplish these goals, rate their self-efficacy to achieve their selected goals, and list barriers to meet these goals [20,22]. The goals are designed to increase patient adherence to low adherent behaviors. A tailored goal-based action plan (AP; “My Action Plan”) is dynamically generated and is printed to review and discuss with the HCP during the clinic encounter (Figures 1 and 2). Page 1 of the AP comprises a summary of the patient’s epilepsy history and current condition, assessment of ESM behaviors and depression (Figure 2). Pages 2 to 4 summarize the selected goal, strategies, self-efficacy, and barriers for seizure, medication, and lifestyle management, respectively.

XSL•FO
RenderX

Table . Measures in MINDSET[a] and user experience testing.

	Description
MINDSET measures (original version)	
Behavior	
Epilepsy Self-Management Scale[b]	A 38-item survey with 5-point Likert scale response format assessing frequency of epilepsy self-management practice in 5 management domains: seizure, medication, lifestyle, safety, and information ("I plan ahead so that I do not run out of seizure medication," "I do things I enjoy to help manage stress," etc). Each item is rated from 1 (never) to 5 (always) with negative behaviors reverse scored. Cronbach α: 0.81 - 0.84 [20,27-30].
Neurological Disorders Depression Inventory for Epilepsy	A 6-item survey with 4-point Likert response format assessing frequency of depressive symptoms within the last 2 weeks (range is 1 "never" to 4 "always or often"). Final score is sum of all responses (range 6 - 24). Scores ≥15 indicate depressive symptoms (specificity: 90%, sensitivity: 81%, and positive predictive value of 0.62 for detecting major depressive disorder [23]). Cronbach α: 0.85, test-retest reliability: 0.78 [31,32].
Clinical outcomes	
Seizure frequency	Frequency of seizures experienced in the past 4 weeks. People with epilepsy input a number in an open textbox format.
Adverse Drug Effects Scale[c]	Assesses medication side effects experienced during the previous 4 weeks from a list of 19 adverse effects. The original uses a 4-point Likert scale response set: 1 (never a problem) to 4 (always a problem). Score range: 19 to 76. Cronbach α: 0.90 (baseline) and 0.91 (3-month follow-up) [24-26].
Missed doses item	Assesses how many doses of anti-seizure medications patients missed in the last 2 weeks. People with epilepsy can select any number between 1 and 20 as well as nonnumeric answers which are "more than 20," "don't know," and "Not currently on any seizure medications."
MINDSET 2.0 measures (enhanced version): MINDSET 2.0 contains all the measures from the original version listed above plus the additional measures listed below	
Behavior	
QOLIE-10[d] Survey[e]	Assesses how often epilepsy has affected the patient's health and daily activities in the last 4 weeks. Scale contains 10 epilepsy-specific items from 3 domains: epilepsy effects (memory, physical, and mental effects of medication), mental health (energy, depression, and general quality of life), and role functioning (seizure worry, work, driving, and social limits). Likert responses vary and include: 1 (all of the time) to 6 (none of the time), 1 (a great deal) to 5 (not at all), and 1 (not at all bothersome) to 5 (extremely bothersome). Test-retest reliability and internal consistency are high [33].
QOLIE-31[f] Survey (single item)[g]	A single item that assesses overall perceived quality of life using a rating scale of 0 (worst possible quality of life) to 10 (best possible quality of life). This item is analogous to a general health question that often "front ends" a clinic visit enquiry. A score is calculated by converting the raw numeric values to 0 - 100 point scores. Higher scores reflect better overall quality of life [34].
QOLIE-31 cognitive subscale	This 6-item self-report subscale assesses how often patients experience epilepsy-related cognitive issues in their daily lives. Response selections vary by item and include 1 (all of the time) to 6 (none of the time), 1 (a great deal) to 4 (not at all), and 1 (not at all bothersome) to 5 (extremely bothersome). A score is calculated by converting the raw numeric values to 0 - 100 point scores with higher scores indicating better cognitive health [34].
Health Leads social determinants inventory[h]	An 8-item social determinants inventory screening tool to assess if patients are having difficulties in 8 areas of their daily lives. People with epilepsy respond Yes or No to each of the 8 items [35].
User experience testing measures	

XSL•FO
RenderX

	Description
MINDSET measures (original version)	
Demographic survey	A 26-item demographics survey that collects information about gender, age, race, ethnicity, residency in the United States, education, marital status, income, employment status, health care status, seizure history, quality of life, computer and smartphone access, and language preference [36].
MINDSET Usability Rating Scale[i]	An adapted 36-item rating inventory to assess usability parameters of acceptability, likability, credibility, motivational appeal, the content, duration to complete the program, usefulness, perceived impact on epilepsy, ease of use, and understandability. Seven items were added to cover new content in MINDSET 2.0. This rating inventory assessed specific functions in MINDSET and enabled comparison with results from previous MINDSET studies [12,37].
Feasibility exit interview[j]	A 30-minute structured exit interview conducted after survey data was collected. A trained facilitator asked 6 questions, with additional prompts as needed, to assess the patient's experience and their perceptions of the strengths, weaknesses, utility, and appeal of MINDSET 2.0, and to elicit recommendations for enhancement [12,37].

[a]MINDSET: Management Information & Decision Support Epilepsy Tool.

[b]MINDSET patients are considered adherent if the positive behaviors occur "usually" or "always." Epilepsy self-management behaviors are flagged by the program as nonadherent if patients report "never," "rarely," or "sometimes" for a positive behavior. This is reversed for negative behaviors.

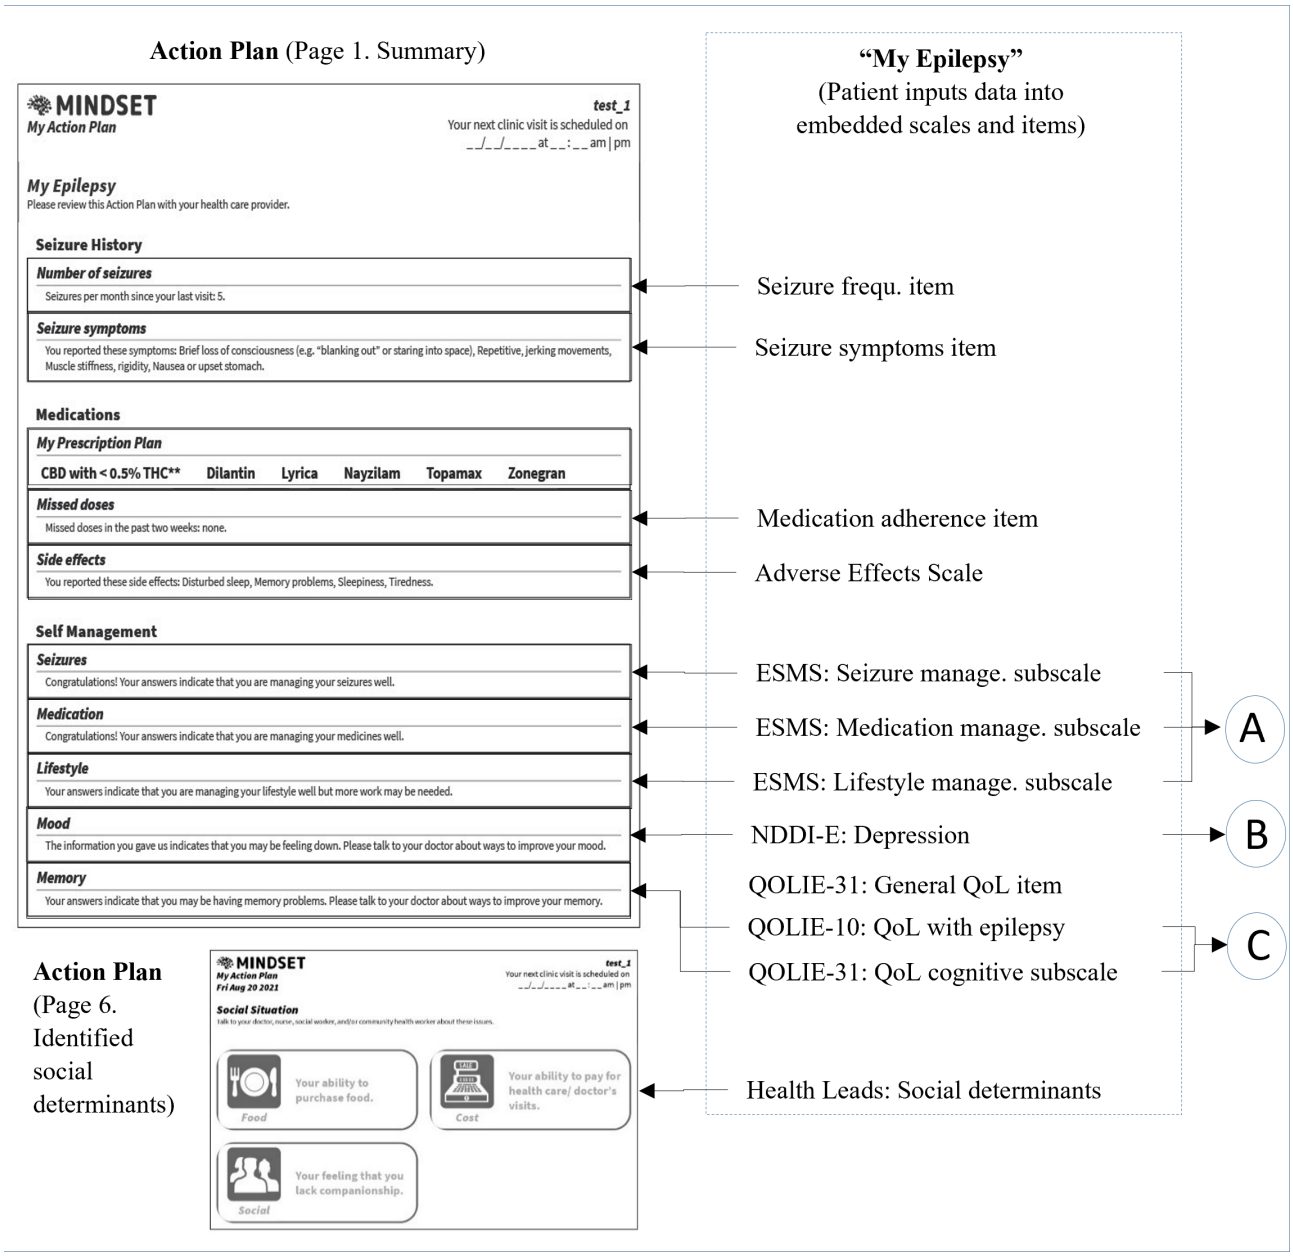
[c]In MINDSET, the response set was adjusted to a check box selection of any side effects and 3 additional adverse effects were included informed by neurologist review. All reported medication side effects are listed on the action plan produced at the end of the program, which helps health care providers identify patients needing treatment adjustments during clinic visits. Adverse drug effects choices: unsteadiness, tiredness, restlessness, aggression, nervousness, hair loss, skin changes or rash, blurred vision, upset stomach, concentration difficulty, mouth and gum problems, shaky hands, weight gain, dizziness, sleepiness, depression, memory problems, and disturbed sleep.

[d]QOLIE-10: Quality of Life in Epilepsy Inventory-10.

[e]Items with opposite response sets are reverse scored so that positive responses are lower numbers and negative responses higher. The total score is calculated by averaging the items answered. Total scores range between 0 and 6, with lower scores indicating better quality of life.

[f]QOLIE-31: Quality of Life in Epilepsy Inventory-31.

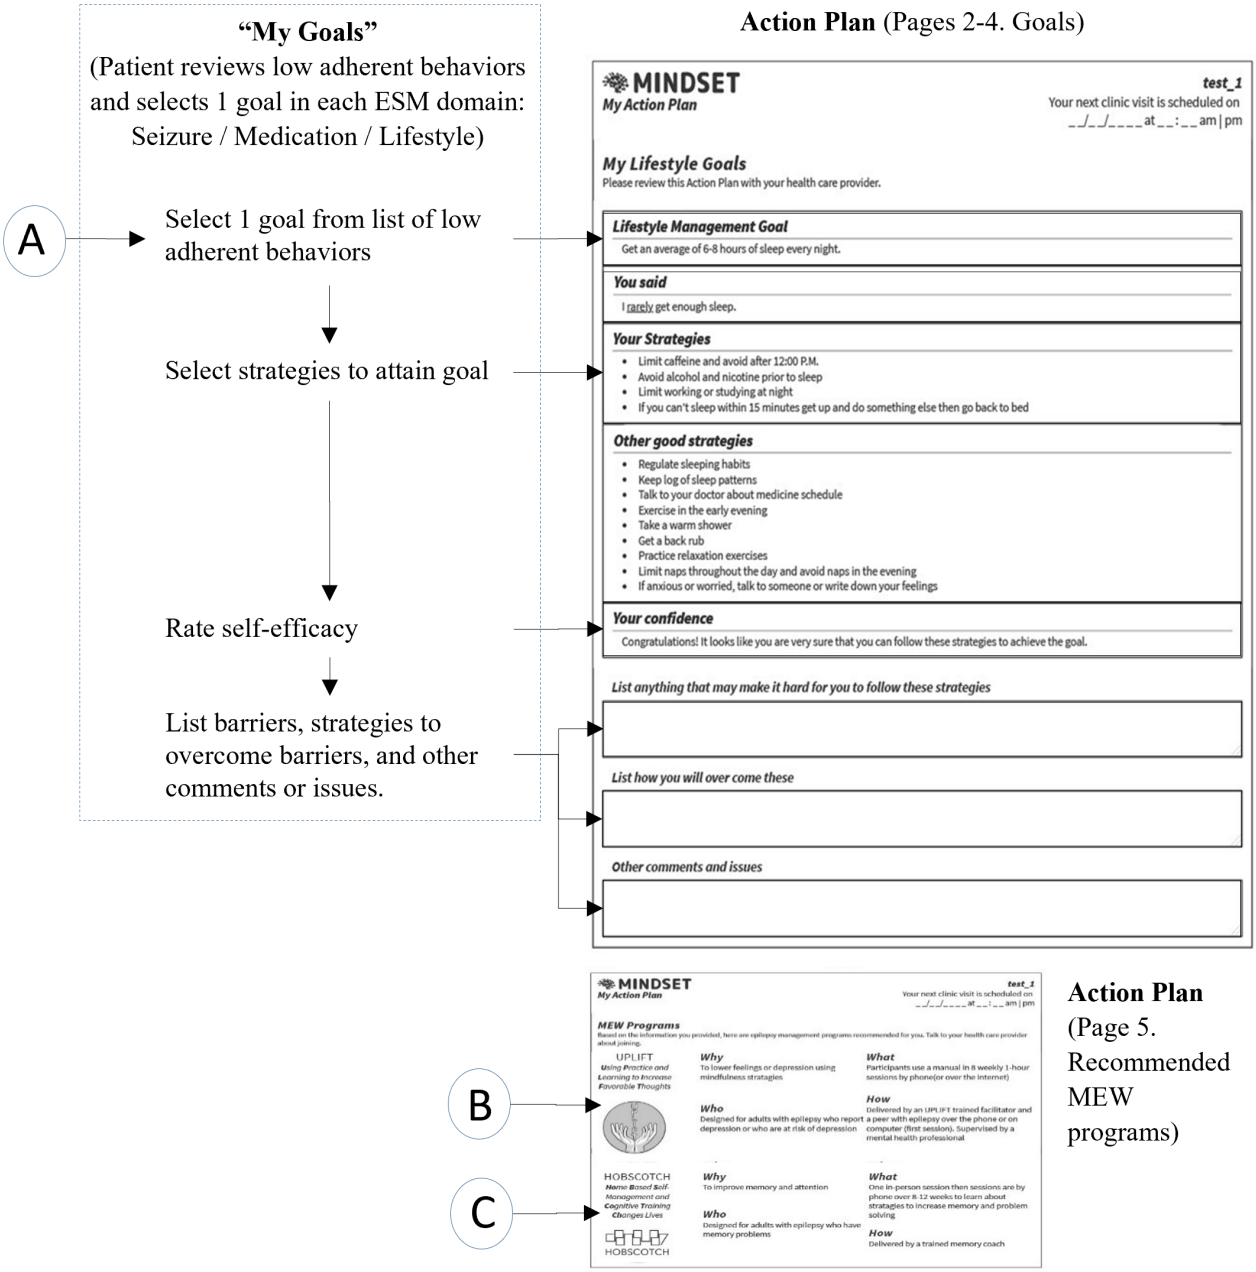
[g]The item is designed for assessing Quality of Life but doesn't itself trigger intervention recommendations. All those who use MINDSET receive a recommendation to Program for Active Consumer Engagement in Self-Management regardless of their answer choices to ensure that everyone has access to more intense intervention should they one day need it.



[h]Health Leader assesses food insecurity, housing instability, financial resource strain, transportation challenges, social isolation, lack of childcare, healthcare illiteracy, and utility needs.

[i]The 36-item inventory provides statements (Table 2) about various aspects of MINDSET 2.0 and the action plan for which the patient provides a rating using binary response options including "yes/no," "helpful/not helpful," "can be trusted/can't be trusted." The patient also rates the structure and design (eg, colors, font size, and screen layout) using a 5-point Likert scale (dislike a lot (1) to like a lot (5)), and ease of use using 4-point Likert scales (not easy (1) to very easy (4)).

[j]Questions included: "Describe your overall experience with MINDSET 2.0; What did you like best or least about MINDSET 2.0 and why?; Was there anything that made you feel upset, embarrassed, or uncomfortable?; How relevant or relatable was the information presented to you?; What would you have liked to see but did not see?; What would you tell other patients about MINDSET 2.0?



XSL•FO
RenderX

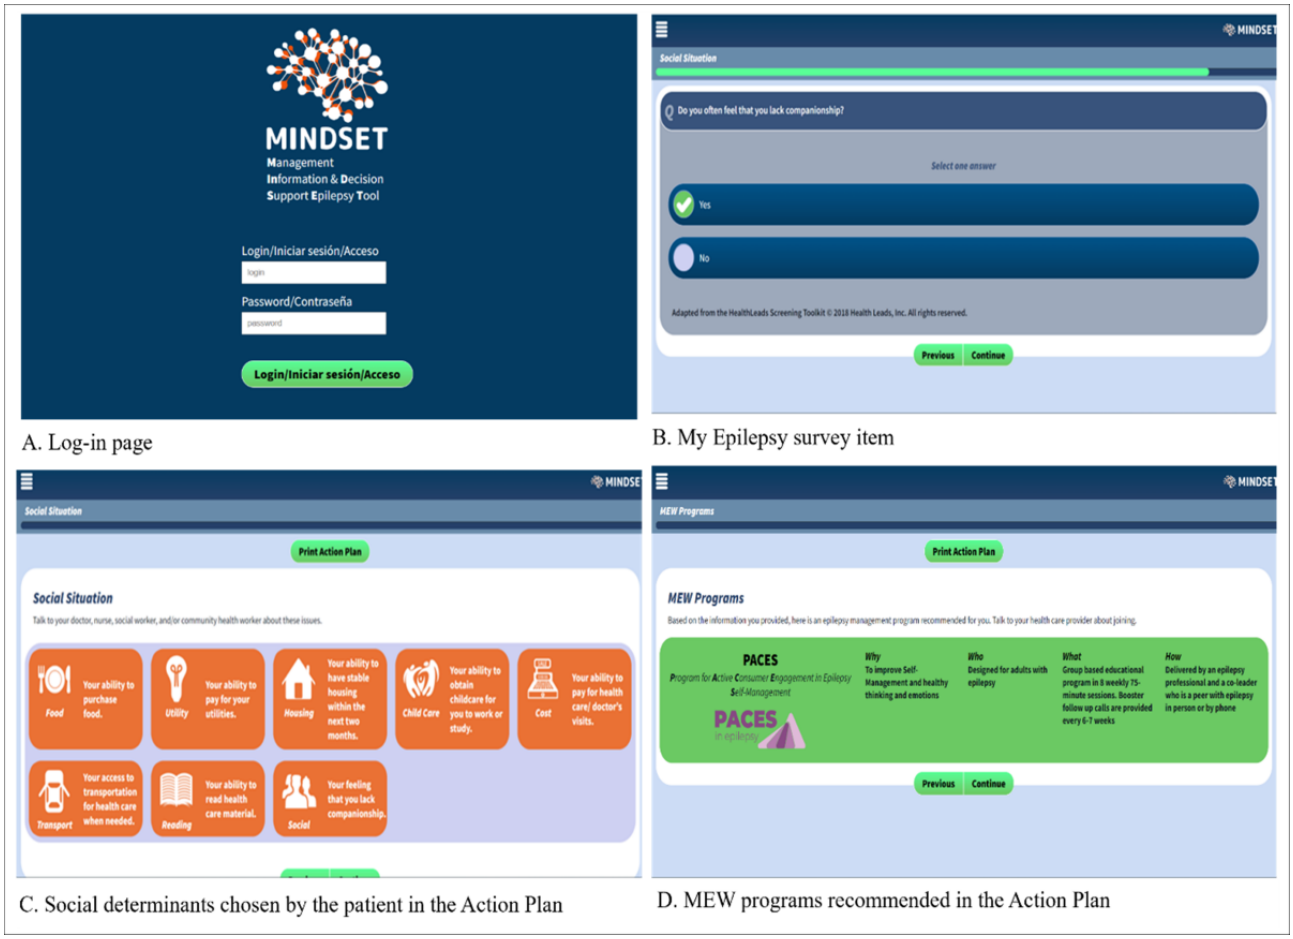

Figure 2. Decision logic for action plan part 2 (pages 2-5). ESM: epilepsy self-management; MEW: Managing Epilepsy Well.

MINDSET has been enhanced to MINDSET 2.0 with added features (Table 1) that include (1) accessibility on any device with an internet connection, (2) assessment of depression using the NDDI-E where a score of ≥15 triggers a summary message in the AP to discuss mood and a recommendation that the patient may benefit from the Using Practice and Learning to Increase Favorable Thoughts (UPLIFT) program designed to train patients with epilepsy to manage comorbid depression [38], and (3) assessment of quality of life using the Quality of Life in Epilepsy Inventory-10 (QOLIE-10) [33] and cognitive (memory) difficulties using the Quality of Life in Epilepsy Inventory-31 (QOLIE-31) cognitive subscale [34]. A QOLIE-31 cognitive subscale score of ≤70 and/or the QOLIE-10 memory item can trigger a recommendation that the patient may benefit from the Home-Based Self-Management and Cognitive Training Changes Lives (HOBSCOTCH) program designed to train patients with epilepsy to manage comorbid memory problems (Figure 2, AP page 5) [39]. Additional features included (4) a default recommendation for the Program for Active Consumer Engagement in Self-Management (PACES) as a foundational ESM training program given its suitability for all patients with epilepsy. UPLIFT, HOBSCOTCH, and PACES are available in English and Spanish. Lastly, MINDSET 2.0 added an (5) assessment of social determinants using the Health Leads social determinant inventory [35] to cue discussion about possible social service needs (Figure 3). The HCP can link the patient to recommended epilepsy programs and connect them with community resources as needed.

XSL•FO

Figure 3. Screen captures of MINDSET 2.0. MEW: Managing Epilepsy Well.

User Experience Testing

In-house alpha testing by the research team was conducted to ensure that the content was accurate and consistent with current clinic practice, that spelling and grammar were error-free, that inputted data corresponded to the backend database, and that the Spanish translation was correct. User experience testing occurred in January 2022. A convenience sample of 7 patients with epilepsy was recruited from the Epilepsy Foundation Central & South Texas (EFCST) clinic in San Antonio, Texas (n=5) and the Banner Clinic in Tucson, Arizona (n=2). Inclusion criteria were that patients be 18 years or older; have a diagnosis of epilepsy; and have access to a computer, phone, or tablet with a working internet connection. MINDSET was designed for patients with epilepsy who are able to self-manage their epilepsy, so neurologists determined exclusion of patients with neurological, medical, motor disorders, or learning problems as well as psychiatric and/or behavioral problems that would excessively inhibit their ability to use MINDSET 2.0, complete surveys, or practice ESM activities.

Clinic staff contacted eligible patients via phone and introduced those who verbally consented to the research team coordinator who arranged a testing session. Sessions were conducted on Zoom (Zoom Communications, Inc), a familiar platform to most participants, due to clinical mandates for COVID-19–related social distancing. In each session, participants completed a consent form, a 26-item sociodemographic survey, accessed all components of MINDSET (eg, the screening tool, patient profile, recommendations, and AP), and then completed an adapted 36-item usability rating scale (Multimedia Appendix 1) and a 30-minute structured exit interview (Table 1). The research team coordinators guided participants through the session and noted any issues in a problem log. The coordinators comprised a doctoral candidate in Behavioral Sciences with 6 years of experience in qualitative research in Texas and an assistant research professor at a state college of public health with an adjunct appointment at a department of neurology in Arizona. A bilingual master's in public health (MPH) student took notes and served as a Spanish translator for patients electing to complete MINDSET 2.0 and study surveys in Spanish. Participants were allowed to complete the study with assistance from caregivers if needed. Participants were compensated for their time with Amazon e-gift cards valued at US $60 at the end of the session. User experience data were assessed with descriptive statistics using Stata 18 (StataCorp LLC) [40]. A priori criteria user agreement of at least 70% was set as a usability benchmark. Features that fell below this were identified for modification. Exit interviews were recorded, and transcripts were assessed and collated to qualify each usability parameter.

Ethical Considerations

The study was approved by the institutional review boards of the University of Texas Health Science Center at Houston (HSC-SPH-19 - 0893) and the University of Arizona (2005674587). Informed consent was obtained from all participants who were given the option to withdraw from the

XSL•FO
RenderX

study at any time. All data collected in the study were deidentified to maintain patient privacy and confidentiality.

Functionality Testing

The functionality assessment comprised (1) noting "bugs" or suboptimal performance in a program log and (2) reviewing algorithm logic fidelity from the user experience testing data, whereby inputted participant data were compared to AP output and assessed against an a priori benchmark for success of 100% correspondence. Staff manually calculated participant scores (eg, NDDI-E depression scores and QOLIE-31 cognitive scores) to predict expected recommendations and compared these to the actual recommendations generated on the AP to test functionality of the algorithms. The assessment also included (3) challenging the MINDSET 2.0 algorithm function with an array of user profile test cases ranging from a "worst case" ESM patient profile to a "best case" and variations between these. A "worst case" patient answered all questions negatively and a "best case" positively. User test cases were assigned unique ESM behavior profiles for seizure, medication, and lifestyle management and varied depression, Quality of Life (QoL), and social determinant indices. Each tester was assigned a predetermined set of responses to ensure that all item answers were inputted at least once. Testers selected the corresponding goal for each assigned at-risk item in the profile to ensure all goals were selected at least once. APs were then reviewed to determine that messages and goals were logically consistent with the data input. Similar to the user experience algorithm review, an a priori benchmark for success was set at 100% correspondence between data input and AP output.

Results

Participant Demographics, Epilepsy, and Self-Management Characteristics

Six participants completed MINDSET. One participant withdrew without completing the AP citing epilepsy cognitive impairment. Participants had a mean age of 37.3 (SD 15) years, were equally male and female (n=3, 50%), Hispanic or Latino (n=6, 100%), with a mean US residency of 23 (SD 13.2) years, mainly with high school (n=3, 50%) or 1 - 3 years of college (n=2, 33.3%) education, single (n=4, 66.7%), with income below US $50K (n=5, 83.3%), and were either health insured (n=3, 50%) or not health insured (n=3, 50%; Table 2). Most reported having access to a smartphone and/or a computer (n=5, ≥83.3%) and preferred English or mainly English for reading, speaking at home, and thinking (n=5, 83.3%).

[a]GED: General Educational Development.

[b]HS: high school.

Participants rated their QoL as mostly "very good" (n=3, 50%; Table 3). Their first ever seizure occurred between ages 2 and 15 years. They had active epilepsy, reporting seizures in the last 12 months (n=6), and in the last 30 days (n=3). They mostly reported 5 to 6 seizures in the last month and 4 seizures since their last clinic visit. They reported adherence to their ASD dosing schedule, on average missing a dose on one day in the last 2 weeks. They reported 3 to 8 side effects. The sample mean NDDI-E score was 12.8 (SD 5.6) with 2 participants scoring ≥15. The mean QOLIE-31 item score was 85 (SD 15.2) and the mean QOLIE-31 cognitive subscale score was 51.6 (SD 33.3), indicating poor QoL. However, the mean QOLIE-10 score was 2.5 (SD 1.02), indicating good QoL in relation to patients' epilepsy. The greatest adherence to ESM was for medicine management behaviors (mean 4.5, SD 0.70), and the lowest adherence was for lifestyle management behaviors (mean 3.9, SD 0.41) and information management behaviors (mean 3.5, SD 0.63; Table 3).

[a]Collected using the demographics survey.

[b]Collected using the data collection portion of the MINDSET program.

[c]ASD: antiseizure drug.

[d]NDDI-E: Neurological Disorders Depression Inventory in Epilepsy.

[e]Responses, Likert scale—never: 1 to always or often: 4; symptoms, maximum score 24, score ≥15 is symptomatic.

[f]Cognitive subscale (items 12, 15, 16, 17, 18, and 26) from QOLIE-31 scale. Combined score of ≥70 is obtained if the memory problem is “little” or “none” of the time.

[g]QoLIE-31 item 1. Higher scores reflect better quality of life; lower ones, worse quality of life. Possible range is 0-100.

XSL•FO
RenderX

[h]QOLIE-10 scale. Total scores range between 0 and 6, with lower scores indicating better quality of life.

[i]Self-management range of mean item scores from a 5-point Likert response set with 1-Never, 2-Rarely, 3-Sometimes, 4-Most of the time, 5-Always

User Experience

Participants took approximately 30 - 60 minutes to complete MINDSET, up to 30 minutes to complete the survey and ratings scale, and up to 30 minutes to complete the exit interview. Participants mostly selected the English language version (n=5, 83.3%). More than 80% of participants agreed that MINDSET 2.0 was acceptable, likable, and motivationally appealing (that they would use it again during future visits and recommend it to others) and indicated it to be "exciting," "colorful," and "relevant" (Table 4). They rated it as credible (n=6, 100%) and of appropriate duration (n=5, 83.3%), and that, in its entirety, it was "easy to use" and "simple" (n=6, 100%), and that the words used were understandable (n=6, 100%), requiring no help to answer survey items (n=5, 83.3%). They commented favorably on its comprehensiveness, stating that it was "thorough" and "in-depth," and appreciated the degree of detail in the tailored AP. They rated it as providing needed (n=5, 83.3%) and helpful (n=6, 100%) information, recommending ESM programs appropriate to their needs (n=5, 83.3%), and that it helped them think about and manage their epilepsy more carefully, and that it would improve decision-making with their HCPs (n=6, 100%). They rated it as more useful than other programs they had used in the clinic (n=5, 83.3%) and described it as an effective and "innovative" evaluation tool that introduced them to new things and assisted them to understand broader lifestyle factors associated with seizure reduction such as sleep, stress, diet, and substance use. Participant recommendations for enhancement of MINDSET content were confined to suggestions that MINDSET "assess family dynamics" due to the reliance of many patients with epilepsy on family members to assist with seizure and medication management, and provide support to mitigate stigma and financial strain [7,13]. Requests were also made that MINDSET 2.0 flag suicidal ideation based on participant experience.

[a]Likert scale: like a lot (1)–dislike a lot (4); Like = “Likes a lot” and “like.”

[b]MEW: Managing Epilepsy Well.

[c]Respondents who have not used another program for comparison (n=5).

[d]Likert scale: very easy–not easy; easy = ”somewhat easy” and “very easy.”

Item Formatting

Patients reported lower agreement with the ease of selecting goals and strategies (n=3, 50%) and understanding and using the AP (n=2, ≤33%). The MINDSET 2.0 AP occasionally provided feedback and goal options that seemed to the participants to be misaligned or incongruous to their daily ESM. Participants expressed some frustration and confusion as to why certain behaviors seemed incorrectly flagged as low adherent. The interviews revealed that many patients had difficulty providing responses to the questions due to a restricted 4-point Likert scale. For example, to the item “I use safety precautions in the kitchen,” a patient in Texas responded “never,” because she is “never in the kitchen.” Given this rationale, the more accurate response would have been “not applicable” rather than a response indicative of nonadherence. A patient in Arizona responded, “all the time” to the statement “I go swimming alone,” their rationale being that they do not need to “hold on to anyone or anything” when going to swim rather than being unaccompanied. Patients’ misinterpretation of the meaning and purpose of the questions suggested problems with understandability at the item level. Despite published findings of empirically sound psychometrics for the ESM survey, this feedback indicated the need to incorporate “not applicable” response options into items to increase response validity. In interviews, most reported difficulties were in the development and understanding of the AP. One participant reported that it seemed “repetitive” and “arduous,” while another expressed difficulty in understanding how to use it, inclusive of selecting goals and strategies, interpreting the output, and AP download.

Patient Profiling and Goal Selection

MINDSET 2.0 exhibited no connectivity or bandwidth lags or data dropout, and back-end data collection was error-free. ESM was positively skewed and highest for medicine, seizure, and safety management subdomains (Table 3). The number of low adherence behaviors per participant ranged from 1 or 2 for seizure management, 2 to 6 for medication management, and 2 to 15 for lifestyle management (Table 5). Most patients (n=4, 66.7%) reported high adherence to medicine management behaviors, which was compatible with the low frequency of missed ASDs. Selected goals were “always keeping enough medicine” to avoid running out and “using a pill container or pill box” for ASDs (Table 5, column 2). All patients were flagged as having at least one low adherent lifestyle behavior. Selected goals focused on stress and relaxation techniques, getting an average of 6 - 8 hours of sleep (n=2), carrying an epilepsy ID, forming social connections, and eating a healthy diet. The goals were unique to each participant apart from “getting enough sleep,” which was selected by 2 patients. For any chosen goal, patients selected between 0 and 7 strategies (Table 5, Column 3). The majority selected one strategy from the list of strategies provided. Two patients listed potential barriers to meeting their goals, both for seizure management, that related to the need to get a primary care doctor or neurologist, and health insurance (Table 5, column 3). No participant self-efficacy ratings were downloaded in the AP. This was traced to an error in coding logic failure that was converting categorical Likert scale scores into binary scores.

Table . Flagged ESM[a] behaviors, participant-selected goals, and strategies[b].

Specific participants	Low adherent (flagged) ESM behaviors[c]	Goal[d]	Strategies[e] and barriers[f]
Seizure management (I Rarely...)[g]		(Always...)	
1	• Call my doctor if I am having more seizures than usual.	Contact your doctor or nurse when you are experiencing increased seizures.	• Other ["Applying for health insurance to have a primary doctor"] • Barrier ["Don't have primary doctor or health insurance"]
2	• Call my doctor if I am having more seizures than usual. • Have blood tests done when the doctor orders them.	Same as above.	• Keep a log of seizures • Barrier ["…to find a neuro that I can work with…"]
6	• Call my doctor if I am having more seizures than usual.	Same as above.	• None ["Memorizando"]
Medication management (I Rarely...)[h]		(Always...)	
2	• Spread out the time between doses when my seizure medication is running out • Plan ahead so that I do not run out of my seizure medicine • Take my seizure medicine at the same time each day • Use a pill container or pill box for my seizure medicines • Have a way to remind myself to take my seizure medicine • Forget to take my seizure medicine[i]	Keep enough medicine.	• Ask for a refill of medicines at least 2 weeks before • If away from home for a period of time, make a plan so that you don't run out of medicine
4	• Plan ahead so that I do not run out of my seizure medicine • Use a pill container or pill box for my seizure medicines	Use a pill container or pill box.	• Use a pill box
Lifestyle management (I Rarely...)		(Always...)	
1	• Have ways to help relax to reduce chances of having a seizure • Eat regular, healthy meals • Keep a record of seizures • Talk to or chat online with other people who have epilepsy • Stay out late at night[i] • Climb on high stools or chairs or ladders[i]	Reduce your stress and practice relaxation techniques.	• Prioritize what is important in your life

XSL•FO
RenderX

Specific participants	Low adherent (flagged) ESM behaviors[c]	Goal[d]	Strategies[e] and barriers[f]
2	• Make sure I get enough sleep • Do things that I enjoy to help manage stress • Eat regular, healthy meals • Keep a record of seizures • Use safety precautions when in the kitchen • Keep track of the side effects of seizure medicine • Check with my doctor before taking other medicines. • Go swimming alone[i] • Climb on high stools or chairs or ladders[i] • Get enough exercise • Avoid driving until seizure free for the minimum amount of time required in my state • Wear a bracelet or necklace, or carry information stating that I have seizures/epilepsy • Tell doctor or nurse when I think I'm having unexpected side effects from seizure meds • Use power tools such as electric saws, electric hedge trimmers, or electric knives without an automatic shutoff[i]	Get an average of 6 - 8 hours of sleep every night.	• Regulate sleeping habits • Keep log of sleep patterns • Exercise in the early evening • Practice relaxation exercises
3	• Do things that I enjoy to help manage stress • Wear a bracelet or necklace, or carry information stating that I have seizures or epilepsy • Carry a cell phone to call someone if I need help • Use safety precautions when in the kitchen • Keep a record of seizures • Keep track of side effects of seizure meds	Always carry an ID stating your epilepsy.	• None selected
4	• Make sure I get enough sleep • Get enough exercise • Wear a bracelet or necklace, or carry information stating that I have seizures or epilepsy • Talk to or chat online with other people who have epilepsy • Stay out late at night[i] • Climb on high stools or chairs or ladders[i]	Get an average of 6 - 8 hours of sleep every night.	• Regulate sleeping habits • Keep log of sleep patterns • Limit working or studying at night • Take a warm shower • Limit naps throughout day and avoid naps in the evening • If anxious or worried, talk to someone or write down feelings • If can't sleep within 15 minutes get up and do something else then go back to bed.
5	• Avoid driving until seizure free for the minimum amount of time required in my state • Talk to or chat online with other people who have epilepsy	Find people to talk to or chat online with who also have epilepsy.	• Join an epilepsy support group (local or community groups or online)
6		Take control of your diet.	• Eat a well-balanced diet

	• Have ways to help relax to reduce chances of having a seizure • Avoid driving until seizure free for the minimum amount of time required in my state • Keep track of side effects of seizure meds • Talk to or chat online with other people who have epilepsy • Get enough exercise • Keep a record of seizures • Keep the water temperature in my home low enough so that it would not burn me if I had a seizure in the shower • Wear a bracelet or necklace, or carry information stating that I have seizures or epilepsy • Do things that I enjoy to help manage stress • Eat regular, healthy meals		

[a]ESM: epilepsy self-management.

[b]Self-efficacy was not collected because the Likert scale response was converted to a binary response. This was repaired subsequent to this study.

[c]Low adherent epilepsy self-management behaviors are defined as having a frequency of "never," "rarely," or "sometimes" on a 5-point Likert scale.

[d]Selected by the participant.

[e]When an "other" category was selected, the patient could provide a written response in the text box provided.

[f]Patients have the option to list barriers that impede their ability to meet goals as well as list strategies used to overcome barriers in an open-ended data entry box if desired.

[g]Participants 3, 4, and 5 had no flagged behaviors.

[h]Participants 1, 3, 5, and 6 had no flagged behaviors.

[i]For negative behaviors, answer selections and scores were reversed.

ESM Program Recommendation Logic

All participants reported having no past use or experience with any of the Managing Epilepsy Well (MEW) Network programs (UPLIFT, HOBSCOTCH, or PACES). In accordance with the MINDSET 2.0 design, all patients were recommended to attend the PACES epilepsy training program, which was the default recommendation. The HOBSCOTCH cognitive skills training program recommendations for patients flagged as having cognitive difficulties (n=5) were also consistent with the MINDSET logic model (Table 6). However, correspondence between predicted and actual recommendations for the UPLIFT program was less than 100% for 2 participants (Table 6, participants #3 and #6). These 2 participants were flagged as having depressive symptoms (NDDI-E score >15) but were not recommended by MINDSET 2.0 to attend the UPLIFT depression program despite no prior history with this program. This represented a failure of the algorithm to translate NDDI-E depression scores into a recommendation to remediate for depression and was traced to incorrect algorithm decision logic.

XSL•FO
RenderX

[a]ESM: epilepsy self-management.

[b]Correspondence of predicted to actual recommendations. The benchmark is 100%.

[c]Represents a specific patient with epilepsy participant.

[d]ESM domains (S=Seizure; M=Medicine; L=Lifestyle). A domain is flagged with a checkmark if a behavior within that domain has low adherence. Goal options are generated for each low adherent behavior for the patient to select during the action plan development

[e]Depression is indicated on the action plan if a patient obtains a summed score of 15 or more on the Neurological Disorders Depression Inventory in Epilepsy scale.

[f]Cognitive issues are indicated on the action plan if a patient obtains a score of 70% or lower on the Quality of Life in Epilepsy Inventory-31 cognitive subscale OR answers 3, 4, or 5 (extremely bothersome) on the Quality of Life in Epilepsy Inventory-10 item about memory OR both.

[g]Past exposure to Managing Epilepsy Well Network programs (P=PACES; U=UPLIFT; H=HOBSCOTCH) is a criterion contributing to determine if a patient receives a recommendation to one or more of these programs. Patients self-report any past exposure as Yes (Y), No (N), or Don't Know (DK) for each of the 3 Managing Epilepsy Well programs.

[h]MEW: Managing Epilepsy Well.

[i]Predicted (pred.) and actual (AP) recommendations for Managing Epilepsy Well Network programs are shown (✓=recommended; - =not recommended).

[j]NDDI-E: Neurological Disorders Depression Inventory in Epilepsy.

[k]QOLIE-31: Quality of Life in Epilepsy Inventory-31.

[l]QOLIE-10: Quality of Life in Epilepsy Inventory-10.

[m]PACES: Program for Active Consumer Engagement in Self-Management

[n]UPLIFT: Using Practice and Learning to Increase Favorable Thoughts.

[o]HOBSCOTCH: Home-Based Self-Management and Cognitive Training Changes Lives.

[p]AP: action plan.

[q]Participants #3 and #6 had noncorresponding results where depression scores should have caused a recommendation for UPLIFT in the action plan.

Social Determinant Feedback

Four patients reported at least one social determinant that may have hindered their epilepsy management, mainly food insecurity (n=3) and financial resource strain (n=3). Other listed determinants were housing instability (n=2), low health literacy (n=2), transportation challenges (n=1), utility needs (n=1), and social isolation (n=1).

Discussion

Principal Findings

The purpose of this study was to assess the usability of MINDSET 2.0 prior to deployment for feasibility testing in neurology clinics that serve patients with epilepsy. The 6 testers, who were people with a doctor's diagnosis of epilepsy, were

XSL•FO
RenderX

experienced in epilepsy management and forthcoming about recommending improvements to MINDSET 2.0 to enhance its comprehensiveness and relevance. Consistent with the health disparities often cited for patients with epilepsy at the national level, the participants reported limited insurance coverage, education, and employment, and the most reported social determinants were food insecurity and financial strain that can impede their ability to manage their epilepsy. The usability findings were largely consistent with previous studies of MINDSET in that the patients agreed that MINDSET 2.0 was acceptable, likable, credible, easy to use, and useful for decision-making and ESM, meeting a priori criteria of 70% agreement [12,37]. Patients reported less overall adherence to, and competency in, information management (monitoring and recording seizures and symptoms, and communicating about epilepsy) and lifestyle management (eg, ensuring adequate exercise, sleep, and strategies to relieve stress) compared to other more medically oriented ESM behaviors of managing medication, safety, and seizures. This was consistent with prior studies on ESM among patients with epilepsy [12,37].

MINDSET 2.0 has added features to screen for comorbidities of depression symptoms and subjective cognitive difficulties and to recommend training programs of UPLIFT and/or HOBSCOTCH, respectively. Patients with epilepsy have a greater prevalence of psychiatric comorbidities than the general population and are at greater risk of being undertreated for depression, which is consistently demonstrated to be inversely associated with successful ESM [41,42]. Consistent with previous studies, more than 33% (n=2) of MINDSET participants reported symptoms of depression. A question item regarding suicidal ideation is also embedded in the NDDI-E survey. Adding an alert in the AP specific to suicidality was suggested that will further highlight this issue. Specific reference to this item has since been included in the neurologist MINDSET 2.0 training.

People with epilepsy have an increased risk for impaired memory, executive function, attention, and social skills in comparison to people without epilepsy [43,44]. Cognitive function can be further compromised by early onset of epilepsy, frequent recurrent seizures, and polytherapy [43]. Low QOLIE-31 cognitive subscale scores (≤70%) were consistent with the prevalence of cognitive impairment of 60% and 70% for patients with epilepsy in general [43,45]. Patients with epilepsy often have cognitive impairments that can compromise their use of MINDSET 2.0. The positive ratings for many usability parameters are encouraging and consistent with previous studies of ESM interventions that report outcomes of increased awareness, feelings of autonomy, ESM adherence, and a sense of hope [13,17] and significant improvement in cognitive health and depression. Previous studies have also reported that between 30% and 50% of patients with epilepsy will underestimate or overestimate their cognitive performance, so objective assessments, in conjunction with caregiver reports as well as mood and anxiety measures, are required to establish truly comprehensive and accurate cognitive assessments [46,47]. MINDSET assists HCPs in identifying and referring those patients who require further objective neuropsychological assessment but does not provide a direct referral pathway for neuropsychological testing nor does it replace neuropsychological testing.

The words used in MINDSET were understandable, suggesting an acceptable reading level. Participants appreciated the program's comprehensiveness while also indicating it was of appropriate duration, appraisals that are typically inversely associated. However, participants had difficulty when responding to and interpreting items that they perceived as incongruous to their experience. The "forced" selection resulted in inaccurate responses. The addition of a "not applicable" response option to previously published survey items and associated adjustment of the decision algorithm logic will help to increase response validity and increase the salience of AP recommendations. While not a majority opinion, the difficulties in AP development reinforced the advantage of involving caregivers in using MINDSET and generating the AP, and of ensuring HCPs reinforce it as well as instruct on its use.

Strengths and Limitations

A large sample size for usability testing is not necessarily required since statistical significance is not a determining factor to establish usability problems, but a limited sample does reduce generalizability to the broader epilepsy population [48]. MINDSET 2.0 offers the potential for increased accessibility and reach. Paradoxically, there is a "digital divide" that may naturally limit reach to some patients. The study's requirement of access to internet-accessible devices introduces a selection bias toward higher socioeconomic status and greater digital literacy. Further, the system supports Spanish, but testing in Spanish was limited (n=1), and thus, no conclusions about user experiences with the Spanish translation can be drawn, but additional testing of the Spanish version is indicated. Patients with more severe forms of epilepsy that impair their ability to use MINDSET were also excluded from this study, further limiting generalizability to the broader population of people with epilepsy. Therefore, future testing of MINDSET among more representative clinical groups is needed.

MINDSET elicits self-reported responses from patients with epilepsy and is therefore subject to associated recall bias. Consistent with their long-term experience with epilepsy, participants were adherent to prescribed ASD dosing and medication management behaviors. However, self-reported medication adherence has low sensitivity for unintentional nonadherence because people with epilepsy tend to overestimate their self-reported medication adherence [49,50] and unintentionally fail to notice suboptimal ASD adherence [51].

MINDSET 2.0 was developed to be used independently, and patients indicated that they could complete it unaided, but the study supported the benefits of enabling assistance from caregivers and/or clinic staff, especially accounting for patients who have comorbid cognitive challenges. Caregiver and family support is an important associated factor, so content addressing this was suggested for inclusion since the concept of "familias" is particularly salient to the Hispanic culture [7]. Inclusion of caregivers, as well as clinic staff, can improve the validity of data collection, goal selection, and AP management. Studies on the application of MINDSET 2.0 in conjunction with caregivers and community health workers are planned.

RenderX

Conclusion

This study indicates that MINDSET 2.0 may be a useful program for addressing low adherent ESM behaviors, providing tailored management intervention based on patient-mediated goals and strategy selection, screening for depression and memory function, identification of salient social determinants, and cuing linkage of patients to local resources designed to alleviate social needs and to evidence-based ESM epilepsy programs. Findings from this formative usability study replicated those from earlier versions of MINDSET but also highlighted the need for flexible protocols to enable caregiver support and lead to the initiation of enhancements to mitigate inaccurate algorithm decision logic and item response formatting prior to feasibility testing in neurology clinics [12,37].

Acknowledgments

We thank all participants who volunteered their time to complete the study as well as the neurologists and staff members at the Epilepsy Foundation Central and South Texas and University of Arizona Banner Neurology Clinics who helped identify and recruit patients. Generative AI tools were not used at any stage in the preparation of this manuscript.

Funding

This research was funded by a CDC Special Interest Project Grant (SIP 19-003, grant number 6U48DP006413-01-01). In addition, the publication was supported with funding from the University of Texas Health Science Center-Houston (UTHealth Houston).

Data Availability

The datasets generated and analyzed during this study are available on reasonable request. Please contact author RS.

Authors' Contributions

RS, RSEP, RA, and DML conceptualized the study and measurement. KM, RSEP, and KC led participant recruitment. KC, RSEP, and AG-Q facilitated the usability sessions. Data transcription and analyses was conducted by KC toward doctoral dissertation research. KC and RS prepared the manuscript draft, and all authors contributed to critical review and revision to develop the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Removal platforms for nonconsensual intimate images (NCIIs) are essential, as they have become the recourse for victims of such abuse; yet their interfaces are not designed around the cognitive and emotional realities of trauma. Safety by Design directs platforms to protect vulnerable users but not how; trauma-informed care defines what that protection requires, while usability heuristics keep interfaces usable but are not themselves trauma-sensitive. However, no framework integrates them into design guidance that is both usable and protective for NCII removal platforms.

Objective: This study develops trauma-informed design, a cohesive framework that integrates trauma-informed care with established usability heuristics under Safety by Design, so that NCII removal platforms protect trauma-affected users while remaining realistically usable; a preliminary, domain-informed evaluation provides initial supporting evidence.

Methods: We used a 2-phase sequential exploratory design, drawing on a globally accessible NCII removal platform as an illustrative case. Phase 1 developed trauma-differentiated personas and mapped each persona's user journey to surface pain points that varied by level of trauma. Phase 2 analyzed a focus group of 8 female Counseling-UX (User Experience) Psychology students who had completed coursework in user psychological safety with consensual qualitative research methodology. Participants assessed the plausibility of the personas and the proposed framework with respect to perceived emotional safety and perceived usability.

Results: Mapping each persona's journey surfaced pain points that differed by level of trauma, which were synthesized into a 6-guideline trauma-informed design framework: emotional scaffolding, process transparency, self-pacing mechanisms, institutional trust signals, context-aware support, and grounding tools. In phase 2, domain-informed evaluators judged the personas plausible, and the framework directions emotionally safer, and potentially more usable.

Conclusions: Integrating trauma principles into user experience evaluation can help identify and address psychological barriers in NCII removal platforms. The framework provides the preliminary, domain-informed foundation that trauma-sensitive design of such platforms requires. Because the framework was not tested with NCII victim-survivors or users actively seeking image-removal support, findings represent preliminary plausibility and acceptability evidence rather than ecological validation or real-world effectiveness.

Introduction

Background

Nonconsensual intimate image (NCII) removal platforms are an essential recourse for victims of NCII abuse. Yet despite real advances in content hashing and proactive detection [1], most removal workflows were built around takedown logistics rather than the psychological realities of trauma, leaving help-seeking more burdensome and distressing than it needs to be [2,3]. Because users must navigate these interfaces while in acute distress, the burden falls on the very people the system aims to protect, thereby contravening Safety by Design's principle that safety should never rest solely on the user [4]. These concerns can deter victim-survivors from seeking help altogether [5]. The problem is therefore not merely technical or regulatory but clinical: it requires understanding how trauma reshapes the cognitive and emotional capacities that digital interaction demands.

Empirical accounts of how victim-survivors experience reporting and removal systems reinforce this concern. Studies of technology-facilitated abuse document that survivors frequently

XSL•FO
RenderX

encounter fragmented, effortful, and opaque help-seeking pathways, and that maintaining safety online imposes a substantial and sustained burden [3]. Research on image-based sexual abuse describes the compounding distress victim-survivors face when navigating institutional and platform responses that are difficult to access, slow, or inadequately explained [6]. Controlled comparison of NCII reporting interfaces across 45 platforms shows that the interaction style of the report itself produces measurable trade-offs in clarity, efficiency, and elicited distress [7]. Survivor-centered work developing digital tools for gender-based violence has further shown that survivor-facing systems often fail not because the underlying technology is inadequate but because they are not designed around victim-survivors' psychological and contextual realities [2]. Taken together, this evidence indicates that the limitations of current NCII removal platforms are experienced by users at the point of help-seeking and justify a design approach grounded explicitly in trauma psychology.

Safety by Design [4], trauma-informed care (TIC) [8], and usability heuristics [9] each address part of what NCII removal platforms require, but none integrates the others into interaction-level guidance, a gap this work addresses. Recent NCII-specific scholarship has mapped how harms arise across sociotechnical layers and where interventions might sit [10], yet no existing work integrates clinical trauma theory, usability evaluation, and platform-level safety engineering into an actionable implementation framework for NCII removal platforms.

The insufficiency of any single tradition is clearest at the points where NCII removal platforms can fall short for the users they aim to serve: the gaps tend to surface at the interaction level, when a victim-survivor must initiate and sustain a multistep reporting process while managing acute distress. Removal workflows implicitly assume a trauma-free user who can tolerate ambiguity, accept opaque data handling, and execute irreversible actions under stress. In contrast, the population served is better characterized by reduced perceived control, dissociative disengagement when retriggered, and fragile reengagement after interruption [11,12]. Such states may manifest in predictable ways: dissociation may interrupt a multistep process, hyperarousal may prompt premature abandonment, shame may inhibit the disclosure some steps require, and learned helplessness may impede reengagement after a process breaks [12]. These patterns are consistent with the clinical conditions that characterize this population, grounded in the neurobiology of interpersonal trauma [13]: the interface tends to assume a user who can negotiate such moments, whereas the trauma-affected user's more likely response may be to withdraw.

To address this gap, we develop and preliminarily evaluate a trauma-informed design (TID) framework for NCII removal platforms through a 2-phase sequential exploratory design. The aim is not to evaluate any single service but to provide a detailed framework, grounded in Safety by Design, for supporting victim-survivors of NCII abuse across removal platforms. The term "trauma-informed design" is not new: related approaches have been advanced for digital systems, including trauma-informed computing [1] and TID heuristics for a social service website [14], building on TIC [8]. Our contribution is not the term but its operationalization, which provides concrete, evaluable design guidance for NCII removal platforms, grounded in Safety by Design. Specifically, we apply trauma-differentiated personas to a representative NCII removal platform to identify barriers invisible to any single framework and subsequently assess candidate design responses with domain-informed student evaluators. By integrating clinical trauma knowledge into user experience (UX) evaluation, this study addresses design barriers shaped by trauma-altered cognition, affect, and behavior among NCII removal platform users. The contributions are 3-fold: (1) a diagnostic methodology bridging TIC, Safety by Design, and usability evaluation to identify psychological design gaps invisible to any one approach; (2) 6 preliminary TID guidelines; and (3) preliminary evidence that domain-informed student evaluators perceived the personas and several design responses as plausible, emotionally safer, and potentially more usable.

Research Questions

The research questions (RQs) are as follows:

- RQ1. When trauma-differentiated personas are applied to the user journey, what trauma-related barriers emerge that conventional usability heuristics alone may not fully capture?
- RQ2. Under Safety by Design, how can TIC and usability heuristics principles be integrated into design guidance that addresses these barriers?
- RQ3. How do domain-informed evaluators judge the plausibility of the trauma-differentiated personas and the resulting design directions with respect to perceived emotional safety and perceived usability?

Methods

Conceptual Framework

Three established traditions each address part of this problem at a different level, and the present framework integrates them. Safety by Design sets the overarching mandate: platforms, not users, must bear the burden of protection (the why); TIC supplies the clinical content of that protection (the what); and usability heuristics govern how the interaction is delivered (the how). We take each in turn and then identify the gap that remains.

Safety by Design

Safety by Design embeds user safety into digital products from conception rather than retrofitting protections after harm [4,15]. Australia's eSafety Commissioner established the framework around 3 overarching principles: Service Provider Responsibility (safety burdens never fall solely on users), User Empowerment (protective defaults with meaningful user controls), and Transparency and Accountability (published enforcement data and accessible policies). The Trust and Safety Professional Association [16] operationalizes these through implementation guidance including proactive risk assessment, friction features (interstitials, pause points, and content warnings), and holistic safety across the full product life cycle.

XSL•FO
RenderX

TIC: Clinical Foundations

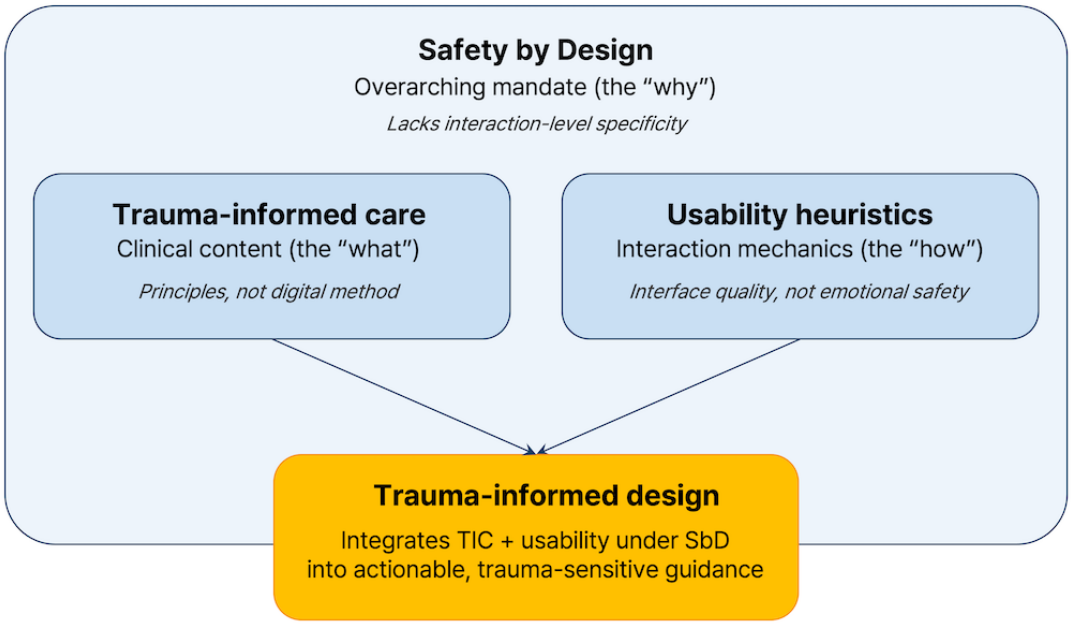
TIC originated in behavioral health as an organizational framework that reframes the service encounter from "What is wrong with you?" to "What happened to you?" [8,15]. Following the Substance Abuse and Mental Health Services Administration framework [8], trauma-informed practice is organized around 6 principles: Safety; Trustworthiness and Transparency; Peer Support; Collaboration and Mutuality; Empowerment, Voice, and Choice; and Cultural, Historical, and Gender Issues. These principles, rather than recovery-oriented treatment, anchor and are operationalized by the present framework. The epidemiological basis is substantial: approximately 90% of US adults have experienced at least 1 traumatic event [17], and World Health Organization data indicate 70.4% lifetime trauma exposure across 24 countries [18]. Adverse childhood experiences alone generate an estimated US $581 billion in annual costs across Europe and North America [19].

For digital platforms serving NCII victim-survivors, the assumption of a nontraumatized user is empirically untenable [1]. This is where TIC's clinical specificity becomes essential for design: trauma does not merely cause distress; it structurally alters the cognitive and emotional architecture that digital interaction presupposes. Posttraumatic stress disorder (PTSD) disrupts executive functions including planning, sustained attention, and working memory [11], precisely the capacities that complex multistep digital workflows demand. Trauma erodes institutional trust [12], making conventional credibility signals insufficient. It produces hypervigilance toward perceived threats, meaning that ambiguous interface elements are processed as dangerous rather than neutral. These are not usability problems in the conventional sense; they are clinical phenomena requiring clinical understanding. TIC's Physical Environment domain provides the conceptual bridge: if physical environments must embody TIC through architecture and spatial design, digital environments must do the same through visual design, information architecture, and interaction flows.

A consistent principle across the sexual violence recovery literature is that disempowerment and loss of control are central to the injury, and that restoring a victim-survivor's sense of control and agency is therefore central to recovery [12,20-22]. This reframes perceived control as more than a clinical outcome: it is a design-relevant construct. Interactions that compel a survivor to surrender control (eg, opaque eligibility decisions, irreversible actions, and unexplained delays) risk reenacting the disempowerment of the original harm, whereas interfaces that return choice, pacing, and transparency can reinforce the recovery process itself. TID accordingly treats the restoration of control and agency as the through line linking clinical trauma care to interaction design, and the design guidelines developed here can be read as its concrete instantiations.

The convergence with TIC is significant: Service Provider Responsibility, User Empowerment, and Transparency parallel TIC's institutional accountability, its Empowerment, Voice, and Choice principle, and Trustworthiness. The 2 operate at different levels; however, Safety by Design governs how platforms and policies are structured, whereas TIC governs how interactions feel and what they presuppose about the user's psychological state. NCII removal platform design therefore requires both structural safety and psychological specificity.

Usability Heuristics: Convergence With and Limits Beyond TIC



Usability heuristics map onto TIC with notable directness [9]: system status visibility corresponds to Trustworthiness, user control to Empowerment, consistency to Safety through predictability, and recognition over recall to Safety through cognitive load reduction [14]. This convergence suggests that good usability and TID share common ground: both prioritize clarity, control, and predictability. However, the convergence has critical limits. Heuristics assess whether interfaces are learnable and efficient for a general user population. They cannot assess whether an interface is emotionally safe, whether it accommodates the specific cognitive deficits produced by PTSD, or whether it replicates relational dynamics of powerlessness (eg, forced workflows without exit, absence of opt-out mechanisms, and institutional opacity that mirrors abuser control) [23]. For NCII removal platforms where users may be in acute crisis, cognitive load reduction is not an enhancement but a prerequisite. This gap between what heuristics detect and what trauma-informed evaluation requires defines the conceptual space TID occupies.

The Remaining Gap

Trauma-informed computing maps trauma principles onto design but warns that design research can resemble psychotherapy without safeguards [1]; like a subsequent scoping review [5], it remains at the principle-mapping stage. Design-justice work further shows that safety cannot be imposed through expert assumption alone but must be grounded in victim-survivors' lived realities [2]. The gap is thus 3-fold: TIC supplies principles without a digital methodology, usability heuristics supply evaluation tools without emotional safety assessment, and Safety by Design supplies structural mandates without psychological specificity. To date, no existing work integrates all 3 into an operationalized framework for NCII removal platforms. Figure 1 illustrates the 3 traditions, their limits, and how TID bridges them.

Research Design

This study used a 2-phase sequential exploratory design [24]. Phase 1 (Design and Diagnosis) constructed trauma-differentiated personas and applied them via User Journey Mapping to identify TIC and Safety by Design misalignments in an existing NCII removal platform. Phase 2 (Domain-Informed Evaluation) evaluated persona plausibility, perceived emotional safety, and perceived usability of TID-informed design response materials through consensual qualitative research (CQR) [25]. The study was conducted at Hankuk University of Foreign Studies in Seoul, South Korea, from March to August 2025, as a preliminary framework development and plausibility evaluation study. Figure 2 illustrates the overall design.

Figure 2. Research design overview. CQR: consensual qualitative research; NCII: nonconsensual intimate image; SbD: Safety by Design; TID: trauma-informed design; UX: user experience.

A globally accessible NCII removal platform was selected as the case based on its content-hashing technology, international user base, and public accessibility [26]. Platform-identifying details are anonymized to protect ongoing operations.

Persona Methodology and User Journey Mapping

The persona methodology [27] creates fictional yet research-grounded user profiles to anchor design decisions in human needs rather than abstract specifications. Personas range along a continuum from assumption-based to data-driven [28]. Our personas were constructed from an evidence synthesis of published findings on NCII victimization, trauma psychology, and adolescent digital risk, rather than from direct survivor interviews, reflecting a deliberate ethical decision to avoid premature survivor involvement in an early-stage framework study [1,29]. Acknowledging the stereotyping risks inherent in personas constructed without direct user participation [28,30], we used 2 mitigations: grounding every persona characteristic in published empirical findings and subjecting personas to preliminary plausibility assessment through CQR with domain-informed student evaluators.

User journey mapping [31] visualizes emotional, cognitive, and behavioral arcs across interaction touchpoints. We adapted it from a generative design tool into a diagnostic instrument: rather than designing new interactions, we used trauma-differentiated personas to surface where existing interactions violate TIC, Safety by Design, and usability principles. This constitutes a specialized trauma-informed variant of the product risk assessments recommended in Safety by Design practice [16], enriched by clinical understanding of how trauma shapes each journey stage.

Phase 1: Persona Construction and Journey Mapping

The personas were developed by the authors through an iterative, evidence-grounded process. Candidate user vulnerabilities, help-seeking contexts, and platform interaction risks were generated and checked against evidence on NCII victimization [1,6], adolescent digital risk [32,33], and intimate partner violence [3,23]. Dimensions that recurred across these sources (trauma severity, perceived control, institutional trust, developmental status, help-seeking autonomy, and capacity to sustain a multistep digital task) differentiated the personas; perceived control was treated as central because it predicts help-seeking engagement and tolerance for uncertainty [34]. The personas were reviewed against Herman's [12] trauma continuum to ensure clinically meaningful rather than merely demographic differentiation, yielding 3 profiles presented in the Results section (Table 1): Sara (low-moderate trauma), Rina (severe trauma with complex PTSD indicators), and Minji (adolescent acute distress with developmental vulnerability).

Table . Trauma-differentiated personas.

Dimension	Sara	Rina	Minji
Age (sex)	28 years (female)	32 years (female)	16 years (female)
Context	Ex-partner shared images post-breakup	Abusive partner distributed images during prolonged IPV[a]	Peer coercion; fear of image leak
Trauma level	Low-moderate	Severe (complex PTSD[b] indicators)	Acute distress and developmental vulnerability
Key drivers	Distrust; desire for clarity	Shame, hypervigilance, and learned helplessness	Fear, confusion, and isolation
Primary goal	Remove images via transparent process	Regain control; requires emotional safety	Understand eligibility; age-appropriate support
TIC[c] principles	Trustworthiness and empowerment	Safety, empowerment, and collaboration	Trustworthiness, safety, and empowerment
Safety by Design	Transparency and provider responsibility	User empowerment and friction features	Provider responsibility and age-specific risk

[a]IPV: intimate partner violence.

[b]PTSD: posttraumatic stress disorder.

[c]TIC: trauma-informed care.

Each persona was applied to 5 interaction stages (Awareness, Consideration, Decision, Action, and Postaction) [31], using a structured matrix documenting anticipated needs, actions, barriers, proposed design responses, and the TIC, Safety by Design, and usability principles implicated. At each stage, the authors recorded both what a standard usability evaluation (Nielsen's heuristics) would flag and what clinical trauma knowledge (TIC and Safety by Design) would flag, surfacing features that can pass conventional heuristic evaluation while failing trauma-informed evaluation. The authors completed the matrix independently and reconciled differences through structured discussion; claims that could not be reconciled were narrowed or excluded. The resulting journey maps appear in the Results section (Table 2).

XSL•FO
RenderX

Table . Trauma-differentiated user journey maps.

Persona and stage	Needs	Action	Current barrier	TID[a]-informed response	TIC[b]	Safety by design
Sara (low-moderate)						
Awareness	Find credible platform	Searches removal	Difficult to locate via search	Visible entry points; onboarding	Trustworthiness	Transparency
Consideration	Understand function	Reads home page cautiously	Governance and data handling unclear	Plain-language data explanations	Trustworthiness	Transparency
Decision	Reassurance; error protection	Attempts case creation	No preview; fears irreversibility	Gentle prompts; preview before submission	Empowerment	Safety
Action	Privacy reassurance	Uploads content hash	Upload triggers shame; no support	Calming messages; grounding tools	Safety	Protective defaults
Postaction	Affirmation; status visibility	Waits for confirmation	Insufficient status visibility	Affirming follow-up; status tracking	Trustworthiness	Accountability
Rina (severe)						
Awareness	Welcoming language	Hesitant search; delays	No welcoming or survivor voice	Affirming, survivor-centered entry	Safety, empowerment	Proactive
Consideration	Non-triggering content	Briefly visits platform	Elements not validated as safe	Validated non-triggering UI[c]	Safety	Protective defaults
Decision	Control; ability to pause	Attempts case but leaves	Rigid; no save; no support	Grounding techniques; save draft	Empowerment	Friction features
Action	Pause without losing progress	Reattempts upload	No support; solitary completion	Pacing indicators; helplines	Safety, collaboration	Empowerment
Postaction	Long-term support pathways	Seeks external support	No pathways to long-term support	Connect to NGOs[d], peer networks	Collaboration	Holistic
Minji (adolescent)						
Awareness	Age-appropriate guidance	Searches due to fear	Unclear guidance for minors	Messaging for minors; youth links	Trustworthiness	Age-specific risk
Consideration	Verify eligibility	Reads cautiously	FAQ–UI[c] conflict	Simplified FAQ[e]; consistent messaging	Trustworthiness	Transparency
Decision	Clarity on access	Looks for eligibility	No minor-specific jurisdiction info	Age-specific legal guidance	Empowerment	Provider responsibility
Action	Support if restricted	Attempts case creation	Block; no guidance or support	Clear alternative steps; reassurance	Collaboration	Empowerment
Postaction	Next-step guidance	Redirected to generic list	Generic list; no minor help	Visible helplines; tailored follow-up	Empowerment	Proactive

[a]TID: trauma-informed design.

[b]TIC: trauma-informed care.

[c]UI: user interface.

[d]NGOs: nongovernmental organizations.

[e]FAQ: frequently asked questions.

Journey findings were translated into low-fidelity TID-informed interface examples for use as phase 2 evaluation stimuli, each reviewed through scenario-based cognitive walk-throughs [35]; these examples were not treated as final design solutions. Crosscutting barrier themes were then derived by grouping recurrent persona-stage barriers and cross-walking each against the TIC principle, Safety by Design principle, and usability heuristic it implicated. The 6 TID guidelines were synthesized from these themes by consolidating barriers with shared design implications into broader intervention targets (eg, opaque data handling, unclear steps, and uncertain timelines into process transparency). Each of the 5 crosscutting barriers was mapped to 1 or more guidelines (Table 3), and every guideline was anchored to the TIC principle and Safety by Design mandate it operationalizes; guideline derivation and labeling followed the

XSL•FO
RenderX

same independent-coding-then-consensus procedure used for journey mapping.

Table . TID[a] guideline framework: derivation and evaluated design responses[b].

Guideline (domain)	Barrier addressed	Persona(s) most affected	TIC[c]	Safety by design	Usability-heuristic overlap	Design response	Interpretive status (phase 2)
G1: Emotional scaffolding (visual and emotional tone)	Emotionally triggering content	Rina, and Sara	Safety	Service-provider responsibility	Aesthetic and minimalist design	Reduce threat cues; supportive language	Perceived as more comforting
G2: Process transparency (language and framing)	Opaque data handling; ambiguous eligibility language	Sara, and Rina	Trustworthiness and transparency	Transparency	System status visibility	Make process, data use, and timelines explicit	Perceived as trust-supporting
G3: Self-pacing mechanisms (self-pacing and grounding)	Multi-step workflows without exit	All	Empowerment, voice, and choice	User empowerment	User control; help documentation	Enable pause, save, and return without penalty	Perceived as reducing pressure
G4: Institutional trust signals (information architecture)	Low institutional credibility	All	Trustworthiness and transparency	Service-provider responsibility	(No direct equivalent)	Show recognizable affiliations and security cues	Consistently perceived as trust-supporting
G5:Context-aware support (information architecture)	Absent tailored or contextual support	Minji, and Sara	Cultural, historical, and gender issues	Service-provider responsibility	Consistency; system–-world match	Tailor guidance to age, jurisdiction, and need	Identified as relevant; requires survivor-centered testing
G6: Grounding tools (self-pacing and grounding)	Absent emotional support	All	Peer support	User empowerment	User control; help documentation	Provide grounding and immediate support options	Perceived as usable; not behavioral evidence

[a]TID: trauma-informed design.

[b]G1-G6 denote the 6 TID guidelines. Columns map each guideline to the barrier it addresses, the personas most affected, its TIC principle and Safety by Design mandate, and the overlapping usability heuristic [9]; the final 2 columns give the candidate design response and its phase 2 interpretive status. Design responses were evaluated as plausibility and acceptability stimuli by domain-informed student evaluators, not tested behaviorally with nonconsensual intimate image victim-survivors or active help seekers.

[c]TIC: trauma-informed care.

Phase 2: Domain-Informed Plausibility Evaluation

Eight female university students (aged 20 - 24 years) majoring in Counseling-UX Psychology at a Korean university were recruited through purposive sampling as domain-informed student evaluators. Participants were selected for their uncommon dual training in counseling psychology and UX: few individuals, and particularly established specialists, command both, yet this combination is what allows an evaluator to read an interface through both the usability-heuristics and the TIC lenses the framework integrates. As young women in the age range most affected by NCII and image-based sexual abuse, they were also demographically closer to the affected user population than older specialists would be, which supported empathic appraisal of the personas' experiences. They were not recruited as credentialed experts, NCII survivors, representative end users, or individuals actively seeking image-removal support. Because trauma-informed digital safety design is an emerging interdisciplinary area and formally established specialist roles are limited in the Korean context, this group was used for preliminary plausibility assessment rather than expert validation. The 8 evaluators were distinct from the persona development team, preserving the independence of the appraisal. Prior to the focus group, participants received a structured briefing on the study purpose, the NCII removal platform context, the 3 persona summaries, a brief explanation of the TID framework and its 6 guidelines, and the distinction between evaluating plausibility and reporting personal trauma experience. The 1-hour semistructured focus group was conducted in a private university setting by a researcher trained in Counseling-UX Psychology. The focus group guide covered four blocks: (1) initial platform navigation and spontaneous reactions; (2) evaluation of persona and journey plausibility; (3) side-by-side comparison of the original interface and TID-informed interface examples instantiating the 6 guidelines, including whether the design responses cohere with the framework; and (4) reflection on emotional safety and willingness to use. The focus group guide is provided in Multimedia Appendix 1. Audio was transcribed verbatim in Korean with representative quotes translated into English by a bilingual researcher and verified by a second.

CQR was selected for its emphasis on researcher consensus through team-based analysis and its demonstrated suitability for exploratory research with small, homogeneous samples [25,36]. Analysis proceeded through 5 steps. First, the 2 coders independently reviewed the transcript and segmented participant responses into meaning units. The 2 coders were a master's-level

XSL•FO
RenderX

practitioner in counseling psychology and the first author (JL), a licensed counseling psychologist with expertise in trauma, digital mental health, and human-computer interaction; assumptions and potential biases were documented prior to analysis following CQR protocol [25] and trauma-informed research guidelines [1]. Second, each analyst abstracted the essential meaning of each excerpt into preliminary core ideas, preserving the participant's intended meaning. Third, the analysis team met to compare core ideas, discuss discrepancies, and reach consensus through iterative discussion. Disagreements were resolved by returning to the transcript and evaluating which interpretation was most strongly supported by the raw data. Fourth, agreed-upon core ideas were clustered into thematic domains and categories through cross-analysis across participants. Fifth, an external auditor, who is a counseling psychology faculty member specializing in digital mental health and was not involved in data collection, reviewed the thematic domain structure, category labels, and representative excerpts, in line with established qualitative trustworthiness criteria [37]. Auditor feedback was discussed by the analysis team, and revisions were made when the audit identified overinterpretation, unclear category boundaries, or insufficient evidentiary support. Frequency labels followed CQR conventions: general (7 - 8 of 8 participants), typical (4-6), and variant (2-3).

Ethical Considerations

This study was reviewed and approved by the Institutional Review Board of Hankuk University of Foreign Studies (approval number HUFS-2507 - 009). It was conducted as a preliminary, minimal-risk UX and plausibility evaluation with adult student evaluators; participants were not recruited as NCII victim-survivors, were not asked to disclose personal NCII victimization or trauma histories, and evaluated summarized persona, journey map, and interface-example materials rather than reporting personal experience. Written informed consent was obtained before participation; participants were advised in advance that the evaluation materials addressed NCII and could be distressing, that they could decline any question or pause or withdraw at any time without penalty, and that psychological support was available, if needed. Privacy and confidentiality were protected by deidentifying transcripts, reporting summarized findings rather than identifiable raw statements, and limiting data access to the research team. Safeguards included advance briefing, unrestricted withdrawal rights, on-site counselor availability during and after the session, and summarized rather than raw presentation of potentially triggering NCII content [1]. No compensation was provided.

Results

Phase 1: Personas, Journey Maps, and Barrier Identification

Phase 1 produced 3 trauma-differentiated personas, summarized in Table 1. Each persona encodes a distinct configuration of trauma severity, perceived control, institutional trust, and capacity to sustain a multistep digital task under stress. Applying each persona across the 5 interaction stages produced the journey maps presented in Table 2, which document, for each stage, anticipated needs, likely actions, the current barrier, a TID-informed response, and the corresponding TIC and Safety by Design principles.

For Sara (low-moderate trauma), absent procedural clarity and opaque data governance violated Trustworthiness and Safety by Design's Transparency principle [23,38,39]. Although a general population user might tolerate ambiguous data-handling information as a minor frustration, Sara's trauma-eroded institutional trust transforms opacity from a usability irritation into a barrier to engagement. Specifically, she cannot proceed without understanding exactly how her sensitive data will be handled, by whom, and under what legal protections. For Rina (severe trauma), the platform's rigid, linear workflow, which lacked any save-progress functionality, forced a complete restart after trigger-induced abandonment. Given that PTSD specifically disrupts executive functions including planning, sustained attention, and working memory [11], this rigid workflow created a functionally inaccessible environment for users in exactly the crisis state the platform was designed to serve. The misalignment was dual: TIC's Empowerment, Voice, and Choice principle requires that users maintain control over the pace and direction of their engagement, while Safety by Design's friction feature guidance recommends pause points and save states precisely to prevent forced completion designs [16]. For Minji (adolescent), ambiguous eligibility criteria violated Trustworthiness: a minor navigating a confusing legal landscape needs unambiguous guidance, not contradictory information across frequently asked questions and interface elements. Generic referral on restriction (ie, redirecting a distressed minor to an undifferentiated list of organizations without age-specific guidance) violated both Safety and Safety by Design's age-specific risk assessment requirement [40,41].

Five crosscutting barrier themes were synthesized across all 3 journey maps (Table 3): ambiguous eligibility language, emotionally triggering content, absent emotional support mechanisms, opaque data handling, and low institutional credibility. Each theme represents a convergent pattern across clinical, platform-safety, and usability lenses rather than a single-source observation; the full derivation appears in Table 3.

Proposed TID Framework

The 6-guideline TID framework (Table 3) integrates TIC and Safety by Design principles across 4 intervention domains: Visual and Emotional Tone, Language and Framing, Information Architecture, and Self-Pacing and Grounding. The framework is specified at the level of design principles and the psychological targets they address; the concrete interface features named under each guideline are illustrative instantiations used here as evaluation stimuli, rather than prescribed or finalized designs for any particular service.

Guideline 1 (Emotional Scaffolding): calming color palettes, nontriggering imagery, and empathetic language implemented as platform defaults rather than user-selected options. This guideline targets trauma-related hyperarousal and the appraisal of otherwise neutral interface cues as threatening [12,13]. Guideline 2 (process transparency): plain-language explanations of data handling, process steps, and expected timelines at every interaction stage. It addresses the hypervigilant threat monitoring

XSL•FO
RenderX

associated with eroded institutional trust while reducing uncertainty that taxes trauma-compromised working memory [11,12]. Guideline 3 (Self-Pacing Mechanisms): save-as-draft functionality, visible progress indicators, and explicit pause points that validate the user's need to step away. It counters learned helplessness and the PTSD-related executive-function deficits, such as planning, sustained attention, and working memory, which cause rigid, multistep workflows to fail for trauma-affected users [11,12]. Guideline 4 (Institutional Trust Signals): prominent display of recognized organizational affiliations, government endorsements, and security certifications. It responds to trauma-eroded institutional trust, for which conventional credibility signals are often insufficient [12]. Guideline 5 (Context-Aware Support): curated resources tailored to user characteristics, including age-specific guidance, jurisdiction-relevant legal information, and culturally appropriate referrals. To operationalize the cultural, historical, and gender issues principle, this guideline further specifies gender- and culturally responsive content, which includes language that explicitly counters victim-blaming, a concern especially salient in the Korean sociocultural context. For instance, displaying a message such as "What do you do if someone is threatening to share your intimate images?" on the main page could potentially place the burden on victims who are already navigating a difficult reporting process. This framing may inadvertently suggest that resolving the situation falls primarily on the victim, which might feel less validating for those seeking support. To avoid this, the guideline mandates that the guidance never implicitly attributes responsibility to the victim-survivor [2,6]. Guideline 6 (Grounding Tools): accessible helpline links, supportive messaging during high-anxiety interaction points, and mobile-first crisis design reflecting the platforms through which victim-survivors most commonly seek help [5]. Consistent with the Peer Support principle, it also offers optional connection to vetted survivor and peer-support networks to address the isolation that frequently accompanies NCII victimization [42]; its grounding components target acute hyperarousal that can exceed a user's window of tolerance at high-distress steps [12,13]. To prevent specific identification of the platform, visual interface details are omitted; instead, the final columns of Table 3 summarize the candidate design responses used as phase 2 evaluation stimuli.

Phase 2: Domain-Informed Evaluation Results

Overview

CQR analysis yielded 5 thematic domains and 14 categories (Table 4). Following CQR conventions, frequency labels are used descriptively to indicate how many participants endorsed a category within this specific evaluator sample. Given the small and homogeneous sample, "General" should not be interpreted as population-level prevalence or generalizability. Rather, it indicates that a theme was consistently observed across the 8 domain-informed student evaluators in this preliminary study.

XSL•FO
RenderX

Table . CQR[a] results: thematic domains and categories[b].

Thematic domain and category	Core idea	Frequency	Representative quote
Initial perceptions			
Unclear site purpose	Users could not discern site purpose	General	"I had no idea what this site was for."
Visual distrust	Design felt untrustworthy	Typical	"The color scheme made it feel cheap."
Cognitive overload	Excessive information caused confusion	Typical	"So much information, I didn't know what to click."
Persona credibility			
Psychological plausibility	Trauma-informed behavior felt realistic	General	"Of course they'd want to avoid repeating steps."
Behavioral journey fit	Reactions matched experience	Typical	"Wanting to double-check safety—that resonated."
Need for diversity	More diverse personas needed	Variant	"Maybe add a male victim persona."
UX[c] feedback			
Trust-building features	Logos created confidence	General	"The official logo made me trust it more."
Comforting elements	Language supported ease	Typical	"'Find support' felt much less intimidating."
Improved flow	Save feature helped	Typical	"Saving progress made a huge difference."
Emotional safety			
Trust based on prior knowledge	Trust needed context	General	"Without background info, I wouldn't trust it."
Fear of fake sites	Impersonation fears	Typical	"I'd question if this was real."
Institutional endorsement	Official affiliation needed	Typical	"Endorsed by a government agency."
Systemic barriers			
Search invisibility	Not found in search	General	"I searched and it doesn't show up."
Desire for human support	Real-time help wanted	Variant	"A chat option mid-process would help."

[a]CQR: consensual qualitative research.

[b]General=7-8 of 8 participants, typical=4-6, and variant=2-3.

[c]UX: user experience.

Domain 1: Initial Perceptions

The platform's purpose was not readily apparent to participants (general). Aesthetic elements, particularly color choices and layout density, elicited active distrust rather than merely failing to inspire confidence (typical). Information density created cognitive paralysis, with participants reporting inability to identify relevant next steps (typical).

Domain 2: Persona Credibility

Personas were received as psychologically plausible, particularly regarding trauma-shaped behaviors: repeated safety checking before commitment, hesitation at irreversible steps, and need for institutional legitimacy verification (general). Journey narratives were emotionally resonant (typical), with participants reporting that they could envision users exhibiting the personas' described hesitations and retreat patterns. The variant-level concern about exclusively female representation warrants attention in future iterations. General-level endorsement provides preliminary support for the plausibility of the diagnostic methodology within this evaluator group, but it does not establish ecological validity with NCII victim-survivors. This finding partially addresses the methodological concern that personas constructed without direct user research risk stereotyping [28,30], while also underscoring the need for subsequent survivor-centered evaluation. Furthermore, domain-informed plausibility rated by participants trained in the same field presents a lower bar than it might appear; establishing external validity ultimately requires evaluators outside this disciplinary overlap.

Domain 3: UX Design Feedback

Institutional logos transformed perceptions from "potentially fraudulent" to "officially endorsed," with participants describing

XSL•FO
RenderX

a categorical rather than incremental shift in willingness to engage (general), supporting guideline 4. Language changes that replaced "Create a case" with "Find support" were perceived as substantially more comforting and less bureaucratic (typical), supporting guideline 1. The save-as-draft function received positive responses (typical), with multiple participants noting that the original rigid workflow would be prohibitive during emotional distress, providing preliminary support for the clinical rationale underlying guideline 3. This convergence between clinical prediction and evaluator feedback suggests that mental health expertise may improve early-stage safety design, although behavioral effectiveness remains untested.

Domain 4: Emotional Safety

Trust was conditional on external endorsement: participants required a trusted intermediary (counselor, teacher, and government website) to vouch for the platform before engaging, regardless of interface quality (general). Fraudulent website fears persisted even after viewing framework-informed interface examples with improved trust signals (typical).

Domain 5: Systemic Barriers

Search engine invisibility was the most prominent systemic concern (general): participants could not locate the platform through standard search queries, rendering interface improvements irrelevant for users who never arrive. Desire for real-time human support was noted (variant), consistent with TIC's Collaboration and Mutuality principle. These findings identify structural prerequisites beyond interface design, including search engine optimization strategy, institutional referral partnerships, and integrated support service connections, consistent with the argument by Chen et al [1] that trauma-informed technology requires systemic organizational transformation, not merely interface-level changes, and with Safety by Design's Holistic principle requiring safety considerations across the full product life cycle [16].

Discussion

Principal Findings

This study developed and preliminarily evaluated a TID framework for NCII removal platforms. Applying trauma-differentiated personas to an existing platform (RQ1) surfaced 5 crosscutting barriers, including ambiguous eligibility language, emotionally triggering content, absent emotional support, opaque data handling, and low institutional credibility, which conventional usability evaluation alone may not fully capture. Jointly operationalizing TIC, Safety by Design, and usability heuristics (RQ2) produced 6 TID guidelines. In domain-informed evaluation (RQ3), evaluators judged the personas plausible and viewed design responses featuring institutional trust signals, self-pacing, and supportive language as emotionally safer and potentially more usable, while emphasizing that survivor-centered validation remains necessary. The study's primary contribution is to operationalize the Safety by Design mandate for NCII removal platforms: pairing TIC, as clinical content, with usability heuristics, as interaction mechanics, to turn a broad protective obligation into concrete, actionable design guidance, thereby helping to close the gap between safety policy frameworks and interface-level guidance.

TIC as a Foundational Framework for Digital Safety Design

The central finding is that the barriers that arise on NCII removal platforms are rooted in the psychological consequences of trauma, and that TIC provides the theoretical apparatus necessary to diagnose them. The rigid, save-progress-free workflow in Rina's journey map illustrates this: in usability terms a minor violation of Nielsen's [9] user-control heuristic, but through a TIC lens a reproduction of learned helplessness, as effort expended and then arbitrarily erased mirrors the powerlessness Herman [12] identified as central to prolonged interpersonal trauma, inadvertently replicating how abusers exploit technology to maintain control [23]. Likewise, ambiguous data-handling policies (a transparency gap in usability terms) activate hypervigilant threat monitoring in users whose institutional trust is compromised [3], and information-dense interfaces (an aesthetic-minimalism violation) exceed the diminished executive function capacity documented in PTSD [11]. This pattern (the same feature receiving qualitatively different diagnoses depending on whether TIC principles are applied) illustrates why TIC is foundational to this diagnostic approach. Prior work mapped heuristic-TIC convergences, demonstrating that the 2 traditions share substantial common ground [14].

Consistent with this interpretation, evaluators' difficulty discerning the platform's purpose and their distrust of information-dense screens map onto the trauma-compromised attention, working memory, and executive function documented in PTSD populations [11], such that information-dense interfaces function as inaccessible rather than merely suboptimal environments. Likewise, the conditioning of trust on external endorsement reflects trauma-eroded institutional trust [12]: for trauma-affected users, procedural transparency is necessary but insufficient without validation from trusted institutions, implying that referral partnerships with counseling services, government agencies, and NGOs may matter more for initial engagement than interface improvements alone.

A Diagnostic Methodology Bridging 3 Traditions

The combination of trauma-differentiated personas with TIC-principled journey mapping provides a methodology that may surface concerns invisible to any single tradition. General-level persona endorsement provides preliminary support for the approach within this domain-informed student evaluator group and demonstrates the unreliability of persona construction without clinical grounding [30]. Centering victim-survivor experiences remains important for digital tool development in the gender-based violence context [2]. The present work does not substitute for such survivor involvement; our contribution is complementary: TID provides a diagnostic method for an earlier phase when direct survivor involvement may not yet be ethically appropriate, producing evidence-grounded foundations that subsequent survivor-centered evaluation can refine and validate. The persona methodology serves as the integration mechanism, whereby personas embody clinical trauma profiles [12,13] in a format that UX practitioners can apply through

XSL•FO
RenderX

journey mapping and that safety engineers can evaluate against risk frameworks [16]. Because clinicians, UX practitioners, and safety engineers each work with diagnostic tools the others lack, surfacing the full range of barriers requires integrating the 3 perspectives rather than relying on any single tradition.

Implications for Policy and Platform Design

These findings also reframe the purpose of TID. Its value lies less in serving as an ethics checklist or a compliance layer added to an existing system than in functioning as psychologically realistic interaction design that anticipates the predictable states of a help-seeking population (reduced control, avoidance, dissociation, and the anticipated cost of disclosure or refusal) and specifies how an interface should respond when a user's capacity to negotiate, object, or reengage is compromised. On this view, the features evaluators endorsed most strongly (institutional trust signals, self-pacing mechanisms, and grounding supports) function not as courtesies but as the system's relational response, situating TID within the interaction model rather than in supplementary policy. This framing extends the logic of survivor-centered conversational systems [43,44] from stand-alone agents to the removal workflow itself.

TID also continues a cumulative design lineage (from Privacy and Security by Design to Safety by Design) that progressively widens the categories of user vulnerability a system is expected to anticipate. As the Digital Services Act [45] and Online Safety Act [46] translate Safety by Design into regulatory obligation, TID offers a candidate interaction-level method for rendering those obligations as user-facing criteria, although transferability should be claimed cautiously. Building on calls for empirically evaluable trauma-informed frameworks [5], we propose a standardized TID heuristic spanning interface-level criteria (emotional tone, cognitive load, and pacing) and systemic criteria (referral pathways and institutional partnerships), applied alongside conventional heuristic evaluation and with clinical expertise embedded in requirements definition rather than added as post hoc consultation.

Limitations and Future Directions

Several limitations warrant acknowledgment. First, the framework was not evaluated with NCII victim-survivors or with users actively seeking image-removal support. This decision was ethically motivated, given the sensitivity of NCII, the possibility of retraumatization, and the need to establish preliminary procedural safety before involving survivors. However, it constrains the ecological validity of the present findings. Future research should evaluate the framework with NCII victim-survivors through ethically robust, survivor-centered methods [2,47]. Second, phase 2 involved a single focus group with 8 female Counseling-UX Psychology university student evaluators. CQR frequency labels provide useful within-sample descriptors, but they do not establish saturation across populations or prevalence estimates. The small, homogeneous, domain-informed student sample may respond differently from victim-survivors, users without counseling-UX training, users with lower digital literacy, or users in acute crisis. Third, all personas and participants were female. Although this reflects the strongly gendered distribution of NCII abuse [6], in nationwide data, women are nearly twice as likely as men to be targeted by nonconsensual intimate imagery [48], and the overwhelming majority of sexual deepfakes is nonconsensual and almost exclusively depicts women [49]. Nonetheless, the variant-level diversity concern raised by participants underscores the need to broaden future persona sets across gender, sexuality, age, disability status, and cultural contexts. Fourth, the framework was developed through a single NCII-focused case and should not be treated as fully transferable to all trauma-related digital services; some findings are likely NCII-specific (eg, fear of image circulation and shame around uploading intimate material), whereas elements such as procedural transparency, user-controlled pacing, and grounding support may transfer to adjacent digital safety contexts. Finally, the dual-lens method is, by design, theory-driven: it applies TIC as an analytic lens to surface barriers that usability evaluation alone tends to leave unexamined. Its contribution is accordingly generative (identifying and specifying candidate barriers and design responses) rather than confirmatory, and establishing that a trauma-informed lens yields outcomes superior to conventional evaluation would require controlled comparative testing, which we identify as a priority for subsequent work.

Conclusions

Emotional safety is a design requirement, not an enhancement: for platforms meant to help people already harmed, designing for the user who cannot readily advocate for themselves is what separates a tool that protects from one that may reproduce the original loss of control. Jointly operationalized through a clinically informed, persona-based diagnostic method, TIC, Safety by Design, and usability principles surfaced psychological gaps that no single method detects alone; the 6 guidelines are an actionable but preliminary starting point, and the personas and journey maps show how Safety by Design can be applied concretely rather than as aspiration. The framework now requires survivor-centered, cross-cultural, and behavioral evaluation before claims of effectiveness or broad transferability. Embedding these principles in removal platforms may enhance both their usability and their adoption, increasing the likelihood that the support these systems are designed to provide reaches the victim-survivors who seek it.

Acknowledgments

The authors would like to thank Sumin Kim, Yeonju Jeon, and the other students who participated in the user experience course and contributed valuable insights to this study. The authors also thank Eunseo Kim, MA, a counseling psychologist, for serving as an independent second coder in the consensual qualitative research analysis. The authors declare the use of generative AI (Gemini) for grammar and language improvement during manuscript preparation. It was not used to generate intellectual content of the study. Responsibility for the final manuscript lies entirely with the authors.

Abstract

Background: Health-related technology use among nondigitally native adults is becoming widespread. Nevertheless, digital health interventions are typically not designed with the unique usability needs and preferences of this population in mind. Furthermore, most of these middle-aged and older adults are managing multiple medical conditions, which can also impact their preferences related to digital health interventions. A prime opportunity to address multimorbidity in nondigital natives using a digital health intervention is the intersection between mental health and chronic pain.

Objective: The goal of this study was to use established frameworks and end-user feedback to identify actionable, usability-related features that can be incorporated into existing digital health interventions and that are preferred among nondigitally native adults. We aimed to identify general usability adaptations, as well as just-in-time adaptive interventions (JITAIs).

Methods: We conducted a qualitative usability study of a convenience sample using a hybrid inductive-deductive content analysis to evaluate an existing mental health app (Wysa for Chronic Pain). Participants were 45 years or older; reported at least moderate symptoms of depression or anxiety (Patient Health Questionnaire -9 ≥10 or Generalized Anxiety Disorder -7 score ≥10); and endorsed having pain at least most days in the past 3 months. The Framework for Reporting Adaptations and Modifications to Evidence-based Implementation Strategies was used to identify potential usability-related adaptations for the target population. Development of usability-related JITAIs was guided by Nahum-Shani's pragmatic framework for JITAI development and the Behavioral Integration Technology model.

Results: Forty-two participants completed usability testing (mean age 57, SD 8 years; women n=32, 76%). Participants identified numerous opportunities to optimize their user experience, primarily by ensuring the app clearly describes how all its features are intended to be used and by minimizing navigation burden. Specifically, participants requested clear, step-by-step orientation and navigation instructions, rather than a brief onboarding experience that relies on user-led exploration and familiarity with conventional app symbols. Participants also recommended a customized experience based on their unique usage patterns. The most common JITAI opportunity identified was to strategically reduce user notifications in order to reduce the risk of notification fatigue and subsequent complete disengagement with the app.

Conclusions: Identifying actionable opportunities to improve usability and prompt engagement with "the right tool at the right time for the right person" holds promise to improve the effectiveness of digital health interventions across the age span. The usability-related refinement opportunities identified in this study are generalizable to other digital health interventions that are relevant to older users who are likely to be managing multimorbidity, are not digital natives, and are more likely than younger users to have physical or cognitive challenges. The integrated framework-based process described in this article can also serve as a model for optimizing other existing digital health interventions.

Introduction

Most digital health interventions are not equally "accessible" to everyone [1]. Specifically, they are typically not designed with the usability needs and preferences of nondigital natives (born before 1980) in mind [2,3]. Technology use is rapidly growing across the age span [4-6], but compared to younger users who grew up "digitally native" with widespread access to technology and for whom many interventions were initially designed, middle-aged and older adults tend to have different habits and characteristics. For instance, they tend to check their mobile devices less frequently, and most do not instinctively search for a technological solution to a problem. In addition, this older population often experiences age-related changes in visual acuity and eye tracking patterns, and some have age-related dexterity or cognitive deficits [4,7-10]. Furthermore, the prevalence of multimorbidity increases with age [11]. As a result, nondigitally native adults tend to prefer different screen layouts than younger technology users; they may benefit from more "push" notifications, and they are more often interested in interventions that address multimorbidity [4,5].

A growing body of evidence is available to guide developers in understanding the usability preferences of nondigitally native adults [4,5,12], but a gap still exists in translating these general preferences into real interface changes that are implemented within existing digital health interventions. Furthermore, just-in-time adaptive interventions (JITAIs) are a relatively new and persistently underused method that aim to deliver the "right intervention at the right time to the right person," and they have the potential to reduce the need for users to initiate interaction with a digital health intervention or to navigate through the intervention independently [13]. We hypothesize that JITAIs may be particularly impactful to improve usability for nondigitally native adults, but they are not yet widely applied to publicly available digital health interventions [14]. Guiding frameworks have also been developed in recent years that can facilitate optimal reach and effectiveness of digital health interventions, but they, too, have not been routinely used in intervention development [15]. Applying these frameworks and JITAI capabilities to adapt existing interventions for key target populations could rapidly improve the accessibility and subsequent effectiveness of publicly available digital health interventions.

A prime opportunity to address multimorbidity in nondigitally native adults using a digital health intervention is at the intersection between mental health and chronic pain [16-21]. Digital mental health interventions are now widely available to address depression and anxiety symptoms [22-27], in large part because they can be effective and improve access to mental health support for people who otherwise may be limited by barriers such as stigma, cost, or geography [27-32]. Nevertheless, chronic pain commonly coexists with symptoms of depression and anxiety, and it reduces the effectiveness of mental health treatments unless pain is simultaneously addressed [20,33-38]. Furthermore, the prevalence of chronic pain increases with age [20,35].

The goal of this study was to use established frameworks and end-user feedback to identify usability preferences among nondigitally native adults for digital health interventions. We specifically focused on nondigitally native adults with chronic pain and coexisting symptoms of depression or anxiety, and we aimed to obtain feedback on participants' preferred general usability adaptations, as well as usability-related JITAIs. Our motivating scientific premise is that incorporating usability-related adaptations will improve overall engagement and subsequent effectiveness of digital health interventions, and evaluation of this potential relationship will be assessed in future work.

Methods

Study Design

This was a formative, qualitative usability study in which participants from the target population of interest completed usability testing of an existing mental health app. Usability testing occurred in 2024, and data analysis occurred in 2024 and 2025. Of note, additional feedback from study participants regarding contextual determinants of engagement with mental health apps was reported separately [12].

This study was performed via an academic-industry partnership. Academic investigators had full independence in designing the study, recruiting participants, conducting the usability testing, performing data analysis, and reporting study results. The industry partner provided access to the mental health app under investigation and created mock-ups of refined app screens and workflows for the iterative usability testing process. The academic investigators shared the study findings with the industry partner so that the industry partner could refine its mental health app accordingly.

Ethical Considerations

Ethical approval was obtained by the Washington University Institutional Review Board via a waiver of written informed consent prior to participant recruitment (Institutional Review Board ID 202311024). Participant data were maintained in secure databases and were deidentified before sharing outside the institutional review board–approved study team. Participants received a US $30 gift card for participation.

Participants or Users

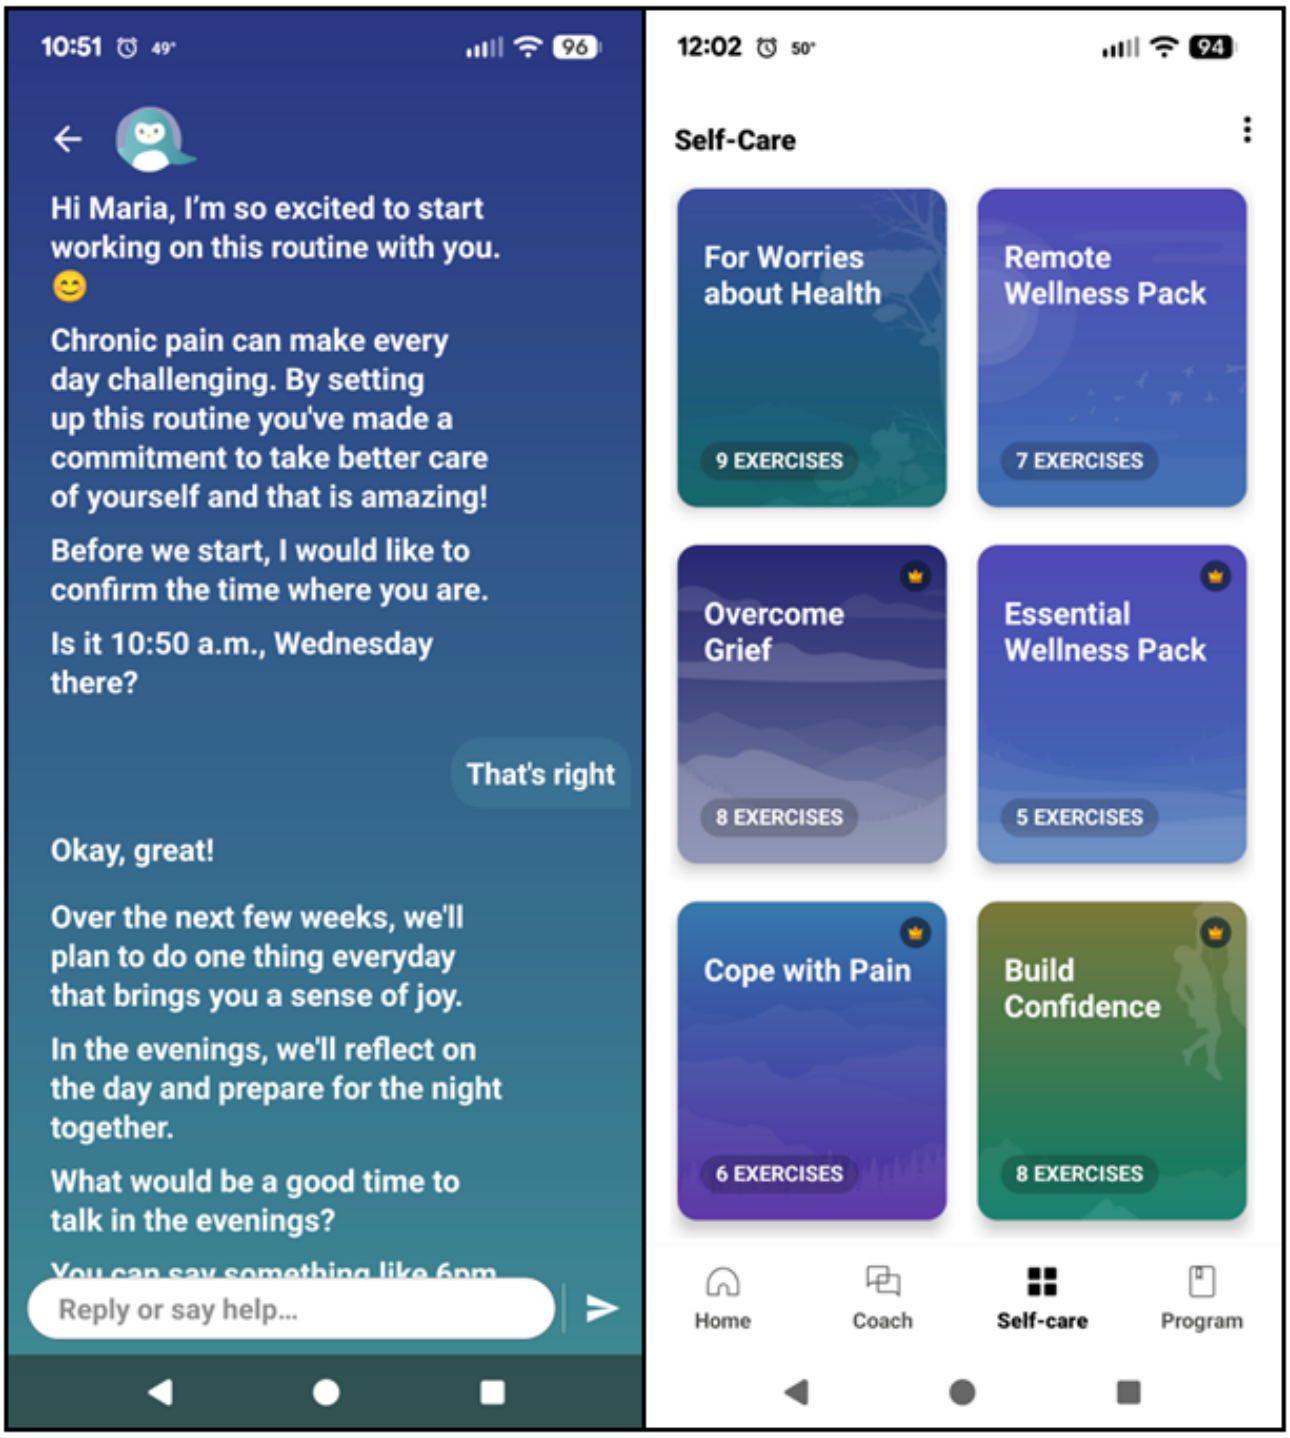
Participants were at least 45 years old, reported at least moderate depression or anxiety symptoms (Patient Health Questionnaire-9 ≥ 10, Generalized Anxiety Disorder-7 score ≥ 10, or both), and endorsed chronic pain (defined as pain on most days or every day in the past three months) [20,39-41].

Exclusion criteria included endorsement of an active mental health crisis that warranted escalation of care (eg, active suicidal ideation and psychosis), cognitive impairment that would interfere with communication with the researcher or meaningful engagement with the mental health app (assessed informally by the research coordinator asking the potential participant to restate the study purpose, activities, and risks, benefits, and alternatives of study participation during the informed consent process), and residing outside the United States.

XSL•FO
RenderX

Recruitment

Participants were a self-selected convenience sample recruited from multiple sources including a chronic musculoskeletal pain clinic at a US academic medical center, email, and social media advertisement via the medical center's volunteer research participant registry, and targeted advertisement in a free online health community (The Mighty). Eligibility screening was performed using a self-reported questionnaire hosted by REDCap (Research Electronic Database Capture; Vanderbilt University), followed by verification by the research coordinator [42,43]. Recruitment was closed when usability testing by additional participants no longer yielded new themes within the convenience sample during the iterative analysis process [44].



Intervention Assessed in Usability Testing

The mental health app assessed in usability testing, Wysa for Chronic Pain, aims to address mental health and chronic pain through a multifaceted approach by facilitating behavioral activation, pain acceptance, and improved sleep quality [45-48]. It guides users through evidence-based cognitive behavioral therapy, mindfulness-based interventions, and sleep support. The app has used a rule-based conversational agent with natural language understanding to deliver therapeutic content since 2016. In 2024, it augmented this approach with the addition of large language models at specific nodal points. Large language model–based capabilities were integrated into check-in conversations to improve the chatbot's ability to understand context-specific content over multiple interactions and respond in a more personalized manner to the user. However, risk-based and crisis conversations have remained completely rule-based and written by a clinician. Although the parent Wysa company offers multiple commercially available products, Wysa for Chronic Pain is not currently commercially available.

The therapeutic tools within Wysa for Chronic Pain are designed to be delivered via a combination of a structured curriculum and optional user-led exploration. By default, the app sends push notifications to users twice daily. The morning notification prompts an activity scheduling and planning task, and the evening notification prompts an activity tracking and mood reflection task and then offers a sleep meditation (Figure 1). Additional therapeutic content such as cognitive restructuring, thought recording, journaling, anxiety management, etc is delivered in a weekly cadence over 8 weeks. Each week, users receive a push notification that directs them to a report that details their app engagement thus far. Accessing the report also launches a congratulatory message for their engagement and unlocks access to new therapeutic tools as a reward for their engagement. Users can also independently navigate to therapeutic tools at any time, which are organized into "tool packs." As a safety feature, the app also includes an "SOS" safety plan feature, which lists crisis hotlines and allows users to enter and store self-reported sources of hope and "safe people or places" to reference in moments of crisis.

XSL•FO
RenderX

Figure 1. Screenshots of Wysa for Chronic Pain.

Usability Testing Process

Participants answered sociodemographic questions via an electronic REDCap questionnaire for descriptive purposes. Usability tests were conducted and recorded using audio and visual conferencing via a secure Zoom (Zoom Video Communications, Inc.) platform, each lasting approximately 45 - 60 minutes. After participants downloaded Wysa for Chronic Pain to their mobile device, they were asked to complete the app's onboarding process and complete several tasks within the app, all while performing "think aloud" testing, during which they described their thoughts and experiences in real-time (Multimedia Appendix 1: interview guide). During this process, the facilitator also took note of participants' hesitations and inaccuracies in navigating the app, and the facilitator requested feedback on potential JITAIs that could be incorporated into the app. JITAI options and their details were iteratively refined throughout the usability testing process via a rapid iterative testing process. Based on feedback from the first 21 participants, mock-ups of revised app screens and workflows were created and shared with the next 13 participants using Figma (Dev Mode) and Twine (Chris Klimas) software. Additional minor refinements were made to the mock-ups for review by the final 8 participants. However, the evaluation tasks and the app's core functionalities remained consistent for all participants.

RenderX

Analysis Frameworks

The Framework for Reporting Adaptations and Modifications to Evidence-based Implementation Strategies (FRAME-IS) was used to identify and report potential usability-related adaptations needed for our target user population (Table 1) (Figure 2) [49]. FRAME-IS builds from the Framework for Reporting Adaptations and Modifications-Enhanced and is organized into modules to systematically document modifications to implementation strategies [50]. We elected to use the FRAME-IS rather than the Framework for Reporting Adaptations and Modifications-Enhanced because our goal was to adapt the delivery of therapeutic content within the digital health intervention (ie, usability and engagement optimizations as an implementation strategy), rather than adapt the core therapeutic content itself (ie, cognitive behavioral therapy, mindfulness exercises, etc as the evidence-based intervention).

XSL•FO
RenderX

Table . Application of the Framework for Reporting Adaptations and Modifications to Evidence-based Implementation Strategies, which guided proposed adaptations to improve usability of a mental health app for nondigitally native adults who have chronic pain.[a]

FRAME-IS[b] module or sub-component	Application of FRAME-IS to target intervention and population
Module 1	
The intervention being implemented is:	• Therapeutic tools within the Wysa for Chronic Pain digital platform
The implementation strategy being modified is:	• Improving usability of the intervention's platform
The modifications being made are:	• General adaptations to the intervention's interface • Incorporation of JITAIs[c]
The reasons for the modifications are:	• To lower the user's navigation burden and frustration through the intervention's interface • To increase the likelihood that the user is aware of, and engages with, relevant therapeutic tools
Module 2	
What is modified?	• Format-related contextual modifications (See Tables 2 and 3)
Module 3	
What is the nature of the content, evaluation, or training modification?	• Refining packaging of intervention content
Optional: what is the relationship to core elements?	• Fidelity-consistent: core elements of the intervention are preserved
Module 4	
What are the goals?	• Increase the usability and acceptability of the intervention to the target user group • Improve intervention fidelity and engagement such that users engage with therapeutic tools as intended (ie, improve retention) • Decrease disparities in intervention delivery (ie, improve uptake and retention by nondigitally native adults)
What is the level of the rationale for the modifications?	• Recipient (end-user)
Module 5	
When is the modification initiated?	• Scale-up phase (ie, after the intervention was developed but before it is made available to the general public)
Is the modification planned?	• Planned, proactive
Module 6	
Who participates in the decision to modify?	• Recipients (end-users), researchers, intervention developers
Optional: who makes the ultimate decision:	• Intervention developers (ie, based on feasibility and alignment with other intervention features)
Module 7	
How widespread is the modification?	• All recipients (end-users) of the intervention

[a]The left column outlines the elements of the FRAME-IS, and the right column outlines the application of the framework to this study's target intervention and population..

[b]FRAME-IS: Framework for Reporting Adaptations and Modifications to Evidence-based Implementation Strategies

[c]JITAIs: just-in-time adaptive interventions

XSL•FO
RenderX

Table . General usability adaptations proposed to improve usability of a mental health app for nondigitally native adults who have chronic pain.

Name of adaptation	Description
Onboarding conversation	Include a thorough, text-based description of how users are intended to engage with the app (eg, timing, frequency, content, goals of engagement). Also explain terms used by the app (eg, "roadmap," "journal," etc).
Onboarding tour	Include a dynamic visual tour of how to navigate the app's interface, including audio explanation and text captions.
Therapeutic approach	Explain the app's therapeutic approach during the onboarding experience. For example, explain "how an app can help with pain" by differentiating pain interference from pain severity and by stating the goals of reducing pain interference and improving pain acceptance.
Search bar	Enable users to rapidly search the library of therapeutic tools based on a tool's name, category, or other feature.
Clarify "SOS"	Appropriately label an app's crisis tools so users do not assume that pushing a button labeled "SOS" will automatically dial 911 (but rather, will direct to creation and reference of user-reported sources of hope and "safe people/places," list of crisis hotlines, etc)
Personalized "flare-up kit"	Create easy reference to a personalized plan for symptom flares (such as what would be developed by the user during a standard cognitive behavioral therapy session). For example, pin a "preparing for pain flares" plan near existing tool packs, which lists users' preferred nonpharmacologic pain management strategies (eg, ice and heat modalities, distraction techniques, mental relaxation techniques, etc).
Pinned toolkit	Maintain a group of in-app therapeutic tools that are useful for acute needs (eg, pain flares) and are always easily accessible from the app home screen (eg, mindfulness exercises, gentle stretches, reminder of user-reported preferred pain management strategies in the "flare-up kit").
Experience customization	Customize and recommend therapeutic tools based on users' responses during onboarding and subsequent conversations within the app (eg, facilitated by generative artificial intelligence).
Other challenges to address	When prompting users to report challenges they are living with, include options for loneliness, health concerns, and finances (which impact overall well-being and should then be incorporated into customizing the user's app experience).
Response to tools within app	Track users' self-reported response to each therapeutic tool, at least after first use. Use this data for future experience customization.
Weekly symptom assessment	Assess symptoms weekly with a brief measure (eg, PHQ-4)[a] [51], to facilitate (app- and user-led) pattern recognition between symptoms and other events (eg, to facilitate future app experience customization and for users to reference while journaling).
Weekly report	Relate symptom changes (eg, mood and pain) to app engagement (eg, which tools, how often), and allow users to add other external events to the report which they believe may have impacted their symptoms (eg, work, family events).
Preparing for hard days	Before closing the "weekly report" experience, ask users, "Do you expect any extra challenges this week?" If so, inquire about the timing and type of challenge. Offer to schedule a personalized tool in preparation for the challenge (eg, grounding exercise before a person with agoraphobia leaves home, meditation exercise for an anticipated activity-related pain flare, etc).
Tip of the day or week	As part of the daily check-in or weekly report, highlight a feature or tool that has not yet been explored by the user or that was rated highly but has not been used recently.
Curriculum change	After a user completes the app's structured curriculum, ask if the user prefers to continue structured check-ins versus transition to only user-led engagement with tools.

[a]PHQ-4: Patient Health Questionnaire-4.

XSL•FO
RenderX

Table . Usability-related JITAIs proposed to improve usability of a mental health app for nondigitally native adults who have chronic pain.

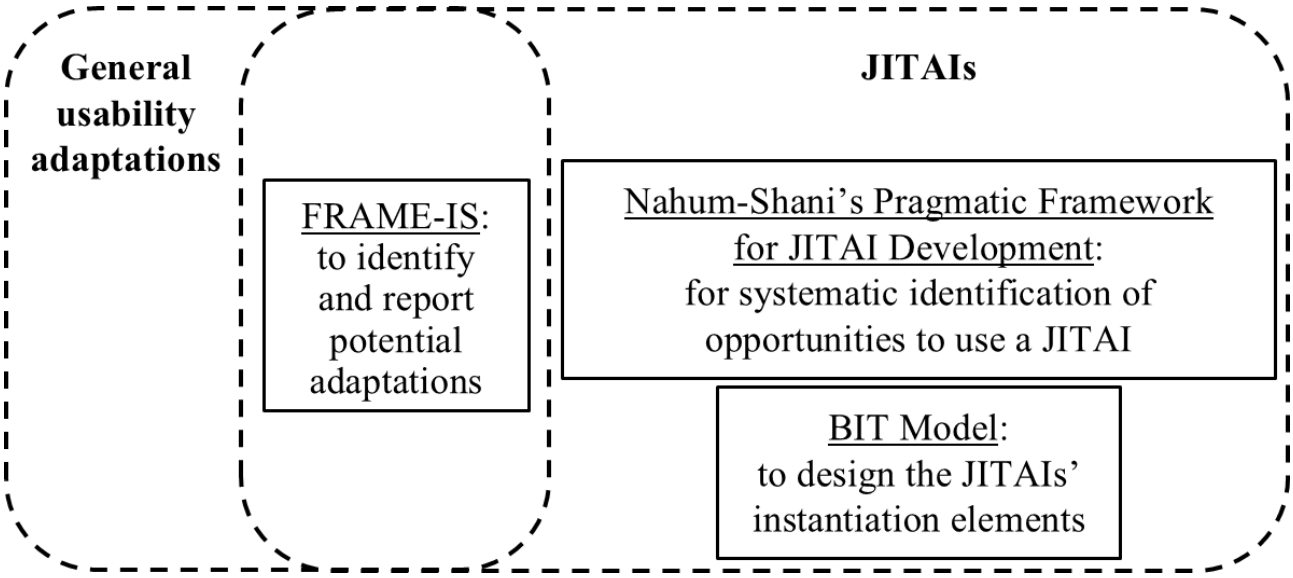
JITAI[a] name	Purpose	Tailoring variables	Intervention options	Proximal outcome(s)
Onboarding	Increase onboarding completion rates	If user downloaded app but did not complete onboarding within intended period	Then, send a notification that encourages the user to finish onboarding.	• Completion of onboarding
Short disengaged	Motivate a user to engage	If no app engagement for short period (eg, 24 h)	Then, send a notification that directly opens to a relevant tool.	• Any engagement[b] • Content engagement[c]
Long disengaged	Respect that users' preferred or needed frequency of engagement may fluctuate based on symptom severity and life events	If no app engagement for a prolonged period (eg, 7 d)	Then, send an "FYI/opt[d] back in"[e] notification, and stop all notifications for a brief period (eg, 3 d). After the brief period, send a notification that directly opens to a relevant tool.	• Any engagement[b] • Content engagement[c]
AM check-ins only	Personalize timing of content delivery to users' demonstrated preferences	If no engagement with PM check-ins but continued engagement with AM check-ins	Then, send an "FYI/opt back in"[e] notification, stop daily "PM check-in" notifications, and move the "activity tracking and mood reflection" task to the AM check-ins.	• Engagement with the "activity tracking and mood reflection" task compared to a preceding time interval • Change in content engagement[c] compared to a preceding time interval
PM check-ins only	Personalize timing of content delivery to users' demonstrated preferences	If no engagement with AM check-ins but continued engagement with PM check-ins	Then, send an "FYI/opt back in"[e] notification, stop daily "AM check-in" notifications, and move the "activity scheduling and planning" task to the PM check-ins.	• Engagement with the "activity scheduling and planning" task compared to a preceding time interval • Change in content engagement[c] compared to a preceding time interval
Sporadic engagement only	Personalize timing of content delivery to users' demonstrated preferences	If no engagement with AM or PM check-ins but continued user-led engagement at other times	Then, send an "FYI/opt back in"[e] notification, and stop daily "AM check-in" and "PM check-in" notifications. Instead, each day, send a single personalized notification that directly opens to a relevant tool.	• Change in content engagement[c] compared to a preceding time interval
Symptom health flare[f]	Offer increased support when increased need is demonstrated	If symptom score (eg, PHQ-4[g] [51]) worsens compared to the preceding score and the user's current push notification frequency is less than maximal frequency	Then, send an "FYI/opt out"[e] notification, and increase notification frequency back to maximal frequency (eg, twice daily).	• Change in content engagement[c] compared to a preceding time interval
Accessibility	Reduce communication barriers	If user's typo frequency interferes with effective communication with the app or if user's typing speed is slower than a designated threshold	Then, send a notification that describes accessibility options (eg, increase font size, speech-to-text, text-to-speech) and offer to direct the user to their mobile device's accessibility settings	• Change in content engagement[c] compared to a preceding time interval

[a]JITAI: just-in-time adaptive interventions

[b]"Any engagement" is operationalized as opening the app during the specified target engagement time interval. This is a binary outcome.

[c]"Content engagement" is operationalized as the total number of tools, conversations, and check-ins the user engaged with during the specified target engagement time interval. This is a continuous outcome.

[d]FYI: for your information.



XSL•FO
RenderX

[e]If the "opt back in" or "opt out" option is selected, the rest of the intervention is not delivered.

[f]The "symptom flare" JITAI over-rides any engagement-related JITAIs which would otherwise reduce the frequency of push notifications to the user.

[g]PHQ-4: Patient Health Questionnaire-4.

Figure 2. Integration of established frameworks to guide identification and development of usability-related adaptations. FRAME-IS: Framework for Reporting Adaptations and Modifications to Evidence-based Implementation Strategies; JITAI: just-in-time adaptive intervention; BIT: Behavioral Integration Technology

Specifically for developing usability-related JITAIs, we applied Nahum-Shani's pragmatic framework for JITAI development and the Behavioral Integration Technology (BIT) model [52,53]. Nahum-Shani's pragmatic framework facilitated the systematic identification of opportunities for intervention using a JITAI [52]. That is, the framework was used to operationalize intended temporal progression of events through the app, which led to identification of promising opportunities for intervention with a JITAI. The BIT model facilitates effective translation of behavioral interventions into digital delivery systems. Specifically, we used the BIT model to design the JITAIs' instantiation elements with intentional incorporation of behavior change strategies, implementation science principles, and user interface design principles that appeal to our target population [54].

Analysis

Using a framework-informed hybrid inductive-deductive content analysis approach [55], iterative versions of general usability adaptations and usability-related JITAIs were developed and refined throughout the usability testing process based on feedback from participants and mapping to the analysis frameworks. As usability tests were completed, audio recordings of the usability tests were professionally transcribed (Rev.com), cleaned, and chunked (CYG). Three members of the study team (ALC, CYG, AM) collaboratively conducted open coding of the first 5 transcripts using an inductive, data-driven approach to identify concepts emerging from the data. Through discussion and consensus, they developed an initial codebook, which was then applied independently to pilot code the next 3 transcripts. Interrater reliability for these three transcripts was approximately 90%, with fewer than 5 coding discrepancies across coders. Discrepancies were resolved through consensus, and the codebook was refined accordingly. As usability tests were conducted with additional participants, the finalized codebook was applied using an independent open coding approach to these additional transcripts, each of which was coded by a single team member (CYG or AM), with periodic cross-checks between coders to ensure coding consistency. Coding was managed using NVivo 15 (Lumivero). Three team members (ALC, CYG, and AM) collaboratively and iteratively grouped related codes into preliminary themes that reflected participants' usability needs and suggested app adaptations, including JITAIs. This process was continued until analysis of additional transcripts no longer yielded new themes. Then, we conducted a deductive analysis by examining the inductively derived themes in relation to the FRAME-IS framework, Nahum-Shani's pragmatic framework for JITAI development, and the BIT model. The 3 team members (ALC, CYG, and AM) reviewed and discussed the themes to determine their alignment with these guiding frameworks, refine interpretation where appropriate, and translate findings into a final set of proposed general usability adaptations and usability-related JITAIs.

Reflexivity Statement

Usability testing was facilitated by a senior female research coordinator who has clinical research experience working with older adults and in the fields of mental health and orthopedics (AM). Participants' only contact with the facilitator was related to study recruitment, consent, and participation. The other 2 research team members who contributed to codebook development included a female physician scientist with a clinical background in physical medicine and rehabilitation (ALC), as well as a female physician trainee in physical medicine and rehabilitation residency (CYG). The clinical and musculoskeletal background of these team members may have influenced data collection and interpretation such that physical barriers and related adaptations were disproportionately considered over

XSL•FO
RenderX

solutions that considered mental health and systems-level factors. We worked to balance this potential bias by incorporating input from a clinician scientist with mental health clinical expertise (SH) and a health information technology expert (JA).

Rigor and Reproducibility

Informal member checking was performed by the facilitator (AM), who paraphrased and restated participants' feedback during the usability testing process to confirm that participants' intent and insights were accurately understood. Additionally, preliminary themes that emerged from early interviews were shared with later participants to assess for perceived validity. Participants generally affirmed the face validity of these themes.

Results

Of the 62 people who completed the screening questionnaire and were determined to be eligible, 42 users participated in usability testing (mean age 57, SD 8 years; women: n=32, 76%; mean chronic pain duration 16, SD 12 years) (Table 4). Reasons for nonparticipation included (1) not responding to invitations to schedule an appointment (or missing a scheduled appointment) (n=4), and (2) achievement of thematic saturation prior to their participation (n=16).

XSL•FO

Table . Characteristics of usability testing participants (N=42).

Characteristics	Values
Age (years), median (IQR; range)	55 (51-61; 45-76)
Sex[a], n (%)	
Female	32 (76)
Male	10 (24)
Race, n (%)	
White	30 (71)
Black or African American	9 (21)
Other	1 (2)
More than one race	1 (2)
Unknown or prefer not to answer	1 (2)
Ethnicity, n (%)	
Hispanic or Latino	3 (7)
Not Hispanic or Latino	36 (86)
Unknown or prefer not to answer	3 (7)
Employment status, n (%)	
Working full-time	11 (26)
Working part-time	4 (10)
Disabled	13 (31)
Retired	10 (24)
Unemployed	2 (5)
Prefer not to answer	2 (5)
Frequency of internet use[b], n (%)	
Most of the day	12 (29)
Multiple times a day	28 (67)
At least once a day	1 (2)
Less than once a day	1 (2)
High-impact chronic pain present[c], n (%)	33 (80)
BPI Pain Interference score[d], median (IQR; range)	7.1 (6 - 8.1; 2.4 - 9)
PHQ-9[e] score (years), median (IQR; range)	14 (12-17; 7-22)
GAD-7[f] score (years), median (IQR; range)	12 (9-15; 1-21)

[a]Sex and gender identity were concordant for all participants.

[b]Self-reported internet use was captured by the Pew Digital Savviness Classifier [56].

[c]"High impact chronic pain" is defined as pain that limits life or work activities on most or every day over the past 3 months [20].

[d]The Brief Pain Inventory (BPI) Pain Interference score ranges from 0 to 10 [57]. Higher scores indicate greater pain interference.

[e]The Patient Health Questionnaire (PHQ)-9 is a 9-item screening measure for depressive symptoms [39]. Scores range from 0 to 27. Higher scores suggest more depressive symptoms.

[f]The Generalized Anxiety Disorder (GAD)-7 is a 7-item screening measure for anxiety symptoms [40]. Scores range from 0 to 21. Higher scores suggest more anxiety symptoms.

We identified general usability adaptations, as well as usability-related JITAIs, that users perceived would enhance their app experience. Rapid, nearly universal convergence was achieved related to suggestions for general adaptations to provide a more thorough onboarding experience to the app (Table 2). Specifically, users requested clear, step-by-step navigation instructions, rather than a brief onboarding experience that relied on user-led exploration of the app and familiarity with conventional app symbols (eg, three vertical

XSL•FO
RenderX

ellipsis dots indicating "more options"). A 49-year-old female stated:

> *For those who may not be as familiar – and you're going to start getting a lot of those much older users, especially in this kind of a world with health concerns – I don't know that they would know what that [icon] means without a tour of the app first.*

Users also appreciated a customized app experience based on their unique challenges and app usage patterns, although specific desired customizations were somewhat varied, and no clear patterns emerged related to demographic characteristics or recruitment source, based on impressionistic observation.

Consistent with Nahum-Shani's pragmatic framework [52], the majority of participants favored that some of the usability-related JITAI opportunities be designed to strategically reduce notifications to the user in order to reduce the likelihood of a negative impact such as notification fatigue and subsequent complete disengagement with the app (Table 5). As one 60-year-old female participant said:

> *If I've not engaged in a week and after three days of nothing bothering me – no notifications – I think that a notification out of the blue would probably kick me back into gear. Give me that little kick start I need.*

When a notification is delivered, application of the BIT model [53] facilitated identification of the notification's instantiation components that were most appealing to users (Table 6).

Table . Application of Nahum-Shani's pragmatic framework which guided development of usability-related JITAIs to improve usability of a mental health app for nondigitally native adults who have chronic pain.

Component of Nahum-Shani's pragmatic framework	Application to target intervention and population
Defining the problem	
Whom are you trying to help?	• Nondigitally native adults, especially those who have chronic pain that coexists with symptoms of depression, anxiety, or both. This target population may be less likely than younger adults to readily and proficiently navigate through an app independently and find tools of interest.
What is the desired distal outcome of the JITAI([c]s)?	• Improve depression and anxiety symptoms (primary outcomes) • Improve behavioral activation, pain acceptance, and sleep quality (proposed mediators of primary outcomes)
What is the temporal progression of key factors towards the distal outcome?[b]	• Morning engagement: for behavioral activation (eg, activity scheduling and planning) • Evening engagement: for behavioral activation (eg, activity tracking, mood reflection), sleep optimization (eg, meditation) • Weekly engagement: for reflection and introduction of new cognitive behavioral skills (eg, cognitive reframing, thought recording) • Sustained engagement (8 wk): for growth, maintenance, and eventual independence with cognitive behavioral and pain self-management skills
What are contender proximal outcomes?	• Tool-specific engagement within the app
Defining just-in-time in the context of the identified problem	
What factors mark a state of vulnerability or opportunity?	• Lack of engagement with the app (as intended or as previously engaged)
What possible intervention options can affect the proximal outcomes?	• A notification or nudge that is noticed by, and appeals to, the user
What factors mark a state of unreceptivity to the selected intervention options?	• Already engaging with the app as intended or more frequently • Not responding to existing notifications or nudges
Formulating the adaptation strategy:	
What are the tailoring variables?	• User's current pattern of engagement
For each possible level of the tailoring variable, which intervention option is likely to have the desired effect on the proximal outcome?	• See Table 3. Additional research is needed to identify optimal cut-points for each tailoring variable.
What plausible decision rules can be generated to operationalize effective adaptation?	• See Table 3. Additional research is needed to identify optimal cut-points for each tailoring variable.

[a]JITAI: just-in-time adaptive interventions.

[b]The temporal progression described reflects how users are *intended* to engage with the app.

XSL•FO
RenderX

Table . Application of the BIT[a] model which guided development of usability-related JITAIs[b] to improve usability of a mental health app for nondigitally native adults who have chronic pain.

BIT component	Application to target intervention and population
Theoretical	
Why: aims	
Clinical aims	Improve depression and anxiety symptoms
Usage aims	Increase engagement with evidence-based therapeutic tools
How (conceptual): behavior change strategies	
Clinical strategies	Improve behavioral activation (eg, through goal setting), pain acceptance (eg, through pain neuroscience education and mindfulness exercises), and sleep quality (eg, through sleep hygiene education and meditation exercises)
Usage strategies	Direct user through a structured educational curriculum and on-demand access to therapeutic tools
Instantiation	
What: elements	Notifications that are delivered with personalized timing and content based on passively and actively collected data
How (technical): characteristics	Each push notification will feature a visual and audio alert, as permitted by the user's self-selected mobile device settings. The notifications direct the user to relevant therapeutic tools, as identified from the user's prior responses (eg, challenges expressed) and app engagement patterns. The content of the notifications is encouraging but not overly cheerful, with judicious use of emojis.
When: workflow	Timing of delivery of the push notifications is determined by event-based rules. However, precise timing relative to occurrence of the event(s) may be adaptive based on the user's engagement history and other characteristics.

[a]BIT: behavioral intervention technology

[b]JITAI: just-in-time adaptive intervention.

We identified 8 potential usability-related JITAIs to consider for build-out and formal effectiveness testing (Table 3). These JITAIs were developed to address the competing priorities of (1) providing predictable support to the user, and (2) acknowledging that pain and mood symptoms (and hence, a user's need for support) can fluctuate. Users reported varying preferences regarding the frequency of push notifications and indications to change the push notification frequency. Therefore, our JITAIs that propose to change the frequency of future push notifications all include an "opt back in" or "opt out" option so that users maintain autonomy over their app experience. As one 48-year-old male described:

> *Some people, if they're in a certain mental state, may need a little bit more persistence, whereas other people may need more space. I feel like me personally – if I didn't engage for a while and then had a [several-day break from notifications], it would be like, 'Hey, we're still here if you need us.' I think that would work for me personally, but I think it would all depend on the individual. If the app gave you an option or the ability to change the [notification frequency] or suggest how you want to be taken care of, yeah, I think that would be a good idea.*

The precise text of each JITAI notification is intended to be engaging and varied over time, even if the same JITAI is triggered more than once. As relevant and possible, the JITAI notifications should leverage information that was previously reported by the user in order to personalize the content and resonate with the user (eg, suggesting tools based on prior challenges reported, tools that were previously rated as helpful, and tools that have not been used yet but are expected to be helpful based on the user's reported challenges and prior tools used). When selected, most of the JITAI notifications are intended to directly open the app to a relevant tool for the user.

Discussion

Principal Results

In this study, we identified adaptations to an existing mental health app that better meet the stated usability preferences and needs of nondigitally native adults who have chronic pain and coexisting symptoms of depression or anxiety. Study participants specifically identified several opportunities to optimize their user experience by ensuring that the digital health intervention clearly describes how all its features are intended to be used and by minimizing navigation burden. For instance, users proposed general usability adaptations for a more robust orientation experience during app onboarding and for ongoing personalized engagement prompts using usability-related JITAIs.

XSL•FO
RenderX

Comparison With Prior Work

Based on prior literature and feedback from participants in this study [15,58], when identifying decision rules for our proposed JITAIs, we aimed to balance the use of passively collected app engagement data and user-directed triggers in order to respect users' dual desires for reduced navigation burden and also maintenance of autonomy and privacy. In related work [12], the majority of users in this target population expressed hesitation about allowing a digital mental health app to collect and use other data, such as physical location that is passively collected from their mobile device or other wearable sensors. Furthermore, older adults and those with multimorbidity are less likely to continuously carry a mobile device or use a wearable sensor, which would limit the impact of JITAIs that rely on datapoints from these sources [59-62]. As a result, the JITAIs developed in this study were intentionally designed to operate using only engagement-related and user-reported data that is collected within the app itself.

From a practical standpoint, the proposed JITAIs identified in this study represent general concepts that were perceived favorably by users. Determining the effectiveness of the proposed JITAIs and identifying ideal specific cut-points for each JITAI's tailoring variables (eg, number of hours or days of no app engagement before delivering an engagement-related JITAI) requires additional investigation. Although preliminary cutoff points for proposed JITAIs can be developed based on qualitative evidence from a usability study such as this, recommended best practices suggest follow-up investigation using complex analytical techniques to refine evidence-based (and potentially adaptive) cutoff points [15]. Implementation of potential JITAIs also depends on feasibility within the digital health platform, as well as confirmation that the final decision rules and cutoff points of the JITAIs do not conflict with one another or with other elements of the intervention's features or user experience. We plan to refine the details of these JITAIs using a series of microrandomized trials and additional qualitative user feedback [41].

In addition to leveraging existing evidence-based frameworks, we also leveraged an academic-industry partnership to expedite the incorporation of evidence-based principles into a digital health intervention with potential for rapid dissemination to the general public [63]. Specifically, the commercial app company facilitated participant access to the intervention and iterative mock-ups for the usability testing. The academic researchers led the usability testing itself and applied evidence-based frameworks to guide data collection and analysis. After the identified adaptations are fully built and subsequently tested for effectiveness, they can rapidly be rolled out to several thousand daily users in a much faster time scale than would be possible if an academic group developed a digital health intervention de novo. Our process to identify implementable usability-related adaptations of an existing mental health app can serve as a proof-of-concept method for relatively rapid refinement of other existing digital health interventions in order to better serve specific target populations, especially for apps that already have robust evidence-based content but could benefit from adaptations for specific subpopulations.

A major strength of this study is the integrated framework-based approach to identify usability-related opportunities for a target user population with unique needs. This approach can serve as a model for other studies, and the usability-related principles that were identified in this study are broadly generalizable for other digital health interventions that are intended for nondigitally native adults with multimorbidity. The robust sample size is also a strength relative to other digital health usability studies [64,65].

Limitations

Some limitations are inherent to the study design used. Observer bias (ie, the Hawthorne effect) may have resulted in participants reporting more confidence or demonstrating greater tenacity with technical features than they otherwise would in a real-world setting. Additionally, the iterative nature of our usability testing resulted in some heterogeneity in participant experiences. While participants were not exposed to identical interfaces, this approach is consistent with user-centered and formative usability evaluation methods, in which iterative refinement is prioritized to rapidly identify and address usability barriers [66]. Furthermore, details of some of the usability-related adaptations and JITAIs that were identified in this study are predominantly applicable to the specific mental health app that was tested. Our proposed adaptations also reflect participants' stated preferences, but quantitative assessment and data-driven refinement was outside the scope of this study. Finally, user preferences among nondigitally native adults may evolve over time as the population's overall experience with technology continues to grow.

Given the demographics of our sample, our study findings are likely most generalizable to middle-aged adults in the United States who are relatively digitally proficient and already use the internet routinely throughout the day. As a result, findings from this study may not fully capture the usability needs and other barriers faced by older adults with low digital literacy, which remains an important and underserved segment of the target user population. Interpretation of generalizability is also limited by the self-selected nature of the convenience sample and the lack of a standardized cognitive screening instrument, especially since the prevalence of mild cognitive impairment increases with age.

Conclusions

Identifying implementable opportunities to improve usability and prompt meaningful engagement at relevant timepoints holds promise to improve the effectiveness of digital health interventions because intervention attrition is a well-known challenge that is suspected to reduce the effectiveness of digital health interventions on a population level [67-70]. In this study, we used an integrated framework-based approach and user feedback to identify usability-related optimizations to an existing mental health app that are preferred among relatively digitally proficient but nondigitally native adults who have chronic pain and coexisting symptoms of depression or anxiety. Users identified general usability-related adaptations and usability-related JITAIs which were appealing for their potential to (1) provide clarity with regard to how to navigate the digital health intervention, and (2) reduce the user's burden of

XSL•FO
RenderX

independent navigation within the intervention. These usability-related refinement opportunities are generalizable to other digital health interventions intended for older users who are likely to be managing multimorbidity, are not digital natives, and are more likely to have physical or cognitive impairments than younger users (eg, medication reminder apps, daily safety monitoring apps, etc). The integrated framework-based approach taken in this study can also serve as a model for refinement of digital health interventions with other target populations, as well.

Acknowledgments

The authors thank Dr Patricia Areán for her contributions to the study conception. Generative artificial intelligence (AI) was not used in any portion of conducting this study or generating this manuscript.

Funding

This study was funded by the National Institute of Mental Health (grant R01MH131989; principal investigator ALC). The funder did not play a role in data collection, management, analysis, or interpretation of the data; writing of the report; or the decision to submit the report for publication. Use of Washington University's instance of REDCap for this study was supported by the Siteman Cancer Center's National Cancer Institute Cancer Center Support Grant P30CA091842 and by the Washington University Institute of Clinical and Translational Sciences Grant UL1TR002345 from the National Center for Advancing Translational Sciences.

Data Availability

The dataset generated and analyzed during this study is available in the National Institute of Mental Health (NIMH) Data Archive (NDA).

Conflicts of Interest

The academic study team was independent and distinct from the employees, developers, and owners of the Wysa for Chronic Pain intervention. Wysa conceived of and developed the original Wysa for Chronic Pain intervention and provided access to the Wysa for Chronic Pain intervention by the study team and study participants. Based on participant feedback obtained by the study team as part of grant R01MH131989, Wysa created intervention mock-ups to be used in the iterative usability testing of this study. Chaitali Sinha is the chief clinical research and development officer at Wysa, and she is a co-investigator on grant R01MH131989. Wysa was not involved in the development of the study design, conduct of the usability testing, data analysis, final interpretation of the data, or final decision to submit study findings for peer-reviewed publication.

Abstract

Background: Older adults with cognitive impairment often face significant challenges in memoir writing, including memory fragmentation, emotional loneliness, and speech and language disorders. Although AI-generated content (AIGC) technologies such as GPT-3.5 show potential in creative tasks, they often lack the personalization and adaptability required for users with dementia. Generic AIGC tools often fail to address the heterogeneous cognitive and emotional needs of this population.

Objective: This study aimed to design and evaluate, as a proof-of-concept, a personalized AIGC-powered chatbot to assist older adults with cognitive impairment in memoir writing and emotional support.

Methods: We developed a multimethod collaborative design framework integrating Kansei Engineering, Quality Function Deployment, Axiomatic Design, and the Technique for Order of Preference by Similarity to Ideal Solution decision model. The system dynamically adapts interaction strategies based on users' Mini-Mental State Examination (MMSE) scores, using a clinical threshold of 20 to distinguish mild (20-26) from moderate-to-severe (<20) impairment. In a single-session, nonrandomized, matched-pair evaluation using minimization-based allocation with an active control condition, performance was assessed via usability testing (System Usability Scale), affect assessment (Positive and Negative Affect Schedule), and blinded psychiatrist-rated memoir quality among 20 participants (10 per arm).

Results: The experimental group showed significantly greater improvement than the active control group in positive affect, negative affect, and psychiatrist-rated memoir quality (all *Ps*≤.03 by matched-pair analysis; all comparisons remained significant after Benjamini-Hochberg correction), with moderate-to-large effect sizes (Cohen *d*=0.85 - 1.03 for affect outcomes; rank-biserial *r*=1.00 for memoir quality). Within the sample (MMSE range 11 - 23), participants in the lower MMSE tier (<20; n=12) appeared to benefit more from AI-driven narrative generation, while those in the higher tier (20-23; n=8) responded better to keyword-based prompting; these subgroup observations are descriptive, given the small cell sizes. The mean System Usability Scale total score of 92.2 (SD 5.1) exceeded the acceptability threshold and fell in the excellent range, though single-session exposure and potential acquiescence bias warrant cautious interpretation.

Conclusions: These findings provide preliminary, hypothesis-generating evidence that a personalized AIGC-based chatbot may support short-term affective and narrative outcomes among older adults with cognitive impairment. The adaptive, multimodal design shows promise for human-AI collaboration in memoir writing and older adult care contexts, but larger, adequately powered randomized controlled trials with verified active control fidelity, multisession follow-up, and content source–differentiated outcome scoring are needed before clinical conclusions can be drawn.

Introduction

Dementia affects over 50 million individuals globally, impairing memory, cognition, language, and emotional processing, and this number is projected to grow significantly with the aging population [1]. Among nonpharmacological interventions, memoir writing has been shown to support cognitive function and emotional healing by preserving personal narratives and enhancing identity [2,3]. AI-driven approaches to structuring fragmented life narratives have shown early technical promise in organizing and preserving personal stories for therapeutic use [4]. However, traditional self-narration methods impose high cognitive demands, particularly for individuals with language difficulties and fragmented memory [5]. Emerging AI-generated content (AIGC) technologies such as GPT-3.5 offer new opportunities for content generation with minimal user input [5,6]; yet, most current systems are not designed to adapt to the cognitive and emotional needs of people with dementia.

By 2050, the global prevalence of dementia is projected to exceed 152 million [1]. Memoir writing, as a fundamental nonpharmacological intervention, has been increasingly validated for its dual benefits in cognitive preservation and emotional healing [2,3]. Nonetheless, the cognitive impediments (eg, memory fragmentation) and emotional requirements (eg, loneliness) of this demographic are predominantly unaddressed by current technologies [5,7]. Generic AIGC tools do not possess the necessary adaptability for dementia care [7]. This research gap highlights the urgent need for personalized, cognition-adaptive AIGC solutions. In addition to cognitive support, memoir writing functions as a means of preserving narrative identity and dignity [8,9]. Bitenc [9] emphasized that coherent life narratives play a crucial role in preserving selfhood in individuals with dementia, reinforcing the emphasis on both cognitive and emotional support in the chatbot design.

Recent studies in human-computer interaction (HCI) emphasize the role of asymmetric collaboration [10,11], where AI systems adapt dynamically to users with varying cognitive abilities. Assistive technologies can act as "ability balancers," helping patients with dementia engage meaningfully despite limitations [12-14]. Yet, most existing tools focus on functional or informational support and do not address the emotional and narrative dimensions central to memoir writing. AIGC tools like Replika have been explored for emotional companionship and mental health applications [15,16], but they often lack medical adaptability and rigorous ethical safeguards required in dementia care [17]. Existing dementia-focused chatbots have primarily targeted family caregivers rather than patients themselves [18], leaving a gap in direct patient-facing conversational support. Traditional dementia-assistive technologies emphasize personalization and usability [7,19], but seldom provide real-time narrative generation or emotion-sensitive feedback.

To address these limitations, we propose a personalized AIGC-powered chatbot that dynamically adjusts its interaction based on user cognitive states measured by Mini-Mental State Examination (MMSE) scores [20] and responds to emotional needs using Kansei Engineering (KE) principles [21]. The system integrates methods from mechanical engineering, packaging design, and HCI, aiming to support memoir writing, improve emotional well-being, and enable adaptive, human-centered AI experiences for older adults with cognitive impairment. This interdisciplinary design adheres to contemporary evidence on nonpharmacological interventions in dementia, which have demonstrated efficacy in improving emotional well-being [22,23], and addresses the demand for emotion-centric and cognition-adaptive assistive technologies in HCI and gerontechnology research [24,25].

This paper makes 3 contributions. First, we present a cognition-adaptive AIGC chatbot designed specifically to support memoir writing among older adults with cognitive impairment. The system combines MMSE-based interaction control with a structured life-event memory system and caregiver-verified memory anchors. Second, we describe a reproducible multimethod design process integrating KE, Quality Function Deployment (QFD), Axiomatic Design (AD), and Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) to translate affective and cognitive needs into system specifications. Third, we report a preliminary matched-pair evaluation involving 20 participants, using a minimization-based allocation procedure to examine short-term changes in affect, psychiatrist-rated memoir quality, and perceived usability. The study is intended as a proof-of-concept evaluation of the system's feasibility and potential rather than evidence of clinical efficacy. Additional design details are provided in Multimedia Appendix 1.

Methods

Research Objectives

This study aimed to design and evaluate a personalized AIGC-based chatbot to support older individuals with cognitive impairment in memoir writing and emotional support. The system dynamically adapts its interaction mode based on users' MMSE scores, offering keyword prompts for those with mild impairment and active narrative generation for those with severe cognitive decline. The chatbot identifies and responds to emotional needs such as loneliness and the desire for achievement through KE principles. Following system design, a user evaluation study assessed effectiveness.

System Design

Design Framework

To develop a personalized AIGC system supporting memoir writing for older individuals with dementia, we adopted a multistage collaborative design framework integrating KE, QFD, AD, and the TOPSIS decision model.

In the first stage, KE was applied to identify users' emotional and psychological needs, drawing on the dementia-care literature on memory loss, caregiver burden, and identity disruption to derive core affective themes such as "frustration from forgetting" and "the desire for recognition." In the second stage, QFD mapped these emotional needs to quantifiable technical specifications, such as ensuring a natural language processing

XSL•FO
RenderX

response delay of less than 2 seconds and incorporating a comforting tone in audio feedback. In the third stage, AD decomposed the system into 3 functionally independent but complementary modules: memory triggering, narrative generation, and emotional feedback. Finally, the TOPSIS method evaluated and selected among 3 intervention strategies (low, medium, and high AI proactivity), with emotional needs weighted more heavily than technical complexity to prioritize emotionally resonant interactions.

This multimethod framework is supported by existing literature. Li and Li [26] demonstrated that combining KE, QFD, and AD can improve user satisfaction in medical product design for older adults, providing empirical support for this multimethod approach. The emotional needs mapping in the QFD phase aligns with the finding of Raghunath et al [24] that translating user needs into structured design specifications can meaningfully reduce cognitive demands on users. The emphasis on emotional needs in the TOPSIS model is further supported by ethical research underscoring emotional well-being as a fundamental outcome in dementia care [23].

System Implementation

The system uses GPT-3.5 as its core AIGC engine, integrated within a companion device intended for home use. The device's main controller processor coordinates a Wi-Fi module for wireless connectivity; ultrasonic sensors and an indicating light for environmental sensing and status feedback; a speech recognition chip linked to a microphone for voice input; a speech decoding and playback module linked to a horn for audio output and to a USB flash drive, TF card, and flash memory for local audio storage; and a TC117 driving chip powered jointly by a battery and an SY8101B power module. Interaction is controlled through prompt engineering: high-level prompt templates define the system's role, task objectives, and interaction norms, with placeholders reserved for cognitive state variables. A typical template reads: "You are a memoir construction assistant for older adults. Based on the user's cognitive level (MMSE score: [X]), guide them to elaborate on life events [Event List] through simple, step-by-step questions. Ensure your responses are concise, empathetic, and aligned with the user's cognitive capacity; avoid complex sentence structures or ambiguous prompts."

Adaptive control logic maps MMSE scores to interaction strategies. The MMSE threshold of 20 follows established clinical practice: scores of 20 to 26 indicate mild cognitive impairment, and scores below 20 indicate moderate-to-severe impairment per standard neuropsychological guidelines [20]. When scores fall within 20 to 26 (mild cognitive impairment), the system prioritizes open-ended guided prompts. When scores fall below 20 (moderate impairment), the system switches to closed-ended, yes or no, or multiple-choice prompts to reduce cognitive load. Generation parameters are dynamically adjusted across three dimensions: (1) prompt granularity, with step-by-step prompts triggered for scores of 20 or below; (2) response length, limited to 50 to 80 words for scores below 20 and 100 to 150 words for scores of 26 or above; and (3) memory retrieval cues, with more sensory and contextual cues incorporated for users with lower scores. In the present sample (MMSE range 11‐23), all participants fell within the below 20 or 20‐26 tiers; the 26-or-above response-length strategy was not triggered.

Recorded life events serve as foundational memory anchors. Initial acquisition follows a 2-step process: trained researchers conduct semistructured interviews of 30 to 45 minutes, and family members or caregivers complete a supplementary questionnaire. Storage uses a structured relational database organized hierarchically to support efficient retrieval. Cross-session updates follow 3 rules: supplemental update of newly mentioned events, semantic deduplication (cosine similarity threshold ≥0.8), and emotional tagging based on subsequent narratives. Feng et al [27] confirmed that emotional tagging enhances memory cue efficacy.

The system combines voice guidance with a visual timeline interface. The voice module delivers preloaded audio responses—recorded and stored locally on the device rather than generated via cloud text-to-speech. Emotional alignment is achieved through a rule-based mapping layer: the adaptive control logic classifies each interaction turn into 1 of 5 predefined emotional states (encouragement, gentle redirection, empathetic acknowledgment, memory affirmation, and session closure) based on MMSE score, topic category, and detected response latency, and selects the corresponding preloaded audio clip. The visual timeline interface presents life events in a hierarchical, chronologically organized format, reducing barriers for users with language and cognitive decline.

Evaluation

Participants

Participants were recruited through online platforms (WeChat, Xiaohongshu, Bilibili, and Baidu) and in-person community outreach in Hebei, Henan, Tianjin, and Shandong provinces in China. Inclusion criteria: aged 65 to 80 years; clinically confirmed diagnosis of cognitive impairment by a neurologist or psychiatrist based on *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) criteria [28]; basic verbal communication abilities; and voluntary participation with written informed consent from participant and legal representative. Exclusion criteria: poor health requiring continuous medical care, severe psychiatric or behavioral symptoms, and severe uncorrectable sensory impairments.

Psychiatrists were recruited as independent evaluators. Inclusion criteria: valid clinical license in psychiatry, active practice in frontline psychiatric settings, at least 5 years of independent clinical experience, and clinical or research experience in geriatric psychiatry or neurocognitive disorders. Psychiatrists were excluded for conflicts of interest, personal relationships with participants, or inability to maintain blinding. All psychiatrists completed standardized rater training before formal scoring.

Ethical Considerations

This study received ethics approval from the institutional review board of Southwest University (SW20250115). All procedures complied with the Declaration of Helsinki. Each participant received about US $15 as compensation. The use of generative

XSL•FO
RenderX

AI in memoir construction for individuals with reduced decision-making capacity raises ethical considerations beyond standard research ethics protocols. Four issues were addressed in the study design. First, informed consent explicitly covered AIGC: participants and their legal representatives were informed that the system may generate or paraphrase narrative text based on caregiver-verified memory anchors, and that this content would be incorporated into the memoir transcript. Second, output transparency was built into the caregiver verification workflow: caregiver-verified memory anchors were flagged in the system database, allowing a postsession distinction between content spoken directly by the participant, content paraphrased by the system, and content generated from verified anchors. Third, data governance: memoir-related inputs processed via the GPT-3.5 API were limited to anonymized life-event descriptors; no personally identifiable information was transmitted to the API, and all locally stored data are subject to deletion upon participant request. Fourth, caregiver verification was required before any memory anchor was added to the database, ensuring that AI-generated narrative content remained grounded in the participant's actual experience rather than system-inferred assumptions [17,23].

Procedures

Researchers collected demographic and clinical information including age, sex, diagnosis, medical history, MMSE score, and years of education. Participants completed the Technology Use Attitudes and Proficiency Questionnaire and the Positive and Negative Affect Schedule (PANAS) and narrated a recent personal story for 5 minutes. Audio recordings were transcribed with consent and rated by psychiatrists using predefined criteria (see Multimedia Appendix 2 for MMSE).

Factor matching minimized baseline imbalance on 4 variables: MMSE total score, baseline memoir quality, years of education, and technology use attitudes and proficiency. Pairs were formed only after all 20 participants had completed baseline assessment. A researcher not otherwise involved in the subsequent group-assignment step reviewed the baseline profiles of all enrolled participants across these same 4 variables and manually grouped them into 10 pairs of participants judged to be most similar in overall baseline profile; this pairing was completed independently of, and prior to, any group assignment. Group allocation used a minimization procedure rather than simple randomization: for each of these 10 pairs, a researcher not otherwise involved in participant recruitment or assessment determined, in real time, which assignment of the 2 paired participants would minimize cumulative imbalance between the intervention and control groups across the 4 matching variables, and assigned the participants accordingly. This was a nonrandomized allocation procedure: assignment was determined by the minimization algorithm's real-time balancing calculation rather than by chance (eg, a random-number generator or coin flip), and no random element was used at any stage of group assignment.

All participants completed a 10-minute oral memoir narration in the same controlled environment. The intervention group received assistance from the AIGC system, while the control group received an active control condition matched to the intervention group in session duration, number of prompting turns, frequency of audio feedback, device novelty, and researcher behavior, with only the AI-generated personalization and memory anchor–driven narrative removed. The entire process was audio-recorded and transcribed with participant consent. After the intervention, all participants completed the PANAS again. For the intervention group, AI-paraphrased content and AIGC were excluded from the transcript prior to rating, using the content-source flags recorded in the system database, so that only content spoken directly by the participant was retained for evaluation. Psychiatrists blinded to group assignment independently rated these participant-only transcripts; control-group transcripts were unaffected by this procedure, as they contained no AIGC. Intervention group participants also completed the System Usability Scale (SUS) and were interviewed about their experience (see Multimedia Appendix 3 for SUS).

All 10 intervention group participants completed a semistructured, one-on-one interview lasting approximately 15 to 20 minutes, using a guide (Multimedia Appendix 4) covering 5 domains: usability experience, emotional experience, perceived authenticity of AIGC, cognitive load, and willingness to continue use. Each domain began with a broad, nonleading question, followed by neutral, nondirective probes (eg, "could you say more about that?") to elicit elaboration without suggesting a valenced response. Interviews were audio-recorded with consent. Because the interview sample coincided with the full intervention arm, no independent saturation criterion was applied.

Data Analysis

Quantitative Analysis

Affective measures were assessed using the PANAS [29], which contains two 10-item subscales measuring positive affect (PA) and negative affect (NA) on a 5-point scale (1=very slightly or not at all; 5=extremely). Both subscale scores range from 10 to 50.

We assessed the consistency of the physicians' ratings, which serves as the foundation for the subsequent data analysis. Interrater reliability was good to excellent: composite memoir quality intraclass correlation coefficient (ICC)=0.82, narrative coherence ICC=0.83, richness of detail ICC=0.81, and personal uniqueness ICC=0.85.

Memoir quality was evaluated by psychiatrists across 3 dimensions: narrative coherence, richness of detail, and personal uniqueness, on a 5-point scale (1=very poor; 5=excellent). All psychiatrists rated transcripts in a fully blinded manner.

System usability was assessed using the simplified SUS [30], in which odd-numbered items are positively worded and even-numbered items are negatively worded; even-numbered items were reverse-scored prior to analysis, and the total score was computed as the sum of all adjusted item scores multiplied by 2.5, yielding a scale of 0 to 100. Technology use baseline was measured using a Technology Use Experience and Attitudes Questionnaire scored 0 to 40.

XSL•FO
RenderX

Analyses proceeded in four steps: (1) baseline comparability, (2) normality testing of within-group pre- and postdifference scores and of matched-pair between-group difference scores using the Shapiro-Wilk test, (3) within-group pre- and postcomparisons, and (4) between-group comparisons conducted on matched-pair differences, treating each matched pair as the unit of analysis. Because participants were allocated within matched pairs using a minimization procedure, the primary between-group analysis used paired *t* tests or Wilcoxon signed rank tests where normality of the matched-pair differences was violated. Parametric paired *t* tests were applied where normality held; Wilcoxon signed rank tests were applied elsewhere. All tests were 2-tailed (α=.05). Effect sizes are reported as Cohen *d* (normally distributed differences) or rank-biserial correlation *r* (nonnormal distributions).

To account for multiple comparisons across the 3 prespecified coprimary outcomes (PA, NA, and psychiatrist-rated memoir quality), we applied Benjamini-Hochberg correction (Q=0.05) to the 6 hypothesis tests involving the experimental condition (3 within-group and 3 between-group matched-pair comparisons). Baseline equivalence tests were excluded, as these test for nondifference and are not part of the confirmatory hypothesis family.

All quantitative analyses were conducted in R (version 4.3.2; R Foundation for Statistical Computing).

Qualitative Analysis

Audio recordings of the interviews were transcribed verbatim after participants gave consent, and researchers then checked the transcripts against the recordings and manually corrected obvious speech recognition errors and dialect expressions to ensure that the transcripts accurately reflected participants' original words. Transcripts were deidentified before analysis, retaining only participant identification numbers and no personally identifiable information, and all coding was carried out in NVivo software (Lumivero) to facilitate code management and retrieval.

The analysis used reflexive thematic analysis. Coding was carried out independently by 2 researchers, each of whom read through all transcripts and assigned initial codes, without aiming in advance for agreement between their coding results. After independent coding was completed, the 2 researchers compared their coding results through discussion, examined each disagreement in turn, reinterpreted the material in light of its original context, and reached consensus through discussion or retained legitimate alternative interpretations, an approach consistent with the methodological position of reflexive thematic analysis, which treats coding as an interpretive and subjective process of knowledge production. Building on the coding, related codes were grouped and merged to progressively develop higher-level themes and subthemes, a thematic map was produced to show the hierarchy and relationships among themes, and a complete audit trail was maintained to document how the coding evolved from initial codes to final themes. Throughout the analysis, the emerging themes were continually checked against the original interview material to avoid overinterpretation detached from the data itself, and the recordings were revisited when necessary to verify tone and context.

Results

Overview

This study recruited 20 participants aged 67 - 80 years. Baseline MMSE scores spanned the range of mild to moderate cognitive decline, and there was individual variation in baseline memoir quality (as assessed by a psychiatrist) as well as in attitudes toward and proficiency in technology use. Participants had 3 - 12 years of education, reflecting the characteristics of an older population with diverse educational backgrounds. Detailed participant information is provided in Multimedia Appendix 5. There were no participant dropouts throughout the entire experimental process.

Quantitative Results

Baseline comparability between the experimental (n=10) and control (n=10) groups was evaluated using paired *t* tests and standardized mean differences (SMDs). No statistically significant differences were found on any baseline variable (all P>.05), and all SMDs were negligible (|SMD|≤0.20), confirming successful group equivalence prior to the intervention (Table 1).

XSL•FO
RenderX

Table . Baseline demographic and clinical characteristics of experimental (n=10) and active control (n=10) participants in a single-session, nonrandomized, matched-pair evaluation of an AIGC[a]-based memoir-writing chatbot among older adults aged 67 - 80 years with clinically diagnosed cognitive impairment, recruited from Hebei, Henan, Tianjin, and Shandong provinces, China.

Variable	Experimental, mean (SD)	Control, mean (SD)	SMD[b]	*t* test[c] (*df*=9)	*P* value
MMSE[d] total score	17.60 (3.84)	17.80 (3.79)	−0.052	−1.000	.34
Psychiatrist-rated baseline memoir quality	2.77 (0.63)	2.85 (0.54)	−0.128	−0.605	.56
Technology attitude and proficiency	18.10 (4.07)	18.20 (4.24)	−0.024	−0.287	.78
Education (years)	6.60 (2.76)	6.10 (2.23)	+0.199	1.861	.10
Age (years)	72.70 (3.74)	73.10 (3.90)	−0.105	−1.500	.17

[a]AIGC: AI-generated content.

[b]SMD: standardized mean difference.

[c]Paired *t* test.

[d]MMSE: Mini-Mental State Examination.

As shown in Table 2, normality of difference scores was assessed using the Shapiro-Wilk test, separately for within-group pre- and postdifferences and for the matched-pair between-group differences that form the basis of the primary analysis. Within-group differences were normally distributed only for PA in the experimental group (W=0.866; P=.09); all remaining within-group differences violated the normality assumption (Ps<.05). Among the matched-pair between-group differences, PA (W=0.909; P=.28) was normally distributed and was analyzed with a paired *t* test; NA (W=0.843; P=.048) and psychiatrist-rated quality (W=0.833; P=.04) violated normality and were analyzed with the Wilcoxon signed rank test.

Table . Shapiro-Wilk tests of normality for within-group and matched-pair between-group difference scores in positive affect, negative affect, and psychiatrist-rated memoir quality, among 20 older adults with cognitive impairment participating in a single-session, nonrandomized, matched-pair evaluation of an AIGC[a]-based memoir-writing chatbot in China.

Difference tested	Group or level	*W*	*P* value	Normal (P≥.05)	Test selected
Positive affect	Within-group, experimental	0.866	.09	Yes	Paired *t* test
Positive affect	Within-group, control	0.774	.007	No	Wilcoxon
Negative affect	Within-group, experimental	0.768	.006	No	Wilcoxon
Negative affect	Within-group, control	0.731	.002	No	Wilcoxon

Positive affect	Between-group, matched-pair difference	0.909	.28	Yes	Paired *t* test
Negative affect	Between-group, matched-pair difference	0.843	.048	No	Wilcoxon
Psychiatrist quality	Between-group, matched-pair difference	0.833	.04	No	Wilcoxon

[a]AIGC: AI-generated content.

Within-group changes were examined separately for each group; all tests were 2-tailed (α=.05). In the experimental group, PA increased significantly from pretest (mean 23.50, SD 4.58) to posttest (mean 25.30, SD 4.74; Δ=1.80, 95% CI 0.55-3.05; t_9=3.25; P=.01; Cohen d=1.03); the control group showed no significant change (Δ=−0.20; W=10.0; P=.54; r=−0.29). NA decreased significantly in the experimental group from pretest (mean 22.10, SD 5.22) to posttest (mean 18.40, SD 3.69; Δ=−3.70, 95% CI −7.19 to −0.21; W=3.0; P=.01; r=−0.89); the control group showed no significant change (Δ=0.50; W=0.0; P=.09; r=1.00). Psychiatrist-rated memoir quality, assessed from participant-generated content only, improved significantly in the experimental group from pretest (mean 2.775, SD 0.63) to posttest (mean 2.95, SD 0.73; Δ=0.175, 95% CI 0.054-0.296;

XSL•FO
RenderX

W=0.0; *P*=.03; *r*=1.00); the control group showed no significant change (Δ=−0.05; *W*=2.5; *P*=.42; *r*=−0.50). Full within-group results are presented in Table 3. Additionally, Multimedia Appendix 6 presents separate ratings for AIGC.

Table . Within-group pre- to postintervention changes in positive affect, negative affect, and psychiatrist-rated memoir quality for the experimental (AIGC[a] chatbot-assisted) and active control groups, in a one-time experimental evaluation among 20 older adults with cognitive impairment in China.

Outcome and group	Preintervention, mean (SD)	Postintervention, mean (SD)	Δ (95% CI)	Test statistic	*P* value	Effect size
Positive affect						
Experimental	23.50 (4.58)	25.30 (4.74)	1.80 (0.55 to 3.05)	t_9=3.25	.01	*d*=1.03
Control	23.10 (4.25)	22.90 (3.96)	−0.20 (−1.14 to 0.74)	*W*=10.0	.54	*r*=−0.29
Negative affect						
Experimental	22.10 (5.22)	18.40 (3.69)	−3.70 (−7.19 to −0.21)	*W*=3.0	.01	*r*=−0.89
Control	25.30 (5.21)	25.80 (4.71)	0.50 (−0.01 to 1.01)	*W*=0.0	.09	*r*=1.00
Psychiatrist-rated quality						
Experimental	2.77 (0.63)	2.95 (0.73)	0.175 (0.054 to 0.296)	*W*=0.0	.03	*r*=1.00
Control	2.85 (0.54)	2.80 (0.57)	−0.05 (−0.16 to 0.06)	*W*=2.5	.42	*r*=−0.50

[a]AIGC: AI-generated content.

Between-group comparisons were conducted on matched-pair differences rather than independent-samples tests, because participants had been allocated within matched pairs, and each pair therefore constitutes the appropriate unit of comparison. Paired *t* tests were used for PA and psychiatrist-rated memoir quality, and the Wilcoxon signed rank test was used for NA, based on the normality of the matched-pair differences (Table 2). The experimental group showed significantly larger improvements than the control group across all 3 outcomes: PA (matched-pair Δ=2.00, 95% CI 0.31-3.69; t_9=2.68; *P*=.03; Cohen *d*=0.85), NA (matched-pair Δ=−4.20, 95% CI −7.59 to −0.81; *W*=2.0; *P*=.008; rank-biserial *r*=−0.93), and psychiatrist-rated memoir quality, assessed from participant-generated content only (matched-pair Δ=0.225, 95% CI 0.093-0.357; *W*=0; *P*=.02; rank-biserial *r*=1.00; Table 4).

Table . Matched-pair between-group comparison of change scores in positive affect, negative affect, and psychiatrist-rated memoir quality between the AIGC[a] chatbot-assisted experimental group and the active control group, among 10 matched pairs of older adults with cognitive impairment in a one-time experimental evaluation in China.

Outcome	Matched-pair Δ, mean (SD)	95% CI	Test statistic	*P* value	Effect size
Positive affect	2.00 (2.36)	0.31 to 3.69	t_9=2.68	.03	*d*=0.85
Negative affect	−4.20 (4.73)	−7.59 to −0.81	*W*=2.0	.008	*r*=−0.93
Psychiatrist-rated quality	0.225 (0.184)	0.093 to 0.357	*W*=0	.02	*r*=1.00

[a]AIGC: AI-generated content.

To account for multiple comparisons across the 3 prespecified coprimary outcomes (PA, NA, and psychiatrist-rated memoir quality), we applied Benjamini-Hochberg correction (*Q*=0.05) to the 6 hypothesis tests involving the experimental condition (3 within-group and 3 between-group matched-pair comparisons). Baseline equivalence tests in Table 1 were excluded, as these test for nondifference and are not part of the confirmatory hypothesis family. All 6 tests remained significant after correction ($q \leq 0.031$; Table 5). The 3 within-group control-condition comparisons, reported descriptively, remained nonsignificant ($P \geq .089$).

XSL•FO
RenderX

Table . Benjamini-Hochberg (BH) false discovery rate correction applied to the 6 confirmatory hypothesis tests (3 within-group and 3 matched-pair between-group comparisons) for positive affect, negative affect, and psychiatrist-rated memoir quality, among 20 older adults with cognitive impairment participating in a single-session, nonrandomized, matched-pair evaluation of an AIGC[a]-based memoir-writing chatbot in China.

Test	Raw *P* value	Rank	BH-adjusted *q*	Significant ($q<0.05$)
Between-group, negative affect	.008	1	.024	Yes
Within-group, positive affect	.01	2	.024	Yes
Within-group, negative affect	.01	3	.024	Yes
Between-group, psychiatrist quality	.02	4	.024	Yes
Between-group, positive affect	.03	5	.030	Yes
Within-group, psychiatrist quality	.03	6	.031	Yes

[a]AIGC: AI-generated content.

System usability was assessed using the simplified SUS [30], in which odd-numbered items are positively worded and even-numbered items are negatively worded; even-numbered items were reverse-scored prior to analysis. The mean SUS total score among intervention group participants was 92.2 (SD 5.1; range 82.5 - 97.5), which exceeds the widely used acceptability threshold of 68 and falls within the "excellent" range (>85) for dementia-assistive technologies [31,32]. Individual scores ranged from 82.5 (Participant 10) to 97.5 (Participant 6 and Participant 7), with no participant scoring below the acceptable threshold. Subscale analysis following Orgeta et al [22] yielded a mean effectiveness score (items 1, 3, 5, 7, and 9) of 4.80 (SD 0.19) and a mean simplicity score (items 2, 6, 8, and 10) of 4.47 (SD 0.40), both on a 1 - 5 scale, indicating consistently high perceived effectiveness and adequate simplicity across participants.

The experimental group showed greater improvement than the active control group across PA, NA, and psychiatrist-rated memoir quality. Because the control condition was matched to the intervention condition in session duration, number of prompting turns, frequency of audio feedback, device exposure, and researcher behavior, the observed differences are less likely to be explained solely by interaction time or device novelty. However, the fidelity of the manually delivered control condition was not independently assessed, and the study was not designed to determine which specific component of the AIGC intervention—personalized prompting, memory-anchor retrieval, narrative generation, or their combination—accounted for the observed differences. The findings should therefore be interpreted as preliminary evidence concerning the integrated intervention rather than as proof of the effectiveness of any single system component.

Subgroup patterns offer additional insight. In the present sample, 12 of 20 participants (experimental: n=6; control: n=6) had MMSE scores below 20 (range 11 - 18), triggering the closed-ended, high-proactivity interaction mode; the remaining 8 (experimental: n=4; control: n=4) had MMSE scores of 20 - 23, triggering the open-ended, keyword-based mode. Participants in the lower MMSE tier appeared to benefit more from AI-driven narrative generation, while those in the higher tier responded better to keyword-based prompting. This is consistent with cognitive load theory [33]: when residual capacity is limited, proactive narrative scaffolding reduces the compositional burden and allows users to engage with their memories without being overwhelmed. Users with greater preserved capacity may find fully automated narrative generation less engaging, though the mechanism remains speculative. These patterns tentatively suggest that cognitive severity may shape the appropriate level of AI proactivity, and that a uniform interaction mode would be inadequate for this population. Given the small *n* within each tier (6 and 4 per group), these observations are descriptive and should not be interpreted as subgroup-level statistical conclusions.

Qualitative Results

First, most participants reported some initial trial and error during the first 1 or 2 conversational turns within the session, but that they became more familiar with the system as the number of turns increased. (Throughout this section, references to "uses" or "times" refer to individual conversational turns or exchanges within the single, approximately 10-minute session, not separate sessions on different occasions.) This pattern of initial difficulty followed by increasing fluency recurred throughout the interviews, particularly with regard to the timing and triggering of voice commands. Many participants mentioned that during their first few turns they were unsure "when they should speak and when they should wait for the system to finish speaking," and this uncertainty clearly diminished as the session progressed.

> *At the beginning I did not really know how to use it, but fortunately the system was simple, and after using it a few times I got the hang of it . Later on I did not really get stuck anymore. (The references to "few times" by the participants here refer to multiple rounds of dialogue, rather than the conduct of multiple experiments.)* [Participant 2]

XSL•FO
RenderX

Second, in terms of emotional experience, participants' descriptions showed a fairly consistent positive tendency. Most described the act of "telling their story" itself as a process of being taken seriously and being listened to. Some participants compared this with their everyday communication with family and friends, feeling that the system "does not interrupt" and "does not get impatient," which they saw as setting it apart from interpersonal communication.

> *It was a lot of fun. I think it gave me a fairly good window that made it convenient for me to express myself. How should I put it, it lets me talk, and I mean that in a meaningful sense, like confiding in someone, it made that more convenient. It was very patient, it did not interrupt me, and it let me finish speaking slowly.* [Participant 1]

Next is the issue of autonomy. This was the theme discussed in the greatest depth in the interviews, and the one on which participants' attitudes diverged most clearly. Most participants felt that even though the system organized and rewrote their spoken content, the resulting story still "belonged to them," because the core facts and emotions came from themselves and the system only played a supporting role in "polishing" or "recording" it.

> *I think the story is my own. As for the final generated result, when I look at most of it, I feel it matches what I wanted to express, and there is not really a problem.* [Participant 3]

However, a small number of participants (such as Participant 6 and Participant 8) expressed more nuanced reservations, noting that the wording the system produced after rewriting sometimes differed from their usual way of expressing themselves. They hoped to have the opportunity to check or revise the rewritten portions rather than simply accepting the final text passively.

> *Even though on the whole I feel most of it is fitting, to be honest some of the details still feel a bit off to me. For example that table, the one it generated, is not entirely how I wanted it to look. But it is true that if you wanted it to be completely accurate, that would probably take a lot of effort.* [Participant 6]

Regarding the system's design of adjusting its prompting style according to cognitive state (open-ended prompts vs stepwise closed-ended prompts), participant feedback showed a divergent trend related to their self-reported cognitive burden. Among participants with lower cognitive burden (corresponding to the MMSE stratum of 20 to 23), some felt that stepwise prompting was "a bit wordy" and preferred to speak directly and freely, feeling that their train of thought was interrupted.

> *I feel it could be more concise. Sometimes it says things that feel unnecessary, and I do not think those are really needed.* [Participant 7]

Participants with higher cognitive burden (corresponding to an MMSE score below 20), by contrast, were more inclined to report that stepwise prompting "was a huge help," reducing the pressure of organizing their language and easing the anxiety of "not knowing where to start."

> *I think it was extremely useful, it helped me a lot. Otherwise, having to do everything myself would really have been difficult.* [Participant 4]

This divergence corroborates the original intent behind this study's MMSE stratified design, namely, that greater cognitive burden calls for more structured guidance. It also suggests that future versions could allow users to actively switch the density of prompting during use rather than having it entirely preset by the system, so as to accommodate the desire for autonomous expression among participants with milder impairment. It should be noted that because this study is only a preliminary formative study with a small sample size, it is difficult to support adequate subgroup analysis, and the description above should be treated only as an indication of a trend.

With regard to willingness to continue using the system, all participants expressed a positive attitude, but this positive attitude often came with specific conditions. For example, whether the system could remember what had previously been said (to avoid the fatigue of repeating the same content) and whether interest would wane once the novelty faded.

> *It is easy to use, a lot of fun, and interesting, but I am not sure whether it can keep a record. I hope it can keep recording continuously and save all of it permanently.* [Participant 10]

One participant, Participant 8, linked the willingness to continue using the system to a deeper motivation, that of "leaving something behind for later generations," which goes beyond a purely instrumental evaluation of the tool and positions the system as a medium for recording and passing things on rather than simply a companion or entertainment tool.

> *After I am gone, this will count as a kind of digital photo album too, and that is a good thing.* [Participant 8]

Discussion

Principal Findings

Improvements in PA and NA, as measured by PANAS, suggest that the system may have supported emotional well-being during the memoir-writing session. This aligns with the KE component of the design framework, which translated affective needs (eg, the desire for recognition and anxiety about forgetting) into features such as empathetic audio feedback and sensory memory cues. Pappadà et al [7] noted that dementia-assistive technologies tend to prioritize cognitive function while underserving emotional needs; these results suggest that emotional engineering principles may contribute meaningful affective benefits.

The empirical findings, together with the design process, suggest 3 implications for future dementia-assistive AIGC systems. First, AI proactivity should adapt to cognitive capacity: more severe impairment calls for greater AI narrative initiative, while milder impairment is better served by user-driven prompting that preserves authorial agency, or the user's sense that the memoir remains their own story. Second, memoir tools should support affective safety alongside memory retrieval. Third, long-term personalization requires a structured life-event

XSL•FO
RenderX

memory system with caregiver verification mechanisms and ethical safeguards to ensure that AIGC remains grounded in the user's actual experience. The multimethod design framework (KE, QFD, AD, and TOPSIS) remains relatively underexplored in dementia-assistive technology [21] and may offer a reproducible starting point for similar work.

Comparison to Prior Work

This study extends prior work on AI-mediated reminiscence and narrative support for older adults [5,12,27]. More broadly, multimodal AI-driven platforms have also shown promise in supporting expressive and creative interventions for home-based older adult care, such as interactive art therapy systems [34], reinforcing the potential of AI-based creative engagement to benefit older populations beyond memoir writing specifically. Wang et al [12] demonstrated that AI-driven multimodal photo albums support personalized reminiscence in cognitively intact older adults; our study extends this to individuals with diagnosed cognitive impairment, using MMSE scores to drive adaptive interaction control. Feng et al [27] found that contextual and multimodal stimuli enhanced engagement in people with dementia during human-robot interaction; our results suggest that similar multimodal principles may be effective in chatbot-mediated memoir writing. Chang et al [35] further demonstrated that reinforcement learning-based AI can deliver personalized adaptive support in dementia care contexts, reinforcing the value of dynamic AI adaptation for this population.

The present findings also converge with recent longitudinal evidence. Kang et al (2025) [36] found that regular AI care calls over 7 months significantly reduced depression scores and improved memory function in 80 community-dwelling individuals with dementia. That study found that sex and education level moderated intervention outcomes, paralleling our subgroup finding that cognitive severity shapes response to AI interaction and reinforcing the view that individual characteristics meaningfully affect how people with dementia benefit from AI-based support.

The findings also speak to HCI discussions of asymmetric human-AI collaboration [10,37], in which AI systems dynamically compensate for differential user capabilities. Here, narrative initiative is inversely calibrated to residual cognitive capacity, so the AI assumes greater responsibility where the user needs it most. This contrasts with many prior dementia-assistive systems that rely on relatively fixed interaction modes [7]. Whether similar mechanisms generalize to other cognitive assessment instruments remains a question for future work.

Limitations

However, this study also has some limitations. First, the sample size (n=20; 10 per arm) is small. Effect sizes derived from small samples are inherently unstable, and the Benjamini-Hochberg correction applied to the 6 confirmatory hypothesis tests should be read with caution: because within- and between-group tests were derived from the same 10 participants per arm rather than independent samples, the positive regression–dependence assumption underlying the procedure was plausible but not formally verified, and several outcomes assessed with Wilcoxon signed rank tests at n=9‐10 yield P and q values that take on a limited set of discrete values. The correction should be read as a conservative response to multiplicity concerns rather than a substitute for replication in a larger, adequately powered, multisite trial.

Second, this study used a nonrandomized design: group allocation used a minimization procedure rather than simple or block randomization. This method was selected specifically to ensure equivalence on 4 baseline variables, given the small overall sample size, and is a recognized alternative to simple randomization in small trials. However, it differs from simple randomization in that assignment for later-entered pairs is partly determined by the accumulated composition of previously assigned groups rather than by chance alone. As a result, unmeasured or unbalanced covariates could, in principle, be associated with allocation in ways that pure randomization is designed to prevent, and a person with knowledge of the algorithm and running group totals could in principle anticipate upcoming assignments. Larger-scale replications should use simple or stratified block randomization with formal allocation concealment to strengthen causal inference.

Third, because participants were allocated within matched pairs, all confirmatory hypothesis tests were analyzed using paired methods (paired t tests or Wilcoxon signed rank tests on matched-pair differences) rather than independent-samples tests, consistent with the matched design. This is a more conservative and design-appropriate approach than treating change scores as independent observations; all 6 confirmatory comparisons remained statistically significant under this analysis and after Benjamini-Hochberg correction, with moderate-to-large effect sizes (Cohen d=0.85‐1.03; rank-biserial r=−0.93 to 1.00).

Fourth, this was a one-time experimental evaluation without follow-up assessment. This has 2 consequences. It precludes conclusions about the durability of affective and narrative gains; whether benefits persist, accumulate with repeated use, or diminish with habituation is unknown. It also means the high SUS scores (mean 92.2, SD 5.1) should be interpreted cautiously: single exposure to a novel system can temporarily inflate satisfaction ratings, and older adults with cognitive impairment are additionally prone to acquiescence bias, meaning the tendency to agree with survey items regardless of content, particularly under limited cognitive resources [38]. Holden [30] noted similar interpretive challenges applying the SUS in this population. Longitudinal, multisession usability assessment is needed to obtain a more reliable estimate of system acceptability.

Fifth, participants were recruited exclusively from 4 Chinese provinces, with a mean education level of approximately 6 years and corresponding technology-use attitudes. System performance may differ in populations with higher digital literacy, different cultural or linguistic backgrounds, or distinct dementia etiologies, and these findings should not be generalized beyond this context without further testing.

Sixth, the system's core AIGC engine relies on GPT-3.5. GPT-3.5 represented a relatively advanced, readily available commercial large language model at the time this system was

XSL•FO
RenderX

developed, and its selection was reasonable within that context. However, given the pace at which generative AI models have since evolved, findings obtained with this specific model may not generalize to systems built on newer architectures. Replication with current-generation models is needed, alongside systematic safety evaluation under diverse real-world conditions, which has not yet been conducted for either version.

Seventh, the control condition requires clarification and cautious interpretation. As described in the Procedures section, the control group received an active control matched to the intervention group on session duration, number of prompting turns, frequency of audio feedback, device novelty, and researcher behavior, with only the AI-generated personalization and memory anchor–driven narrative content removed. This design was intended to isolate the specific contribution of AI-generated scaffolding rather than general attention or novelty effects. However, no formal fidelity check (eg, independent rating of researcher adherence to the matched protocol) was conducted to confirm that the manually delivered control condition in fact replicated the intervention's interaction structure and pacing. Residual, unmeasured differences in perceived responsiveness or engagement between human-delivered and AI-delivered support therefore cannot be fully excluded, and this should be addressed in future trials through structured fidelity monitoring or a non-AI digital comparator.

Eighth, psychiatrist-rated memoir quality was assessed from transcripts with AI-paraphrased content and AIGC excluded, so that scores reflect participant-generated narrative content specifically rather than the system's language capabilities.

Conclusions

AI-assisted memoir construction for people with reduced decision-making capacity raises important questions about authorship, narrative authenticity, and data governance. As described in the Ethical Considerations section, this study addressed these concerns through explicit consent for AIGC, caregiver verification of generated narratives, anonymized API data transmission, and postsession transparency about system outputs. Future deployments should extend these safeguards to longitudinal use by formalizing policies for data retention, access, revision, and deletion [17,23].

Future studies should evaluate the system across multiple sessions and with stronger comparison conditions, such as structured human prompting or non-AI digital memoir tools, to better isolate the contribution of AI-generated scaffolding. A larger and more diverse randomized controlled trial would also enable subgroup analyses by dementia etiology, severity, education, and cultural context. Finally, because the current MMSE-based adaptation logic remains relatively coarse, future versions could incorporate real-time behavioral signals, such as response latency, lexical complexity, and speech-detected emotional tone, to support more fine-grained within-session adaptation [39]. Together, these steps would help move the system from a promising single-session prototype toward a clinically useful and ethically accountable long-term reminiscence support tool.

Acknowledgments

The authors thank all the older participants and physicians for their outstanding contributions to this study. Generative AI (GPT-3.5) was part of our design; however, it was not used for research or writing the paper.

Abstract

Background: Virtual clinics allow doctors to connect to patients in difficult-to-reach locations. While this can result in improved access to care, implementing existing virtual clinics in these locations is difficult due to their contextual constraints. To address these challenges, a virtual clinic system for remote, rural, and underserved areas was developed based on user-centered design principles. To complete the user-centered design cycle, the developed system was then implemented and evaluated in the target contexts.

Objective: This study aimed to conduct a pilot study with the developed user-centered virtual clinic system to evaluate its performance in resource-limited settings. Patient, doctor, and nurse feedback was collected to understand how the virtual clinic system and implementation strategy might be improved before long-term implementation.

Methods: A pilot study was conducted at 2 health care facilities in South Africa—1 underserved public primary health clinic in the city of Cape Town, and 1 remote occupational health clinic in the Northern Cape Province. Doctor and nurse dyads participated in using the system to consult with real patients in each clinic. Patients received both virtual and physical examinations by the same doctor, and these 2 consultations were compared with one another. Surveys were conducted to gather patient feedback pre– and post–virtual clinic consult. Observations of system usage were collected, and doctor and nurse participant interviews were conducted at the conclusion of each day. Qualitative data were thematically analyzed to understand barriers and facilitators of virtual consultations, as well as patient satisfaction.

Results: A total of 12 patient consultations were conducted using the virtual clinic system across 2 health care facilities. Two doctors and 2 nurses participated in the study as users. Doctor and nurse confidence in using the system increased over time. Doctors were confident that the virtual consultation format could be used to diagnose patients remotely. Key indicators of patient satisfaction were being included in consultation communication and understanding the benefits virtual care could offer. Potential barriers to virtual consultations were infrastructure offered by the implementation environment and medical device limitations.

Conclusions: The results from this pilot study indicate that virtual clinic consultation is possible in low-resource settings using the developed virtual clinic system. This system can support patients in remote, rural, and underserved areas to receive certain health care services from a doctor without the doctor having to be physically present in the facility. The results encourage further scaling of the system to support long-term implementation in low-resource health clinics in South Africa and other sub-Saharan African countries.

Introduction

Background

Virtual clinics are a type of digital health solution that connect health care professionals to patients and other staff through digital means [1]. Implementation of virtual clinics is associated with many advantages: better quality and continuity of care [2-5], greater efficiency leading to reduced wait times [6,7], and reduced costs for both patients and health systems [8,9]. Due to the COVID-19 pandemic, the number of virtual clinics has grown [10], and implementations have been realized globally with a range of different applications.

Virtual Clinics in Sub-Saharan Africa

While virtual clinics have become common in many urban and developed areas, they have not yet reached many remote, rural, and underserved areas. This is because these areas present contextual challenges, including a lack of telecommunication infrastructure [11,12], limited access to electricity [13], and low levels of digital literacy [14]. Current virtual clinic services have not been adequately designed for these constraints, contributing to a lack of adoption in these areas. Furthermore, populations in remote, rural, and underserved areas often lack proper health facilities and skilled health professionals [15]. Virtual clinics have the potential to greatly improve access to care in these areas [16].

National programs in sub-Saharan Africa have attempted to implement digital health policy and services with mixed results. A national telemedicine program was implemented in Cabo Verde to connect doctors across the 9 inhabited islands of the country [16]. There were several technical challenges with this implementation, including a cyberattack that affected service provision, extensive financial investment, and the inability to maintain the hardware. Evidence collected in a review of telemedicine in sub-Saharan Africa corroborates these challenges [17]. Ogundaini and Mlitwa [18] discuss how digital health initiatives across sub-Saharan Africa require improved capacity building, knowledge sharing, and resources to be successful. South Africa, Kenya, and Nigeria have emerged as leaders on the continent for telemedicine implementations; however, digital literacy limitations, regulatory gaps, and infrastructure constraints were mentioned as limiting factors to success [19]. Implementation recommendations from the World Health Organization [16] and the International Telecommunication Union [20] provide some guidance for addressing these challenges, but alignment between recommendation and existing digital health system design still persists.

User-Centered Design for Virtual Clinics

User-centered design (UCD) is a methodology that may be applied during the design and development process to align the needs of the context with the digital health system [21-25]. UCD focuses on user needs to iteratively develop solutions [26,27]. There are 4 steps in the UCD process, which are (1) specify context of use, (2) specify requirements, (3) create design solutions, and (4) evaluate designs. Incorporation of UCD can lead to improved user interfaces and functionalities within the system. By incorporating user feedback early in the design process, development time decreases and user acceptance increases [28,29]. Several virtual clinics that have implemented UCD methods have shown improved user experience and system uptake [30,31].

Previous work outlined the application of UCD methods to develop a virtual clinic system for sub-Saharan Africa [32]. In brief, a situational analysis was conducted to understand the challenges associated with health care provision and digital health in austere environments in sub-Saharan Africa and South Africa. This addressed step 1 of the UCD process. From this situational analysis, system requirements were developed, addressing UCD step 2. The virtual clinic was designed according to these requirements, completing UCD step 3. Initial usability testing was conducted with nurses and doctors in Cape Town, completing UCD step 4. This completed the initial UCD iteration. Another UCD iteration was then begun by using the feedback from the usability study to further improve the next prototype.

The virtual clinic was designed for provider-to-provider synchronous telemedicine. In this model, a patient would visit their regular health clinic in a remote, rural, or underserved location. It is assumed that there would be limited or no doctors available to provide services in person. If the nurse or community health worker is unsure how to diagnose or treat a patient, they would typically refer the patient to a district or tertiary health facility or ask them to wait for the doctor to visit the facility. Instead, using the virtual clinic system, the nurse can call an available doctor who can advise on how to proceed with the patient remotely. The patient would either be adequately treated via the virtual consultation, or the doctor can confirm that the patient should be referred. This reduces unnecessary referrals, which is an advantage for both the patient and the health care system.

This design acknowledges the needs of low-resource settings in several ways. First, the provider-to-provider model reduces the onus on the patient that is typically associated with virtual care. The patient does not need to purchase any devices or have proper infrastructure such as electricity or internet in their home to participate in virtual consultations. The nurse is the user who facilitates the digital connection for the patient. Additionally, the system and infrastructure can be concentrated at a central point (the existing clinic facility) and shared among many patients, addressing the potential lack of resources for health care in these areas. Finally, it allows patients to have access to a doctor. Many patients do not fulfill referral appointments for various reasons, including cost, lack of transportation, long distances with poor health, and lack of child or older adult care. By implementing the virtual clinic system, barriers to care are reduced, and patients have an opportunity to receive better quality health care.

Research Objectives

In this paper, we present results of the evaluation of the virtual clinic system that was developed using UCD methods in an effort to address access to care in remote, rural, and underserved areas in sub-Saharan Africa. The improved system was evaluated

XSL•FO
RenderX

during this study in real-world contexts, completing step 4 and thus the second iteration of the UCD process.

The UCD method emphasizes usability and contextually relevant design, so this evaluation was focused on understanding how the virtual clinic system performed in real-world environments and how the users experienced the system. Specifically, the objectives were to understand how the virtual clinic performed in a real-world setting and to identify potential barriers that could be encountered during a scaled-up implementation, which answer the following three research questions: (1) What barriers do users encounter when delivering primary-level care using the virtual clinic? (2) What user behaviors are commonly present in successful virtual clinic consultations? (3) How satisfied are patients with receiving primary-level care using the virtual clinic? The following sections present the methods used for answering these research questions, the results of the data collection, and the recommendations for future implementation, as well as the limitations of this study.

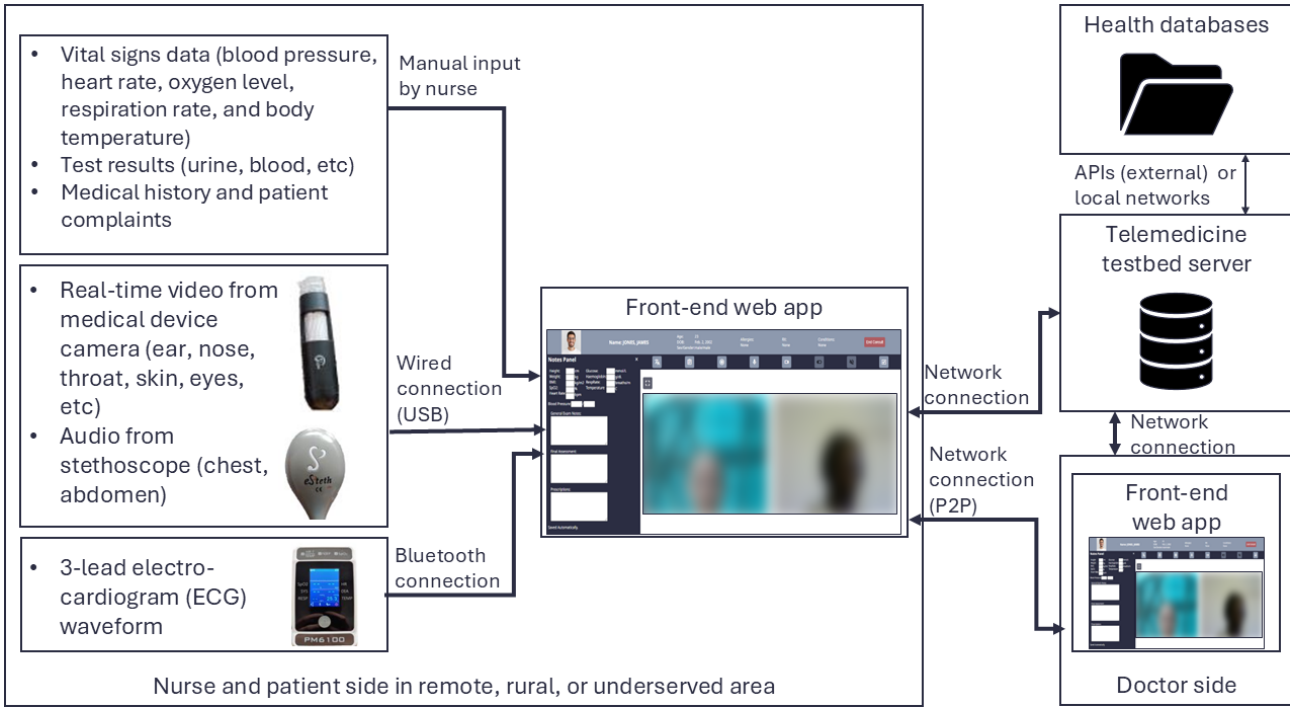
Methods

Theoretical Background

There is extensive literature documenting the evaluation of telemedicine systems, and these evaluations vary significantly in their objectives. Ekeland et al [33] provide a review of methodologies for evaluating telemedicine systems and highlight the difficulties in aligning these methodologies. They highlight that telemedicine exists at the intersection of medical, technological, and social sciences, and it can be difficult to reconcile evaluation methods that satisfy each of these fields. The differences can be summarized as positivism versus naturalism. Positivism uses objective observation and measurement to develop generalizable laws, while naturalism focuses on understanding phenomena within their natural context, often through qualitative methods, and acknowledges the influence of various factors on human behavior. Both approaches can yield valuable insights, with positivist evaluations such as randomized controlled trials being important for establishing clinical and generalized outcomes and naturalist evaluations establishing context-relevant information and human experience and behaviors. They highlight that the context of the telemedicine implementation and objectives of the evaluation should dictate the appropriate approach.

In regions where telemedicine is still evolving, such as sub-Saharan Africa and South Africa, the strict design of positivist evaluations may not always be appropriate. Randomized controlled trials may not account for rapid developments in technology, leading to results that may not be relevant by the time the study concludes [34]. Furthermore, in contexts where telemedicine has not yet been implemented, gathering human experience and feedback via a naturalistic approach can be advantageous to understand the cultural and contextual effects of telemedicine implementations [35]. This also allows for refinement of implementation techniques that are context-based.

Given that the developed virtual clinic system is still at an early technology readiness level, and telemedicine within remote, rural, and underserved areas in South Africa has not yet been widely attempted, the evaluation approach used in this study leans naturalist rather than positivist. However, elements of both are incorporated to strengthen the study design and outcomes. Therefore, a mixed methods feasibility study was used to evaluate the virtual clinic.



Virtual Clinic System

The developed virtual clinic system was used for virtual consultations during this study. The system consists of a web app with integrated medical devices, as described in Figure 1. It includes three main subsystems: (1) the consultation platform, which facilitates real-time communication and transmits real-time health data; (2) the electronic health record, which houses patient health data and consultation data from consultations hosted on the virtual clinic platform; and (3) a help desk to support user training and troubleshooting while using the system. Each of the subsystems was designed with user input and consideration of the contexts for which the system was intended.

There are three main medical devices that were integrated with the web app: (1) a digital stethoscope, which collects real-time auscultation sounds; (2) a medical camera, which provides general-purpose high-quality magnified video of the patient and has an otoscope adapter to provide ear, nose, and throat video; and finally (3) a vital signs monitor that can transmit 3-lead electrocardiogram readings via Bluetooth. The medical camera, which provides magnified medical images, is distinct from the webcam, which provides a real-time video of the nurse and patient interactions to the doctor. Images, recordings, and notes are captured during virtual consultations and stored in the electronic health record subsystem, so that this information can be referenced in future consultations. The devices used in this study can be substituted with similar devices. This allows clinics the ability to interchange devices depending on their budget, medical needs, and market availability in the region of implementation. For example, if the digital stethoscope used in the implementation in South Africa is not sold in other countries, implementers could replace it with a similar device, which may also be cheaper. This is in contrast to many existing telemedicine systems, in which medical devices and hardware are linked and cannot be interchanged. This design improves feasibility in the target contexts of remote, rural, and underserved areas.

XSL•FO
RenderX

Figure 1. Virtual clinic platform architecture.

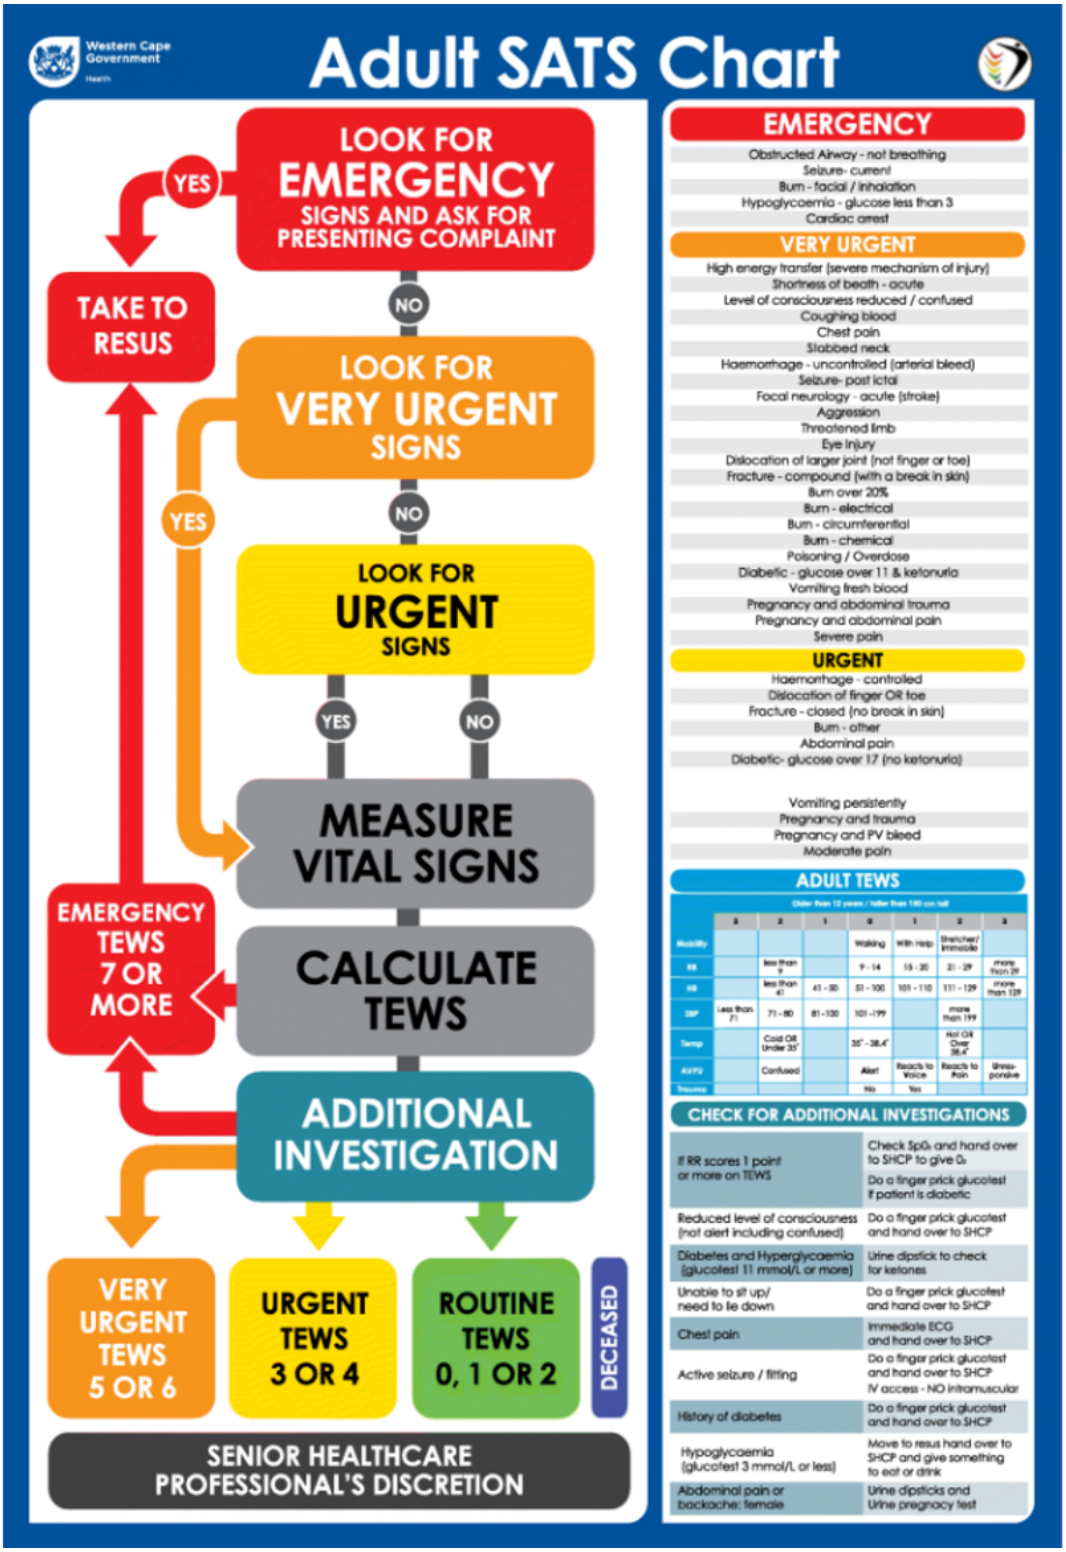
A help desk is also integrated into the consultation platform. The help desk contains extensive training material for users, including video demonstrations and written guides on how to use the medical devices and software. There are also 4 case studies developed as training material, which users can go through as independent practice with the system. This setup allows users to become comfortable with the tools on their own time, rather than assuming that training time will be provided during implementation.

Study Sites and Participant Recruitment

Two study sites were used for virtual clinic implementation: Mitchell's Plain Community Health Centre in Cape Town and the Occupational Health Clinic at the Klerefontein Base for the South African Radio Astronomy Observatory (SARAO) Square Kilometre Array (SKA) project in Northern Cape Province. These sites are hereafter referred to as sites 1 and 2.

Site 1 is a public health facility in Mitchell's Plain township in Cape Town. It is estimated that the clinic serves approximately 1.2-million patients, including Mitchell's Plain and surrounding areas, with approximately 46,000 patients seen per month [36]. Despite being located in the urban center of Cape Town, there are still difficulties involved in getting doctors to the facility. Safety is a concern in Mitchell's Plain; the area has the highest reported assault and sexual assault rates in South Africa and is in the top 10 areas for robbery-related crimes [37]. This can make it difficult for doctors to get in and out of the facility. Therefore, virtual clinics offer a potential solution for remote clinical consultation without requiring doctors to physically visit the clinic. The study was conducted over 2 consecutive weekend days at site 1.

Site 2 is an occupational health clinic that serves approximately 200 employees at the SARAO SKA site. The nearest town is Carnarvon, which is approximately 16 km away. The clinic has an on-site nurse who provides day-to-day care. In addition, an occupational health nurse and doctor fly to the site once every 3 months for 1 day. During these visits, medical consultations are conducted for approximately 5 hours. The on-site nurse arranges for the patients who are in most need of the doctor to come to the clinic during these site visits. Alternatively, the workers may visit the community health clinic or the district hospital in Carnarvon, where there are an estimated 3 doctors who provide services between these sites. These facilities can also provide some trauma care in case of an emergency, although more serious cases of trauma must be transported to the tertiary hospital in De Aar, which is 200 km from Carnarvon. At site 2, the study was conducted over 1 day, during a site visit by the occupational health doctor.



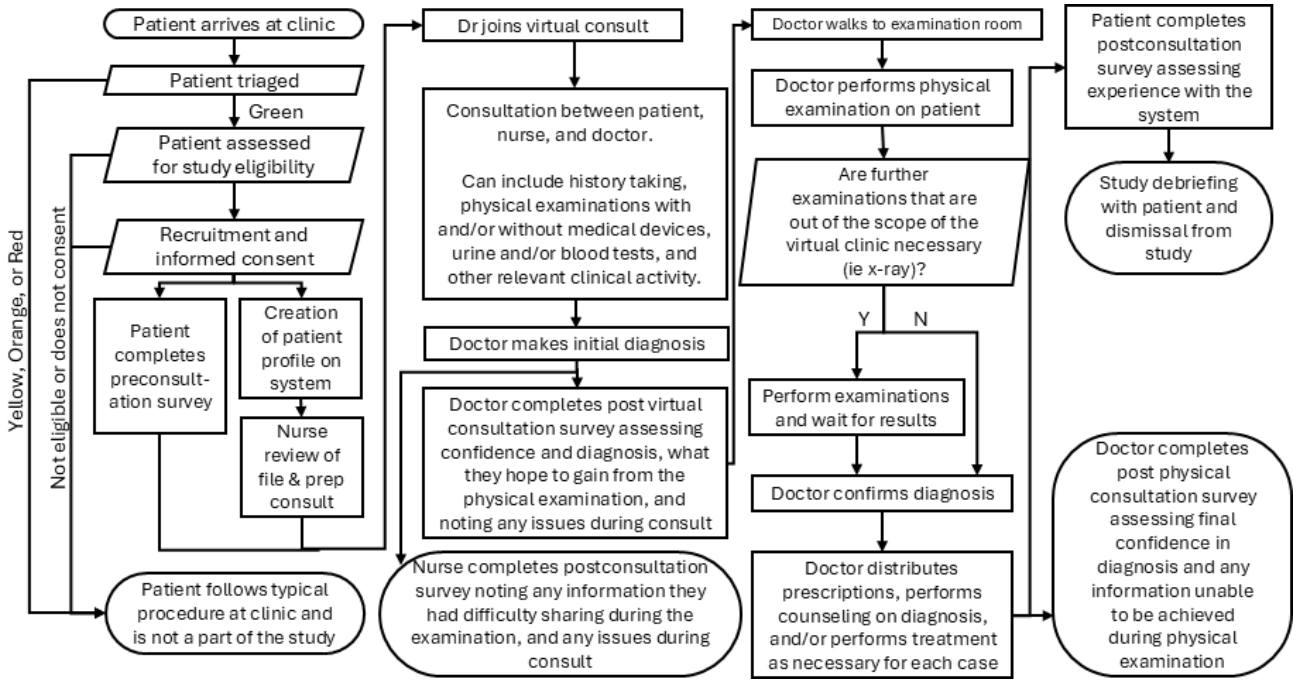
Patients were recruited from each clinic using a convenience sampling method. Inclusion criteria for patients were adults who were fluent in English. Patients were also required to be triaged as level green according to the South African Triaging Scale protocol, shown in Figure 2 [38]. Level green is the lowest risk patient, with a routine-reported Triage Early Warning Score of <3. At site 1, patients underwent triaging after entering the clinic facility. At site 2, the on-site nurse recruited patients who fit the inclusion criteria in advance of the study day. These patients were scheduled for consultation times on the study day. Exclusion criteria were patient cases in which the main complaint required a procedure, such as a catheter replacement, as these cases did not involve a diagnosis and therefore did not fit the study design.

Doctors and nurses were recruited using a snowball sampling method. Participants recruited for the doctor role were required to have a valid Bachelor of Medicine and Bachelor of Surgery qualification and a current registration with the Health Professions Council of South Africa. Participants recruited for the nurse role were required to have a National Qualifications Framework level 7 nursing degree or diploma and current

XSL•FO
RenderX

registration with the South African Nursing Council. The inclusion criteria for both doctors and nurses were that they should have no prior clinical experience using real-time virtual consultation systems.

Figure 2. The SATS flowchart for adults (adapted from the SATS training manual) [34]. SATS: South African Triaging Scale.



Study Design and Overview

To evaluate the developed virtual clinic system, a mixed methods, cross-sectional, pre-experimental pilot feasibility study was conducted. The virtual clinic system was implemented in 2 field clinic settings with patient, doctor, and nurse participants. A detailed depiction of the consultation study procedure is shown in Figure 3. The study commenced by training the doctor and nurse participants on the virtual clinic system. For doctors, the training took place the morning of their first study day for approximately 30 minutes. A dedicated training session was done for the nurses a day before the system evaluation at the clinic. This was because the nurses needed to familiarize

XSL•FO
RenderX

themselves with the medical devices, whereas the doctors only viewed the data collected from the devices, which did not require extensive training. Consultation sessions began in the clinic after the doctor and nurse completed their training on the system. During the system evaluation phase, patients participated in a virtual consultation facilitated by the nurse, with a doctor present virtually. The doctor was located in the same health facility as the nurse and the patient, but in a separate room, so they could not hear or see the examination other than through the virtual clinic system. The nurse then facilitated the conversation between the doctor and the patient, provided the medical history, and performed physical examinations as instructed by the doctor. After the virtual examination was finished, the doctor then entered the examination room and performed a physical examination to compare virtual and physical examination results. The study day concluded by conducting dyadic interviews with the doctor and the nurse about their experience with the system.

Figure 3. Study procedure used during the virtual clinic field pilot study.

Data Collection and Analysis

Both quantitative and qualitative data were collected during the study. A total of 5 different structured, self-report questionnaires were administered, which included 2 patient questionnaires, 2 doctor questionnaires, and 1 nurse questionnaire. A mixture of quantitative (scale rankings or binary) and qualitative (open answer) questions was included. The questionnaires are provided in Multimedia Appendix 1. Clinical notes were recorded during each section by the doctors and nurses in the virtual clinic platform. Simple observational data were collected by the researcher, which included the duration of each consult, examinations performed, and challenges encountered. Dyadic unstructured interviews were conducted with the nurse and the doctor at the conclusion of each study day to gather self-reported user feedback regarding the virtual clinic system.

Regarding research question 2 (What user behaviors are commonly present in successful virtual clinic consultations?), a successful virtual clinic consultation was defined as a consultation conducted using the virtual clinic where the doctor came to a diagnosis during the virtual consultation and reported a confidence level equal to that reported during the physical consultation. Regarding question 3, patient satisfaction was defined as a combination of “quality of care, similarity to face-to-face encounter, perception of the interaction” [39], willingness to use the service again, and willingness to recommend the service. Two standardized tools were incorporated within the patient and doctor questionnaires: the Telehealth Satisfaction Survey (TeSS) and a 5-point Likert scale diagnostic confidence ranking, respectively. TeSS was used to understand patient satisfaction during virtual consults. This questionnaire was developed by Yip et al [39] and has since been used to evaluate rural patients’ satisfaction with telemedicine in several studies [40,41]. To define successful consultations, a 5-point Likert scale was used to assess doctor confidence in virtual and physical diagnosis. This method has previously been used to rank confidence in diagnosis across many domains [42,43]. Although more detailed surveys have been developed for assessing diagnostic confidence, such as the Primary Care Confidence Scale [44], due to the short time span between virtual and physical consultations it was important to use a quick and simple questionnaire. Thus, the Likert scale confidence ranking was used.

The data collected were transcribed and cleaned as necessary to remove identifying information. Qualitative data were analyzed using an adapted practical thematic analysis method for health service research proposed by Saunders et al [45]. There are 3 steps of the method. The first is to read and annotate the data to understand the breadth and depth of the results. Then, the data are coded with descriptive titles that report detailed themes. After this, the low-level titles are synthesized to identify broad themes from the results. This results in 3 levels of

XSL•FO
RenderX

thematic codes. An iterative procedure, conducted by multiple reviewers, was taken to ensure data saturation. NVivo (Lumivero) was used to complete thematic analysis. Quantitative data from surveys are reported but not statistically analyzed due to the small sample size and nature of the study design [46].

Ethical Considerations

To maintain participant confidentiality, all data collected from participants were deidentified. To ensure that patient participants received the proper quality of care, patients were seen by a doctor both physically and virtually. Only the lowest risk patients were recruited for the study. Patients received a R100 grocery voucher as compensation for their time. The nurse and doctor participants were compensated at a standard hourly rate based on their qualifications for their time conducting consultations. There were no foreseen risks with participation in the study for any of the participant groups. The medical devices that were used for virtual examinations were all approved by the Federal Drug Administration and the Conformité Européenne for use in clinical diagnostics. This study was approved by the University of Cape Town Human Research Ethics Committee, reference number HREC322/2024. The relevant organizational bodies, including the Western Cape Department of Health (study number WC_202411_029), Mitchell's Plain Community Health Centre, and SARAO SKA management, also provided approval for the study.

Results

Cases and Consultations

Two doctor-nurse dyads participated in the virtual clinic visits, with 1 team per site. The doctor and nurse conducting visits at site 1 had not met before data collection. The doctor and nurse at site 2 were familiar with each other and had worked together previously. A total of 12 patients were seen during the study, with 9 at site 1 and 3 at site 2. This participant recruitment size is in line with similar research studies [47]. The average patient age was 42 years, with a range of 23 - 73 years. Female patients accounted for 66.6% of the population for both sites. An overview of the participants and cases is shown in Table 1. For patient participants, the presenting complaints are listed along with a brief description of the final assessment made by the doctor.

The full results of the thematic analysis are provided in Multimedia Appendix 2. The following 6 sections provide descriptions of each of the 6 themes identified and their supporting codes and evidence.

Table . Overview of patient participants and brief description of cases.

Site	Day	Age, years	Sex	Presenting complaint	Final assessment
1	1	73	Male	Pain in back and buttocks	Skin lesion
1	1	45	Female	Abdominal pain	Suspected TB[a]
1	1	44	Female	Headache and dizziness	Hypertension medication nonadherence
1	1	28	Female	Headache and cough	Flu
1	1	51	Male	Chest pain with cough	Pneumonia
1	2	43	Female	Back pain	Suspected TB
1	2	38	Male	Pain in nose and face	Gingivitis and abscessed teeth
1	2	23	Female	Abdominal pain and nausea	Bladder infection
1	2	55	Female	Body aches	Sciatica flare-up
2	3	30	Male	Raised bump on eye	Eye nodule + hypertension
2	3	32	Female	Abdominal pain	Gastritis and acid reflux
2	3	36	Female	Abdominal pain during certain activities	Potential bladder prolapse, referral to gynecology

[a]TB: tuberculosis.

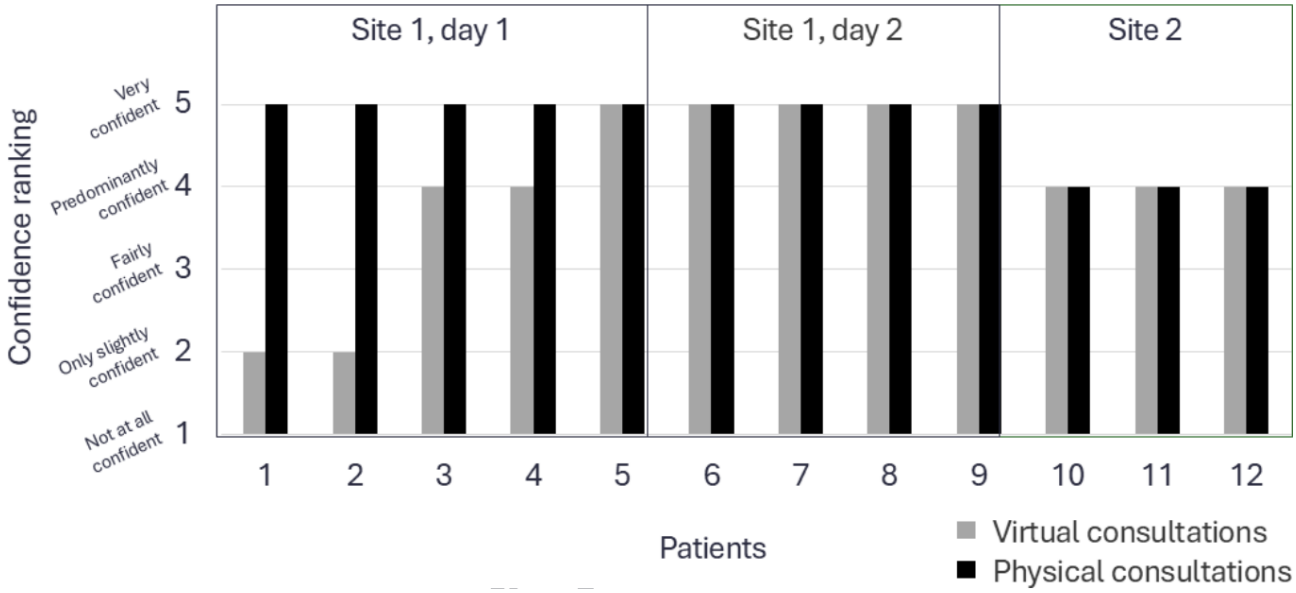
Characteristics of Successful Virtual Clinic Consultations

First, experience was an enabler of confidence and success for new users. For both doctor-nurse dyads, confidence was reported to grow over time as more consultations were conducted. Doctor's confidence in diagnosis from virtual and physical examinations over time is reported in Figure 4, where it is demonstrated that confidence grew over time for the doctor at site 1. The confidence between consultations became equal starting at the end of day 1, and the pattern continued into day 2, demonstrating sustained confidence. In addition to doctor's confidence, the time spent verifying the outcomes of the virtual examination during the physical examination shortened over

XSL•FO
RenderX

time, as shown in Figure 5. This aligns with both doctors' questionnaire responses, which state that as consultations progressed, they were using only the physical examination to verify the findings they had made during the virtual examination.

Figure 4. Doctor-reported Likert-scale rankings of confidence in final assessment between virtual and physical consultations for each patient.



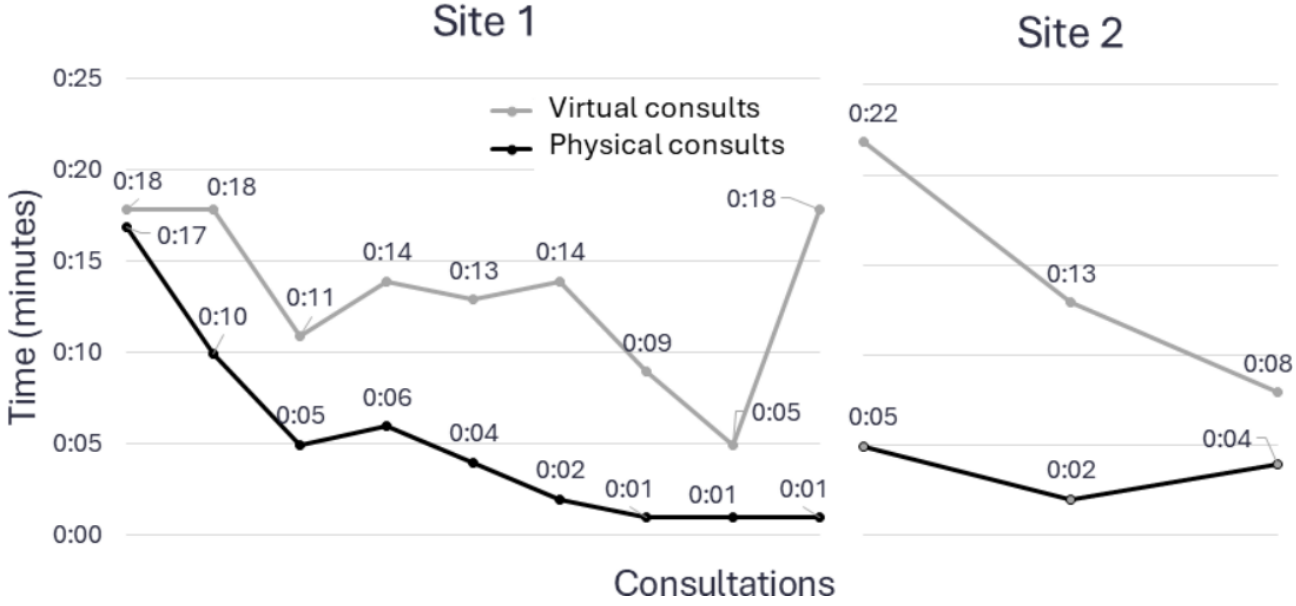


Figure 5. Duration of virtual and physical consultations for each site.

The nurse at site 1 had the following to say about her experience with the virtual clinic on the first day:

> *It was not as bad as I thought. I really thought it was going to be hard to collect the information, [and] the patients would be uncomfortable with not knowing exactly who they're speaking to. And to patients, what they also like is they like to be touched. So I was quite uncertain about it. And then, the more we got to do it, I got more comfortable with the system.*

Both doctors mentioned the importance of being able to exclude emergency diagnoses during virtual consults. During several consultations for both doctors, emergency diagnoses could be excluded through a combination of history taking and physical examinations conducted by the nurse. For the second case on day 1, the doctor noted that she was able to exclude signs of meningitis through the nurse's physical examination reports. The doctor at site 2 also reported that he was able to exclude emergency diagnoses for all 3 patients during the virtual consults.

The study design itself may have also contributed to building confidence in virtual diagnosis. Although not initially intended to do so, comparison between virtual and physical examinations allowed doctors to build trust in the technology and the nurse they were working with. The doctor at site 1 stated the following regarding her experience after the first day of using the system:

> *Initially I was very sceptical because we rely a lot on clinical examination to make a diagnosis. Especially as South African clinicians, because we don't always have special investigations, so to touch, to feel, to smell, yeah, it does make a difference. So I was*

XSL•FO
RenderX

> *sceptical. But then as we progressed, it got easier. And then, what [the nurse] found and what I found was more or less the same thing, when we examined.*

She also had the following to say regarding the exercise of comparing virtual and physical diagnoses:

> *Because like with [the patient] who needed an X-ray, which you need an in-house consultation, I'm kind of like would that actually have made a difference to my treatment in the end? Because based on what we found in the clinical examination, the X-ray just confirmed what we already decided, so I think it is beneficial just to rule out any really bad things. But, I think we did still get to the right diagnosis through the first virtual consultation.*

As consultations continued, confidence in virtual consults built among the doctors and nurses. The exercise of verification of diagnoses between virtual and physical formats is theorized to have contributed to this confidence-building, as it allowed for the establishment of trust between the nurse and the doctor. The ability to exclude emergency diagnoses is also theorized to have contributed to building confidence. The confidence demonstrated by the conclusion of the study days motivates for proof that successful virtual clinic consultations can be conducted in remote, rural, and underserved areas with the virtual clinic system.

Clear, descriptive communication between providers facilitated successful consults. An observed element of successful consultations was clear communication. This is discussed in the previous section with reference to both patients and providers, but provider-to-provider communication is also extremely important in the virtual setting. During consultations, both doctor and nurse pairs were able to conduct physical examinations over the virtual clinic platform, with the nurses providing detailed descriptions and the doctor directing the examination. Physical examinations on several areas of the body were conducted in this fashion, including the head, neck, abdomen, back, and buttocks. The doctor at site 1 noted the importance of communication in these examinations with the following:

> *I think you just you need to be very good at explaining things. It helps with [the nurse] because she already asks the questions and does the things, but if you don't have someone that's as experienced, you would just need to be able to relay that information. Like this is the particular examination that I want, [and] this is how you conduct that examination.*

These descriptions can also be important when complementing the information obtained from the medical devices. The nurse at site 1 noted during one of the examinations:

> *Unclear otoscopic images made it difficult for the doctor to see clearly, and therefore ask[ed] further investigations/assessment questions.*

Both doctors noted that they liked working with a provider-to-provider virtual clinic model rather than a patient-to-provider model. The doctor at site 2 noted that having a professional nurse on the ground who has medical experience is helpful when conducting the physical examinations and could also build trust and confidence in the patient receiving the service. The site 1 team corroborated this comment with the following:

> *Nurse: I'm just thinking if someone was at home and you don't have a nurse on the other end, it would be difficult.*
>
> *Doctor: It would be very difficult. Yeah. So what makes this flawless is having an experienced sister, because if it is a patient at home and I'm just gathering information by speaking, I can't touch them. There is no one there that can do it. I can't listen to the chest so I could see that guy who looks fine. Maybe just the green sputum is the only thing that would make you think infection, but it would make it difficult.*

Finally, the usefulness of this communication was highlighted by the nurse and the doctor at site 1. They stated that the ability to verify diagnoses and referrals between providers would be beneficial to building health care workers' experience and confidence working in remote, rural, and underserved areas. When asked whether this service would be helpful to the nurse at site 1 during her previous work in the Eastern Cape, she said:

> *Extremely. I remember when I was a nurse, the only thing we had was the group on WhatsApp with all of us, and then we helped each other. And that we would have one doctor that was nice enough to accept our patients and he would be like, OK, have you done this? Have you done that? And then eventually the doctor would be like, OK, you can refer. So yeah.*

The doctor at site 1 followed by stating:

> *And even for junior doctors [this would be helpful]. Yeah, because you are running a hospital on your own. And you don't have enough experience. And then you need to try and get to a specialist at the other hospital, who doesn't necessarily have time.*

Therefore, by providing a platform for establishing communication between providers, detailed accounts of physical examinations can be shared to improve health care delivery.

Patient Satisfaction With Virtual Care

Patient satisfaction was demonstrated when patients understood the benefits of virtual consults and were included in communication. Overall, patients lacked experience with virtual clinics but reported positive experiences after participating in a virtual consult. Results from preconsult and postconsult patient surveys are reported in Table 2. On the preconsult survey, only 1 patient participant answered yes to having previously used telemedicine services. On the postconsult surveys, patients indicated satisfaction with the system, with the majority of TeSS responses falling in the "good" or "excellent" categories. All patients reported that they would use the service again and would recommend the service to another person.

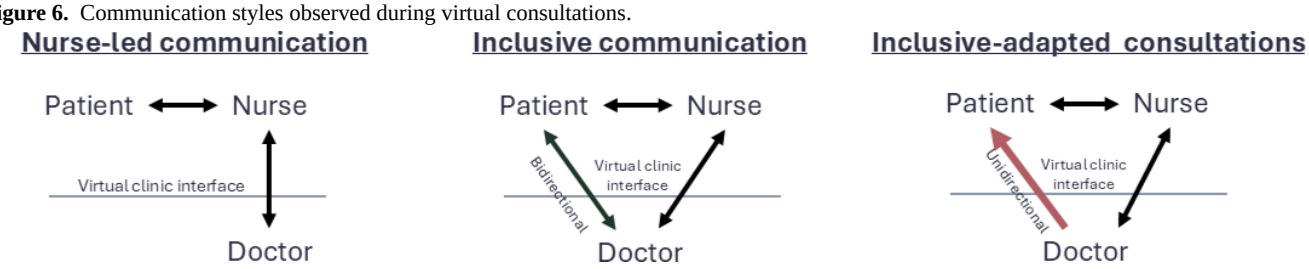
XSL•FO
RenderX

Table . Summary of the patient responses to pre- and postconsult surveys.

Survey item	Response					
	Yes, n (%)	No, n (%)	Excellent, n (%)	Good, n (%)	Poor, n (%)	Fair, n (%)
Preconsult patient survey: have you consulted a doctor or a nurse through phone or video before?	1 (8.3)	11 (91.7)	—[a]	—	—	—
Postconsult patient survey statement. How satisfied were you with:						
The voice quality of the equipment?	—	—	6 (50)	5 (41.7)	0 (0)	6 (50)
The visual quality of the equipment?	—	—	6 (50)	5 (41.7)	1 (8.3)	6 (50)
Your personal comfort in being seen using the virtual clinic system?	—	—	8 (66.7)	4 (33.3)	0 (0)	8 (66.7)
The length of time with the doctor you saw?[b]	—	—	5 (45.5)	5 (45.5)	1 (8.3)	0 (0)
The explanation of your treatment by the virtual clinic doctor?	—	—	9 (75)	3 (25)	0 (0)	0 (0)
The thoroughness, carefulness, and skillfulness of the virtual clinic doctor?	—	—	9 (75)	2 (16.7)	1 (8.3)	0 (0)
The courtesy, respect, sensitivity, and friendliness of the virtual clinic doctor?	—	—	10 (83.3)	2 (16.7)	0 (0)	0 (0)
How well the virtual clinic doctor respected your privacy?	—	—	7 (58.3)	4 (33.3)	1 (8.3)	0 (0)
How well the staff answered your questions about the equipment?[b]	—	—	5 (45.5)	5 (45.5)	1 (8.3)	0 (0)
Your overall treatment experience using the virtual clinic?	—	—	7 (58.3)	5 (41.7)	0 (0)	0 (0)
Would you recommend the virtual clinic service to another person?	12 (100)	0 (0)	—	—	—	—
Would you use the virtual clinic service again?	12 (100)	0 (0)	—	—	—	—

[a]Not applicable.

[b]Questions that were not answered by 1 respondent each.



XSL•FO
RenderX

The nurse at site 1 had the following to say about one of the patient's demonstrated behaviors during a virtual consultation:

> *At the beginning, there was the lady that came, the one who just had the headache. She was a bit unsure at the beginning. She was very edgy, but then once she realized that, actually, I'm going to see a doctor, then I think she started relaxing.*

An observation during consultations was that the model of communication between the doctor, nurse, and patient was not always consistent. The observed models of communication are demonstrated in Figure 6. The optimal mode of communication was when the patient, nurse, and doctor all spoke directly to one another, labeled as inclusive communication. This also involved using a video view where both the patient and the nurse were included. This was important for the doctor to see nonverbal communications, such as body language or shaking of the head "yes" or "no" to answer questions. In one case, the doctor was able to determine that the patient was nasally congested by speaking directly to the patient and hearing their voice. However, in some cases, inclusive communication was not used. Particularly, these were in earlier consultations for site 1, but in some cases, this style of communication was also not feasible. Two other models of communication were thus observed, and these were labeled nurse-led and inclusive-adapted. In nurse-led communication, the nurse fully facilitated communication between the doctor and the patient. This was necessary during consultation 1 on the first day, when the patient was hard of hearing and the doctor's comments had to be repeated to him by the nurse. In inclusive-adapted communication, the doctor spoke directly to the patient, but the patient would respond through the nurse. Whether the patient intended to speak to the doctor directly was difficult to assess; in some cases, the patient was soft-spoken, and in other cases, their body language indicated that they were speaking to the nurse. In both the nurse-led and inclusive-adapted models, there was increased repetition of information that could have contributed to longer consultation durations. However, these styles of communication may be more comfortable for certain patients and thus should not be discounted. Rather, nurses and doctors should be informed about these styles of communication and be directed to make a conscientious choice that balances patient comfort and communication efficiency.

Figure 6. Communication styles observed during virtual consultations.

Additionally, patients who participated in the study may have received higher-quality care than they would have received in the traditional clinic setting. This was mentioned as particularly true for the green-triaged patients at site 1, who often face extremely long wait times as the day progresses, when more emergency cases take priority. In fact, 2 patients were recruited for the study on day 1, approximately 1 hour after the clinic opened. Neither patient met the inclusion criteria and was thus not included in the study. At the conclusion of the study day on day 1, approximately 5 hours after the nonincluded patients had entered the clinic, these patients were still in the queue and had not yet been seen. The long wait times are corroborated by the doctor and the nurse at site 1, who have previous experience working in other public clinics across the country.

> *Doctor: [The virtual clinic] actually makes a big difference, because we have a lot of clinics [that] don't have doctors and then that patient gets referred to a facility with a doctor. And it takes them weeks or months to get a date to see the doctor.*
>
> *Nurse: It's actually hard to get a date, especially in the rural areas. I'm not looking just at the Western Cape, but thinking Eastern Cape.*

While the quality-of-care impact is stark for the patients recruited in this study because they were green, or low priority, patients, it is recognized that this may not be the case for all virtual clinic implementations. However, what can be acknowledged is that patients were satisfied to receive care from a real doctor and nurse, with a physical examination component, and that these elements could be provided by the virtual clinic service.

Barriers to Virtual Clinic Care Delivery

Barriers caused by infrastructure and the implementation environment were able to be addressed adequately during the study. They did, however, threaten the success of the virtual consultations. Therefore, proper consideration should be given to these barriers to ensure that they have been addressed adequately.

On day 1 of the site 1 implementation, several technical issues were encountered. As this was the first implementation of the virtual clinic in a real-world setting, this was not surprising. The major challenge was establishing a quality network connection. The doctor was connected to the virtual clinic app using a tablet, which was receiving internet connection from a mobile phone hotspot that was connected to a local mobile network provider. The nurse's computer was connected directly to the mobile network, using a USB SIM modem. Throughout day 1, there were intermittent disconnections along with video and audio lag, which disrupted virtual consults. The mobile phone hotspot was suspected to be contributing to the poor connection, and various SIM cards, phones, and settings were adjusted throughout the day to try to improve this. It was also attempted to use USB tethering to hotspot the mobile network, and with this, the network quality improved. However, this

XSL•FO
RenderX

caused the battery of the tablet to drain quickly, and the tablet died, interrupting a virtual consultation. With these challenges, virtual consults could still take place, but the duration and confidence associated with these consults were low. These challenges were highlighted in a written response by the doctor referencing a consult with network issues:

> *Video lag. Network issues. Online consultation tends to take long due to lag issues (network).*

The nurse also noted the potential risks with loss of network connection during one of the consultations:

> *Only 1 difficulty was encountered, network glitching. Resulted in the doctor repeating suggestion/questions, or possibly missing some information from my side to the doctor or from the doctor to my side.*

There were several actions taken between day 1 and day 2 at site 1 to improve the quality of the virtual clinic consultations, and these were carried over into the site 2 study day. The laptop webcam was substituted by a high-quality HD1080p camera, and a USB SIM modem was used to provide mobile network to a laptop on the doctor's side, instead of a tablet. The pair of headphones that the doctor had been using was adjusted to provide better sound quality. These changes had a drastic impact on the success of virtual consultations. There were no observed or mentioned network challenges on day 2 at site 1, despite using the same network providers and the same location. This indicates that the network challenges experienced on the first day were due to the hardware used and not due to the service provider.

Some contextual factors of the clinic environment caused brief challenges in communication, particularly due to the background noise. At site 1, there were intercom announcements that interrupted communication, and at site 2, there were construction noises and a heater which caused background noise. However, the doctor at site 2 noted that the background noise was present but not disturbing when using the headphones.

Another environmental factor that affected virtual consultations was the arrangement of the examination space. At site 1, the examination bed had to be positioned approximately 4 meters from the laptop and camera, while at site 2, the examination bed could be positioned only 1 meter away. The arrangement at site 1 caused challenges during the demonstration of physical examinations that were not present during site 2 consultations. The nurse at site 1 reported:

> *Since the laptop is situated on the desk and the bed is further away, when doing an abdominal exam, it would be nice if the video camera would be closer so the doctor can see what areas are being palpated and what the abdomen looks like, direct where to palpate, and what kind of palpations/assessments to do.*

It is important to note that if these environmental factors are not considered, it threatens the ability of the system to streamline existing clinical workflows. The doctor at site 1 mentions this, saying:

> *So if I was in a busy setting, kind of having to communicate via another person to speak to the patient, there is time that that takes, whereas I wouldn't even have sat and asked as many questions as I usually do. So you would need to have a flawless system where there's no lags in between all of the [consults]. Yeah, it would not be as relaxed as it is now. Because if I had to see 30 patients in this time, [or] five who took so long?*

As such, pilot studies such as this are extremely important in identifying these concerns and mitigating them through future design and recommendations. Another barrier encountered during virtual clinic consultations was that medical device data were not always suitable for conveying certain types of health information. During consultations, the medical devices were used with the virtual clinic platform to provide real-time health data. An overview of how the medical devices were used for each consult is provided in Table 3. The vital signs monitor was not included in the table, as no consult required electrocardiogram usage. During initial consults at each site, the vital signs monitor was used for vital signs examination. However, at site 1, the triaging report data were used from consult 3 onward to capture patients' vital signs. At site 2, the nurse preferred to use the clinic's devices to take measurements, potentially due to the familiarity that they provided.

XSL•FO
RenderX

Table . Medical device usage during virtual consults.

Site	Day	Medical device usage (yes/no) and description of usage	
		Medical camera	Stethoscope
1	1	No	No
1	1	Yes: pupil reactivity to light	No
1	1	Yes: pupil reactivity to light, inside ear, and throat	No
1	1	Yes: inside throat	Yes: chest examination
1	1	No	Yes: chest examination
1	2	No	Yes: chest examination
1	2	Yes: inside mouth and throat	No
1	2	No	No
1	2	No	No
2	3	Yes: eyelid examination	Yes: chest examination
2	3	No	Yes: abdominal examination
2	3	No	No

The medical devices were not always able to properly convey what the nurse saw or heard on the ground. The stethoscope was reported to provide variable sound quality. When comparing the performance of the digital stethoscope with her own stethoscope, the doctor at site 1 noted:

> *Digital stethoscope note: audio very loud can over-amplify sound which could lead to overinterpretation of pathology. Low frequencies are very loud, high frequencies not audible.*

For the first patient at site 2, the doctor could not hear the breath or heart sounds from the digital stethoscope, as can be seen from the following note:

> *Stethoscope sound quality was not sufficient to assess heart sounds.*

However, the sounds could be heard for the subsequent 2 patients at site 2, and the doctor reported high sound quality for these patients. The doctor at site 2 determined that this could be due to the faintness of the breath and heart sounds in the first patient, which the nurse could hear but he could not. Therefore, while the stethoscope demonstrated satisfactory performance for some patients, this was not consistent between patients. Furthermore, the examination camera was more useful in sharing dermatological images rather than otoscopic images. The nurse at site 1 provided the following comment:

> *During this consultation it was a bit challenging to demonstrate clearly using the otoscope, to show the mouth clearly. For the light (otoscope) I tried removing the black head and focuser but the light wasn't able to clearly show the focused part of the mouth/throat and show the gingivitis/swelling and infection in the gums and teeth. After removing the black head for the clear head and focuser, it still wasn't easy to see the mouth/gums/teeth. It seems the colour of the light (light blue light) doesn't work well, we tried using the light from the ward's otoscope and it was more yellow/orange and the viewing/imaging was much better in that light.*

So, to alleviate the challenges from the medical camera, the device was used in combination with the light provided from the clinic otoscope. In addition, it was mentioned several times that the medical camera could not show a clear view of the tympanic membrane in the ear. This was a similar comment received during usability testing, which motivated a redesign of the otoscope to allow for a narrower tip to navigate the ear canal. However, this redesign was not able to change the design of the device itself, which may need to be adjusted to improve this capability.

Although the devices used were Federal Drug Administration– and Conformité Européenne–approved, they did not end up providing the quality necessary during all examinations. The evidence provided supports user-guided feedback on how the devices may be improved. These conclusions also motivate further development of open medical devices that are not tied to proprietary software, as the market options for these types of devices are limited. Development and improvement of these devices for use in systems such as the developed virtual clinic will be advantageous to providing better quality virtual care.

Finally, there were limitations of the virtual clinic system in providing primary health-level services. While most consults conducted using the virtual clinic were successful, there were some limitations of the system that should be mentioned. Some challenges simply cannot be addressed, given the current technical capabilities of virtual consultation. For example, the nurse at site 1 highlights one piece of information she struggled to share with the doctor during a consult:

> *The warm of the patient's hands, that had to be described extensively.*

At the current state, it would not be feasible to add a device that can convey this information with certainty; however, there could be additional training or research in description or examination

XSL•FO
RenderX

that could assist with conveying the necessary information to the doctor. Ultimately, it was not within the scope of this study to determine what cases are not appropriate for virtual care and which are best suited, but this is recommended for further research.

Discussion

Principal Findings

The results from this study inform recommendations for digital health systems for remote, rural, and underserved areas. These recommendations are summarized in Table 4. There were still some areas for improvement in the system design, as demonstrated by clinical implementation feedback, but most of the user feedback centered around implementation feedback rather than system design feedback. This transition demonstrates how UCD-based iteration proved effective in taking user feedback to develop an improved virtual clinic system that addressed user needs [28].

Table . Summary of virtual clinic recommendations.

Result	Supporting evidence	Recommendation
Experience is an enabler of confidence and success for new users.	• As consults progressed, doctors reported less reliance on the follow-up physical examinations to diagnose. • Physical consult time reduced as consults progressed. • Doctors' confidence in virtual diagnosis increased as consults progressed.	• Nurse and doctor users should participate in training and hands-on practice with the system.
Patients' satisfaction is demonstrated when patients understand the benefits of virtual consults and are included in communication.	• Patients reported high satisfaction with the virtual clinic system postconsultation. • Wait times were reduced for patient participants in comparison with other patients in the clinics. • Three communication styles emerged, which had different effects on patient involvement during the virtual consult.	• Nurse and doctor users should be educated on the different communication styles for virtual consults and apply them based on the patient context. • Patients should be educated on the potential positive impacts of virtual consults to encourage adoption.
Clear, descriptive communication between providers facilitates successful consults.	• Nurses used verbal descriptions to convey the patient's condition to the doctor during virtual consultations. • Doctors could confidently diagnose patients based on verbal description supplemented with medical device data.	• Nurse and doctor users should be trained together on using descriptive verbal communication during virtual consults. • Nurse and doctor users should practice virtual and physical consults together to build trust in one another's skills.
Barriers caused by infrastructure and the implementation environment can be addressed adequately but must not be ignored; otherwise, success could be threatened.	• Changing the network access hardware for the virtual clinic app correlated with better quality of service and an increase in doctors' confidence in virtual diagnosis. • Nurse and doctor users commented positively on the higher-quality camera implemented on the second day of study.	• High-quality periphery devices (cameras, headphones, and network access devices) should be used with the virtual clinic app to enable virtual consult success. • The physical clinic setup should support virtual consults, including positioning the examination bed and the patient near the camera and microphone.
Medical device data may not be suitable for conveying certain types of health information.	• The stethoscope device did not convey soft or shallow breath and heart sounds adequately for the remote doctor to hear. • The medical camera could not show mouth, teeth, and ear images adequately for the remote doctor to see.	• Existing medical devices should be improved based on the user's feedback provided in this study. • There should be more open medical devices for open software apps, such as the virtual clinic. • Nurses should be trained on how to supplement medical device data with verbal descriptions.
There are limitations of the virtual clinic system in providing primary health-level services.	• The virtual clinic system could not convey data regarding the warmth of a patient's hands, which the nurse deemed important for diagnosis.	• The constraints of the virtual clinic system should be further defined based on additional studies. • The virtual clinic system should consider the health data requirements of the implementation context and the feasibility (cost and market availability) of the technology used to convey these health data.

XSL•FO
RenderX

The user feedback provided during clinical implementation aligns with the Capabilities, Opportunities, Motivation, and Behavior (COM-B) framework for behavioral change [48]. COM-B states that users need the capacity to engage, a conducive sociophysical environment, and the drive to perform a behavior. In this context, capability refers to the user's ability to interact with the system, which is supported by help desk materials and exposure to the system. Opportunities can involve the infrastructure used to support the implementation. Motivation included the intrinsic desire of the health care worker to provide proper care to their patients [49], which was enabled by the virtual clinic system. This result has been reported in the development of other digital health solutions that used UCD principles [50,51]. Doctor and nurse participants highlighted the need for a solution in the public health care system and expressed a greater tendency for behavior change after they felt more capable of using the system. Working in teams was an enabler of success for both users, as trust was built and effective communication styles were established. This aligned with similar findings of virtual clinic implementations [52]. The threats of the physical environment and technology that were experienced, such as the network issues on day 1 of implementation, did have a negative effect on the provider's experience with the system, aligning with the opportunities aspect of COM-B and the consensus in literature that technological functionality has an effect on provider telemedicine satisfaction [53]. Additionally, there was a demonstrated improvement from the previous results of usability testing [32], where users indicated that they would like more training with the system. This aligns with the capability aspect of the COM-B framework, as users were provided an opportunity to build their confidence with the virtual clinic system before consulting with patients [54]. This included hardware and software components. The help desk subsystem, including the hands-on training that was incorporated, provided for this aspect of motivation. This design also supported potential threats identified, such as a lack of generational digital literacy [55]. Motivation was still clearly existent, as the providers also understood the needs of the health care system and the benefits that the virtual clinic system could provide. Therefore, when the technological challenges were addressed, all factors of the COM-B framework were addressed, and participants had a greater likelihood of wanting to implement the virtual clinic system. At site 2, these challenges had been addressed, and therefore quicker uptake of the virtual clinic system was demonstrated.

The results of this evaluation serve as a proof of concept that the system can work in real-world environments and motivate for further research and implementation based on these recommendations. Not only does this information provide insights into the virtual clinic, but it also provides insights into the landscape and readiness of South Africa for digital health implementations. The information, such as patient satisfaction with virtual clinic services, provider opinions toward virtual clinic consultations, quality of service of various African and South African networks, and hardware considerations for better design, motivates for implementation of virtual clinic and digital health solutions in these areas.

Conclusions

The results of this study support the acceptability and feasibility of the developed virtual clinic system in a real-world setting. Furthermore, the results of this study provide evidence of virtual clinics in remote, rural, and underserved areas of South Africa. This research highlighted that provider experience and confidence with using the digital health system was an enabler of successful virtual clinic consultations. Additionally, clear communication between the health care worker in the remote, rural, or underserved area and the remotely located doctor resulted in quicker consultations. Patient feedback emphasized that when providers directly communicate with patients during virtual consultations, and when the patient understands the benefits of using virtual clinic consultations, patients have improved experience. Finally, barriers that are discussed in similar implementations, including limited infrastructure [11-13] and contextual challenges [14,15], were also observed during this study. However, these contextual challenges could be overcome with appropriate design methodologies such as UCD. This included selection of medical devices that align with the needs of the context and the limitations of the environment.

The current evidence of interventions in remote, rural, and underserved areas is limited; therefore, these results contribute not only to the development of this system but also to the development of other digital health solutions. The nature of the feedback and observations provides insights into the motivation and behaviors of doctors, nurses, and patients using virtual clinic services in low-resource South African contexts. The recommendations from the Results section provide a framework of how other digital health developers might consider implementation in these contexts, aligning with the monitoring and evaluation phase of the World Health Organization Telemedicine Implementation Guidelines [16].

There were some methodological and contextual limitations of this study. There was a lack of additional reviewers and coders used during thematic analysis. While this is important to reduce bias, other measures, such as reporting direct quotes and performing iterative thematic analysis, were introduced to reduce bias. Considering the patient population recruited, there may have been bias in patient satisfaction with the system, particularly at site 1. This is because patients who were recruited were green-triaged patients, who are the lowest priority patients at the clinic. Often, these patients face the longest wait times as the other, higher priority patients take precedence over them. Some green-triaged patients do not see a doctor at all when entering the clinic, particularly on a weekend when clinic staff is limited. They may also be limited to seeing a nurse only, and not a doctor at the clinic, depending on their complaint. Their participation in the study allowed them to see a doctor almost immediately after being triaged at the clinic. As such, they may have indicated satisfaction due to the speed and quality of care they were provided by their participation in the study. Given this, further validation of patient satisfaction results during long-term virtual clinic implementation is needed. Finally, it is suggested that additional studies incorporate a direct comparison between diagnosis during virtual and diagnosis during physical examinations. This allows for a better comparison between the 2 interventions.

Abstract

Background: Esports athletes face substantial psychological stressors comparable to those experienced by traditional athletes, yet mental health tools tailored to their specific needs remain scarce.

Objective: This study addresses this critical gap by introducing MindAthlete, a prototype for a user-centered mobile health (mHealth) app intended to enhance mental health monitoring and support among esports athletes.

Methods: A 3-stage development process was used over 5 months. First, structured qualitative interviews were conducted online via Google Meet with 7 experienced (sports) psychologists recruited through snowball sampling within professional esports networks. The interviews explored current mental health monitoring practices and key feature requirements for MindAthlete. Data were analyzed using Mayring's approach to qualitative content analysis. Subsequently, a 32-screen high-fidelity prototype was developed in Figma based on the identified requirements. In the final stage, usability testing was conducted with 25 semiprofessional and professional esports athletes recruited via convenience and snowball sampling. Participants interacted with the Figma prototype and completed an online questionnaire administered via LimeSurvey, which included demographic items, the validated 10-item System Usability Scale (SUS) rated on a 5-point Likert scale, and open-ended questions on navigation, aesthetics, and overall functionality. Inferential analyses included Mann-Whitney *U* tests, Kruskal-Wallis tests, and Spearman correlations. Open-ended responses were analyzed using Mayring's content analysis.

Results: Expert interviews identified 8 core features for mental health monitoring in esports, clustered around 3 themes: continuous self-monitoring, structured assessment, and intervention and insight. Athlete usability testing yielded a median SUS score of 77.5 (IQR 67.5-87.5), classifying usability as "good" and exceeding a benchmark median of 68.3 derived from comparable mHealth apps. No significant differences were found by sex, age, years of professional experience, or prior mHealth usage. Qualitative feedback highlighted strengths including intuitive navigation and appealing aesthetics, alongside areas for improvement such as shorter animations and clearer initial onboarding. However, findings must be interpreted in light of the sample's demographic homogeneity, which limits generalizability to the broader esports population.

Conclusions: This research provides a stakeholder-driven, empirically validated blueprint for esports-specific mental health monitoring via mHealth. Future work will focus on technical implementation, integration of wearable sensor data, and broader evaluations with larger, more diverse samples to confirm generalizability and enhance usability.

Introduction

Esports is defined as playing video games regulated through ranking systems and official leagues via electronic devices, encompassing a spectrum from amateur players to elite professionals [1]. While esports participation broadly covers various levels, this work focuses specifically on competitive esports athletes operating at semiprofessional and professional tiers. As participation and competitiveness have grown, understanding the health profile of esports players has become a central focus. Recent systematic and scoping reviews indicate that esports participants do not inherently exhibit poorer baseline mental health than nonparticipants [2], although high-volume participation is associated with specific physical, lifestyle, and psychological vulnerabilities [3,4]. Crucially, psychological states and health risks differ across competitive tiers.

XSL•FO
RenderX

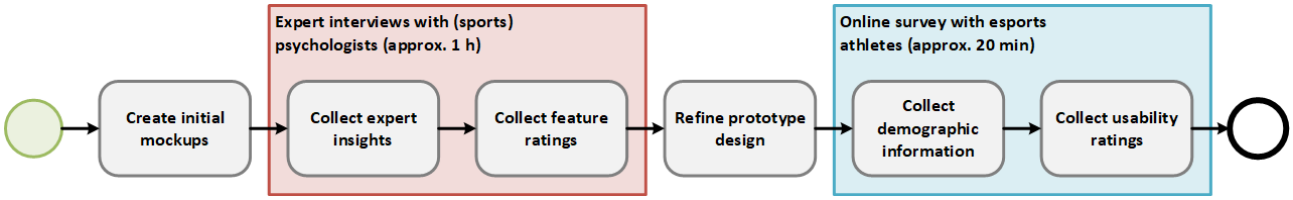
Nonprofessional and amateur players primarily face lifestyle-related risks, such as sedentary behavior, elevated body fat, and gaming disorder tendencies [2]. In contrast, semiprofessional and professional athletes, who operate under structured team environments, contractual expectations, and tight competition schedules, face intense domain-specific stressors, including performance expectations, team conflicts, and demanding tournament schedules [4-7], which predict a high prevalence of mental health challenges [8,9]. Among competitive players, these multidimensional demands frequently result in elevated stress, anxiety, depression, burnout, sleep disturbances, and night-eating tendencies [10-13]. These conditions highlight an ethical imperative to address mental health concerns proactively in esports, as untreated issues can compromise immediate performance and long-term psychological well-being [7,14]. However, the esports industry still lacks sufficient mental health support systems [15]. While players report positive attitudes toward psychological support [16], hiring dedicated staff is costly (especially for smaller organizations), and continuous manual monitoring is time-consuming. Mobile health (mHealth) apps may offer a scalable alternative to streamline screening and ongoing monitoring [17-19].

Although mHealth tools have demonstrated efficacy in symptom tracking for broad clinical conditions such as stress, depression, and posttraumatic stress disorder [20-23], they target general psychopathology rather than performance-related distress and contextual triggers unique to competitive athletes. Furthermore, such generic tools frequently suffer from poor usability and low long-term engagement [24,25]. In sports specifically, mHealth apps have demonstrated feasibility for mood tracking, automated risk detection, and psychological skills training, though tool quality and evidence bases vary widely [17,26]. Blended models combining in-person and digital components have been proposed to enhance athlete accessibility and real-time clinical decision-making [27,28]. However, these sport-specific tools are typically embedded within colocated, traditional training environments, and their design assumptions around physical load, coaching structures, and recovery processes often do not align with the screen-bound workflows of esports team structures, limiting their transferability. The esports ecosystem itself has seen a rise in performance-enhancement tools lacking scientific validation [1], and players may also engage with generic mindfulness apps or game-embedded focus aids. However, these tools are designed to support general relaxation or productivity rather than to screen for or monitor mental health risk, offer no structured pathway to practitioner oversight, and do not capture the specific performance, organizational, and social stressors that distinguish this population [5,7], limiting their value as tools for proactive mental health support.

Given these limitations, we developed MindAthlete—a novel, noncommercial mHealth prototype designed specifically for mental health screening and monitoring in esports athletes. It is shaped through direct consultation with practicing esports psychologists and esports players, ensuring that each design decision reflects real-world clinical needs rather than assumed requirements.

To guide this development process, 2 research questions were formulated:

Research question 1: What features are essential for mental health monitoring in esports athletes according to (sports) psychologists?



Research question 2: How do esports athletes rate the usability of the prototype, and what do they identify as strengths, areas for improvement, and additional feature needs?

Methods

Study Design

In this study, we followed a 3-stage development process (Figure 1). This process was guided by the design thinking methodology, which emphasizes iterative, user-centered development and encourages early stakeholder involvement to ensure the solution fits real-world needs [29]. While user-centered design typically involves end users at every stage, our approach used a phased stakeholder engagement strategy. Given that MindAthlete is designed for a dual-user ecosystem (athletes for data entry and specialized practitioners for clinical monitoring), we prioritized the "expert-user" during the initial define and ideate phases. This choice was driven by the clinical necessity to ensure that the app features were scientifically valid and actionable for practitioners, who serve as the primary stakeholders for data interpretation and intervention. The first stage involved systematically gathering functional and nonfunctional requirements through structured interviews with domain experts. In the second stage, we created a design prototype to visualize the user interface and intended workflow. In the final stage, we conducted usability testing with semiprofessional and professional esports athletes to empirically evaluate MindAthlete's usability and collect targeted feedback for further refinement.

Figure 1. Overall study design. Red: expert interviews with (sports) psychologists; blue: online survey with esports athletes.

XSL•FO
RenderX

Expert Interviews

The recruitment phase for the expert interviews followed a snowball sampling approach, as the population of practitioners specialized in esports psychology and mental health is extremely small globally. This scarcity is reflected in the broader industry reality, where dedicated sports psychology support remains absent across much of the professional landscape [15]. Leveraging initial contacts within a professional network via email, additional suitable experts were identified through recommendations, ensuring that participants had highly relevant and specialized expertise. Snowball sampling was particularly appropriate given the niche nature of the esports psychology field. Inclusion criteria required participants to hold an academic degree in psychology or sports psychology and to have at least 3 years of professional experience. Additionally, eligible participants had to be actively involved in the esports industry as practitioners, either working with athletes competing in higher divisions of the European Regional Leagues or providing guidance to professional esports players in international top-tier competitions. Finally, participants had to be proficient in German or English. These criteria were selected to ensure that only experts with a solid academic background and direct practical experience in supporting esports athletes' mental health contributed to the study.

After the experts gave their informed consent, an online meeting was scheduled. The interviews followed a predefined interview guide to ensure a standardized procedure (Multimedia Appendix 1) and were conducted by the first author (LS), who possessed domain expertise in esports player performance and formal training in qualitative research methodologies. At the beginning of the interview, experts were asked about the necessity and current practices of mental health monitoring in esports. Then, they were introduced to mHealth apps and asked about the required features for MindAthlete. Eight potential features were preselected based on a literature review of mHealth apps for mental health and the evaluation of leading apps in this domain. This helped to identify core functionalities commonly recommended or implemented for psychological self-monitoring. These features were presented to the experts via screen sharing and explained in detail. Experts were then invited to provide feedback regarding the potential benefit of these features. Additionally, they could suggest additional features, which were then verbally refined in close collaboration. Experts were then asked to rank both the preselected and their own suggested features based on perceived importance and usefulness. While all experts ranked the 8 preselected features, the total number of ranked items varied because experts could also rank their own suggested features. However, the scale always remained fixed at 8 points for the highest-ranked item down to 1 point for the eighth. The 8 highest-ranked features across all interviews were selected for implementation. A point-based system was introduced, assigning 8 points to the highest-ranked feature, 7 to the second-ranked feature, and continuing in this manner until the eighth-ranked feature, which received 1 point. In cases of equal point totals, features were ranked by evaluating their specificity to esports mental health vs broader health contexts and prioritizing the feature with more immediate relevance to professional esports. Finally, experts were asked about their preferences regarding the user interface, platform accessibility, and data privacy concerns.

All interviews were recorded and automatically transcribed using the aTrain software [30] and manually checked for accuracy. Data analysis involved both deductive and inductive content analysis, following Mayring's approach [31]. Two researchers were involved in the qualitative analysis. The first author (LS) conducted the initial coding. Deductive categories were derived from the interview guide and covered the perceived importance of mental health tracking, past and present monitoring methods, their sufficiency, comprehensive metrics for mental health assessment, feedback on each of the 8 literature-based candidate features, further expert-suggested features, interface preferences including colors and platform, data security concerns, feature ratings, and reasons for those ratings. The feature-related deductive categories were each coded along two dimensions: expert opinions on the feature and specific suggestions or requirements for its implementation. To capture unanticipated themes, inductive categories were derived directly from the transcripts following Mayring's inductive category formation procedure. The criterion of selection was defined to include any statement addressing contextual factors, organizational conditions, or operational requirements not covered by the predefined feature matrix. Text segments meeting this criterion were open-coded, grouped by thematic similarity through iterative reading, and subsumed into broader categories (cooperation with support staff, the perceived purpose of the application, user engagement strategies, and challenges in application adoption). A senior supervisor (JS) reviewed the full code structure to ensure consistency and resolve discrepancies, providing feedback on category definitions and relevance (Multimedia Appendix 1). Following the coding process, categories related to feature ratings and expert rationale were used to calculate the point-based feature ranking system, while interface and contextual categories informed nonfunctional design decisions for the prototype.

Design Prototype Development

The insights and user requirements identified through expert interviews were systematically aggregated, evaluated for coherence, and directly integrated into a high-fidelity design prototype using the prototyping software Figma [32]. A total of 32 screens were designed, representing the primary user flow from onboarding to feature interaction, including feedback elements and animations. The 8 highest-ranked features, as determined by experts, were implemented. Decisions to include, modify, or exclude certain feedback were guided by their alignment with expert consensus and evidence, and their coherence with established best practices identified in the literature. Additional feedback was retained if (1) the suggestion was voiced by at least 4 of the 7 experts, a threshold chosen to reflect clear majority consensus, or (2) the expert provided a concrete scientific or clinical rationale. Feedback that did not meet these criteria was archived for future iterations.

Low-fidelity mockups were iteratively refined into a high-fidelity prototype by the main author (LS) and the supervisor (JS), directly informed by the synthesis of the expert interviews. Choosing a high-fidelity prototype at this stage was

XSL•FO
RenderX

justified by the need to closely simulate real user interactions, enabling an accurate assessment of usability. All screens and interaction flows were designed following user-centered design principles, drawing on Nielsen's usability heuristics [33], Norman's design principles [34], and empirical guidelines from health usability research [35], to ensure consistent layouts, clear navigation, and immediate feedback.

Applying these principles, the resulting prototype comprises the key features depicted in Figure 2. The Home Screen (Figure 2A) provides an overview of sessions, daily tips, and gamification status, with a sidebar for navigation. The Mood Tracker (Figure 2B) uses a slider and context tags to log current or daily mood. The Dashboard (Figure 2C) presents interactive graphs that users can filter by year, month, or week. Sport psychological questionnaires (Figure 2D) also include a weekly check-in for lifestyle data. The selection of specific validated instruments is ongoing and will be finalized in the next development phase. Instruments of interest are the World Health Organization-Five Well-Being Index (WHO-5 [well-being]), Generalized Anxiety Disorder-7 (GAD-7 [anxiety]), Patient Health Questionnaire-9 (PHQ-9 [depression]), Perceived Stress Scale (PSS [stress]), or Athlete Psychological Strain Questionnaire (APSQ [athlete-specific psychological strain]). Grounded in self-determination theory [36], gamification mechanics were incorporated to enhance engagement: each completed survey or tracked entry triggers a sky lantern animation (Figure 2E) that floats upward to symbolize progress and award points, ranks, and trophies, directly mirroring the reward systems native to competitive esports environments. This prototype formed the basis for subsequent usability testing.

Figure 2. Screenshots of the Figma prototype. (A) Home Screen displaying the next session with the (sports) psychologist, daily tips, and gamification elements. (B) Mood Tracker allowing players to select their mood and add descriptive words. (C) Dashboard presenting results from the mood and stress trackers as well as questionnaires. (D) Example of a sport psychological questionnaire. (E) Sky Lantern animation representing the gamification theme and the metaphorical sense of letting go.

Athlete Usability Testing

Participants were recruited through a combination of convenience and snowball sampling. Leveraging personal and professional contacts within the esports industry, initial invitations were distributed directly to esports athletes, teams, and affiliated organizations. Additional invitations were sent via professional esports networks to maximize outreach across different teams and regions using email and Discord, a primary communication platform within esports communities. Inclusion criteria required that participants be at least 18 years old and proficient in English, and actively competing in esports at a semiprofessional or professional level. Specifically, professional status was defined as athletes competing in top-tier continental leagues under full-time contracts, while semiprofessional status included athletes in regulated national or regional leagues (eg, Division 1 or 2). The participants in the latter category also operated under professional conditions, characterized by fixed salaries, official team affiliations, and commitment to training and competition. All participants provided their informed consent before participating.

Participants were invited to test the MindAthlete design prototype and complete an online questionnaire administered through LimeSurvey [37]. Usability was assessed using the validated 10-item SUS questionnaire, rated on a 5-point Likert scale [38]. The SUS was chosen due to its proven reliability and widespread acceptance in usability research. A target sample size of 20 to 30 participants was deemed sufficient based on recommendations for usability testing with the SUS [39]. Additionally, open-ended questions were included to solicit detailed feedback on navigation, aesthetics, and overall functionality of the prototype. The questionnaire also collected demographic and contextual information, including age, sex, nationality, esports experience (total and paid years), primary income status, and prior mHealth usage. All items were mandatory for completion, and the athletes were able to change their answers through a back button.

Data analysis consisted of three steps. First, descriptive statistics were computed to summarize the data. To determine the appropriate measures of central tendency, normality was assessed using the Shapiro-Wilk test, and outliers were examined using the IQR method. Second, inferential analyses were conducted to examine prespecified group differences and

XSL•FO
RenderX

relationships. Specifically, SUS scores were compared across sex groups (female, male, and other) and age groups (18-21, 22-25, 26-29, and 30-33 y) using the Mann-Whitney *U* test and Kruskal-Wallis test, respectively. Associations between SUS scores and continuous variables (years of professional experience and paid years of experience) were assessed using Spearman correlations. Additionally, group comparisons were performed for main income status (esports as primary income: yes/no), prior mHealth usage (yes/no), and nationality. A Bonferroni correction was applied to control the family-wise error rate across all inferential tests. Each obtained *P* value was multiplied by the total number of comparisons performed (k=7) and compared against the nominal significance threshold of α=0.05. Finally, open-ended responses were analyzed qualitatively using Mayring's content analysis approach [31] by the primary coder (LS) and reviewed by (JS), following the 2-tiered deductive-inductive procedure described previously. Top-level deductive domains were anchored directly to the 3 open-ended survey prompts: positive feedback, areas for improvement, and suggestions for additional features. Within each deductive domain, inductive subcategories were derived directly from the response text through line-by-line coding and iterative thematic grouping. For positive feedback, inductive analysis yielded 3 categories: perceived learnability and low cognitive load, aesthetic acceptance, and perceived safety through help-seeking visibility. Areas for improvement produced 5 categories: gamification fatigue, onboarding deficit, navigation ambiguity, information density, and individual usability concerns. Feature suggestions yielded 4 categories: behavioral prompting and habit formation, intelligent clinical integration, privacy-controlled communication, and holistic well-being expansion.

Researcher Characteristics and Reflexivity

The research team possessed an interdisciplinary background combining expertise in game development, esports, and health informatics. The first author previously worked as a project manager within the esports industry. This prior insider knowledge aided in the contextual interpretation of data across both studies. The second author, serving as the supervisor, is an experienced researcher in digital health who reviewed all coding decisions to mitigate potential bias. These characteristics were considered throughout the research process, particularly during data analysis, where iterative discussions between both researchers aimed to balance insider familiarity with critical distance.

Ethical Considerations

All participants were asked to give their informed consent after reading information about the purpose of the project, the investigators, the length of time, data protection, and the questionnaire domains. To safeguard participant information, all data were treated confidentially. Expert interview recordings were pseudonymized immediately after transcription, with participants assigned neutral identifiers and the original recordings subsequently deleted. Athlete questionnaire data were collected anonymously, with no personally identifiable information retained. Ethical aspects were reviewed and approved by the Joint Ethics Committee of the Universities of Applied Sciences of Bavaria (GEHBa) in accordance with current scientific best-practice guidelines (GEHBa-202403-V-170).

Results

The following section presents the results of both studies, highlighting key findings and outcomes relevant to the research questions.

Expert Interview Results

Structured qualitative interviews were conducted with 7 (sports) psychologists via Google Meet (Table 1). The participants represented 5 different nationalities and included sports psychologists (4/7, 57%) and general psychologists (3/7, 43%). The aim was to explore their perspectives on mental health monitoring in esports and to identify key requirements for MindAthlete.

Table . Information on interview partners and interview details.

Expert ID	Sex	Degree	Language	Duration, min
Expert 1	Female	Sports Psychology	German	108
Expert 2	Male	Sports Psychology	German	100
Expert 3	Female	Psychology	German	56
Expert 4	Female	Sports Psychology	English	95
Expert 5	Female	Psychology	German	50
Expert 6	Female	Psychology	German	81
Expert 7	Male	Sports Psychology	German	53

Current Mental Health Monitoring Practices and Gaps

Experts affirmed the need for systematic monitoring given athletes' vulnerability to mental health issues (perceived importance of mental health tracking). Current practice, relying on questionnaires, passive observation, and informal check-ins (past and present monitoring methods), is limited by subjectivity, declining engagement, and uncertain self-report honesty, as Expert 7 noted: "I'm just a bit dependent on it: do they tell me the truth?" (sufficiency of these methods). Comprehensive monitoring should integrate psychological, behavioral, emotional, and physical dimensions, with mood as an early indicator and an esports-adapted context (comprehensive metrics for mental health assessment). This is reflected in the prototype's

XSL•FO
RenderX

combined use of validated assessment tools, lifestyle-focused context input, and behavioral self-report tasks that pair quantifiable ratings with contextual, esports-specific detail, directly addressing experts' concern that passive observation alone relies too heavily on subjective interpretation, while still capturing an esports-adapted picture that generic clinical tools do not offer.

Feature Requirements

Experts evaluated 8 candidate features (feedback on literature-based candidate features), most strongly endorsing the mood and stress trackers and a dashboard providing trend views for both athletes and practitioners, as Expert 3 put it: "You need a dashboard where I can glance at trends, spreadsheets simply don't cut it." Sport psychological questionnaires and mental health risk screening, both grounded in validated measures, were also well-supported. Stress relief techniques and help-seeking options were valued as around-the-clock resources, given esports' irregular schedules. Experts also proposed features beyond the preselected set (expert-suggested features), most notably a weekly check-in capturing lifestyle contexts, such as sleep, social contacts, and fitness, alongside push notifications, journaling, goal-setting, and a buddy system, of which only the weekly check-in ranked among the top 8. The ratings (feature ratings and reasons for ratings) converged strongly across psychologists and sports psychologists, with data collection features rated highest, as Expert 4 summarized: "All the trackers are the most important bit for me...But what is the point of having trackers if you do not have a dashboard?" This convergence highlights a shared need to turn raw data into actionable clinical insight, not merely to collect it. The 8 highest-ranked features (Table 2) directly informed the final feature set, clustering into continuous self-monitoring (mood tracker, stress tracker, and weekly check-in), structured assessment (sport psychological questionnaires and mental health risk screening), and intervention and insight (stress relief techniques, help-seeking options, and dashboard), reflecting a balance between mental health monitoring and on-demand support. Help-seeking options were prioritized over messages in a tie-break, as there are other already existing channels. Psychoeducation, while supported, raised feasibility concerns and did not rank in the final 8.

Table . Top 8 features for MindAthlete and their total points.

Feature	Points
Mood tracker	48
Stress tracker	43
Dashboard	27
Sport psychological questionnaires	21
Stress relief techniques	20
Mental health risk screening	19
Weekly check-in	13
Help-seeking options	11

Design and Implementation Considerations

Two deductive categories addressed practical design requirements. Experts favored nonclinical, gaming-familiar aesthetics, including a dark mode, a gaming-inspired color scheme, and consistently preferred desktop access for practitioners' data review alongside mobile access for athletes (interface preferences including colors and platform). Both the dark mode and color scheme were incorporated into the mobile prototype, and the platform preference directly shaped MindAthlete's dual-platform design: a mobile app for athletes and a web-based practitioner dashboard planned for future development. Experts also emphasized data security given the sensitivity of mental health data, recommending anonymized identifiers, biometric or PIN-based access, and transparent communication about data use (data security concerns), as Expert 4 noted: "Kind of considering the ethics of this, like where is the information going? Who has access to information?" These measures have not yet been implemented, having been deprioritized in favor of the top 8 core features and initial engagement mechanics.

Broader Application Context

Experts envisioned MindAthlete as a support ecosystem that reduces practitioners' administrative burden through preanalyzed data (purpose of the application), as Expert 1 put it: "I should not be looking at the data myself, it needs to land on my desk already analyzed." They also anticipated adoption barriers, including practitioners' limited review time, athletes' limited emotional literacy and tendency toward socially desirable responding, and a self-reinforcing risk of declining engagement if athletes perceive no tangible benefit from their input (challenges in application adoption). A related category emphasized the need for shared understanding among all staff, including ways for nonspecialist staff such as coaches to contribute their own observations about an athlete (cooperation with staff). Finally, experts recommended sustaining engagement through positive reinforcement, gamification, and minimal interaction friction (user engagement strategies). These insights were reflected in several design decisions. To address athletes' limited emotional literacy, the mood and stress trackers were designed with selectable response options, lowering the barrier to reporting. Experts' engagement recommendations were directly operationalized through the prototype's gamification features, confirming the relevance of the

XSL•FO
RenderX

point-based mechanic and rank system. Their suggestions regarding staff cooperation have not yet been implemented. Together with the broader vision and adoption risks described above, these considerations extend beyond the current prototype's scope and inform priorities for future development.

These expert insights directly address research question 1 by identifying and prioritizing the core features considered most relevant for mental health monitoring in esports.

Athlete Usability Testing Results

A total of 134 esports athletes, identified as competitors in 1 of 5 different video games, were contacted for this study. This cohort primarily reflected the male-dominated demographic typical of the professional esports scene. After excluding 3 incomplete responses, the final sample comprised 25 participants. The sample was predominantly female (n=17, 68%) and heavily concentrated in the 22 to 25 age bracket (n=14, 56%). The cohort consisted almost entirely of League of Legends players (n=24, 96%), with an average professional experience of 4.8 (SD 3.2) years, and 17 of 25 (68%) relying on esports as their primary income source. Notably, 22 of 25 (88%) reported no prior experience with mHealth apps. Complete participant demographics are detailed in Table 3.

Table . Participant demographics (N=25).

Characteristic	Participants, n (%)
Age group (y)	
18 - 21	2 (8)
22 - 25	14 (56)
26 - 29	8 (32)
30 - 33	1 (4)
Sex	
Female	17 (68)
Male	7 (28)
Other	1 (4)
Nationality	
Germany	12 (48)
France	4 (16)
Great Britain	3 (12)
Spain	2 (8)
Other	4 (16)
Primary game	
League of Legends	24 (96)
EA Sports FC	1 (4)
Esports as main source of income	
Yes	17 (68)
No	8 (32)
Prior mHealth app usage	
Yes	3 (12)
No	22 (88)

The distribution of SUS scores significantly deviated from normality (Shapiro-Wilk *W* 0.915, N=25; *P*=.04), showing moderate left-skewness (skewness −0.81). Therefore, the median is reported as the primary measure of central tendency: median 77.5 (IQR 67.5 - 87.5), range 42.5 - 92.5, classifying as "good" usability according to established SUS benchmarks [40]. Analysis using the IQR method did not identify outliers (Table 4).

XSL•FO
RenderX

Table . Descriptive summary of System Usability Scale (SUS) scores overall and by sex and age.

Group	n (%)	Median (IQR); range
Total	25 (100)	77.5 (67.5 - 87.5); 42.5 - 92.5
Sex		
Female	17 (68)	75.0 (65.0 - 82.5); 42.5 - 92.5
Male	7 (28)	82.5 (73.8 - 86.3); 47.5 - 92.5
Other[a]	1 (4)	90.0[b]
Age (y)		
18-21[a]	2 (8)	80.0[b]
22 - 25	14 (56)	73.8 (61.3 - 79.4); 42.5 - 90.0
26 - 29	8 (32)	86.3 (79.4 - 88.1); 47.5 - 92.5
30-33[a]	1 (4)	82.5[b]

[a]SD is not reported for n<2. Data are left-skewed; the median (IQR) is reported as the primary measure.

[b]IQR and range are not reported for n<3.

Sex differences in SUS scores (female: n=17, 68%; male: n=7, 28%; other: n=1, 4%) were evaluated using the Mann-Whitney *U* test for female and male participants only. Females had a median SUS of 75.0 (IQR 65.0 - 82.5), and males had 82.5 (IQR 73.8 - 86.3). The Mann-Whitney test revealed no significant difference (U=74.0, z=−0.89, adjusted P>.99, r=0.19). Comparing age groups, the 22 to 25 (n=14, 56%) group showed a median SUS of 73.8 (IQR 61.3 - 79.4), and the 26 to 29 (n=8, 32%) group had 86.3 (IQR 79.4 - 88.1). Initially, the Mann-Whitney *U* test indicated a difference (U=26.5, z=−2.06, P=.047, r=0.43), but after Bonferroni correction, the adjusted P=.33, rendering the difference nonsignificant. Age groups with fewer than 5 participants (18 - 21 y: n=2, 8%; 30 - 33 y: n=1, 4%) were reported descriptively only. Spearman correlations between SUS scores and years of professional experience (ρ=0.14, adjusted P>.99) as well as paid experience (ρ=0.12, adjusted P>.99) were nonsignificant. A Mann-Whitney test comparing SUS by main income status (yes vs no) showed no significant difference (U=62.5, z=−0.29, adjusted P>.99, r=0.06). Similarly, prior mHealth usage yielded no significant difference (U=27.0, z=−0.47, adjusted P>.99, r=0.10). A Kruskal-Wallis test for nationality differences was nonsignificant (H[7]=6.29, adjusted P>.99), and small group sizes in some nationalities precluded further inferential analysis.

Table 5 summarizes the qualitative feedback provided by participants in response to the open-ended questions and is grouped into 3 domains: positive feedback, areas for improvement, and suggested features.

XSL•FO
RenderX

Table . Athlete qualitative feedback categories from open-ended responses (N=25).

Domain and category	Participants, n (%)	Description
Positive feedback		
Perceived learnability and low cognitive load	13 (52)	Interface experienced as immediately accessible without prior instruction
Aesthetic acceptance	7 (28)	Visual design perceived as engaging rather than clinical
Perceived safety through help-seeking visibility	5 (20)	Prominent emergency support options contributed to a sense of psychological safety
Areas for improvement		
Gamification fatigue	5 (20)	Lantern and trophy animations perceived as disruptive with repeated use
Onboarding deficit	3 (12)	Absence of a first-launch guide created uncertainty despite an intuitive interface
Navigation ambiguity	2 (8)	Bottom-menu icons lacked sufficient labeling
Information density	2 (8)	Home screen perceived as visually crowded
Individual usability concerns	3 (12)	Isolated issues, including a mobile scrolling bug, session-scheduling stress, and ranking-system confusion
Suggestions for additional features		
Behavioral prompting and habit formation	4 (16)	Reminders and alarms requested to sustain daily tracking behavior
Intelligent clinical integration	3 (12)	Desire for automated follow-up recommendations linking data to professional support
Privacy-controlled communication	2 (8)	Need for a private reflection space and a separate staff communication channel
Holistic well-being expansion[a]	1 (4)	Nature-sound relaxation, gamified daily-streak tracker, sleep and nutrition tracking, weekly summary dashboard

[a]Each suggestion was raised by a single participant and did not meet the threshold for a distinct category.

Positive feedback centered on ease of use, most prominently in the perceived learnability and low cognitive load category (13/25, 52%), reflecting athletes' experience of the interface as immediately accessible without prior instruction. As P3 remarked, "The basic level of the UI made it feel very easy to understand and use when needing to enter information, making conveying what I felt into the application be done confidently." Athletes also perceived the visual design as engaging rather than clinical and reported that prominent help-seeking options contributed to a sense of psychological safety. Together, these categories suggest that the design achieved both functional usability and the emotional accessibility necessary for engaging with sensitive self-monitoring content.

Critical feedback concentrated on motivational elements, initial orientation, and visual clarity rather than core functionality. The most frequently cited concern was gamification fatigue (5/25, 20%): while gamification elements were implemented to enhance engagement, the animations were perceived as disruptive with repeated use, as P1 noted, "the speed at which the lantern and trophy animations are played...feels like it could become annoying." Onboarding and interface clarity issues were also raised. These findings suggest that MindAthlete's core design foundations are sound, with targeted refinements needed in motivational calibration and onboarding.

Suggested features extended beyond aesthetic preferences toward a more integrated vision of the app. The most common request was for behavioral prompts such as reminders and alarms to sustain daily tracking (4/25, 16%), followed by a desire for automated follow-up recommendations that link daily data to professional support, reinforcing the dual-user ecosystem underlying the prototype's design.

These findings provide a direct answer to research question 2, demonstrating that the prototype is perceived as user-friendly while also highlighting concrete areas for refinement and future development.

Discussion

The following section discusses the key findings of this study, reflects on methodological limitations, and outlines implications for future research and development.

Interpretation of Key Findings

Experts' unanimous recognition of mental health tracking as a core professional responsibility reflects esports athletes' high vulnerability to burnout and anxiety, as well as related stressors such as performance pressure and demanding schedules [5,6,10-12], with untreated issues compromising both immediate

XSL•FO
RenderX

performance and long-term well-being [5,14]. This is also consistent with documented pathways from esports-specific stressors to mental ill health [8], including burnout [12] and night-eating [13]. Furthermore, experts' emphasis on comprehensive mood tracking and dashboard visualization mirrors findings that early mood deterioration predicts severe episodes [41] and that continuous data visualization supports clinical decision-making [25,42], while future sensor integration enriches self-reported psychological data [43]. Feature ratings indicate an underlying rationale: partial deployment (eg, providing tracking features without an integrated dashboard) may limit their practical value. This suggests that MindAthlete's features may be most useful when considered together, rather than as fully independent components. Inductive categories highlight engagement and organizational integration as central challenges. The fear of a self-reinforcing cycle in which absent feedback leads to indifferent athlete input mirrors persistent engagement drop-off documented across mHealth self-reporting tools more broadly [24,25], underscoring that closing the feedback loop is essential for sustained use. Similarly, organizational integration may be as important as technical functionality, consistent with evidence that workflow integration, institutional culture, and staff engagement are among the most prevalent determinants of mHealth adoption, often outweighing technological considerations [44].

MindAthlete's usability score exceeded the benchmark median of 68.3 for mHealth apps, excluding physical activity applications [45], aligning with comparable athlete-facing tools ranging from 72.89 to 78.5 [46-48], despite being an unpolished prototype. Athletes' qualitative feedback suggested that MindAthlete achieved emotional accessibility alongside functional usability, a distinction SUS scores alone cannot capture, particularly relevant given evidence that stigma and embarrassment limit engagement with mental health apps [49]. This is consistent with evidence that esports players welcome personalized, trustworthy support [16], suggesting MindAthlete may address these expectations. Furthermore, their requests for behavioral prompts and privacy controls reinforce health informatics research highlighting the necessity of trust and social scaffolding for long-term engagement [50].

Traditional sports mHealth tools often focus on physical workload, psychological skills training, or mood tracking, but are not designed for esports-specific stressors and rhythms [17,26], while generic mental health apps rely on nonspecialized screening and face persistent engagement challenges [23-25]. By grounding assessment categories, terminology, and gamification mechanics directly in esports culture, MindAthlete represents an initial step toward adapting mHealth principles to the specific performance context of esports.

Potential Implications for Practice

These findings suggest several potential applications for MindAthlete beyond the current prototype stage, though each would require further development and validation. For organizations without dedicated psychological staff, the always-on trackers and screening features may offer accessible first-line support, and experts noted that a future practitioner dashboard could help nonspecialist staff recognize concerning trends. In organizations with existing psychological support, such a dashboard could complement rather than replace informal monitoring practices. More broadly, MindAthlete's approach is consistent with blended models that combine digital self-monitoring with in-person or remote psychological support, which have been associated with improved continuity of care [27,28], though realizing this potential would require careful attention to data ownership and escalation protocols in future iterations.

Limitations

Several limitations merit acknowledgment. First, relying primarily on experts during requirements gathering risked overlooking athlete-led innovations from lived experience. Experts were used exclusively at this stage because they could ground candidate features in established clinical and sport psychology practice, and we mitigated the resulting bias by validating and extending these features through athlete usability testing and open-ended qualitative feedback (research question 2). Only 7 experts were recruited, though strong thematic convergence suggests key requirements were captured despite the absence of full saturation. Snowball sampling may have introduced homogeneity among participating experts, and no formal intercoder reliability statistics were calculated, though a senior supervisor reviewed the coding structure to resolve discrepancies. Additionally, implementation constraints limited the prototype to 8 features, though experts could still propose novel features beyond this set to capture insights outside our literature-based preselection. Suggestions varied considerably across experts, but one novel feature was requested multiple times and ultimately incorporated. While this open approach increased data variability, it enriched the evaluation with previously unconsidered practitioner perspectives.

Regarding the usability testing, additional limitations exist that must be considered. Most notably, 68% of participants were female, a marked mismatch with the male-dominated professional esports industry. Although 134 predominantly male athletes were contacted, the final sample reflects strong self-selection toward female participation, consistent with evidence that men are less likely to engage in routine health-related help-seeking and survey participation [51,52]. Because engaging with a mental health application can itself be understood as help-seeking behavior, usability scores and open-ended feedback should be interpreted with caution. The sample was also highly homogeneous, concentrated in League of Legends (96%) and Germany (48%), reflecting the regional concentration of the European esports ecosystem and our recruitment network within it. Regional differences in working hours, training structures, and health-seeking norms—for instance, the considerably longer and less regulated training hours reported among professional esports athletes in China [53]—may limit the generalizability of usability perceptions to less structured competitive environments.

Relatedly, the cognitive and physiological demands of League of Legends as a Multiplayer Online Battle Arena (MOBA) title differ from those of other genres, with First-Person Shooter titles eliciting greater cardiovascular stress than MOBA titles [54], and MOBA gameplay emphasizing strategic planning and

XSL•FO
RenderX

coordination over the reaction-time demands of First-Person Shooter and Real-Time Strategy titles [1]. These genre-specific profiles are relevant to the feature set, as stressors such as team communication breakdowns are structurally absent in individual titles such as fighting games or sim racing, and League of Legends' team size may have provided athletes with more immediate social support, potentially reducing perceived need for MindAthlete.

Finally, only athletes aged 18 and older were included, and evaluations were based on a high-fidelity prototype rather than a final product. Motivation loss, notification fatigue, and long-term engagement could not be assessed, and positive usability scores may not reflect sustained real-world use. Cultural or prior experience factors may also have influenced the interpretation of SUS items.

Conclusions

This study addressed the need for efficient mental health monitoring in esports by defining practitioner-driven requirements through expert interviews, translating them into an interactive prototype, and evaluating its usability with esports athletes. By grounding the prototype in esports-specific expert and athlete input, this study offers a practical foundation for future mental health tools tailored to the competitive esports context, rather than adapted from generic or traditional sports solutions. MindAthlete's median SUS score of 77.5 demonstrates good usability for this niche audience. However, these findings must be interpreted in light of the sample's demographic homogeneity. Future work should begin with the technical implementation of the mobile app and a web-based practitioner dashboard, the development of a validated crisis intervention protocol, and the establishment of robust data privacy and security mechanisms, developed together with (sports) psychologists, who are also being consulted on instrument selection and escalation management. Athlete feedback from this study should inform the next design iteration. Moreover, further studies should be conducted with larger sample sizes. Specifically, future research must deliberately target cross-cultural and longitudinal studies, focusing on non-European regions, other competitive game titles, and more male-dominated cohorts to explore whether usability and feature preferences differ, and to assess long-term engagement. Finally, integrating passive data collection via wearables could further enable objective monitoring and remote intervention, though this would require careful management of data overload, false positives, and privacy concerns.

Acknowledgments

The authors thank the esports athletes for their participation and candid feedback, and the (sports) psychologists whose expertise was essential in shaping MindAthlete's feature set.

Parts of the manuscript were refined using generative AI tools: Gemini (Google DeepMind) and ChatGPT (OpenAI) were used for translation and grammatical editing, while Claude (Anthropic) was used for text condensation and language editing (all accessed in September 2026). The authors have reviewed and take full responsibility for all final content.

Abstract

Background: Clinical guidelines recommend integrated, person-centered care with control of modifiable risk factors and coexisting conditions in patients with atrial fibrillation (AF), but many receive insufficient risk factor management. Digital health technologies may provide valuable support in addressing this gap.

Objective: Our aim was to evaluate the usability of a co-designed digital platform for supporting person-centered management of modifiable risk factors in individuals with AF.

Methods: This mixed methods usability study was conducted at a tertiary university hospital in Sweden between March and April 2025. Eligible participants with AF were recruited to evaluate the co-designed digital platform using the System Usability Scale (SUS) and semistructured interviews analyzed with inductive manifest content analysis.

Results: A total of 22 patients were included (mean age 67.7, SD 7.6 y); 32% (7/22) were female, the mean BMI was 27.7 (SD 3.6) kg/m^2, 65% (14/22) had paroxysmal AF, 36% (8/22) had persistent AF, and the median AF duration was 26 (IQR 13.3-72.8) months. Relevant comorbidities were hypertension (17/22, 77%), heart failure (8/22, 36%), diabetes mellitus type 2 (3/22, 14%), and ischemic heart disease (4/22, 18%). Usability was rated high, with a median SUS score of 78.8 (IQR 63.8-86.9), indicating above-average user acceptance. Participants' requirements were summarized into 4 main categories and 10 subcategories. First, they valued a *clear layout*, *simple design*, and *easy navigation*. Second, they appreciated *positive content*, which is *informative*, *inclusive*, and *motivating*. Third, they requested *personalized information* on *different aspects* and provided on *different levels*. Fourth, they desired *individualized medical recommendations* that are *personalized* and *flexible* but *open to individual choice*.

Conclusions: Participants found the usability acceptable and valued specifically a *clear layout*, *positive content*, *personalized information*, and *individualized medical recommendations*.

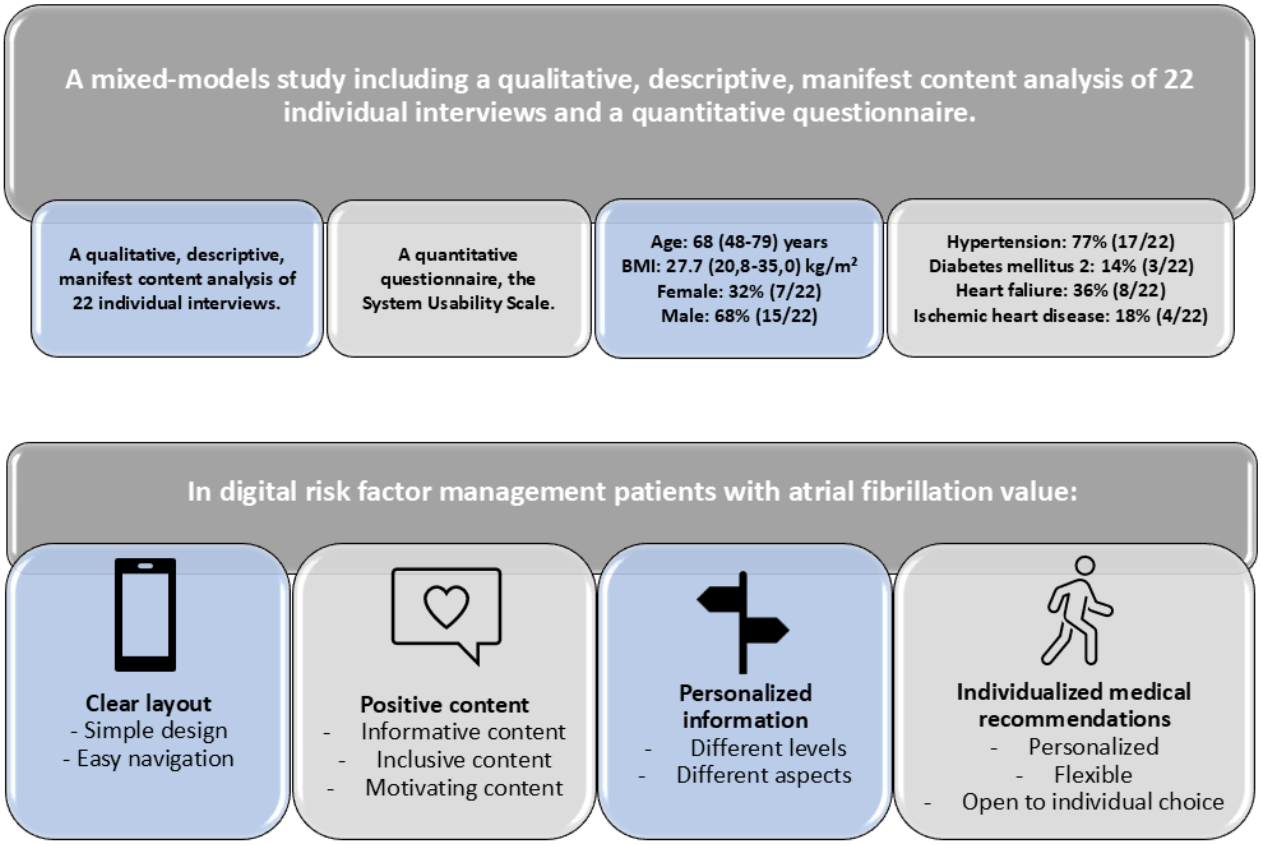
Introduction

The incidence of atrial fibrillation (AF) increases with age and affects more than 3% of adults in a population-based Swedish study, making it the most common cardiac arrhythmia [1]. Patients can experience paroxysmal or persistent AF, and for symptomatic patients, guidelines recommend restoring sinus rhythm, which can be achieved by medical treatment, electrical cardioversion, or more permanently via catheter ablation [2].

AF is associated with nonmodifiable risk factors such as increasing age, height, and male sex [3]. However, it is also associated with modifiable and dynamic risk factors related to comorbidities including hypertension, hyperglycemia, obesity, obstructive sleep apnea, and mental health conditions, but also to unhealthy lifestyle choices including risk consumption of alcohol and physical inactivity [3]. Over half of AF cases in middle-aged adults can be attributed to inadequate control of modifiable risk factors [4]. Several studies have shown that better risk factor management is associated with lower risk of incident AF [5-7], sinus rhythm maintenance [8], and improved outcomes after catheter ablation [9]. Therefore, guidelines specifically recommend integrated management of modifiable risk factors for all persons with AF, especially those undergoing rhythm interventions [3]. Furthermore, the benefits of person-centered care have recently been emphasized, including multidisciplinary, coordinated, and tailored solutions focusing on shared decision-making [10].

Digital health interventions may facilitate person-centered care by supporting self-management and risk factor modification. Although such interventions have shown promising results in cardiovascular disease and other chronic conditions [11,12], evidence in AF is still limited. We therefore co-designed a digital platform to support person-centered management of modifiable risk factors in patients with AF where we now aim to evaluate usability.

Specifically, we aimed to investigate how patients with AF evaluate design, function, and user experience of a digital platform, to identify how to further optimize it according to the needs of the patients, the end users.



Methods

Description of the Co-Design Process

We co-designed a digital platform with the aim of improving support for patients with AF in the management of modifiable risk factors (Figure 1). As a first step, we conducted a study where we identified unmet needs with regard to modifiable risk factors among individuals with AF and further explored the specifics of the desired functions and usability of such a platform [13]. Specifically, participants with AF requested *person-centered information*, support in *managing healthy lifestyle habits*, and more *regular communication* with caregivers [13]. There was a general desire for person-centered care, defined as a partnership where interdisciplinary health care professionals actively listen to and involve the patient in forming a health plan together [14-17]. A prototype was developed based on these findings, tested with the same patient group, and subsequently adjusted according to their feedback, resulting in the co-designed digital prototype evaluated in this study. In this next step of the co-design, we aim to more broadly evaluate the usability of the prototype of our digital platform for supporting person-centered management of modifiable risk factors in individuals with AF.

Figure 1. Graphical abstract.

Description of the Digital Platform

The platform can be used on a smartphone or computer, where patients waiting for catheter ablation for AF enter their medical information, including data on comorbidities and medications, and answer questionnaires about symptoms and lifestyle. Based on their input, an algorithm identifies which factors are scored outside of targets recommended by the European Society of Cardiology guidelines for AF. For example, regarding comorbidities, if a patient enters a BMI>27 kg/m^2 or blood pressure>130/80 mm/Hg, the algorithm identifies these possible targets to optimize based on guidelines. Questionnaires are used in a similar fashion to identify responses that might merit additional attention, for example, individuals who do not reach recommended targets of healthy eating habits or physical activity. These areas are then presented as suggestions to the user to improve. However, the choice of which recommendations to work with remains with the users. Based on the users' choice, a week-long sprint is initiated, providing advice on their areas of improvement. These have been developed with a nurse, dietitian, physician, and physiotherapist and are targeted at each area of improvement with a new task each week. For example, the advice can include weight management support for elevated BMI, physical activity recommendations specific for patients with AF, and healthy recipes to improve eating habits. Users can also follow the progress of measurable values such as blood pressure and BMI over time. Examples of these interventions are illustrated in Figure 2 and Figure 3. Development is purely research-based, and there are no commercial interests involved.

Study Design

This was a mixed methods usability study including quantitative components to evaluate and rate our co-designed tool, as well as a qualitative component to further explore patients' needs and perceptions and identify areas of improvement. In this study, the initial phase of the platform was tested, including signing up, answering questionnaires, and going through the suggested areas of improvement, and provided recommendations for feedback. First, a widely used quantitative scoring questionnaire for the usability of digital tools was used. Second, a qualitative, descriptive study was conducted with an inductive approach, based on semistructured individual interviews that were analyzed by manifest content analysis [18,19].

Recruitment

Eligibility included patients with (1) a confirmed diagnosis of AF who were (2) admitted to the elective Cardiology ward at Karolinska University Hospital (Stockholm, Sweden), specifically for this condition during the interview period of 2 weeks (March 31, 2025, to April 11, 2025). The sole exclusion criterion was not being able to understand or speak Swedish. Eligible patients were identified among those admitted to the cardiology ward during the study period. They were approached in person by the first author (SK), who is a medical doctor and PhD student, and she had no prior relationship with any of the study participants. All participants first received oral and written information about the study; those who accepted participation were then asked to provide written informed consent. Signed forms were collected before data collection.

Data Collection

Immediately after informed consent, first author SK collected baseline data from patients and medical records on age, sex, weight, BMI, medical conditions, as well as previous and ongoing treatments and medications. After this, SK left the room so that patients could begin the usability test alone with a study-provided smartphone with the prototype on the screen. They were suggested to take 1-2 hours to do this by themselves in their single-patient rooms at the cardiology ward but were able to call on the interviewer sooner if ready with the usability test or to request more time if needed. Most patients took about an hour for the usability test, and none demanded more time than 2 hours.

The testing procedure consisted of a structured usability test. Detailed instructions were given in writing to all participants (for exact translated instructions, refer to Multimedia Appendix 1) and included the following steps: creating a user, filling in questionnaires, choosing one of the recommended target areas suggested by the algorithm, and then going through the given recommendations within their suggested area, including, for example, requested measurements, activities, recipes, etc.

Immediately after testing, patients were first asked to answer a System Usability Scale (SUS) Questionnaire [20] (Multimedia Appendix 2). It is a widely used and well-known scoring system for the usability of digital tools consisting of 10 statements where participants answer each one on a Likert scale from 1 to 5 between "strongly disagree" and "strongly agree" [21]. Results are calculated to a total score between 0 and 100, where a higher score reflects a better perceived usability. Above 68 points is considered acceptable usability [21]. Second, directly after filling in the questionnaire, a semistructured individual interview was conducted by author SK, using a structured interview guide (Multimedia Appendix 3) covering topics of design, function, usability, and user experience.

Data Analysis

Quantitative SUS data were analyzed using descriptive statistics, median (IQR). The interviews were recorded (audio), and a contracted transcription service was used to transcribe all interviews verbatim. The qualitative, descriptive, manifest content analysis with an inductive approach was performed according to Graneheim et al [18], Graneheim and Lundman [19], and Krippendorff [22]. The analysis was inductive, and categories emerged from the interview material. The transcripts were read several times and relevant meaning units were identified, condensed, and coded. Codes with similar content were then grouped into subcategories and broader categories. Examples of meaning units, codes, and categories are shown in Table 1. The analysis was conducted after completion of all interviews and included reading the transcribed interviews several times, identification of initial meaning units, condensation (reduction), labeling with codes, and creation of initial categories and subcategories. Wording was completely emergent from the interviews. Analysis was first done separately by author SK and author ML, who is a specialist nurse in cardiology and PhD and experienced in qualitative methods. The process was then further discussed with the author ES and FB, who are both electrophysiologists in the field of AF. They were presented with both raw and already coded material, and the developing categories and discussions were held to strengthen trustworthiness. Where disagreement, discussions were held until consensus was reached among all authors.

Table 1. Examples of meaning units and codes related categories.

Meaning units	Codes	Categories
…do not complicate it with many colors and arrows…	Simple design	Clear layout
…as easy and clear as possible to that you cannot go wrong …	Easy navigation	Clear layout
…inform without frightening…	Informative	Positive content
…non-binary, other…	Inclusive	Positive content
…it doesn't have to be boring to be healthy…	Motivating	Positive content
…atrial fibrillation, what it is…	Different aspects	Personalized information
… with more for those who are extra interested…	Different levels	Personalized information
…depending on the patient…	Personalized	Individualized medical recommendations
…if one doesn't want to, then one can just skip…	Flexible	Individualized medical recommendations
…one should be able to choose…	Open to individual choice	Individualized medical recommendations

Ethical Considerations

The study protocol adhered to the Declaration of Helsinki and was approved by the Regional Ethical Review Board (Dnr 2025-01228-02). All participants were informed of the premises of the study beforehand, participation was voluntary, and they could at any time choose to discontinue their involvement in the study without having to state a reason for it. Data were transcribed anonymously and stored in a designated locked room at the Cardiology Research Department. A detailed COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist is provided as a supplement (Multimedia Appendix 4).

Results

Participant Characteristics and Interviews

In total, 30 participants were eligible and approached. Out of 30 participants, 22 were included and 8 declined participation with the main reasons stated being lack of time and/or interest. The interviews of the 22 participants lasted, on average, 24.3 (SD 9.7) minutes each and resulted in a total interview time of 535.2 minutes with material for analysis. Baseline characteristics are presented in Table 2.

Quantitative Results – System Usability Scale

The SUS questionnaire resulted in a median score of 78.8 (IQR 63.8-86.9) points, presented in Table 3.

Table 3. Results: System Usability Scale scores by item and total.

System Usability Scale Score	Median (IQR)
I think that I would like to use this system frequently	4 (3.5-5)
I found the system unnecessarily complex	1 (1-2)
I thought the system was easy to use	4 (4-5)
I think that I would need the support of a technical person to be able to use this system	1 (1-2)
I found the various functions in this system were well integrated	4 (3-5)
I thought there was too much inconsistency in this system	2 (1-3)
I would imagine that most people would learn to use this system very quickly	4 (3-5)
I found the system very cumbersome to use	2 (1-2.5)
I felt very confident using the system	4 (3-5)
I needed to learn a lot of things before I could get going with this system	2 (1-3)
Total score	78.8 (63.8-86.9)

Responses were relatively consistent across the individual SUS items, with median scores ranging from 1 (IQR 1-2) to 4 (IQR 4-5) on the 0-5 scale. One participant indicated responses between 2 response options on the 1-5 Likert scale; these responses were recorded as the corresponding midpoint values (eg, 1.5 or 3.5). In exploratory subgroup analyses, the median SUS score was 85.0 (IQR 75.0-95.0) among female participants and 72.5 (IQR 60.0-83.8) among male participants. Participants aged <70 years had a median SUS score of 80.0 (IQR 71.3-86.3), compared with 76.3 (IQR 49.4-86.9) among those aged ≥70 years. These analyses were descriptive, and no statistical testing was performed. The 2 participants with the highest SUS scores gave all items the best possible rating. However, the 2 participants with the lowest SUS scores also expressed during the subsequent qualitative interviews that they found the platform unnecessarily complex and cumbersome and that they would need to learn more before using it.

Qualitative Results—Categories

Overview

Some patients made initial comments regarding the developed digital tool:

> *…It is so good that you are working on this type of tool.*
>
> *…I would absolutely want to use this.*
>
> *…This app, I think it can be meaningful, because the wait is long and you have a lot of questions.*

The qualitative analysis of interviews revealed four main categories and 10 subcategories related to participants' preferences and perceptions, and these are summarized in Textbox 1.

XSL•FO
RenderX

Textbox 1. Results: categories and subcategories.

Clear layout

- Simple design
- Easy navigation

Positive content

- Informative
- Inclusive
- Motivating

Personalized information

- Different aspects
- Different levels

Individualized medical recommendations

- Personalized
- Flexible
- Individual choice

First, they value a *clear layout* with *simple design* and *easy navigation*. Second, they appreciate *positive content*, which is *informative*, *inclusive*, and *motivating*. Third, they request *personalized information* on *different aspects* and provided on *different levels*. Fourth, they request *individualized medical recommendations* that are *personalized* and *flexible* but *open to individual choice*.

Clear Layout

The first category, a *clear layout*, was consistently emphasized throughout the interviews and included the subcategories *simple design* and *easy navigation*.

Participants expressed that it was a digital tool with a *simple design*, which is more likely to be understood and used by users of different ages and different backgrounds. One participant noted that:

> *I like that it is simple and not too many different colors, because often diagrams and such can become too much with different colors and a little difficult to read. I like this simplicity, and the text is a good size.*

Frequently brought up was that using different colors, texts, and figures can become cluttered and be frustrating to users. One individual summarized that:

> *It is good, it is simple, it is easy to read. Do not complicate it with many colors and arrows, it is not necessary. I think that most appreciate simplicity.*

Participants agreed that a simple design, without unnecessary complexity, is essential in a digital tool they would see themselves using over time.

One issue repeatedly raised by participants was the importance of *easy navigation* as an important determinant to further improve satisfaction with the digital tool. As one individual suggested:

> *You should be able to go back in an easy way, a go-back button, you should try to make this intuitive.*

It was clear amongst participants that ease of navigation is essential to facilitate and avoid unnecessary frustration for users.

Positive Content

The second category, the desire for *positive content*, recurred throughout interviews and included the subcategories *informative*, *inclusive*, and *motivating* content.

Central for participants was that the content provided should focus on being *informative*. It was agreed that informative content is appreciated, but that it is not received well if presented as too demanding or alarming. As 1 participant pointed out about our information:

> *It is an important balance, so that you do not scare people. Inform without frightening.*

Information also needs to be adapted to the intended users, as 1 participant mentioned:

> *Not in medical language.*

This highlights how the overall tone of the content needs to be informative, yet accessible to be received positively by users.

Participants also valued our content that was perceived as *inclusive* to individuals regardless of age, gender, economic, and social situation. One participant noted and appreciated:

> *Do you have non-binary or other? Yes, you do.*

Some brought up that the recommendations provided on healthy eating habits need to also be inclusive of individuals with different preferences and lifestyles, for example, regarding eating habits to include also:

> *What is gluten-free and vegetarian.*

The findings underscore the importance of framing information in a way respecting diversity.

XSL•FO
RenderX

It was agreed that content needs to be *motivating* to the intended users. Many mentioned how motivating content is perceived as more respectful, and that motivation is much more likely to have an effect as compared with shaming or lecturing users. One participant emphasized that it is essential to encourage and inspire users and convey:

> *That it should be joyful as well, it does not have to be boring to be healthy.*

This demonstrates how essential it is to present information in a way that is motivating and respectful to users to empower them.

Personalized Information

The third category, *personalized information*, emerged and included the subcategories of personalizing information on *different aspects* and providing it on *different levels*.

Participants expressed a desire for personalized information on *different aspects* tailored to their individual needs. Some participants wanted basic information on, for example:

> *What it is that you do during an ablation. And concerning atrial fibrillation, what it is.*

Others requested in-depth information on associated topics such as causes, risk factors, genetics, mechanisms, medication, interactions, exercise, psychological effects, and effects on sexual function. Some suggested having links or icons leading to more detailed information.

This highlights the need for a wide variety of information on different aspects but personalized to support both users with limited prior knowledge and those seeking more detailed understanding.

The importance of information at *different levels* was another need that came up consistently in all the interviews. Some participants felt that they wanted only general information, while others felt that they had already had a lot of information on AF.

Some participants wanted much more and in-depth information provided, such as:

> *You could maybe press a button for references, for the best studies and meta-analyses.*

Thus, having access to information on different levels is essential.

Individualized Medical Recommendations

The fourth central category was the desire for *individualized medical recommendations*, which included the subcategories of *personalized* and *flexible* but *open to individual choice*.

An important feature requested by participants was that medical recommendations should be *personalized*. Participants brought up the heterogeneity in the group of individuals with AF, with a large range of knowledge, engagement, motivation, and different lifestyles. It was mentioned how frustrating it is to get recommendations to stop smoking and reduce alcohol consumption to individuals who stopped smoking and drinking years ago. Some felt frustrated getting recommendations on physical activity that they could not perform due to other diagnoses and disabilities. There was general agreement that the recommendations provided should be personalized.

Participants also expressed a desire for *flexibility* in the medical recommendations provided. There should be no shame in some not being able to perform a certain recommendation, and as 1 participant suggested, they should be able to choose digitally from recommendations they felt were appropriate, such as:

> *Today I choose… click… a 20-minute walk.*

This underlines the importance of being flexible in recommendations so as not to lose user interest and involvement.

Also central in the interviews was the importance of recommendations being open to *individual choice*. Most participants requested some level of individual choice in different terms, and many pointed out how each patient is an individual with their own preferences:

> *People react to information in different ways, and what one may think is good, another might feel this is not something I want.*

They emphasized the desire not to feel mastered but to feel respected as adults and to feel like they had a choice and would be supported regardless. This reflects a preference for personalized, nonprescriptive guidance that accommodates individual needs and circumstances.

Discussion

Principal Results

In this study, participants reported overall satisfaction with our developed digital tool. The SUS score is a validated measure of perceived usability [23]. Our digital tool achieved a median SUS score of 78.8 (IQR 63.8-86.9). The fact that the 2 lowest scorers found it to be unnecessarily complex and cumbersome, and that they would need to learn more before using it, aligned with the findings in the qualitative analysis, which revealed that persons with AF particularly valued a *clear layout, positive content, personalized information*, and *individualized medical recommendations*. The quantitative and qualitative findings complemented one another, with the SUS indicating overall acceptable usability while the interviews identified specific design features that influenced participants' experiences and highlighted priorities for further development.

The layout emerged as central to determining our participants' satisfaction with the digital tool. Regardless of the content, people may be less likely to use a digital tool if considered too difficult and complex to use. For example, a previous meta-analysis on 114 digital health apps found that apps with a higher SUS score were more likely to be adopted and used consistently [21]. The same meta-analysis aimed to investigate whether the SUS score could be used for assessing usability and found it to be reliable and that a mean score above 68 was acceptable [21]. In our interviews, participants appreciated simple layouts, and this was strengthened by the overall median SUS score of 78.8 (IQR 63.8-86.9), which confirmed the acceptability to users. Furthermore, it is important to consider the demographics of the intended users, who, in the case of individuals with AF, tend to be slightly older; in our study, the

XSL•FO
RenderX

age range was 48-79 years. A systematic review of 132 studies, for a population older than 60 years of age, demonstrated that simplified interfaces, clear navigation, and readable fonts were especially important to this group [24]. Because of the age range of users, it is essential to clarify and simplify layout, design, and navigation in health apps.

Maintaining an informative, inclusive, and motivating tone throughout the content provided was crucial to the participants in this study. This is in line with findings in our previous study where participants requested information conveyed in an appropriate manner without being condescending or moralizing [13]. The participants valued communication that was inspiring and motivating [13]. This theme has been recognized by other authors, for example, in a review of digital weight management interventions where regular and encouraging feedback was appreciated by participants requesting that the tone should not be too generic or impersonal [25]. In a review on lifestyle management intervention, it was identified that customized and personalized feedback was one of the features responsible for successful implementation of digital interventions [26], highlighting the need for positive and motivating content.

Personalized information was central to our participants, which relates to the concept of person-centered care, where the patient is an active part in jointly planning individualized care [14]. Similarly, in our prior study, participants specifically desired person-centered and customized information [13]. In both studies, they wished for information about many different aspects of AF, such as healthy lifestyle, eating habits, physical activity, alcohol consumption habits, stress, and medication [13]. Participants in both studies also requested information to be readily available but at different levels, so as to fit each individual's backgrounds, prior knowledge, and preferences [13]. Another study evaluated the "INFORM-AF" program, a co-designed digital AF educational program developed by Ferguson et al and delivered to participants' smartphones via the QStream platform, and they reported an excellent SUS score of 84 [27,28]. This was higher than in our study, demonstrating that the present digital platform has room for improvement in terms of usability.

Regarding the medical recommendations given, personalization and flexibility emerged as central to users. In cardiovascular medicine, there is a need for a shift toward multidisciplinary, coordinated, and tailored solutions focusing on shared decision-making [10]. To achieve person-centered care, an essential component is "respecting the patient's information needs and preferences" [29], which could mean integrating tailored information with shared decision-making. Tailored information was also requested by participants in our previous study [13]. Furthermore, a review of digital weight management interventions concluded that personalization is an essential component for the success of the intervention [25]. Additionally, a systematic review of the literature on mobile health (mHealth) apps for managing AF found that an app for tailored patient education rated positively on all aspects [30]. The mAFA app, developed by Guo et al [31], includes clinical decision-support tools with educational materials, patient involvement strategies with self-protocols and structured follow-up [31]. It was found to be easy, user-friendly, and helpful, and resulted in increased knowledge of AF, improved drug adherence and satisfaction, and quality of life scores [31]. It was also associated with a lower rate of the composite outcome (ischemic stroke, systemic thromboembolism, death, and rehospitalization), and lower rates of rehospitalization [32]. These findings highlight the potential of digital health intervention to improve outcomes, which warrants further research.

The digital platform used in this trial has been co-designed with a group of patients with AF who were initially interviewed for requests and requirements of a digital platform for lifestyle and risk factor management. [13] The same individuals were then asked to test the platform further and provide their feedback on further development. In our current trial, we have included patients who were not part of the original development to test the digital platform. From this trial, we will set out to further develop the platform, focusing particularly on navigation, simplicity, layout, and personalization. The co-design process shaped the platform by turning patient feedback into design changes, especially a simpler interface, clearer navigation, and less visual clutter. Patients also pushed for more control and less directive advice, which led to a choice-based system with layered information at different levels. These decisions likely improved usability and acceptability in the findings by making the tool easier to use and more aligned with how patients want to engage. Many recommendations for managing comorbidities and healthy lifestyle habits for patients with AF are similar to those for other patient groups. However, this study highlights that the unpredictable nature of AF, the wide range of functional impact, and its association with psychological and physical stress and reduced quality of life require flexible, individualized support for patients with AF.

Trustworthiness of a qualitative study can be evaluated through credibility, transferability, dependability, confirmability, and authenticity [18,19]. This study demonstrates high credibility, as the participants had relevant experience with AF and risk factors. Transferability is good as baseline characteristics are representative of individuals with AF undergoing intervention. There were no current smokers in the study population, which is consistent with the low prevalence of smoking in Sweden. However, this may limit the generalizability of the findings to individuals who smoke. To maintain dependability, confirmability, and authenticity, coding was done independently, and then ongoing discussions were held throughout the analysis process until consensus was reached. In this study, we support the conclusion by providing citations supporting the results and analysis.

Limitations

Although the results are likely generalizable to persons with AF as reflected by the baseline characteristics (Table 2), a main limitation is that all participants were recruited from a single Swedish tertiary hospital with a large AF ablation service, which may reduce generalizability. It is worth noting that they were hospitalized specifically for AF, and this might create a selection bias of patients who have a slightly better understanding of AF in general. Although the SUS score is widely used and recommended for scoring perceived usability [23], it has inherent limitations, as it yields a single overall usability score

XSL•FO
RenderX

without identifying domain-specific problems or offering qualitative insights, since it does not allow participants to elaborate on their responses. To address this, we also performed a qualitative analysis using a structured interview guide designed with open-ended questions to encourage participants to speak freely, to allow for a person-centered exploration of themes, perceptions, and meaning, and thereby reduce the risk of bias. Furthermore, the results were independently coded by 2 of the authors (SK and ML), and any disagreement was discussed multidisciplinary until consensus was reached among all authors. Nevertheless, no repeat interviews, field notes, or member checking were performed, and some risk of subjective interpretation and potential bias remains and cannot be fully excluded

As generative AI becomes more widely available, disease-specific platforms might complement these tools by providing individualized, guideline-based support integrated with clinical care. These findings will guide further development of digital tools for better risk factor management for individuals with AF undergoing intervention. Future testing is planned to be performed at home in a real-world setting, and we also aim to include other AF groups than those hospitalized. In addition, we will also aim to make sure we have a representative sample of older patients, and individuals with lower digital literacy. Future research should assess the effectiveness of digital tools in promoting better management of risk factors in AF, improved outcomes after AF intervention, and better utilization of resources.

Conclusions

Persons with AF desire support in managing modifiable risk factors and find it likely that a digital tool could be used to facilitate this. In our digital tool for risk factor management, participants valued specifically a *clear layout*, *positive content*, *personalized information*, and *individualized medical recommendations*. This feedback will be used to guide development and guide work to develop digitally aided and person-centered management of modifiable risk factors for persons with AF, hopefully improving outcomes and reducing the cost of care.

Acknowledgments

We are grateful to all the patients who participated in the study and provided valuable insights to further develop care for patients with AF.

Abstract

Background: It is unclear why some smartphone apps designed for people with psychosis are engaging, while others are not. One possible explanation is the apps' persuasive features and the operationalization and implementation of these features.

Objective: This systematic review set out to quantify and describe the persuasive features used in smartphone apps for psychosis, investigate whether there was any association between persuasive features and attrition or adherence rates. and document the quality of the included apps.

Methods: We searched electronic databases PsycINFO, PubMed, and Google Scholar for eligible papers published between the years of 2013 and 2025. Hand searches of reference lists were completed. Apps were selected if they were designed for people with psychosis and there were published empirical studies investigating the apps. Two reviewers from the review team (TT, JP, DK, and SD) independently screened papers and extracted data on adherence and attrition, as well as coded papers for evidence of persuasive features according to the persuasive systems design (PSD) model. Available data were synthesized descriptively and narratively. We attempted to access apps via app stores or by correspondence with the research team.

Results: We found 22 apps for psychosis, with 30 associated published papers. The persuasive features were as follows: personalization (18 apps); reminders (15 apps); suggestions (11 apps); tunneling and self-monitoring (10 apps); reduction (9 apps); liking (8 apps); social role (6 apps); rehearsal, praise, and similarity (5 apps); rewards (4 apps); simulation, real-world feel, and social learning (3 apps); surface credibility and normative influence (2 apps); and trustworthiness, social comparison, and social facilitation (1 app). Expertise, authority, third-party endorsements, verifiability, cooperation, competition, and recognition were present in zero apps. Features in the categories of primary task support and dialogue support were well represented, while social support and system credibility support were underused. It was found that there was no association between the number of persuasive features and attrition; an association between persuasive features and adherence could not be assessed. The quality of the apps could not be judged due to 20 of the 22 apps being inaccessible either through the research papers' authors or through app stores.

Conclusions: Our findings indicate that in psychosis apps there is potential to include a broader range of persuasive features, which might maximize engagement. Psychosis apps may benefit from incorporating more features that leverage the persuasive impact of having users interact (social support) and incorporating features that emphasize system credibility and trustworthiness. Further studies could determine whether an increase in the number of persuasive features will impact app engagement and which features are most impactful in this context.

Introduction

Background

There is a well-recognized global gap between the need for and provision of services to prevent, identify, and treat mental health conditions [1]. People who experience psychosis are among those with the highest need for support [2]; thus, interest and research into digital treatments for this condition have grown over the last decade. A recent meta-analysis of randomized controlled trials (RCTs) assessing apps designed for symptom reduction in patients with schizophrenia found statistically significant symptom reduction across positive (standard mean difference [SMD]=−0.205, 95% CI −0.388 to −0.022) and negative symptoms (SMD=−0.406, 95% CI −0.791 to −0.020) [3]. However, adherence to smartphone apps for mental health is notoriously low in both trial and real-world conditions. For example, a systematic review of 93 popular publicly available mental health and well-being apps found that only 3.3% (IQR 6.2%) of users were still accessing the app after 30 days [4].

XSL•FO
RenderX

Specifically relating to mental health apps, a meta-analysis of 70 RCTs found that adherence consistently declined with time [5]. One potential contributor to disengagement is insufficient attention to system design and how it affects users' experience of apps [6]. Increasing researcher and app designer understanding of the role the technology is playing in digital interventions has the potential to shift patterns of user disengagement [7].

Prior Work

One area of system design that can be applied to app development is persuasive systems design (PSD). The PSD is defined as the use of computer-mediated products that aim to influence or change people's cognition and behaviors [8]. A framework has been developed that transforms persuasive principles into software requirements and system features, namely primary task support, dialogue support, system credibility support, and social support [9]. For example, an app praising a user after they complete a session is a system feature of the PSD principle "dialogue support," which pertains to the feedback an interactive system provides to its users to help them move toward their goal.

It has been hypothesized that persuasive features will increase alliance, adherence, and engagement, in turn leading to better treatment outcomes. Kelders et al [10] conducted a systematic review of web-based health interventions and found persuasive features accounted for a significant difference in adherence scores. However, more recent research on apps has produced mixed results. A review of 70 apps for health and wellness available to the public found a positive correlation between apps' ranks of popularity (based on ratings and installation) and the apps' persuasive features [11]. In contrast, Alqahtani et al [12] found no link between the number of persuasive features in mental health apps and efficacy or engagement. Interestingly, a recent meta-analysis looking at efficacy, engagement, and persuasive design in smartphone apps for depression and anxiety found persuasive features were linked to increased effect sizes; however, an increased number of persuasive features was also linked to rising attrition [13]. Thus, the relationship between persuasive design, efficacy, and engagement is multifaceted and opaque. It may be that for some client groups, persuasive design or over-application of persuasive design has the opposite of the intended impact, causing users to disengage. This requires further investigation.

There is evidence that motivation type [12] and psychological and demographic characteristics [14] impact mobile health users' proclivity to persuasive design, meaning the characteristics of the user may be relevant to understanding how they relate to an app's features. People with psychosis may have unique needs. For example, a review on the implementation of digital interventions with people with psychosis and bipolar disorder found that this client group may have cognitive impairments that make engagement with complex interventions challenging [15]. A related difficulty for people with serious mental illness is difficulties in social functioning [16,17]. Furthermore, in human-to-human psychosis interventions, the quality of the therapeutic alliance has been found to be associated with treatment outcome; thus, the quality of this client group's interaction with the therapeutic agent (app) may be paramount to the intervention's success [18]. Thus, understanding how apps are being designed for people with psychosis and the links between system design and app adherence could provide valuable information for improving these interventions going forward.

Goal of This Study

There is a gap in the literature for a review that looks in a granular manner at persuasive features within mobile apps designed for people with psychosis. This review aimed to answer the following questions: (1) what PSD features do apps aimed at people with psychosis have? (2) Which PSD features of smartphone apps aimed at people with psychosis are associated with app adherence and attrition rates? (3) What is the quality of apps aimed at people with psychosis?

Methods

Overview

This study's protocol was preregistered on the Open Science Framework [19]. The data associated with this review are also available at the same location on the Open Science Framework. The electronic databases searched were PsycINFO, PubMed, and Google Scholar. Due to the fast-evolving nature of technology, database searches were limited from the year 2013 onward and searched in November 2023 and March 2025, respectively. Query strings were (smartphone* or "mobile phone" or "cell phone") AND ("app" or "apps" or "application" or "applications") AND ("schizophrenia" or "schizo" or "psychosis" or "psychotic"). To identify articles not found in the original searches, we reviewed the reference lists of included papers for relevant apps. The authors also used prior knowledge of apps to identify additional inclusions and linked these with their associated papers. Where papers could not be accessed, study authors were contacted.

Study Eligibility and Screening

The "unit of interest" in this review was the smartphone apps themselves, as we were aware that multiple papers may be published relating to various aspects of the same app (eg, pilot studies, clinical trials, and qualitative papers). We linked together multiple papers where they related to the same app and included those most relevant for gathering the information for this paper.

Inclusion criteria for eligible apps were as follows:

1. The app has associated with it a minimum of one peer-reviewed journal article reporting empirical data.
2. The app is aimed at people with psychosis.
3. The study sample has been confirmed to have psychosis via a prior diagnosis, psychometric measures of symptoms clinically relevant to psychosis, or a clinical interview.
4. App features were sufficiently described in the associated publications, provided by the authors upon request, or the intervention was accessible to the review team.

Exclusion criteria were as follows:

XSL•FO
RenderX

1. The app targets medication adherence, another condition (eg, cannabis addiction, smoking, or diabetes), or is aimed at supplying the user information (eg, on their legal rights).
2. The app is aimed only at monitoring or accessing treatment records.
3. Other digital interventions, for example, computer-based interventions, text, email, online counseling, and videoconferencing.
4. Apps that require other digital devices (eg, virtual reality [VR] headsets).
5. Apps targeting families of people with psychosis or the care team.

Covidence was used for all stages of review, including screening and data extraction. After duplicate records were excluded, 2 reviewers (TT, DK, SD, and JP) independently screened each paper at both title and abstract and full-text review. All screeners completed training, and a consensus check on a small selection of papers was done to ensure consistency between screeners. The initial agreement between screeners was 81% at title and abstract review and 70% at full-text review. Where there were conflicting decisions between screeners, consensus was reached by discussion and with input from the senior author (PJ) when needed.

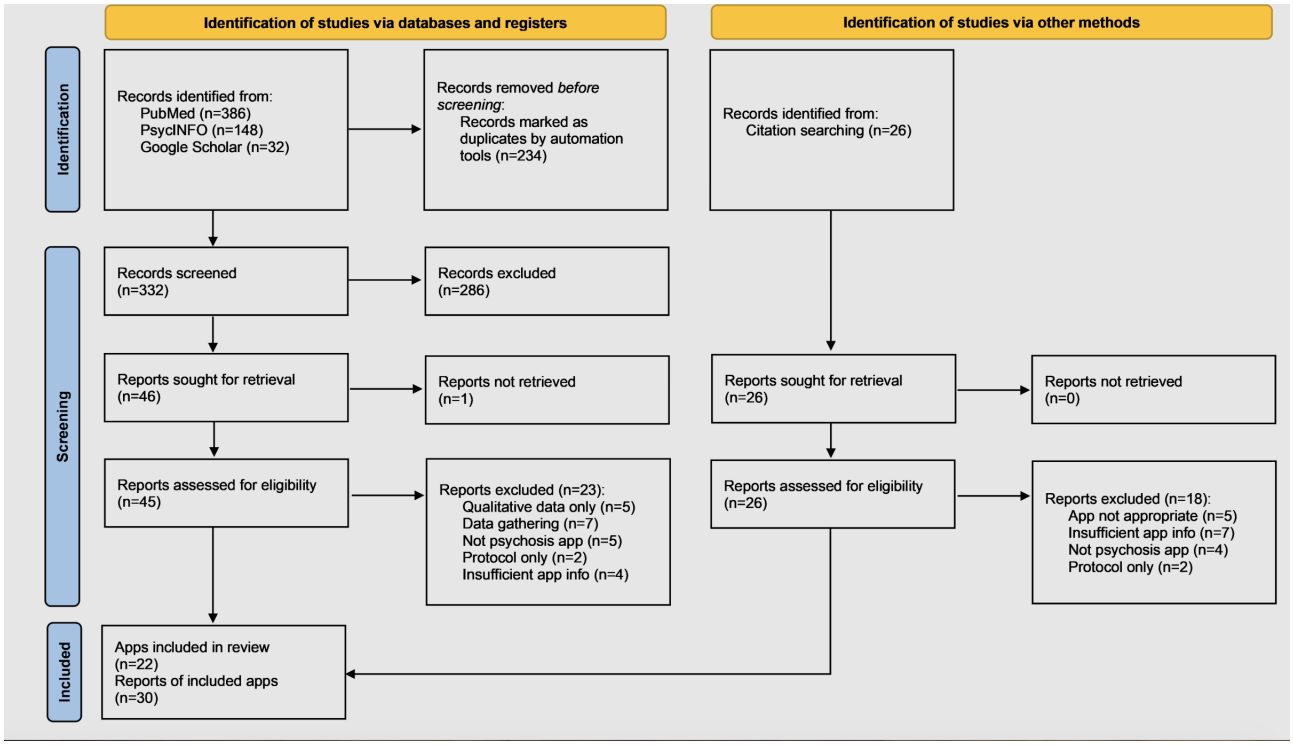
Data Extraction

Relevant data from included studies were extracted in duplicate independently by 2 reviewers (TT or JP and DK or SD) using a predetermined data collection tool. Oinas-Kukkonen and Harjumaa [9], which lays out descriptions of persuasive features and examples of how the features can be defined, and their implementation was used as a coding guide for determining the persuasive features. Prior to extraction, reviewers piloted the data extraction tool and discussed discrepancies. During extraction, regular meetings allowed discussion of the coding guide and resolution of discrepancies. The review team extracted information on the apps, including the intervention name, a brief description of the app, treatment target, whether the app was automated (used without a human intervention component alongside) or blended (used with an accompanying human therapist), intended frequency of intervention, and intended duration of intervention. Blended interventions with human support may inherently include persuasive elements outside the app interface, which was out of scope for this review.

From the most recent empirical paper on the app, information describing the study was extracted (study design, location, sample size, participant mean age and diagnoses, attrition during trial, and available adherence data). Missing data were reported in the write-up. “Interrater reliability was assessed across all 22 included apps and 28 PSD features (616 coding decisions). Cohen Kappa was κ=0.95 (98.4% observed agreement).”

Quality Assessment

The reviewers had planned to assess the quality of the apps using the Mobile Application Rating Scale [20], a quality assessment tool for health apps with published psychometrics [21]. The Apple and Android app stores were searched, and the corresponding authors were contacted to request access to the apps. However, only 2 of the 22 included apps could be accessed; thus, assessing app quality could not be done meaningfully, and this was not completed.



Results

Overview

The search identified 566 studies, including 234 duplicates. After title, abstract, and full-text screening, 30 [22-51] eligible papers reporting on 22 apps were included. The screening process is summarized in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses; Checklist 1) diagram (Figure 1). App names, treatment targets, and whether the app is automated or blended are detailed (Table 1). Further information on the apps, associated outcome study characteristics, and attrition and adherence rates is provided (Multimedia Appendix 1) and a matrix of persuasive features of each app (Multimedia Appendix 2). Across 22 apps, 21 categories of persuasive features were identified. Primary task support and dialogue support were the most common, with social support and system credibility support coded considerably less often.

Table . Table depicting the included app's names, their treatment target, and whether the apps were an automated or blended intervention.

App name	Treatment target	Automated or blended
A4i (MEMOTEXT Corporation) [22,23]	Medication adherence, personal recovery, and psychiatric symptomatology	Automated
Actissist (University of Manchester) [24]	CBT[a]-informed early psychosis intervention	Automated
ChillTime (Psyxnovation Inc) [25]	Emotional regulation in dual diagnosis psychosis and substance use disorder	Automated
CBT2go (Center for Technology and Behavioral Health; Dartmouth College) [26]	CBT for negative symptoms. Aims to reduce the severity of defeatist performance attitudes	Blended (group therapy+app)
Connect+ (University of Manchester) [27]	Loneliness	Automated
Focus (Northwestern University and University of Illinois at Chicago) [28,29]	Sleep, mood, social, meds, and voices	Automated
Focus-AV (Northwestern University) [30]	Sleep, mood, social functioning, medication adherence, and voices	Automated
Grasp (New York State Psychiatric Institute and Columbia University) [31]	Social cognition and social functioning	Blended (group therapy+app)
IMPACHS (King's College London) [32,33]	Reducing psychotic and depressive symptom severity	Blended
MASS (University of California Los Angeles) [34]	Social skills training	Automated
Moneo (University of Cambridge) [35,36]	Cognitive training/cognitive rehabilitation	Automated
My Journey (Dartmouth College) [37,38]	Develop self-management skills, achieve self-determined recovery goals, and avoid future relapses	Blended
MCI-S (University Medical Center Hamburg-Eppendorf) [39]	Metacognitive beliefs, psychotic symptoms, and social functioning	Automated and blended versions
PEAR004 (Pear Therapeutics) [40]	Positive and negative symptoms of schizophrenia	Automated
PRIME (University of California San Francisco) [41]	Motivation, cognition, and negative symptoms	Blended (app+ coaches)
Savvy (University of Groningen) [42,43]	Voice hearing	Blended
Sleep app (University of Oxford) [44]	Sleep	Blended
SlowMo (King's College London) [45,46]	Paranoia	Blended
SMART app (University of Melbourne) [47]	Improve social functioning and psychiatric symptoms	Automated
TechCare (King's College London) [48,49]	Positive and negative symptoms of schizophrenia	Automated
TemStem (University Medical Center Utrecht) [50]	Voice hearing, emotionality, and vividness	Automated
WeCOPE (University of Hong Kong) [51]	Improvement in schizophrenia symptoms and personal and social functioning.	Automated

[a]CBT: cognitive behavioral therapy.

Research Question 1: PSD Elements

Twenty-one categories of persuasive features were found across the 22 apps [22-51]. The most coded areas of persuasive features were primary task support and dialogue support, with social support and system credibility support being coded significantly less frequently. The maximum number of PSD elements in an app was 11, while the least was 2 (Multimedia Appendix 2).

Primary Task Support

The primary task support category includes features that support the user to carry out their primary tasks in the app [9].

Personalization

Personalization, defined as the app noting user inputs and adjusting content accordingly, was the most common primary task support feature, present in 18 of 22 reviewed apps [22,24-26,28,30,33,34,37,40-42,44,46,47,49-51]. Personalization encompassed tailored goals [37,41,51], steps toward goals [22,26,34], encouragement [26,44,50] (eg, in the TemStem [University Medical Center Utrecht] app, if the user assessed themselves as feeling "powerless," an avatar would give them personalized support such as "You are strong!" [50]), using the user's name [46], customizable skill toolboxes [22,33,40],

XSL•FO
RenderX

ecological momentary assessment informing personalized coping strategies [24,28,42,47,49]. The ChillTime (Psyxnovation Inc) app allowed users to give feedback on the personalized coping strategies offered and used artificial intelligence to improve future suggestions [25]. Some apps provided multiple ways to interact with content, such as video or audio [25,30,33], while the WeCOPE (University of Hong Kong) app allowed the user to choose either a male or female voice in audio recordings [51]. Other examples of personalization included customizing the app's looks [24] and the app triggering a personalized crisis plan [49], and multiple apps allowed users to personalize notification frequency [26,28,37,40]. Hornstein et al [52] suggest 4 personalization levels (intervention content, content order, and guidance/communication level) and 4 underlying mechanisms (user choice, provider choice, decision rules, and machine learning). Most reviewed apps are personalized at the intervention content level, using user choice or decision rules.

Tunneling

Tunneling was found in 10 reviewed apps [22,24,26,27,31,33,34,39,41,50]. Tunneling means the app content changes progressively with use, providing various opportunities for the user to be persuaded to make behavioral changes. Observed tunneling strategies included content that changed in a stepwise fashion toward goals [22,26,34,39,41] and progressively more challenging modules [27,41,50].

Self-Monitoring

Self-monitoring, a feature enabling users to track symptoms or goal progress, was found in 10 apps [22,24,26,27,33,34,37,41,42,50]. Capturing data and feeding it back to users can encourage behavior change. Several apps provided graphs for self-monitoring [22,24,33,37,41,50], and the IMPACHS app linked self-monitoring with customizable action plans [33].

Reduction

Reduction, which simplifies complex behavior into simple tasks, was found in 9 apps [25,27,30,31,33,34,44,50,51]. This feature was implemented through simplified language [25,33], standardized content for familiarity [25], breaking tasks into components [31,33,34], and ensuring tasks were quick to complete [25,27,44].

Simulation

Simulation, a feature allowing users to observe cause-and-effect relationships (eg, increased physical activity and weight loss), was found in 3 apps. In all instances, an actor demonstrated a skill and its contribution to achieving the user's goal [27,30,34].

Rehearsal

Rehearsal provides a way for users to rehearse a behavior in the app that they then use in daily life and was present in 6 apps [26,28,30,31,42,46].

Tailoring

Tailoring means there are different user groups that are shown different versions of the app, which was featured in 2 apps [34,44].

Dialogue Support

Dialogue support incorporates the features a system uses to increase interactivity between the app and the user.

Reminders

Reminders are notifications that remind the user of their target behavior, and these reminders were the most widely used dialogue support feature (present in 15 of 22 apps) [22,24-27,31,34,36,37,40,42,44,46,47,49]. Besides encouraging app access, reminders were sent to promote medication adherence [22,36,37,47], symptom assessment [47,49], health care appointments [22], daily activities like hygiene [47], goal-focused behavior change [26,37,44], and coping strategies such as positive self-talk [42]. While the SlowMo (King's College London) app made notifications optional [46], most apps sent multiple daily notifications without specifying if users could disable them.

Suggestion

Suggestion, a feature where apps recommend skills or behaviors to users, was found in 11 apps [22,24-28,33,34,40,41,47]. Most apps stated that various cognitive and behavioral strategies were encouraged without detailing these [22,24,28,33,40,41]. However, some apps clearly defined their suggestions, such as CBT2Go's (Dartmouth College) behavioral experiments to test beliefs (eg, "Try asking someone to go for a short walk") [26] and MASS's (University of California Los Angeles) step-by-step actions toward goals like making a new friend [34]. Apps also varied in applying suggestions; for example, ChillTime suggests random strategies to encourage trying new things [25], while the SMART (University of Melbourne) app matches suggestions to the user's mood [47].

Liking

Liking, the app's visual appeal to the user, was considered and implemented in 8 reviewed apps [24,25,27,28,33,37,41,46]. Strategies for creating visually attractive apps included using multiple images [24], visual simplicity [25], color [37], user customization of visuals [24,46], and familiar visual formats, such as Connect+'s (University of Manchester) Instagram (Meta Inc)-like design [27].

Social Role

The system adopted a social role in 6 reviewed apps [22,26,33,36,37,41], primarily related to user interactions with health care professionals. This included connecting users to health care providers [22], collecting information to facilitate deeper conversations between users and health care professionals [26,33,36,37], and arranging appointments with health care providers [36]. Only the PRIME (University of California, San Francisco) app actively encouraged user-to-user interaction [41] by generating daily prompts like "Share a silly selfie!" or "Write down a list of things you are grateful for" to encourage participants to share responses.

Similarity

Similarity, in which the system meaningfully reminds users of themselves (eg, by describing relatable scenarios or using familiar language), was reported in 5 apps [24,27,34,39,44].

XSL•FO
RenderX

Some apps used videos depicting others in comparable situations progressing toward their goals [24,27,34], such as Actisist's (University of Manchester) video story "William walks away from weed" about a person with psychosis quitting cannabis [24]. Connect+ aimed to imitate youth language for increased relatability [27]. Several apps valued input from people with lived experience to create these features [24,27,34,44].

Praise

Praise, a form of positive persuasive system feedback, was found in 5 reviewed apps [26,34,41,44,50]. The MASS app used praise to increase anticipatory pleasure for future social experiences in accordance with the temporal experience of pleasure model in schizophrenia [34]. CBT2Go praised high confidence ratings for goal-related tasks while challenging low ratings [26].

Rewards

Rewards are a tactic to reinforce target behaviors and were present in 4 apps [26,27,44,50]. For most apps, rewards were given in the form of points, stickers, or stars; however, the CBT2Go app allowed a selfie to be taken after an achievement [26].

System Credibility Support

System credibility support, an umbrella term for the ways a system promotes the perception of its own credibility and therefore increases its persuasiveness, was poorly represented in the reviewed articles. Assessing apps in this area was challenging, as most publications lacked details, and only 2 apps, Actisist and ChillTime [24,25], out of 22 apps, were directly accessible. These 2 apps met the surface credibility threshold (competent look and feel). A real-world feel, where a system provides information about its content creators to build credibility, was found in 3 apps [24,25,30]. Two apps provided details of involved clinicians, such as names and work addresses [24,25], while 2 showed videos of clinicians demonstrating skills or explaining content rationale [24,30]. One app's qualitative data showed evidence of trustworthiness, with users calling it "honest" [27]. No evidence could be found of third-party endorsements (the system provides endorsements from other sources), authority (the system refers to people in the role of authority), expertise (provides information showing knowledge, experience, and competence), or verifiability (the system provides means to verify the accuracy of the program via outside sources) in the apps or their associated papers.

Social Support

Social support encompasses how a system harnesses social influence to motivate users, such as enabling users to observe others' behaviors or compare their own behaviors to others. By leveraging the persuasive power of social interaction, a system can motivate individuals to achieve their target behavior. Social support was detailed in 4 apps [27,34,39,41]. Social learning, where users observe others performing target tasks or behaviors through the system, was present in 3 apps [27,34,39]. One app used social facilitation, allowing users to discern that others are performing the behavior alongside them, while 2 engaged normative influence, using peer pressure to encourage target behaviors [22,41]. A4i (MEMOTEXT Corporation) included a moderated, anonymized platform for users to share strategies and tips [22]. PRIME used social comparison, facilitating performance comparisons between users, and automatically generated accomplishment posts for completed challenges, providing opportunities for social reinforcement [41]. No examples of competition, cooperation, or recognition were found in the examined apps.

Research Question 2: Which PSD Features of Smartphone Apps Aimed at People With Psychosis Are Associated With App Adherence and Attrition Rates?

The number of persuasive features and attrition percentage for each app showed no evidence of an association (Pearson r=0.07, 95% CI −0.4 to 0.5). However, this finding assumes equal weight for each PSD feature, which is likely unjustifiable. Certain features may be more strongly associated with attrition than others, if any relationship exists, but these data are insufficient for this level of analysis. Inconsistent adherence reporting across apps prevented comparisons regarding adherence-persuasive feature links.

Research Question 3: What Is the Quality of Apps Aimed at People With Psychosis?

App stores were searched, and corresponding authors were contacted to access all apps. However, only 2 apps were accessible, making a quality assessment impossible, as it would have required opening and using the apps to evaluate each criteria point.

Discussion

Principal Results

This review assessed PSD features in mobile apps for people with psychosis, aiming to describe the features, links to adherence and attrition, and app quality. The categories of primary task and dialogue support were well-represented, while social support and system credibility support were underused, potentially impacting app efficacy and engagement, as both social connectivity (social support) and a user having ways to judge a system's credibility (system credibility support) could impact motivation with this client group. No link was found between persuasive features and attrition; the relationship with adherence and app quality couldn't be assessed.

Comparison With Prior Work

No previous study has systematically documented the PSD features present in apps for psychosis. The finding that personalization, self-monitoring, and reminders were among the most common strategies is consistent with previous findings on physical activity, mental health, and health apps [11,12,53]. However, the existence of these features does not guarantee a positive impact on users; how these features are applied is crucial to their utility. For example, reminders were a prominent persuasive feature in the psychosis apps reviewed; however, most apps did not give users a choice in notification frequency. One of the postulates of persuasive systems is that the system should aim to be unobtrusive, and inappropriate or ill-timed reminders may have a reverse of the desired impact [54]. Persuasion depends on symbolic strategies to trigger emotions

XSL•FO
RenderX

[55], and a blunt, unskilled approach such as sending countless reminders to use the app per day can provoke a negative emotional response, which is counterproductive. Similarly, self-monitoring is considered a fundamental feature of several evidence-based psychological therapies, including cognitive behavior therapy [56], dialectical behavior therapy [57], mindfulness [58], emotion-focused therapy [59], and acceptance and commitment therapy [60]. Thus, it is logical that psychosis apps would utilize self-monitoring to help users track their feelings, thoughts, and behaviors. However, the apps reviewed in this study limited data gathering to manual input, prompted by several daily notifications. Manual entry of personal data can be time-consuming and tedious [61] and may be a barrier to people with serious mental health difficulties. Thus, in the context of psychosis, it is unclear if self-monitoring promoted engagement in the manner intended or had a reverse to desired impact due to the frequency and high cost to the user of multiple manual inputs per day.

Research indicates that psychological and demographic variables influence susceptibility to persuasion [14]; thus, in planning these interventions, these variables should be considered. For example, in this review, reduction (simplifying tasks) and suggestion (suggesting actions to users) were among the top strategies used. However, in a review of mental health apps, these 2 strategies were used in fewer than 5 of 103 apps [12]. Thus, these strategies, which facilitate ease of app use, may be more widely implemented and necessary in a psychosis sample due to cognitive impairment and disability associated with this client group [15-17].

This study also found that apps relied heavily on the primary task support and dialogue support categories of persuasive design, with social support and system credibility support underrepresented. This means that attempts to be persuasive are unbalanced; there is emphasis on helping users to complete tasks and the interactiveness of the app, while techniques to make the app more trustworthy and credible to users and methods to leverage the impact of social forces to support behavior change are ignored. Social support strategies have been found to be more widely implemented in physical than in mental health apps [62]. However, social support is an important strategy for users who experience mental health issues because it is common to feel isolated or stigmatized, and digital interventions could benefit from intervening at the level of the social rather than limiting treatment targets to internal drivers for poor mental health. Lack of system credibility support is common across multiple types of apps [12,62]. A postulate of persuasive systems is that they should always be open to the user and reveal designer bias behind the system both to protect fairness and increase persuasiveness. We argue that system credibility support is fundamental in this time, where technology is developing at a rapid rate and users cannot be expected to understand a system's functions without guidance. Users need to be assured of not only the effectiveness, reliability, and evidence base of the app's content, but also that their data will be protected (privacy). Furthermore, without this in place, it is difficult to advance other features such as passive monitoring if users are not fully assured of the app's credibility.

Our findings suggest that the number of persuasive features used in psychosis apps is not linked to attrition rates. However, this is not necessarily an indicator that the persuasive features were not assisting the user to achieve their purpose with the app. Some authors propose that disengagement is not a barrier to efficacy if a user has achieved their goals with the digital intervention at the point of disengagement [63]. For example, a recent meta-analysis looking at efficacy, engagement, and persuasive design in smartphone applications for depression and anxiety found increased persuasive features were linked to increased effect sizes and increased attrition rates [13]. However, there may be other factors explaining the disconnect between increased persuasive features and engagement in this review; for example, there is a lack of evidence on which persuasive features are the most effective at increasing adherence and reducing dropout. Therefore, it is likely that totaling persuasive features is insufficient. Using one appropriate feature is preferable to multiple inappropriate features, too many features from one persuasive category, or a combination of appropriate and inappropriate features [64]. Furthermore, although PSD is commonly used to inform app development, the model does not contain a guideline on operationalizing the features [9]. Consequently, the same persuasive feature can be shaped differently in different interventions. We found some apps with highly creative implementation of PSD, while others executed persuasive features in a minimal manner. This mirrors the results of Sporrel et al [65], who examined 29 physical activity apps and found heterogeneity in how the features were executed, which appeared to influence the effectiveness of the intervention. These diverse implementations mean that interventions with the same persuasive feature might evoke different user responses, rendering it difficult to draw a conclusion about the impact of a specific persuasive feature at the theoretical level. Furthermore, technological advancements mean that some apps used features that did not fit within the PSD framework [53]. Thus, the lack of clarity on how many persuasive features are optimal, the lack of guidance on the operationalization of features, and the lack of acknowledgment of emerging features highlight the need to extend the PSD model. Furthermore, extension of the PSD model could include standardized checklists or algorithms for the implementation of persuasive features as guidance to app developers and reviewers.

This study's findings provide possible guidance to app developers. The finding that, although reminders are a prominent feature, little choice of their frequency was offered indicates that app engagement may benefit from offering users choice when providing notifications. This review found that self-monitoring was a common feature; however, given the functional impairments this patient group frequently faces, passive monitoring may lower the burden on the user. To implement these more advanced features, user trust is crucial. Thus, given this review's finding that system credibility features were not common, developers could benefit from including trust-building features such as highlighting the team, evidence, endorsements, backend and data storage of the app system, and real-world institutions behind the app product. This client group faces social isolation, and this review found there was little focus on social support features; thus, developers can consider integrating peer-to-peer interactions or content that gives an

XSL•FO
RenderX

indirect indication of peers and others using the app (eg, leaderboards) into apps for psychosis.

Limitations

This review has several methodological strengths, including a preregistered protocol, a systematic search strategy, and 2 independent raters throughout study selection and data extraction. However, several limitations should be noted.

The most significant constraint on interpretation is that only 2 of the 22 apps could be tested directly, rather than through reading their described features in their associated research papers [24,25]. This means the review may not fully capture the persuasive features present in each app, particularly those that are less tangible or harder to articulate—such as system credibility support—which researchers may be less likely to describe explicitly. The reported prevalence of feature categories should therefore be interpreted with this in mind, as it may reflect limitations in how apps are described in the literature as much as the features themselves.

Identifying persuasive features is also an inherently interpretive process; review teams may conceptualize and operationalize features differently. Relatedly, this review's feature-counting approach assumes equivalent value across different persuasive features, which may not hold in practice; however, a more nuanced weighting of features was beyond the scope of this analysis.

The absence of a formal risk of bias assessment is a further limitation. Although a quality appraisal of the apps was planned, it was not feasible given their inaccessibility. Additionally, attrition and adherence data were either unreported or reported inconsistently across studies, preventing any meaningful analysis of the relationship between persuasive features and these outcomes. Together, these constraints limit conclusions about feature effectiveness, and further empirical work is needed.

Finally, while non-English articles were not explicitly excluded, studies would only have been identified if their abstracts were available in English, meaning relevant research published in other languages may have been missed.

Conclusions

Our findings indicate that in psychosis apps there is an uneven use of persuasive features, with most apps relying on primary task support and dialogue support features, while social support and system credibility support remain underrepresented. This may be impacting the efficacy and engagement of these interventions. Psychosis apps may benefit from incorporating more features that leverage the persuasive impact of having users interact (social support). There is a human instinct to respond to social forces, and thus incorporating these domains into psychosis apps may allow developers to engage nonengagers. Incorporating features that emphasize system credibility and trustworthiness to the user is also crucial. As technology advances, there is an increasing need for designer openness about their positioning, bias, and how data are stored and used, and further technological advances can only be widely applied if users have confidence in the systems that gather their data. Future research could explore expanding the PSD model, as this review indicates it no longer encompasses all features apps are using, and although the underlying principles may remain sound, the way the model quantifies and describes features is becoming outdated with rapid technological advancements. Furthermore, there is a lack of clarity on how many persuasive features are optimal, how to operationalize features, and how persuasive categories work together. It may be that certain features are more effective in this context than others, and emphasis should not be on increasing numbers of persuasive features but on those most likely to influence adherence, attrition, and efficacy. In future research, a positive deviance approach could be used to examine the features of the most engaging and effective apps, while correlational or experimental research designs could explore the impact of different features on adherence and attrition. Qualitative interviews with users may shed light on what features are experienced as most impactful by users and contribute to understanding their emotional valence and possible impacts on effectiveness.

Acknowledgments

A machine tool (Claude Opus 3) was used to suggest language to improve within the manuscript, for example, grammar, and spell check on content written by the research team. Responsibility for the final manuscript lies entirely with the authors. Generative AI tools are not listed as authors and do not bear responsibility for the final outcomes. Abstract

Background: Digital interventions for mental health and well-being are increasingly moving beyond screen-based applications toward more embodied approaches, necessitating design methodologies that emphasize bodily experiences. Soma design offers a distinctive interaction design approach that integrates bodily awareness with aesthetic appreciation, viewing the mind and body as an inseparable whole.

Objective: This scoping review aims to map and analyze the emerging applications of soma design within digital mental health and well-being (DMHW) interventions, offering a comprehensive overview of this holistic design methodology for researchers and practitioners.

Methods: This review was conducted in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. Studies were included if they used soma design to develop DMHW intervention.

Results: Nine papers were eligible for inclusion. The interventions varied in their stage of development: 5 were conceptual design concepts created by adolescents, while 6 were prototypes or experiential artifacts developed by researchers and/or participants. All interventions incorporated soma awareness exercises, with Feldenkrais lessons being the most commonly used. Toolkits, such as Soma Bits and the Menarche toolkit, supported the design of 2 interventions. Soma design methods benefited both designers and users: designers used embodied practices to inform interaction design, while users reported increased bodily awareness, full-body engagement, emotional comfort, and relaxation.

Conclusions: Soma design represents a valuable approach for developing embodied, user-sensitive DMHW interventions. It offers a participatory, holistic co-design methodology that can meaningfully engage end users. However, many interventions identified in this review remain in early stages of development and lack systematic evaluation. Advancing the field will require interdisciplinary collaboration among mental health professionals, human-computer interaction researchers, clinicians, industry partners, and individuals with lived experience. These partnerships are essential for co-designing, testing, and implementing interventions that are both effective and scalable, ultimately extending the reach and impact of soma design in digital mental health contexts.

Introduction

Background

Overview

The use of digital interventions to support mental health and well-being (MHW) is rapidly expanding [1]. These interventions harness technology to deliver accessible, scalable, and often cost-effective solutions for a wide range of psychological conditions. To date, the most studied digital mental health tools are screen-based, typically delivered through websites and mobile apps [2-4].

However, there is growing interest in more embodied digital interventions, those that engage the body through movement, sensation, and physical interaction. Technologies, such as virtual reality (VR) therapy, socially assistive robots, and wearable

XSL•FO
RenderX

devices, are increasingly being explored for their potential to create more immersive and physically engaging therapeutic experiences [5-7]. As the field moves toward more embodied approaches, design methodologies that center bodily experience become increasingly relevant. One such methodology that has gained traction in human-computer interaction (HCI) is soma design, which offers a holistic design stance on embodied interaction that could inform the development of future digital mental health and well-being (DMHW) interventions.

Embodiment in MHW

Embodiment refers to the concept that our mental and emotional experiences are deeply intertwined with our bodily sensations and movements [8]. Embodiment interventions are based on the idea that changes in bodily movements or postures can generate or enhance emotional experiences and activate related cognitions [9]. Neuroscientific evidence supports this bidirectional relationship, showing that bodily states, such as facial expressions, hand contractions, and posture, can influence both emotional experience and cognitive functioning [10].

A recent literature review highlights the therapeutic benefits of various embodied approaches in treating mental health symptoms [8]. For example, Dance Movement Therapy reduced depression while it improved well-being and overall health [11-13]. Similarly, relaxation training, such as mindful deep breathing, has demonstrated efficacy in alleviating symptoms of anxiety disorders [14].

Digital mental health interventions are also increasingly incorporating embodied technologies. One prominent example is VR exposure–based treatment, which immerses patients in controlled, interactive environments that facilitate gradual exposure to feared stimuli. This method has demonstrated efficacy in treating conditions such as post-traumatic stress disorder and eating disorders, offering patients the ability to tailor exposure scenarios and modulate their intensity [15-18].

In addition, socially assistive robots have shown potential in supporting MHW. A recent systematic review highlights their promise, though it also underscores limitations in the current body of research, including a narrow scope, limited generalizability, and methodological weaknesses, pointing to the need for more rigorous studies [6].

Wearable technologies are also emerging as effective tools in clinical contexts. For instance, a wrist-worn device that delivers rhythmic electrical stimulation to the median nerve has been shown to significantly reduce the frequency and intensity of tics in individuals with Tourette syndrome, illustrating the therapeutic potential of neuromodulation through wearable interfaces [7].

Overall, the evidence suggests that embodiment practices, both analog and digital, offer valuable contributions to MHW interventions, warranting further exploration and integration into DMHW frameworks.

Soma Design

Soma design and embodiment are closely intertwined concepts. Soma design is a distinctive approach within HCI that foregrounds the role of the body in interaction design, integrating bodily experience with aesthetic and sensory engagement. Rooted in the philosophical framework of *somaesthetics*, developed by Richard Shusterman, soma design draws on the concept of the *soma*, the living, sentient body as experienced from within, and *aesthetics*, the cultivation of sensory awareness and appreciation [19]. This framework emphasizes the integration of body, movement, thought, and emotion, placing embodied subjectivity at the center of design [20,21].

Building upon Dewey's notion that aesthetic experience arises through active engagement rather than being an inherent property of objects [22], Shusterman's *somaesthetics* encourages a deepened awareness of sensory experience. Soma design translates these philosophical insights into a practical design methodology that challenges traditional mind-body dualisms. It embraces a holistic view of human experience, recognizing that cognition, emotion, and perception are inseparably linked to bodily states and movements [23,24].

This approach invites designers to create technologies that enrich users' lived, embodied experiences. It does so by incorporating the designer's own bodily awareness and the physical-digital materials they engage with as integral components of the design process [24-26]. This involves paying attention to how users feel, move, and perceive their interactions with technology and creating designs that enhance these experiences in a harmonious and integrated manner. This integration ensures that the resulting interactive systems/artifacts can effectively influence and enhance the end users' and the designers' sensual appreciation and movement experiences [26].

Central to this methodology is the cultivation of somatic awareness through practices, such as body scans [27], Feldenkrais exercises [28], Alexander technique [29], yoga, and other movement-based activities [30-32] (Table 1). These practices help designers attune to their own bodily sensations and develop a first-person understanding of embodied experience, which then informs the creation of interactive systems for others [23,25]. This shift from verbal or cognitive ideation to movement-based exploration enables designers to "do" rather than "talk," anchoring their process in the subtleties of sensation and presence [21,33].

XSL•FO
RenderX

Table . Definitions of soma awareness exercises.

Soma awareness exercises	Definitions
Alexander technique	A mindfulness practice and somatic modality that helps people become consciously aware of their habitual movement patterns and posture, with the goal of releasing inefficient or harmful physical habits that create tension and pain
Body scans	A type of mindfulness-based stress reduction exercise in which practitioners systematically direct focused attention to bodily sensations throughout different parts of the body in sequence
Feldenkrais exercises	A somatic movement practice developed by Moshe Feldenkrais that focuses on increasing awareness of habitual movement patterns, through slow, mindful movements guided by a practitioner, aiming to help people discover more efficient ways of moving by reducing unnecessary effort while achieving optimal results. The method helps individuals rediscover alternative movement patterns they may have forgotten, particularly beneficial for those experiencing pain or movement difficulties
Other bodily practices	Other bodily practices include various introspective physical activities and experiences, such as movement exploration, touch awareness, and horseback riding that designers engage with to inform and ground their design work

Philosopher and dancer Maxine Sheets-Johnstone further enriches this perspective by emphasizing the moving, living body as central to how we inhabit and make sense of social, physical, and temporal spaces [34]. Soma design aligns with this view, encouraging designers to engage with the body not as an object, but as a dynamic, expressive medium of experience.

To deepen bodily awareness and disrupt habitual perception, soma design often employs Soma Bits, technologies embedded in soft, body-worn materials that use heat, vibration, or inflation to evoke unfamiliar sensations and prompt reflection (see Table 2) [35,36]. These tools help both designers and users become attuned to the nuances of the embodied interactions.

Table . Definitions of toolkits.

Toolkits	Definitions
Soma Bits	Soma Bits is a design toolkit consisting of foam shapes covered in elastic cotton textile that can be placed on different body parts, combined with various actuators (heat pads, vibration motors, and pneumatic shape-changing materials) that can be inserted into shapes pockets. The toolkit serves as a living, growing library intended to help designers explore and ideate with smart materials by providing the immediate, direct experience of potential soma designers through different combinations of shapes and actuators on the body.
Menarche Bits	Menarche Bits is a customizable prototyping kit of soft, silicone, body-worn interfaces that respond to pressure through air-actuated chambers. Designed for young adolescents experiencing menarche, it includes both preprogrammed components with haptic feedback and modular pieces that can be interconnected, allowing users to create personalized technologies that help them better understand and trust their menstruating bodies.

Soma design has gained traction in HCI over the past decade. However, its application in DMHW remains underexplored. It is also unclear whether existing Soma-based interventions primarily support general well-being or target specific mental health conditions. Digital mental health is defined as “the application of digital technologies in mental health care which can be used for many purposes, including MHW promotion and prevention, well-being maintenance/self-care, early intervention, or for treating specific mental illness…” [37] While well-being can encompass physical, mental, social, and environmental dimensions [38], in this review, we focus specifically on mental well-being.

Aims and Research Questions

This scoping review aimed to explore soma design applications in DMHW interventions.

To guide this review, we formulated the following research questions:

- Main question: What DMHW interventions have been designed using soma design methods?
- Subquestions:

1. What soma awareness exercises and other embodied activities have been employed in these interventions?
2. Who participated in the design process?
3. Do these interventions primarily engage general well-being or target specific mental health conditions?

XSL•FO
RenderX

4. What evaluation approaches were used to assess these interventions?
5. What outcomes were reported?

Methods

Study Design

The scoping review was conducted to map the existing literature in this research area [39,40], following the 5-stage framework: (1) identifying the research question, (2) identifying relevant studies, (3) selecting studies, (4) charting the data, and (5) collating, summarizing, and reporting the results [39] and the principles of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines (Checklist 1) [41].

Search Strategy and Data Sources

Two of the authors (SI-J and AHK) conducted initial literature searches relevant to the research question using databases, including Google Scholar. These initial searches were exploratory and aimed to identify relevant literature and refine the search strategy. Based on the relevant literature found during the initial searches, the search terms for the scoping review were discussed and selected during meetings among the authors. The search terms were combined using Boolean operators as follows:

((“somaesthetic*” OR “soma design”) AND (“health” OR “wellbeing” OR “wellness” OR “illness” OR “care” OR “therap*” OR “affect*” OR “emotion*” OR “feeling*”) AND (“digital mental health” OR “DMH” OR “digital technolog*” OR “technolog*” OR “digital health” OR “digital” OR “mHealth” OR “telehealth” OR “telemedicine” OR “electronic health” OR “mobile apps” OR “mobile health” OR “online based” OR “mobile*” OR “eHealth*” OR “electronic mental health” OR “e-mental health” OR “online-based*” OR “internet-based*” OR “web-based*” OR “computer-based”))

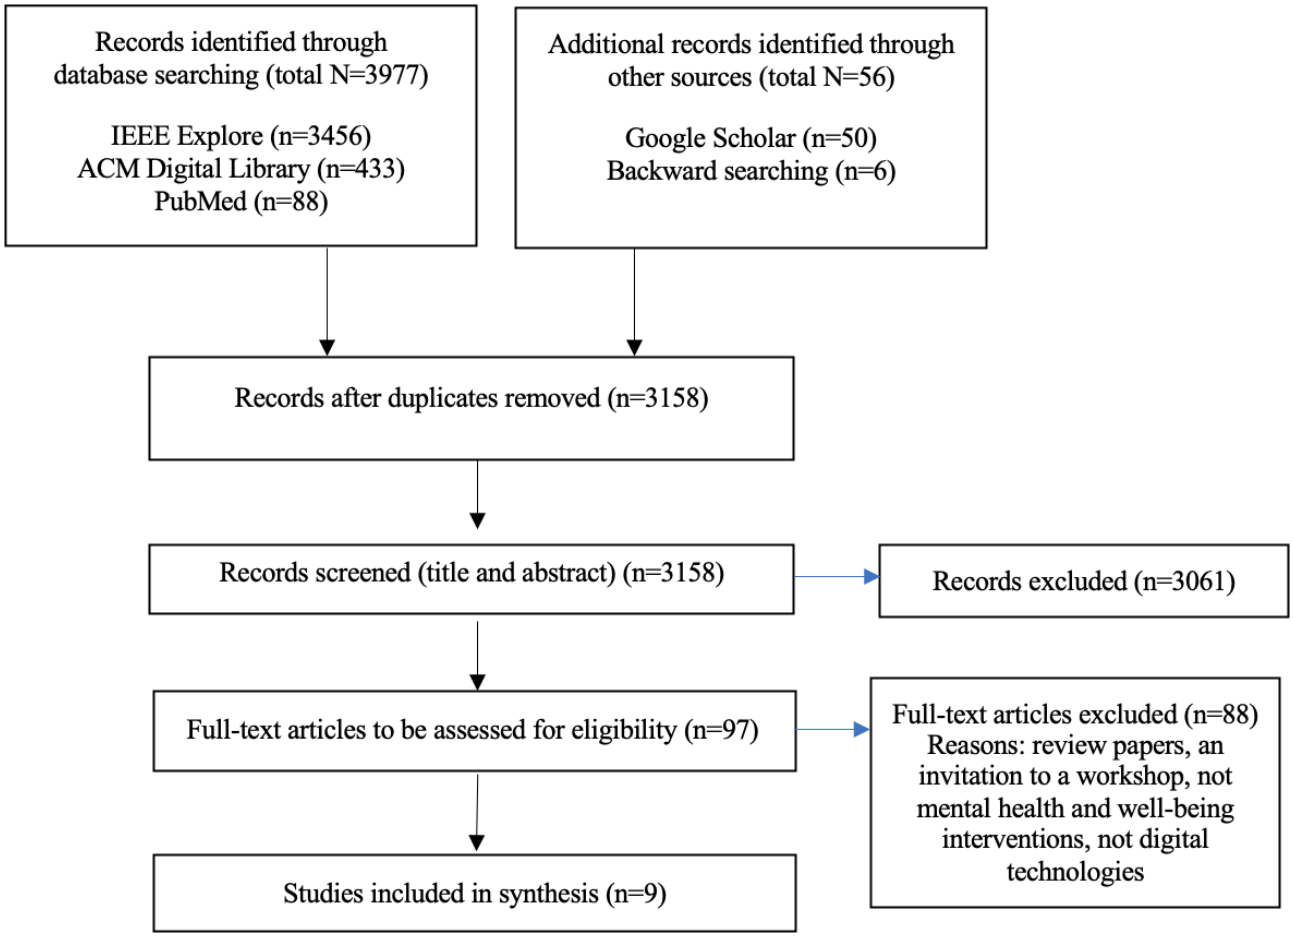
Three databases, PubMed, IEEE Explore, and ACM Digital Library, were searched on March 21, 2024, and again on January 18, 2026, and all results were imported into Rayyan [42] for screening. These databases were selected to capture the most relevant literature across health and medical research (PubMed), engineering and technology (IEEE Xplore), and HCI and design (ACM Digital Library). To enhance the comprehensiveness of the review, we additionally searched Google Scholar (first 50 records) and conducted backwards citation tracking.

Study Selection and Data Extraction

Studies were eligible for inclusion in this review if they met the following inclusion criteria:

1. Concept: digital mental health or well-being interventions designed using soma design methods and explicitly described as targeting or supporting mental health or well-being
2. Context: studies published in the English language, in any country

Studies were excluded from this review if they met any of the following exclusion criteria: review papers, an invitation to a workshop, papers that did not specifically state that the interventions targeted or supported mental health or well-being, interventions that did not involve digital technology, or papers that did not include sufficient details about the intervention (eg, soma design methods used, soma awareness exercises employed, or the purpose of the intervention).



Results

Selection of Sources of Evidence

In total, 3977 articles were identified from the electronic database searches (3456 IEEE Explore, 433 ACM Digital Library, and 88 PubMed), and an additional 56 records were identified through other sources. Following title and abstract screening, 97 articles were selected for full-text review. Two authors (SI-J and AHK) independently reviewed the articles and resolved disagreements through discussion until consensus was reached. Finally, 9 papers met the eligibility criteria and were included in this review (see Figure 1 for the PRISMA-ScR flow diagram).

XSL•FO
RenderX

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram of the study selection process.

Several papers described distinct stages or facets of prototype development, while others presented multiple prototypes, design concepts, or experiential artifacts. In total, 11 such items were included in the analysis.

Data Extraction

Data extraction was conducted independently by 2 of the authors (SI-J and AHK). Extracted information included lead author, year of publication, country of study, digital mental health intervention(s), stage(s) of the product development, MHW framing and timing (ie, whether the importance of MHW was prespecified by designers [predesign] or emerged through collaboration with prospective users and whether mental health conditions or well-being were focused), designers and/or participants, sample size (n), age range, soma awareness exercises and other activities, documentation methods, analytical approaches, and primary outcomes or conclusions (see Tables 3 and 4).

XSL•FO
RenderX

Table . Characteristics of the sources of evidence and outcomes.

Author, year of publication, and country	Digital mental health intervention(s), stages of the product development, MHW[a] framing and timing	Designers/ participants and soma awareness exercises and other activities
Ezer et al [43], 2024, Israel	Somaesthetic Meditation Wearable, prototype, predesign (well-being)	Participants, n=5 (varying experience in meditation) 1. A 10-minute meditation session, followed by an interview about their awareness of various body locations. 2. Researchers (experienced meditators) explored various low-fi wearable designs with participants. Participants, n=4 1. Researchers tested low-fi wearable designs with 4 participants. Participants, n=3 1. Researchers tested the next design iteration with 3 participants during meditation. Eastern medicine expert 1. Researchers designed the final prototype. 2. Safety and health consultation with Eastern medicine expert. Participants, n=20, age range: 24-59 years 1. 10-minute warm-up. 2. 10-minute meditation: Half of the participants meditated with the wearable and half without. 3. 2-4 minutes reflection sessions. 4. 10-minute meditation session: Half of the participants meditated with the wearable and half without. 5. A postexperience interview.
Höök et al [20], 2016; Stahl et al [35,44], 2016, 2022, Sweden	Soma Mat and Breathing Light, prototypes, predesign (well-being)	Researchers 1. Feldenkrais-lessons once a week for 2 years. 2. Researchers touched, felt, interacted with the materials and created the first prototype. Participants, n=7 1. Seven participants tried the prototypes, leading to a range of refinements of the prototype. Participants, n=22, tried the prototype in a 1-hour study: 1. Body map. 2. 30 minutes doing a body scan in the prototypes. 3. Body map. 4. Unstructured interview. Participants in 4 households for 3 months: 1. Use the prototypes 3-5 times a week. 2. Semistructured interview.

Table . Characteristics of the sources of evidence and outcomes (continued).

Author, year of publication, and documentation methods	Analytical approaches	Primary outcomes/conclusions
Ezer et al [43] (2024)		
• Interview	• N/A[a]	• Low-fi wearable designs • Participants prefer the circular shapes and to explore various body locations • The need to support easy placements on a variety of body parts • No risk • Recommended starting with the lower abdomen or lower back
• Semistructured interview (questions adapted from the State Mindfulness Scale)	• Thematic coding process	• The warmth provided emotional comfort
Höök et al [20] (2016); Stahl et al [35,44] (2016, 2022)		
• Body map before and after the session • Unstructured interview	• N/A	• Overall, the experience was very positive, and participants expressed that they wanted to have these at home as a relaxation tool
• All interviews were transcribed verbatim	• Storytelling	• Through using the prototypes, the users learned a new experience, which gave them an alternative way of being in the world
Jung et al [45] (2021)		
Workshop: • Notes • Pictures • Videos • Soma body sheets/body maps	• N/A	• These sessions enabled the authors to narrow down the physical schematics that would facilitate meaningful interactions. They included a set of suitable pad shapes/sizes and bodily placements that could be embedded into a wearable interactive system, later finalized by one of the researchers • Four experiential esthetic qualities were developed • Calm and relaxed feelings
La Delfa et al [46] (2020)		
• Embodied sketching (use the body to act out design ideas in situ, capturing them on media like video as they unfold in time)	• Applied the method in reflective encounter with the materials	• N/A
• Video recording • Body sheets after the sessions • Semistructured interviews	• Thematic analysis	• Initially the hands were demanding the most attention. By the second session, most participants were moving more fluidly, coordinating the whole body to produce smooth moving hands • Feeling relaxed
Montoya et al [47,48] (2023)		
• Body maps, written descriptions, and video recording before, after, and where possible during these experiences	• N/A	• N/A

XSL•FO
RenderX

Author, year of publication, and documentation methods	Analytical approaches	Primary outcomes/conclusions
• Semistructured interview	• Inductive thematic analysis	• Four themes, including "Fluito as a facilitator for relaxation." All participants reported relaxation due to additional reasons relating to the interactive technology.
Søndergaad et al [49] (2021) Researchers: • Video recording • Notes • Photos Participants: • Body maps • A-lab sheets • Phone video recording	• Transcribed the participants' videos and the key moments from the video recording • Wrote thick descriptions	• The participants designed five technologies that respond to their experiences of menstrual cycles in sport. The design concepts demonstrate interactions with breathing, touch, modularity, and rhythms on intimate placements on the body, including the pelvis bone and chest • Throughout the workshop, the participants' accounts of menstrual cramps and depressive and anxious feelings went from linguistic to embodied.

[a]N/A: not applicable.

Stages of the Product Development

The products described across the included papers varied considerably in their stage of development. Some were fully developed prototypes created by researchers and evaluated by participants, while others represented earlier phases of the design process, such as design concepts or experiential artifacts. *Design concepts* refer to bodily informed, experience-driven ideas for potential future products. *Experiential artifacts* are intentionally designed systems that elicit specific experiences based on the properties of a chosen digital material, serving as exploratory tools for design teams rather than goal-oriented, deployable products [50]. Throughout this paper, we use the terms, *prototype, design concept, or experiential artifact*, to accurately reflect the development stage of each product. When discussing collectively, we use the term *interventions* for clarity and readability.

Eleven DMHW interventions created using soma design methods were found. The *Soma Mat* is a body-sized mat, which directs the user's attention by providing heat feedback to different parts of their body while they follow the instructions of a prerecorded Feldenkrais lesson [20,35,44]. The authors recommend that the *Soma Mat* should preferably be used with another intervention, the *Breathing Light* [20,35,44]. The *Breathing Light* is a lamp that measures the user's breathing, creating an ambient light that dims in cadence with their breathing. The user is recommended to lie on the *Soma Mat* while placing the *Breathing Light* above their face to provide them a private space.

The *deep touch pressure (DTP) garment* is an experiential artifact created to help increase breathing awareness and appreciation through interaction with breathing-based deep pressure [45]. *Fluito* has a combination of technology (a flotation tank, a VR headset, a heart rate sensor, and a pneumatic system), which creates different experiences for the user, including relaxation [47,48]. *Drone Chi* is inspired by the martial art of Tai Chi, providing a close-range human-drone experience by the user either following or leading the drone [46]. The *Somaesthetic meditation wearable* is a novel targeted warmth wearable intended to be used during meditation [43].

Adolescent athletes developed 5 innovative menstrual technology concepts to address menstrual cramps and premenstrual depressive and anxious feelings [49]. Using Menarche Bits [49], participants designed technologies that incorporate touch, breathing rhythms, and modularity in intimate body placements (see Table 2). *Värme Plagget* (heat garment) is a wearable garment that provides heat to alleviate menstrual pain in the lower abdomen. *The Calm-inator* is a blouse equipped with air pumps that massage the chest area, helping to increase breathing awareness. *U-formen (The U-shape)* consists of 2 heat cushions that warm the lower abdomen and pumps that create pulsating sensations on the hip bones. *Korven (The Sausage)* is a portable heat cushion to relieve menstrual pain and bloating before and during menstruation. *Transformer* consists of heat and pumping machines, which can be placed in the middle of the stomach to ease menstrual pain.

MHW Framing and Timing

Across most interventions, MHW considerations were prespecified by the designers, typically framed around goals, such as relaxation or calmness, rather than clinical treatment. In one study, the relevance to MHW emerged during collaboration with prospective users, although emotional dimensions had already been implied by the authors [49]. Overall, all included interventions focused on general well-being rather than addressing specific mental health conditions.

XSL•FO
RenderX

Designers

Five of the interventions were designed primarily by researchers. At the time of the papers' publication, 1 intervention (*DTP garment*) had been developed solely by the research team [45], whereas 4 interventions (*The Soma Mat*, *The Breathing Light*, *Drone Chi*, and *Fluito*) were first designed by researchers and subsequently tried by participants, who provided experiential feedback [20,46,47].

The *Somaesthetic Meditation Wearable* was designed by participants with varying experience in meditation [43]. The 5 menstrual technologies were designed by adolescents who played sports [49]. Specialist expertise was integrated into 2 studies: one study involved a "somatic connoisseur," a consultant specializing in a particular bodily practice (in this case, a Tai Chi master) who contributed to a co-design session [46], whereas the other consulted an expert in Eastern medicine during the design process [43].

Soma Awareness Exercises and Toolkits

Soma Awareness Exercises

The soma awareness exercises practiced most frequently during the design processes were Feldenkrais lessons. Researchers practiced Feldenkrais lessons before designing 3 of the interventions: *Soma Mat*, *Breathing Light*, *and DTP garment* [20,45], while adolescents practiced them before creating the 5 design concepts of the menstrual technologies [49]. The types of Feldenkrais lessons varied depending on the focus of each project. Other soma awareness exercises tried by the designers included Tai Chi, meditation, interacting with water, and engaging in sports [43,46,47,49].

Toolkits

The *Soma Bits Toolkit* and the *Menarche Bits* were specifically designed and created for soma design practice [26,51]. The *Soma Bits* were used to design the *DTP garment* [45], whereas the *Menarche Bits* were used by adolescents to design the 5 menstrual technologies [49] (see Table 2).

Documentation Methods

In addition to taking notes during workshops and conducting participant interviews, researchers employed a range of strategies to document the soma experiences encountered during the design process. To capture how designers or participants felt in their bodies, each person filled out the body maps [52] before and after bodily activities in 8 studies (Table 5). These body maps were filled out by researchers in the development of 2 interventions (*DTP garment* and *Fluito*) [45,47], by adolescents during the co-design of 5 menstrual technologies [49], and by participants to report their experiences with 3 of the interventions: *Soma Mat*, *Breathing Light*, and *Drone Chi* [20,35,44,46].

Table . Definitions of body maps and experiential qualities.

Documentation	Definitions
Body maps	Body maps are tools for body awareness consisting of preprinted body silhouettes on paper that can be annotated and drawn upon. They serve as a method to document and reflect on one's lived bodily experience, allowing individuals to externalize and track changes in body awareness, particularly before and after somatic practices, such as Feldenkrais. By sharing these visual representations, body maps help develop a more refined vocabulary for describing bodily experiences while fostering trust and comfort among participants.
Experiential qualities (XQs)	XQs are characteristics embedded in a design and felt during user interaction, serving as guiding principles throughout the design process while allowing creative freedom in translating somatic experiences into multiple design ideas and materials.

Researchers also frequently used video recordings to document key moments during the design process and interviews. For 3 interventions, such as *DTP garment*, *Drone Chi*, and *Fluito*, researchers recorded soma design workshops to reflect on their own experiences [45-47]. Additional recordings captured participants using the *Drone Chi* intervention [46] and adolescents engaging in the design of menstrual technologies [49]. In one study, participants were asked to record short videos on their phones to present their design concepts (menstrual technologies) [49].

Analytical Approaches

In all studies, designers engaged in first-person, subjective reflection to foreground experiential insights, facilitate iterative exploration, and foster reflective practice throughout the design process. To analyze the data collected from participants, a range of qualitative methods was employed. Thematic analysis was conducted to analyze semistructured interviews with participants for 3 of the interventions, such as *Somaesthetic Meditation Wearable*, *Drone Chi*, and *Fluito*, to identify recurring patterns and themes [43,46,47]. For the *Soma Mat* and *Breathing Light* interventions, a storytelling approach was adopted to capture and interpret individual participant experiences [35]. In many of the studies, the use of video data, which captured the moments from the design process or participant interviews, was not explicitly detailed. However, in the case of *Drone Chi*, video content was integrated into the interviews and analyzed thematically [46]. For the menstrual technologies project, researchers produced thick descriptions of key workshop moments to support interpretive analysis [49].

Outcomes

For Designers Developing the Interventions

Designers reported a range of outcomes from applying soma design methods in the development of 7 interventions. In the

XSL•FO
RenderX

case of the *DTP garment*, engagement in soma-based activities, such as Feldenkrais practice and body mapping, enabled the designers (ie, researchers) to identify physical schematics that would support meaningful interaction. These practices also helped uncover key experiential qualities [53] (see Table 5) that informed the design of the intervention [23,45].

Similarly, adolescent designers who participated in a soma design workshop to develop menstrual technologies experienced a shift in how they articulated their symptoms. Their descriptions of menstrual cramps, depression, and anxiety evolved from linguistic expressions to embodied understandings. Through this process, they began to perceive their bodies and minds not as separate entities, but as interconnected aspects of their lived experience. Their resulting design proposals aimed to alleviate menstrual discomfort by incorporating pain relief and breathing techniques to address both physical and emotional symptoms [49].

For Participants Experiencing the Interventions

Five of the 11 interventions developed using soma design were evaluated by participants who had not been involved in their creation. Overall, these participants reported positive and meaningful experiences when engaging with the interventions. For instance, users of *Fluito* described an increased awareness of their breathing, which contributed to both mental and physical relaxation [47]. Similarly, participants interacting with *Drone Chi* demonstrated a gradual shift in their engagement. Initially focused on hand movements, they began to move more fluidly over time, incorporating their entire bodies to produce smooth, coordinated gestures. Analysis of body maps, video recordings, and interviews revealed that *Drone Chi* supported a range of mental states, including meditative experiences characterized by present-moment focus and relaxation [46]. Participants using *Somaesthetic Meditation Wearable* during meditation reported that the warmth provided emotional comfort [43].

Participants who used the *Soma Mat* and *Breathing Light* for 30-minute sessions also reported positive experiences and expressed a desire to use these tools at home for relaxation. Notably, after 3 months of home use, participants reported being able to self-regulate and calm themselves during stressful moments, even without the physical presence of the prototypes, suggesting a lasting impact on their embodied coping strategies [35].

Discussion

Current Evidence for Soma Design in DMHW

This scoping review mapped the current landscape of DMHW interventions developed using soma design methods. All included studies reported positive outcomes associated with soma design. Among the 5 interventions tested by participants, users reported increased bodily awareness, full-body engagement, enhanced emotional comfort, and relaxation. Notably, 2 of the interventions demonstrated lasting effects, with participants applying the skills they had developed, such as self-regulation and relaxation, beyond the duration of the intervention sessions. Designers also reported significant benefits from using soma design. These included the identification of experiential qualities that informed the design process and a shift in how adolescent designers perceived their bodies, not as separate from the mind, but as integrated aspects of their whole being. These findings suggest that soma design can offer meaningful value for both designers and users.

However, the balance of evidence is inconclusive due to the heterogeneity in the stage of design development (ranging from conceptual designs to functional prototypes), the identity of the designers (eg, researchers vs adolescents), the extent of end-user involvement, and the analytical approaches employed. In the following section, we explore both the opportunities and challenges in advancing soma design within the DMHW field.

Opportunities and Challenges in Advancing Soma Design for DMHW

This scoping review highlighted the value of mind-body-focused approaches within DMHW, drawing attention to the often-overlooked role of bodily awareness in design processes. While much of DMHW has traditionally centered on cognitive and screen-based interventions, soma design underscores the importance of attending to the body as a site of both experience and intervention [54]. It adopts a first-person, subjective stance in which the designer's own bodily experience becomes a source of insight and knowledge production [33]. Grounded in the principles of Research through Design, soma design values reflective practice, iterative making, and somatically grounded engagement with materials and technologies [21]. These epistemological foundations not only distinguish the soma design methodologically but also enable the development of more nuanced, embodied, and user-sensitive DMHW interventions.

In doing so, soma design may offer a bridge between 2 emerging trends in health care: digital mental health and digital physical health. While these domains have often evolved in parallel, one focusing on psychological well-being through digital therapeutics, the other on physiological monitoring and movement-based interventions, soma design invites a more integrated perspective. It encourages the design of technologies that do not treat the mind and body as separate domains but instead recognize their continuous interplay [24]. This integration is particularly relevant in conditions where mental and physical symptoms co-occur [55]. By fostering embodied awareness and sensory attunement, soma design opens up new possibilities for interventions that are not only technologically innovative but also deeply attuned to the lived, felt experience of users. In this way, it contributes to a more holistic vision of digital health, one that supports the whole person, rather than isolating mental or physical aspects of well-being.

This integrative approach aligns with a broader movement within HCI and DMHW toward more body-centric technologies and interaction paradigms. Similar to HCI, the DMHW field is increasingly moving beyond traditional screen-based or VR-focused interventions and embracing emerging modalities, such as wearables, soft robotics, and other forms of embodied interaction that integrate seamlessly with the body [54]. As such, soma design contributes to ongoing conversations about the future of DMHW, suggesting that embodied, somatically

XSL•FO
RenderX

informed design practices may play a critical role in shaping more holistic and responsive mental health technologies.

This holistic vision is operationalized through a range of embodied design techniques that lie at the heart of soma design practice. These include soma awareness exercises, body mapping exercises, and the use of Soma Bits, technologies that deliver unfamiliar sensations through heat, vibration, or inflation to disrupt habitual perception and foster deeper bodily engagement [54]. These methods serve as generative design strategies, enabling participants and designers to access and articulate subtle aspects of embodied experience. In doing so, they help ground the design process in lived bodily sensation, reinforcing soma design's commitment to creating technologies that are attuned to the full spectrum of human experience.

Cocreation and Stakeholder Engagement

While soma design offers a compelling framework for creating more holistic and embodied DMHW interventions, realizing its full potential depends on meaningful engagement with the people that these technologies are intended to support. However, the studies reviewed revealed varying degrees of user participation. Only 2 studies involved end users from the onset, resulting in the development of 1 prototype and 5 distinct design concepts. In contrast, others engaged participants only during later testing phases.

In mental health research, cocreation is widely recognized as a cornerstone of effective intervention design. It involves engaging end users as active stakeholders throughout the design, development, implementation, and evaluation of digital interventions [56]. This approach aligns with the principle of responsible research and innovation, which emphasizes the importance of creating technologies that are ethically sound, socially desirable, and aligned with users' values and needs [56].

Participatory soma design holds significant potential as an embodied, holistic coproduction approach. While cocreation has gained traction in mental health research, it has predominantly focused on cognitive-based interventions, often through patient and public involvement workshops or focus groups. Participatory soma design methods present new opportunities for mental health research by offering a more embodied and experiential approach.

This is particularly important when designing for populations that differ from the researchers themselves. For example, Søndergaard et al [49] demonstrated the value of involving adolescents in the design of interventions targeted at their age group. Similarly, including individuals with lived experience of neurodiversity or mental health conditions is essential to ensure that interventions are both relevant and effective.

However, the time- and resource-intensive nature of soma design can make sustained user involvement challenging. Ideally, end users should be engaged from the early stages of design. Where this is not feasible, researchers should still involve users in later stages of refinement to ensure that interventions align with their embodied needs and preferences. Adapted or phased models of participation may help balance feasibility with meaningful engagement.

Addressing these challenges requires not only thoughtful engagement strategies but also broader collaboration across disciplines and stakeholders to support the development and implementation of effective soma design interventions.

Collaborations to Create Effective Mental Health Interventions for the Users

While soma design offers a compelling framework for embodied DMHW interventions, its broader impact relies on the ability to translate rich, experiential practices into solutions that are scalable and accessible. Despite its potential to support MHW in diverse contexts, the field currently lacks systematic evaluation frameworks to assess the effectiveness of these interventions. Much of the existing research remains exploratory, limiting its integration into DMHW practices that require rigorous validation and replicability.

Additionally, this review found a notable distribution between mental health conditions and well-being: no included intervention explicitly targeted a specific mental health condition (eg, anxiety and depression). Instead, current applications predominantly focus on well-being outcomes (eg, relaxation and calm). Addressing this gap is essential for understanding the therapeutic potential of soma design and guiding its future applications in both clinical and everyday settings. The interventions currently available may inform the development of future condition–targeted digital mental health interventions.

Furthermore, the interventions reviewed in this study varied widely in their stage of development, ranging from early-stage design concepts to advanced prototypes undergoing iterative testing. In many cases, the primary focus was on exploring and refining the methodological aspects of soma design rather than producing interventions intended for broader deployment. While this has contributed valuable insights into embodied design practices, it has also limited the immediate applicability of soma interventions in real-world mental health contexts. Nevertheless, examples, such as *Soma Mat* and *Breathing Light* [20], demonstrated the potential of soma design to deliver meaningful, positive experiences to a broader audience. These examples illustrate how embodied interaction can support well-being through sensory engagement and bodily awareness.

To fully realize this potential, interdisciplinary collaboration is essential. Bringing together mental health professionals, HCI researchers, industrial partners, and individuals with lived experience can foster the co-design, evaluation, and implementation of interventions that are both effective and scalable. Such partnerships ensure that interventions are grounded in robust design methodologies while remaining responsive to diverse user needs and real-world constraints. In particular, deepening collaboration with clinical partners and mental health researchers will be crucial for moving soma design beyond exploratory prototypes toward clinically relevant, deployable DMHW solutions.

Strengths and Limitations of This Review

This paper presents the first scoping review to systematically map existing research on DMHW interventions developed using soma design methods. To our knowledge, it is also the first to introduce soma design to the digital mental health research

XSL•FO
RenderX

community in a structured and comprehensive manner. A rigorous literature search was conducted across 3 major databases, supplemented by Google Scholar screening and backward citation tracking to ensure comprehensive coverage. Study selection and data extraction were performed in duplicate to enhance reliability. Through this process, this review offers a valuable synthesis of current knowledge and highlights the potential of soma design to contribute novel, embodied approaches to MHW research.

Despite these strengths, several limitations should be acknowledged. First, the review included only studies published in English, which may limit the cultural and geographical diversity of the findings. This narrow scope may overlook relevant work published in other languages. Second, the included studies varied widely in terms of methodological detail and reporting quality, which may affect the consistency and comparability of findings. Finally, while this review maps the current landscape of soma design in digital mental health, it does not assess the clinical effectiveness of soma design interventions, as no included studies have conducted formal evaluations.

Future research should address these limitations by involving more diverse populations of designers and participants, including individuals from underrepresented cultural and linguistic backgrounds as well as those with lived experience, such as people with mental health conditions or neurodivergence. Broadening both the methodological and demographic scope of soma design research will be essential for realizing its full potential and ensuring its relevance and effectiveness in digital mental health contexts.

Conclusions

This scoping review provides the first comprehensive synthesis of DMHW interventions developed using soma design methods. The findings suggest that soma design offers a distinctive, embodied approach that can enrich both the design process and user experience by fostering bodily awareness, relaxation, and meaningful engagement.

At the same time, the review identifies important gaps in current literature, particularly around evaluation practices, user involvement, and the diversity of design contexts. Addressing these gaps will be essential for advancing soma design from an exploratory methodology to a widely applicable framework for DMHW innovation.

Looking forward, soma design presents a valuable opportunity to reimagine how DMHW interventions are conceptualized and cocreated. By fostering deeper collaboration among mental health researchers, HCI practitioners, clinicians, industry partners, and individuals with lived experience, future work can support the development of more inclusive, effective, and embodied mental health technologies. In doing so, soma design may help shape a more holistic and human-centered future for digital mental health.

Abstract

Background: Population aging is associated with a growing prevalence of neurocognitive disorders among adults aged 65 years and older. Digital health technologies offer promising opportunities to support cognitive health and well-being in this population. However, their effectiveness largely depends on users' level of engagement. Despite the recognized importance of engagement in digital health, limited evidence exists on how engagement is conceptualized, measured, and related to intervention outcomes among older adults living with neurocognitive disorders.

Objective: This scoping review aimed to describe how engagement with digital health technologies among older adults with neurocognitive disorders is conceptualized and measured, examine the relationship between engagement and the effectiveness of digital health interventions, and identify factors that facilitate or hinder engagement.

Methods: A scoping review was conducted following the Joanna Briggs Institute methodological guidance and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. A comprehensive search strategy, developed in collaboration with an information specialist, was applied to MEDLINE, Embase, CINAHL, Web of Science, and Google Scholar, without date restrictions. Empirical studies involving adults aged 65 years and older living with neurocognitive disorders and using digital health technologies were included. Study selection and data extraction were performed independently by at least 2 reviewers, and the results were synthesized narratively.

Results: Of the 1665 records identified after duplicate removal, 2 studies met the inclusion criteria. One study examined computerized cognitive stimulation and cognitive engagement programs among community-dwelling older adults with mild neurocognitive disorders, whereas the other explored the use of a personalized digital reminiscence application in long-term care settings among individuals with major neurocognitive disorders. No study used a validated instrument to directly measure engagement. However, observable indicators and markers related to the behavioral, cognitive, and affective components of engagement were reported. Both studies also documented concurrent cognitive or psychosocial outcomes. Factors facilitating engagement included professional support, content personalization, and involvement of informal caregivers, whereas limiting factors included cognitive fluctuations, fatigue, technical complexity, and reliance on external support.

Conclusions: This scoping review highlights a significant gap in the literature regarding the explicit conceptualization and standardized measurement of engagement with digital health technologies among older adults living with neurocognitive disorders. The findings underscore the need to develop and apply multidimensional, context-sensitive engagement measurement tools tailored to this population to better understand and optimize digital health interventions.

engagement; older adults; neurocognitive disorders; digital health technologies; eHealth

Introduction

Background

Population aging is a rapidly accelerating global phenomenon [1]. Between 2015 and 2050, the proportion of older adults worldwide is expected to nearly double, increasing from 12% to 22% [1,2]. Aging, defined as the progressive decline of physiological functions necessary for survival and reproduction [3], is frequently associated with an increased prevalence of neurocognitive disorders [4].

Neurocognitive disorders refer to an alteration in one or more cognitive functions, regardless of their underlying mechanism, etiology, or reversibility [5]. Such impairments may result from neurological, psychiatric, pharmacological, or other causes [5] and can affect various cognitive domains, including attention, memory, executive function, visuospatial abilities, and language [5]. In clinical and diagnostic literature, neurocognitive disorders are generally classified into 2 main categories according to the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-5*) [6]: mild neurocognitive disorder, which corresponds to the concept historically referred to as mild cognitive impairment (MCI), and major neurocognitive disorder, which largely corresponds to what is described as dementia in the International Classification of Diseases, still widely used in the international literature [6,7].

Major neurocognitive disorder is characterized by a significant, acquired, and progressive decline in cognitive abilities that are severe enough to interfere with independence in activities of daily living [5]. In contrast, MCI involves objectively measurable cognitive decline with relatively preserved functional autonomy [5,8].

Although most individuals living with neurocognitive disorders are aged 65 years and older, cognitive disorders can also affect younger populations [9]. In this scoping review, the term “older adults” refers to individuals aged 65 years and older, in accordance with commonly used criteria by statistical and public health organizations in Quebec and Canada [10-12].

Globally, the prevalence of MCI among older adults is estimated to range from 15.6% to 23.7%, depending on community or institutional settings [13]. In addition, approximately 55 million people worldwide are currently living with major neurocognitive disorders, nearly 73% of whom are older adults [14]. This number continues to rise rapidly, with nearly 10 million new cases diagnosed each year [14]. Major neurocognitive disorder encompasses several clinical entities, including Alzheimer disease, which accounts for 60% to 70% of cases, and cerebrovascular diseases, and less common forms, such as frontotemporal degeneration, dementia with Lewy bodies, and mixed neurocognitive disorders [9,14].

In Canada, in 2025, it is estimated that nearly 771,939 individuals may live with major neurocognitive disorders, a number projected to reach approximately 1 million by 2030 and 1.7 million by 2050 [15]. The consequences of neurocognitive disorders, whether mild or major, are substantial for older adults themselves as well as for their informal caregivers (family members and friends) and formal caregivers (health and social care professionals). For example, informal caregivers in Canada provide more than 580 million hours of care annually to older adults living with neurocognitive disorders, equivalent to approximately 290,000 full-time jobs [15]. The associated costs of care and support exceed CAD $10 billion per year [9].

In response to this growing burden, strategies aimed at preserving cognitive health in older adults have become a public health priority. Two key mechanisms have been identified in the literature: cognitive reserve and vascular reserve [16]. Cognitive reserve refers to the brain’s capacity to recruit alternative neural networks and strengthen synaptic connections to compensate for neuropathological damage, thereby maintaining cognitive performance despite underlying brain changes [16,17]. Vascular reserve, in turn, reflects the ability of the cerebral vascular system to maintain adequate oxygen and nutrient delivery despite vascular insults or hemodynamic variations, contributing to overall brain resilience [16,17]. Together, these complementary mechanisms may delay the clinical expression of neurocognitive disorders.

Several protective factors that may influence these mechanisms have been identified, including physical activity, social participation, and cognitive engagement [16,18-20]. These factors can be supported through various interventions, including the use of digital health technologies.

Digital health technologies encompass stand-alone software applications as well as integrated systems and devices accessible via computers, smartphones, tablets, wearable devices, or environmental sensors [21,22]. Among older adults, these technologies, often referred to as gerontechnologies, are used to support multiple aspects of health care and health promotion, such as cognitive stimulation, physical activity monitoring, and communication with family members and health care professionals [4,23].

However, for digital health technologies to achieve their intended benefits, user engagement remains a central determinant. Engagement with digital health technologies is commonly conceptualized as a multidimensional construct comprising 3 interrelated components: behavioral, cognitive, and affective [24-27]. The behavioral component refers to patterns of technology use, including frequency, duration, intensity, and depth of use [26]. The cognitive component encompasses constructs, such as attention and interest directed toward the technology [24,25]. Attention reflects the allocation of cognitive resources to specific information at the expense of competing stimuli [25], whereas interest represents a more enduring preference for certain activities, promoting voluntary engagement and the use of specific cognitive strategies [27]. Finally, the affective component relates to emotional responses elicited by the technology, including hedonic valence (pleasure or displeasure) and emotional activation [27].

XSL•FO
RenderX

Within digital health interventions, technologies function as stimuli designed to reinforce use, attention, interest, and affective responses to support behavior change [28]. Nevertheless, the literature reveals considerable heterogeneity in how engagement with digital health technologies is defined and measured. Engagement is frequently conflated or used interchangeably with related constructs, such as use, adherence, acceptability, satisfaction, feasibility, adoption, or retention [27,29]. In this scoping review, engagement is examined according to the 3-component conceptualization (behavioral, cognitive, and affective) to ensure theoretical consistency [24-27].

Although the effectiveness of digital health technologies for individuals living with neurocognitive disorders has been widely documented [20], knowledge regarding engagement with these technologies among older adults with neurocognitive disorders remains fragmented. Yet, the effectiveness of digital interventions largely depends on their adoption, sustained use, and integration into daily life, all of which require sufficient user engagement [30]. Engagement is therefore considered a key factor in explaining why certain digital health technologies are beneficial for some older adults but not for others [31].

In practice, some older adults may have access to digital health technologies and possess the necessary skills to use them, yet choose not to engage, often due to issues related to design, content, or functionality [26,32]. Others may initially engage but discontinue use over time. For example, a systematic review examining attrition and adherence in mobile mental health interventions among older adults reported attrition rates of up to 30%, with particularly low adherence rates ranging from 2% to 10% [33]. Factors associated with disengagement included dissatisfaction with perceived progress, time and effort demands, and limited usability [30].

Given the limited and heterogeneous evidence on engagement with digital health technologies among older adults living with neurocognitive disorders, there is a clear need to map existing knowledge. A comprehensive understanding of how engagement is conceptualized, assessed, and related to intervention effectiveness is essential to support the development, adaptation, and implementation of more relevant and inclusive digital health interventions for the prevention and management of neurocognitive disorders in older adults.

Study Objectives and Research Questions

The objective of this scoping review was to describe how engagement with digital health technologies among older adults living with neurocognitive disorders is conceptualized and assessed in the scientific literature. It also aimed to explore factors that facilitate or hinder engagement and to examine the relationship between engagement and the effectiveness of digital health interventions.

The review addressed the following research questions:

1. How is engagement conceptualized and operationalized in studies examining digital health technologies for older adults living with neurocognitive disorders?
2. What measures are used to assess the level of engagement of older adults living with neurocognitive disorders in digital health technologies?
3. What factors facilitate or hinder engagement with digital health technologies among older adults living with neurocognitive disorders?
4. What relationships are reported between engagement levels and the effectiveness of digital health interventions?

Methods

Study Design

This study adopted a scoping review methodology to map the existing body of knowledge, clarify conceptual boundaries, and identify gaps in the literature regarding engagement with digital health technologies among older adults living with neurocognitive disorders [34]. Scoping reviews are particularly appropriate when concepts are heterogeneous, variably defined, and examined using diverse methodological approaches [34].

We conducted the review following the Joanna Briggs Institute (JBI) methodological guidance for scoping reviews [35]. Reporting followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Checklist 1) [36] to ensure transparency and reproducibility.

Eligibility Criteria

Eligibility criteria were defined a priori using the Participants (Population), Concept, and Context framework recommended by the JBI [35].

Population

Studies involving older adults aged 65 years and older living with neurocognitive disorders, whether mild or major, were considered eligible. Given the variability in how age was reported across studies, exceptions were allowed. Specifically, studies were included when the mean or median age of participants was greater than 65 years [37]. Furthermore, several conceptual frameworks and recent evidence syntheses indicate that the involvement of caregivers, whether formal or informal, is a key determinant of digital engagement among individuals living with a neurocognitive disorder. This is largely due to their role in content personalization, support for technology use, and technological mediation between the user and the digital tool [38-40]. Accordingly, although caregivers were not considered the primary population of interest in this review, their data were included when they directly informed the engagement of older adults living with a neurocognitive disorder in the use of digital health technologies.

Concept

The central concept of this review was engagement with digital health technologies. No restrictions were imposed on how engagement was defined in the included studies, in order to capture the diversity of conceptualizations present in the literature. Digital health technologies included stand-alone software applications as well as integrated systems and devices accessible via platforms, such as computers, smartphones, tablets, wearable devices, and environmental sensors [21,22].

XSL•FO
RenderX

Context

Studies conducted in any setting (eg, health care facilities, long-term care settings, residential facilities for older adults, or community-based environments) were eligible for inclusion, with no geographical restrictions.

Exclusion Criteria

Publications that did not report original empirical data were excluded. These included knowledge syntheses, such as systematic reviews and narrative reviews, as well as commentaries, editorials, and study protocols. Conference abstracts, theses, dissertations, and gray literature were also excluded.

Search Strategy

The search strategy (Multimedia Appendix 1) was developed in collaboration with an experienced health sciences librarian specialized in knowledge synthesis (FB). It combined free-text terms and controlled vocabulary related to the concepts of *engagement*, *digital health*, *older adults*, and *neurocognitive disorders*, including relevant synonyms and spelling variants.

An initial comprehensive search was conducted on April 4, 2024, and updated on October 9, 2025. The databases searched included MEDLINE (Ovid), Embase, CINAHL, Web of Science, and Google Scholar. Considering the known limitations of search engines and based on preliminary testing, we elected to perform a series of structured subsearches [41]. To maximize the effectiveness of the relevance-ranking algorithm, each subsearch was restricted to the top 20 results. In total, this strategy produced 160 records, including those retrieved during the update. Only studies published in English or French were included. No other restrictions were applied. Finally, backward citation searching was performed on all included studies to identify further relevant publications.

Study Selection

All records retrieved from the databases were imported into Covidence (Veritas Health Innovation), a web-based collaborative software designed to manage systematic and scoping reviews [42]. A total of 780 duplicates were eliminated using the automated function of Covidence, and 5 duplicates were removed manually.

Study selection was conducted in two stages: (1) title and abstract screening and (2) full-text review. At each stage, eligibility criteria were applied independently and blindly by several reviewers (SMARD, FN, SA, ARY, FY, JP, and CC). Discrepancies were resolved through discussion and consensus, and when necessary, by consultation with the senior investigator (MPG).

A PRISMA 2020 flow diagram was used to document the identification, screening, eligibility assessment, and inclusion of studies, as well as reasons for exclusion at the full-text review stage [43].

Data Extraction

A standardized data extraction form was developed by the research team using Microsoft Excel. Data extraction was performed independently by several reviewers (SMARD, ARY, FN, and SA) and subsequently validated by the senior investigator (MPG). Discrepancies were resolved through consensus among the reviewers involved or, when needed, with the support of a third team member.

The following data were extracted: (1) study and intervention characteristics, such as title, authors, year of publication, country, study design, eligibility criteria, care setting, target population, type of digital health technology, duration, and reported effectiveness; and (2) engagement-related variables, such as conceptualization of engagement, operationalization of engagement, engagement indicators (behavioral, cognitive, and affective), and measurement tools used.

In addition, variables derived from the PROGRESS-Plus framework for health equity were extracted [32]. This framework includes 8 core dimensions (place of residence, race/ethnicity, occupation, gender, religion, education, socioeconomic status, and social capital) and an additional "Plus" component intended to capture other characteristics that may influence health inequities. The use of this framework allowed for an examination of the extent to which digital health technologies were accessible and adapted to potentially vulnerable subgroups, including older adults living with neurocognitive disorders [44].

Data Analysis

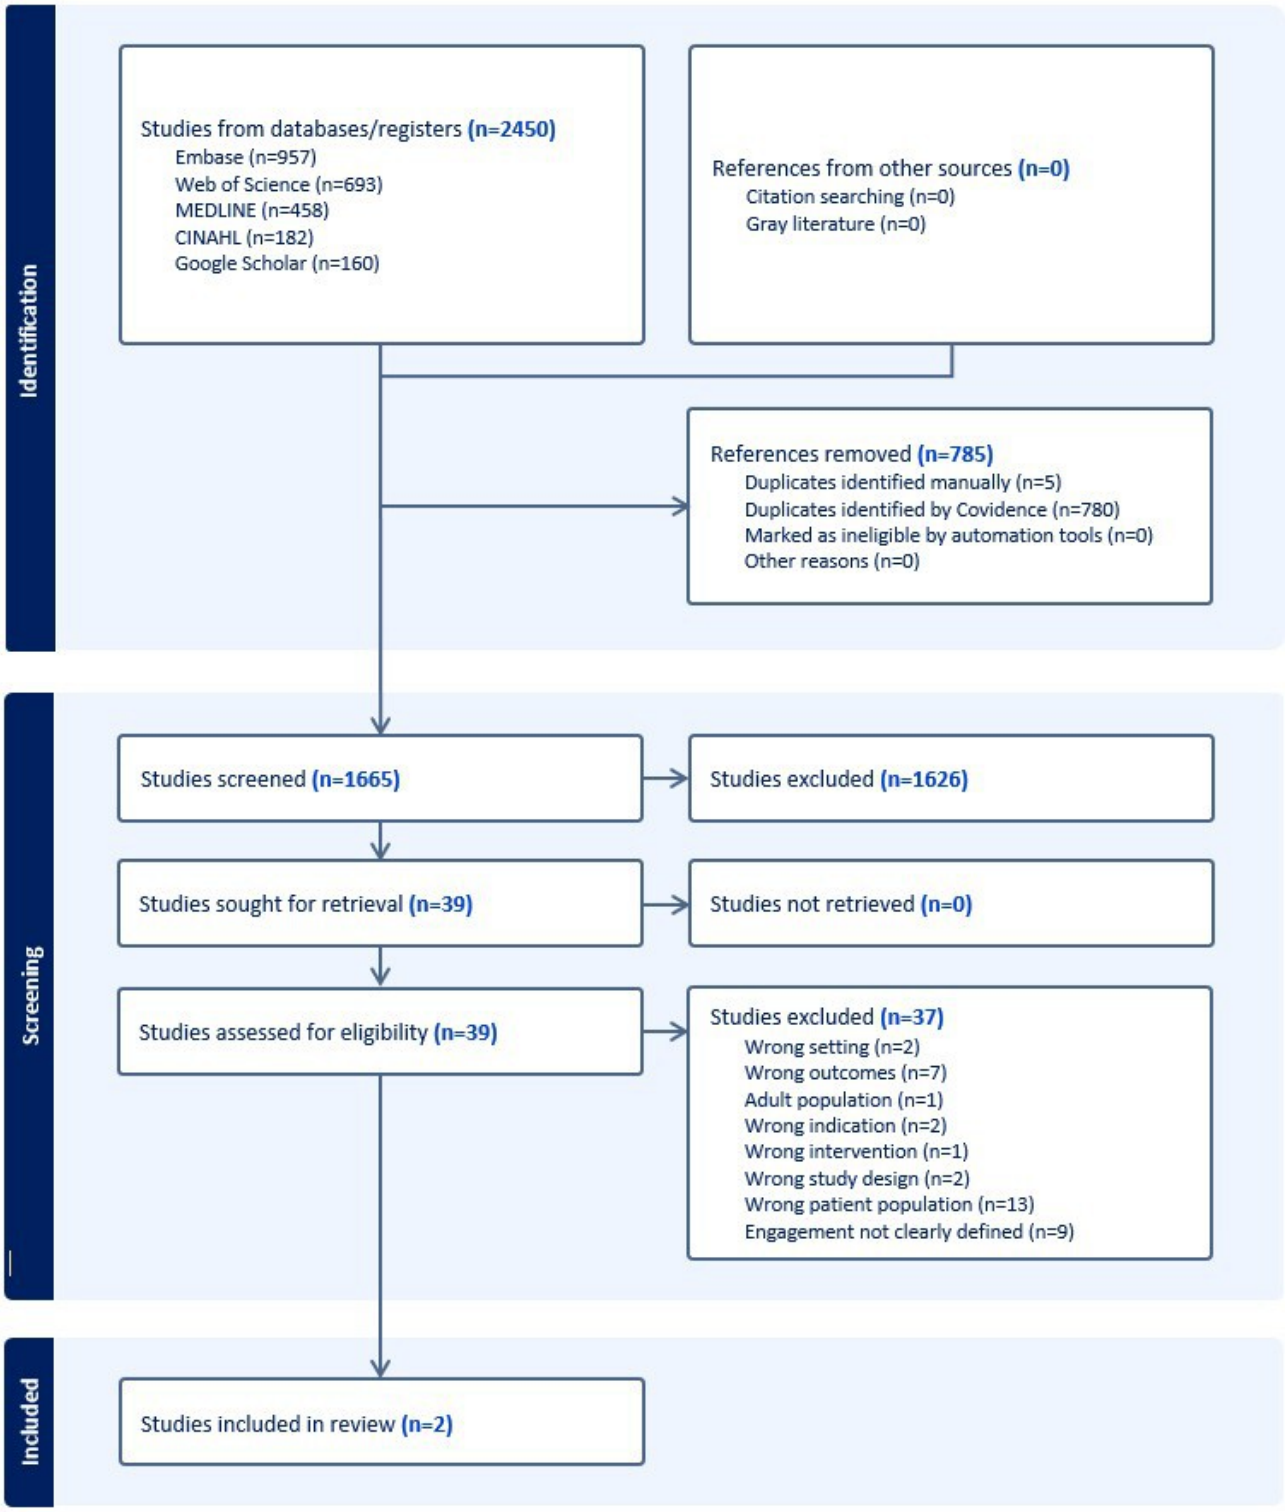
A descriptive analysis was conducted to synthesize the characteristics of the included studies, which were presented in a tabular form.

To synthesize findings on engagement with digital health technologies, we used a 3-dimensional conceptualization of engagement (behavioral, cognitive, and affective) as a descriptive analytical tool [24-27]. This framework served solely to organize and categorize elements reported in the included studies, without assessing the relevance, validity, or psychometric properties of the conceptual model. This approach aligns fully with the purpose of a scoping review, which aims to map concepts, definitions, and operationalization modes of engagement in the existing literature [34].

Variables reported in the included studies were recoded a posteriori by the research team, under the supervision of the principal investigator (MPG), into engagement indicators corresponding to the 3 components, to ensure a theoretically coherent interpretation of findings derived from heterogeneous study designs.

We did not assess the methodological quality of the included studies, in accordance with the JBI guidance for scoping reviews [35]. The objective of this review was to map existing evidence rather than evaluate effectiveness or draw conclusions based on the level of evidence.

Results



Study Selection

The search strategy identified a total of 1665 records after the removal of duplicates (Figure 1). During the first screening stage, based on titles and abstracts, 37 publications were retained for full-text review. Following full-text assessment, 2

XSL•FO
RenderX

publications [45,46], reporting on 2 distinct studies, met all eligibility criteria and were included in the scoping review.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flowchart for study inclusion [43].

Study Characteristics

The first study [45] assessed the feasibility and acceptability of 2 distinct digital interventions among older adults living with MCI. It compared a computerized cognitive stimulation (CCS) program with a computerized cognitive engagement (CCE) program. The CCS program aimed to stimulate multiple cognitive domains through computerized cognitive exercises combined with structured social interactions among participants. In contrast, the CCE program focused on learning to use a digital tablet, combined with the stimulation of social interactions within the group.

This study used a single-blind randomized controlled trial design. Participants were community-dwelling adults aged 60 years and older with MCI, recruited from a memory clinic in France. A total of 20 participants were randomly and equally

XSL•FO
RenderX

allocated to the CCS and CCE groups. The mean age was 78.2 (SD 7.0) years in the CCE group and 75.2 (SD 6.4) years in the CCS group. Both groups participated in weekly group sessions lasting 90 minutes over a 3-month period. Sessions were facilitated by a trained neuropsychologist who was blinded to the outcome assessments.

The second study [46] explored strategies to enhance engagement among older adults living with dementia in a long-term care setting using a digital reminiscence application called *Memory Keeper*. This application, developed by the study authors, aimed to support well-being and engagement among individuals with dementia by stimulating personal memories through personalized multimedia content.

The authors examined barriers and facilitators to using the application, perceived benefits of its integration into long-term care, and its potential use within existing care practices. Participants included 3 residents (2 men and 1 woman) aged 76 to 87 years with major neurocognitive disorders, 6 informal caregivers (family members or close relatives), and 1 formal caregiver (the facility's lifestyle coordinator). Participants were recruited using purposive sampling.

Informal caregivers contributed to the creation of personalized content (photographs and image libraries) integrated into the application and were trained in its use. Among the residents with major neurocognitive disorders, 1 had a diagnosis of dementia with Lewy bodies, 1 had Alzheimer disease, and 1 had dementia of an unspecified type. Although the study design was not explicitly stated in the *Methods* section, data collection and analysis procedures were qualitative in nature (see Table 1 for detailed study characteristics).

Table 1 presents the main characteristics of the included studies, including country and year of publication, study population, type of neurocognitive disorders, digital health intervention, study design, duration, and setting.

Table . Characteristics of included studies.

Study and year	Country	Population	Type of neurocognitive disorders	Intervention	Design	Duration	Setting
Djabelkhir et al [45] (2017)	France	20 community-dwelling older adults; mean age >75 years; CCE[a]: 78.2 (SD 7) years; CCS:[b] 75.2 (SD 6.4) years	MCI[c]	CCS versus CCE	Randomized controlled trial, single-blind	3 months, weekly 90-min sessions	Community
McAllister et al [46] (2020)	Australia	3 residents (ages 76 - 87 y); 6 informal caregivers; n=1 formal caregiver	Dementia: Alzheimer, Lewy body, and unspecified	Digital reminiscence application (Memory Keeper)	Qualitative methods	Duration not specified (real-world exploration)	Long-term care facility

[a]CCE: computerized cognitive engagement.

[b]CCS: computerized cognitive stimulation.

[c]MCI: mild cognitive impairment.

Conceptualization and Operationalization of Engagement With Digital Health Technologies

Conceptualization of Engagement

Both included studies [45,46] conceptualized engagement as a sustained interaction between older adults living with neurocognitive disorders and digital health technologies, mediated by digital stimuli and embedded within a social dimension.

More specifically, the study involving older adults with MCI [45] conceptualized engagement through participation in cognitively stimulating group-based activities combining computerized cognitive exercises and structured social interactions. In contrast, the study conducted among individuals with dementia in long-term care [46] conceptualized engagement as observable reactions and dyadic interactions elicited by personalized digital stimuli (reminiscence content) within a caregiving context.

Operationalization of Engagement

Engagement with digital health technologies was operationalized heterogeneously across the included studies [45,46]. However, the analytical recoding conducted in this scoping review enabled the alignment of all reported indicators with the 3-component conceptualization of engagement (behavioral, cognitive, and affective) [24-27], which was used as the analytical framework.

It is important to note that this 3-component analytical framework was applied a posteriori to heterogeneous data for analytical purposes rather than evaluative assessment, in accordance with the objectives of a scoping review.

At the behavioral level, engagement was documented through indicators, such as session attendance and attrition [45]. In the long-term care context, behavioral engagement was reflected by the frequency and duration of visits and by observable interaction-related behaviors during application use, including dancing or tapping movements [46]. The cognitive component of engagement was operationalized using standardized

XSL•FO
RenderX

neuropsychological tests, including the Trail Making Test Part A (TMT-A, attentional speed), Trail Making Test Part B (TMT-B, error reduction), free recall tasks (RL/RI-16), and the visuospatial memory test [45]. In another study, cognitive engagement was reflected by qualitative markers, such as sustained attention to the application and spontaneous recall of names or details associated with personalized reminiscence content [46]. Finally, the affective component of engagement was operationalized through indicators, such as motivation, self-esteem, and technology acceptance [45]. In the long-term care context, affective engagement was reflected by observable emotional markers, including smiling, singing, positive facial expressions, absence of negative reactions, and visits perceived as more pleasant by caregivers [46].

Measurement of Engagement

This section describes the approaches used to measure engagement as reported in the included studies and highlights the diversity of methods used to discuss capture engagement with digital health technologies among older adults living with neurocognitive disorders. It also specifies the participant groups to which the different measures were applied, in order to reflect study-specific data collection modalities, as well as the engagement components documented in the existing literature.

None of the included studies [45,46] used a validated instrument specifically designed to directly measure engagement with digital health technologies. However, in a study by Djabelkhir et al [45], a combination of validated instruments was administered to participants in the CCE and CCS groups to assess selected indicators associated with engagement. Executive functions were measured using the TMT-A and TMT-B. Episodic memory was assessed using the RL/RI-16 free and cued recall test as well as the visuospatial memory test from the cognitive efficiency profile. Global self-esteem was measured using the Rosenberg Self-Esteem Scale, and acceptance of information and communication technologies was assessed using a technology acceptance questionnaire. In the other study [46], engagement among residents living with dementia was documented using observable qualitative markers, primarily collected during interactions with the application, based on observations reported by caregivers and staff.

From an analytical perspective, the reported measures were subsequently examined according to the behavioral, cognitive, and affective components of engagement, while considering the participant groups associated with each type of measure.

The behavioral component was assessed using participation- and use-related measures collected from participants in the CCE and CCS groups in the study by Djabelkhir et al [45], and from residents in the study by McAllister et al [46], including indicators related to attendance, attrition, and the frequency and duration of interactions, supplemented by observations of interaction-related behaviors.

The cognitive component was documented through cognitive performance assessments administered to participants in the CCE and CCS groups, as well as through qualitative markers reflecting attention and memory processes mobilized by residents during technology use.

Finally, the affective component was captured using psychosocial indicators collected from participants in the CCE and CCS groups and through observational markers documenting emotional responses and residents' perceived experiences during interactions, as reported by caregivers.

Together, these approaches allowed engagement to be examined across behavioral, cognitive, and affective components (Table 2).

XSL•FO
RenderX

Table . Indicators and markers by engagement component.

Engagement component and type of measure	Participant groups	Instruments/markers used
Behavioral		
Participation measures	Participants in the CCE[a] and CCS[b] groups (study [45])	Attendance at activities and attrition
Use-related measures	Residents living with dementia (study [46])	Frequency and duration of interactions with the application
Behavioral observation	Residents, observations reported by caregivers and staff (study [46])	Interaction-related behaviors with the technology (eg, movements and gestures)
Cognitive		
Cognitive performance assessments	Participants in the CCE and CCS groups (study [45])	Trail Making Test (parts A and B), free and cued recall (RL/RI-16), and VST[c]
Qualitative cognitive markers	Residents, observations by caregivers and staff (study [46])	Attention to the application and engagement of memory processes during interactions
Affective		
Psychosocial indicators	Participants in the CCE and CCS groups (study [45])	Motivation, self-esteem (Rosenberg Self-Esteem Scale), and technology acceptance
Observational affective markers	Residents, observations reported by caregivers (study [46])	Emotional responses and perceived experience during interactions

[a]CCE: computerized cognitive engagement.

[b]CCS: computerized cognitive stimulation.

[c]VST: visuospatial memory test.

Relationship Between Engagement and the Effectiveness of Digital Health Interventions

Across the included studies, different analytical approaches were used to present the findings. A study by Djabelkhir et al [45] adopted a quantitative approach, relying on pre-post statistical analyses to examine cognitive and psychosocial data collected from participants in the CCE and CCS groups; for selected indicators, effect sizes were also reported to characterize the magnitude of the observed changes. In contrast, a study by McAllister et al [46] used a qualitative descriptive approach and used a framework analysis to structure and synthesize observational data derived from interactions between residents living with dementia and the digital application, *Memory Keeper*.

In this scoping review, these analytical methods are reported for descriptive purposes only, to contextualize how the findings were generated, without inferring any causal relationship between engagement and the reported outcomes.

Both included studies [45,46] provided data that enabled the concurrent examination of engagement manifestations and cognitive or psychosocial outcomes associated with digital health interventions among older adults living with neurocognitive disorders, across different contexts and levels of severity.

In the study involving older adults with MCI [45], sustained engagement with digital health interventions was observed alongside improvements in cognitive performance. These improvements included gains on the TMT-A and TMT-B, a medium effect size for free recall, and a trend toward improvement in visuospatial memory.

In the long-term care study involving older adults with dementia [46], engagement was not assessed using standardized measures. However, qualitative observations indicated that active participation by residents, characterized by sustained attention, recall of personal details, and increased interactions with caregivers, coincided with positive experiences during the use of the digital reminiscence application.

At the affective level, both studies reported convergent indicators [45,46]. High motivation, improved self-esteem, and increased technology acceptance were documented in a study by Djabelkhir et al [45], whereas the other study reported positive emotional expressions, interactions perceived as more pleasant, and an absence of negative reactions during the application use [46].

Facilitating and Limiting Factors of Engagement With Digital Health Technologies

Overview

The facilitating and limiting factors of engagement with digital health technologies identified in the included studies are presented in Table 3. These factors were identified transversally based on the data reported in the studies [45,46] and interpreted in light of the 3-component conceptualization of engagement (behavioral, cognitive, and affective), which was used as the analytical framework in this scoping review.

XSL•FO
RenderX

Table . Facilitators and barriers to engagement.

Factor type and reported factors	Engagement components involved	Studies
Facilitating		
Structured and professionally supervised activities, integration of technologies into existing contexts (group sessions and family visits), and intuitive interfaces	Behavioral	[45,46]
Guided learning, task adaptation, and personalization of digital content	Cognitive	[45,46]
Motivation, sense of personal value, and positive technology acceptance	Affective	[45]
Limiting		
Time constraints, reliance on caregiver or staff availability, and perceived activity duration	Behavioral	[45,46]
Fatigue, drowsiness, and fluctuations in cognitive state and attention	Cognitive	[46]
Loss of personal relevance of content, sedated states, and emotional disengagement	Affective	[46]

Facilitating Factors of Engagement

Several facilitating factors of engagement were reported across the included studies, although their nature varied according to the intervention context and the population studied.

At the behavioral level, engagement was facilitated by participation in structured and professionally supervised activities as well as by the integration of technologies into existing use contexts, such as group sessions in community settings [45] or family visits and interactions with staff in long-term care settings [46]. Ease of use and the intuitive nature of digital interfaces were also reported as factors facilitating interaction with technologies [45,46].

At the cognitive level, facilitating factors included guided learning in the use of technologies and the adaptation of tasks or digital content to participants' abilities [45]. The personalization of digital content, particularly in the form of reminiscence materials, was also described as supporting attention and cognitive engagement, especially among individuals living with dementia [46].

Finally, at the affective level, facilitating factors, such as sustained motivation to participate, a sense of personal value, and positive acceptance of digital technologies, were reported [45]. These elements were primarily described in the study conducted among older adults living with MCI.

Limiting Factors of Engagement

The included studies also identified several limiting factors of engagement with digital health technologies. At the behavioral level, organizational constraints, such as limited time available for technology use or reliance on the availability of caregivers or staff to initiate use, were reported as barriers to engagement [46]. In some cases, the perceived duration of certain activities was also identified as a source of frustration [45].

At the cognitive level, fluctuations in the cognitive state, including fatigue, drowsiness, or variations in attention, were described as factors limiting engagement, particularly among individuals living with dementia [46]. These factors could restrict the ability to maintain sustained interaction with the technologies.

Finally, at the affective level, limiting factors were reported when digital content lost its personal relevance or meaning for participants [46]. Sedated states or transient emotional disengagement were also mentioned as elements likely to limit the experience perceived as positive during technology use [46].

Facilitating and limiting factors are presented in Table 3.

Discussion

This scoping review aimed to examine how engagement with digital health technologies is conceptualized, operationalized, and measured among older adults living with mild or major neurocognitive disorders and to explore its relationship with intervention effectiveness.

Principal Findings

The findings highlight a major gap in the scientific literature regarding engagement with digital health technologies among older adults living with neurocognitive disorders. Despite a comprehensive search strategy across multiple databases, only 2 empirical studies [45,46] met the inclusion criteria among the 1665 records identified after the removal of duplicates. These findings suggest that empirical research explicitly addressing engagement in older adults living with neurocognitive disorders remains limited. The results show that although engagement was neither explicitly defined nor directly measured in the included studies, the reported data encompassed all dimensions commonly associated with engagement in digital health, as described in the literature. These manifestations included high attendance and low attrition, signs of sustained attention and cognitive mobilization, and positive affective responses during technology use. In addition, this review identified several factors that facilitated or hindered engagement, which were related to

XSL•FO
RenderX

technological characteristics, individual factors, and contextual conditions.

Although the studies reported engagement-related indicators alongside cognitive or psychosocial outcomes, the absence of standardized and explicit engagement measures precludes any causal interpretation. These findings highlight the need to better conceptualize, operationalize, and measure engagement with digital health technologies among older adults living with neurocognitive disorders, while accounting for individual, social, and contextual determinants.

Conceptualization and Operationalization of Engagement

The findings of this review indicate that engagement with digital health technologies among older adults living with neurocognitive disorders remains variably and often implicitly conceptualized. This observation is consistent with previous literature showing that engagement is frequently conflated with related constructs, such as use, adherence, acceptability, or retention, rather than being treated as a distinct concept [29,31].

In the included studies, engagement was implicitly conceptualized as sustained interaction between the individual and digital stimuli, embedded within a social context (group-based or dyadic). This implicit conceptualization aligns with dominant theoretical frameworks in digital health, which describe engagement as a multidimensional process comprising behavioral, cognitive, and affective components [22,24-27].

Although the 3-component conceptualization of engagement was not explicitly adopted by the included studies, the results indicate that the observed operationalization, reconstructed a posteriori in this review, covered all 3 components. This suggests that among older adults living with neurocognitive disorders, engagement extends beyond mere technical use and encompasses central cognitive and affective dimensions.

Recent methodological work emphasizes the importance of adapting engagement measurement to the context of use and study objectives, acknowledging that available tools variably capture different engagement components [25,26]. A key methodological contribution of this review lies in the application of a 3-component analytical framework to harmonize findings derived from heterogeneous study designs. This approach highlights that, in older adults living with mild or major neurocognitive disorders, observable affective responses (eg, smiling and singing) may be as informative as traditional behavioral usage metrics [24,26,28].

Measurement of Engagement

None of the included studies used a validated instrument specifically designed to measure engagement with digital health technologies in older adults living with neurocognitive disorders. This limitation mirrors broader challenges in the digital health literature, including the lack of methodological consensus and the predominance of indirect indicators [22,27].

In long-term care contexts, the use of validated observational tools, such as those developed to assess engagement among individuals with neurocognitive disorders [28], could allow for a more nuanced assessment of experiential engagement, particularly among individuals with major neurocognitive disorders. The absence of standardized engagement measures limits comparability across studies and constrains the ability to formally examine engagement as a mechanism of action in digital interventions.

Facilitating and Limiting Factors: The Central Role of Context and Human Support

Facilitating factors identified in this review included content personalization, ease of use, professional supervision, and involvement of informal caregivers. These findings are consistent with user-centered models emphasizing alignment between individual capacities, technological design, and contextual conditions [24,47].

Conversely, several limiting factors were identified, including technical complexity, loss of personal relevance of content, fatigue, drowsiness, fluctuations in cognitive state, and organizational constraints in care settings. Reliance on external support to initiate technology use emerged as a particularly important barrier, underscoring that engagement cannot be considered independently of the social and institutional environments in which technologies are deployed.

Engagement and Effectiveness of Digital Health Interventions

Although the number of included studies was limited, the available data allow for a cautious discussion of the potential link between engagement and intervention effectiveness. The studies reported concurrent engagement manifestations and cognitive or psychosocial outcomes, without enabling causal or directional conclusions. This limitation is consistent with the broader digital health literature, in which engagement is often assumed to be a key mechanism but is rarely empirically tested as such [22,30].

These observations align with a wider body of evidence suggesting that well-designed and appropriately adapted digital interventions may yield modest to moderate cognitive benefits among individuals living with neurocognitive disorders, despite substantial methodological heterogeneity [48,49]. However, the included studies were not designed to formally test engagement as a mediator or moderator, and any association between engagement and effectiveness must therefore be interpreted cautiously.

Strengths and Limitations

This scoping review has several strengths. First, a major strength lies in its theoretically informed analytical approach. Engagement-related data were recoded a posteriori using a 3-component conceptualization of engagement (behavioral, cognitive, and affective), which served as an analytical framework to harmonize heterogeneous data without aiming to validate or test this conceptual framework. This approach is particularly relevant in a research field characterized by substantial conceptual and methodological variability. Second, the review explicitly incorporated a health equity perspective using the PROGRESS-Plus framework. Although such information was rarely reported in the included studies, its systematic consideration allowed for the identification of an

XSL•FO
RenderX

important gap in the literature and strengthened the scope of the evidence mapping.

Despite these strengths, several limitations should be acknowledged. First, the available evidence is constrained by small sample sizes, the underrepresentation of individuals living with major neurocognitive disorders, heterogeneous study designs, and the absence of standardized instruments specifically developed to measure engagement with digital health technologies. These factors limit the robustness and comparability of the findings. Moreover, engagement was most often inferred or reconstructed a posteriori rather than explicitly defined and systematically measured as a primary construct. Second, considerations related to health equity were largely absent from the included studies. Variables encompassed within the PROGRESS-Plus framework were infrequently reported, limiting the examination of how social, demographic, and contextual factors may influence engagement and restricting the generalizability of the findings to diverse populations of older adults. Third, the limited number of eligible studies and their predominantly exploratory nature reflect the early stage of development of this field of research. Although this limits the scope of conclusions that can be drawn, it also underscores the appropriateness of adopting a scoping review approach to map existing evidence, identify gaps, and inform future research directions.

Future Directions

The findings of this review have implications for both practice and research. The identified facilitating factors, particularly content personalization, professional supervision, and caregiver involvement, suggest that digital health technologies for older adults living with mild or major neurocognitive disorders should be developed and implemented in close alignment with users' cognitive capacities, care contexts, and available support networks.

The findings also highlight the need to develop validated, multidimensional engagement measurement tools tailored to specific contexts of use and to conduct larger-scale studies that integrate equity considerations.

Conclusion

This scoping review highlights a substantial gap between the theoretical recognition of engagement as a key determinant of the effectiveness of digital health technologies and its empirical operationalization among older adults living with neurocognitive disorders. It shows that engagement with digital health technologies in this population remains an emerging research area, characterized by significant methodological challenges and considerable potential for development.

There is a critical need to develop contextualized, rigorous, and population-sensitive engagement measurement tools as well as to ensure the systematic and explicit integration of the behavioral, cognitive, and affective dimensions of engagement. Addressing these priorities is essential to strengthen the design, evaluation, and implementation of digital health interventions that are more relevant and better tailored to supporting cognitive health among older adults living with neurocognitive disorders.

Abstract

Background: With the global increase in population aging, promoting walking as a health behavior to maintain and enhance well-being among older adults has become increasingly important. In recent years, advances in information and communication technology and mobile health have supported the development of health interventions delivered through smartphone apps. However, no review to date has included psychological aspects such as motivation or intention to walk, and the behavior change techniques (BCTs) embedded in smartphone apps that effectively promote walking remain unclear.

Objective: This study had 2 primary aims: (1) to evaluate the effects of smartphone app use on walking behavior and intention to walk among community-dwelling older adults and (2) to identify the specific BCTs delivered through these apps that may promote walking behavior and intention effectively.

Methods: Eligible studies were those published in English or Japanese between March 1, 2015, and February 28, 2025, that focused on community-dwelling older adults, implemented smartphone app–based interventions, and reported walking-related outcomes. A systematic search strategy was designed using keywords such as “older,” “smartphone,” and “walking.” Risk of bias was evaluated using the Study Quality Assessment Tools. The features of the apps described in the selected studies were examined to identify the BCTs they used, as categorized by the BCT Taxonomy.

Results: Of the 296 studies initially retrieved, 8 met the inclusion criteria. These studies varied in terms of participant characteristics, intervention duration, app features, and outcomes, and most were pilot studies. While several apps were designed specifically to increase walking, others included features that facilitated social interaction among users. In addition, 2 studies also reported improved motivation to walk. Apps that were associated with statistically significant improvements in walking behavior frequently used BCTs from the following clusters: (1) goals and planning, (2) feedback and monitoring, and (4) shaping knowledge. Notably, 5 BCTs were not incorporated into any of the reviewed apps.

Conclusions: Although smartphone apps have the potential to improve walking behavior and intention among community-dwelling older adults, the current body of evidence remains limited. Apps that deliver walking-related knowledge, facilitate goal setting, and support behavioral monitoring appear especially effective and may strengthen walking behavior and intention in this population.

KEYWORDS

ICT; information and communication technology; smartphone; apps; walking; BCT; behavior change technique; older adults

Introduction

In 2024, Japan officially became a super-aged nation, leading a global demographic shift [1,2]. In aging societies such as ours, it is imperative to maintain and improve older adults’ health, especially given the growing burden of chronic diseases and the resulting pressure on health care systems [3]. Walking has been shown to reduce mortality among older adults [4-6] and is consequently recommended as a key health behavior [7,8]. Moreover, walking is one of the most widely adopted and

XSL•FO
RenderX

preferred forms of physical activity among older adults [9]. Accordingly, it is particularly important to identify and systematize interventions that promote walking as a strategy for maintaining and enhancing health.

Techniques used to support behavior change have been systematically classified in the Behavior Change Technique (BCT) Taxonomy, which provides a useful framework for analyzing and developing health interventions [10]. Details regarding the BCT Taxonomy, comprising 93 individual techniques organized into 16 clusters, are provided in Multimedia Appendix 1 [11]. Previous studies have demonstrated the effectiveness of BCT-based interventions in promoting physical activity among older adults [12]. Moreover, interventions targeting older populations have already been categorized using the BCT Taxonomy, emphasizing its use in designing and implementing behavioral programs [13]. However, to the best of our knowledge, the specific BCTs that effectively promote walking have not yet been systematically investigated. Therefore, analyzing existing intervention studies on walking promotion through the lens of the BCT Taxonomy and systematically extracting effective intervention components as BCTs is warranted.

In recent years, an increasing number of intervention studies have used smartphone apps in studies involving older adults within the framework of mobile health (mHealth) [14]. Previous reviews have focused on outcomes such as sedentary behavior [14] and physical performance [15], yielding comprehensive insights into specific mHealth features effective in promoting walking among older adults [16]. However, few studies have reported on the psychological effects of mHealth use in this population [17], and to the best of our knowledge, no systematic review has addressed psychological outcomes such as the intention to walk. Existing studies have also underscored the need to address this limitation [16]. Furthermore, current research remains insufficient in elucidating the psychological changes and underlying mechanisms associated with interventions targeting older adults [18,19]. Therefore, it is essential to comprehensively organize both the physical and psychological outcomes related to walking and to determine which smartphone app-based interventions effectively enhance walking behavior and intention among older adults. Moreover, the rapid advancement of information and communication technology (ICT), including the integration of large language models and generative artificial intelligence in health care [20], necessitates continuous knowledge updating and reorganization to maintain relevance and applicability.

Building on the above, the aim of this study was 2-fold: first, to clarify the effects of smartphone app use on walking behavior and intention to walk among community-dwelling older adults; and second, to identify the BCTs delivered through these apps that may effectively promote walking behavior and intention. This study addressed the following research questions:

1. Does the use of smartphone apps improve walking behavior and intention to walk among older adults?
2. Which BCTs, incorporated into smartphone apps, are effective in promoting walking among older adults?

Methods

Research Design

This study used a systematic review approach to investigate whether the use of smartphone apps promotes walking behavior among community-dwelling older adults. The review protocol was registered with PROSPERO (International Prospective Register of Systematic Reviews; CRD420251007296) before the commencement of the database search. The PRISMA checklist is available in Checklist 1.

Search Strategy and Inclusion Criteria

Keywords were identified based on the review questions, and a systematic search was conducted across 5 databases in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The databases were selected for the following reasons: PubMed, a leading database in medical and health sciences, provides extensive coverage and supports searches using Medical Subject Headings. CINAHL (via EBSCOhost) was included due to its specialization in nursing and allied health literature, which is often underrepresented in traditional medical databases. The Cochrane Database of Systematic Reviews and the Cochrane Central Register of Controlled Trials, both accessed via Wiley Online Library, were selected for their focus on systematic reviews and clinical trials. Finally, Ichushi-Web was included for its comprehensive coverage of Japanese-language literature in medicine, nursing, and health sciences.

The search strategy was developed using a combination of Medical Subject Headings and relevant free-text terms. To reflect the rapidly evolving landscape of eHealth and mHealth research, priority was given to studies using smartphone apps. Consistency in search procedures was ensured to accurately capture studies targeting community-dwelling older adults. To enhance the comprehensiveness of the review, no restrictions were applied to study design during the initial screening phase. The search was conducted on March 19, 2025, and the Boolean operators used are summarized in Table 1. The complete list of search terms is provided in Multimedia Appendix 2. Studies were included if they met the following eligibility criteria:

- Studies were peer-reviewed original research articles.
- Participants were older adults. Given that the definition of older adults varies across countries and studies, older adults were defined as individuals aged 65 years or older, or those explicitly referred to as older adults in the original study, to accommodate regional variation (eg, adults aged ≥60 years in China).
- Studies targeting institutionalized or hospitalized older adults were excluded.
- The intervention used smartphone apps to promote walking. This included apps designed specifically to increase walking, as well as apps with other primary purposes that incorporated walking-promotion features.
- No restrictions were placed on the duration of the intervention.
- Studies in which participants used the app in their daily lives were included, whereas studies conducted in controlled

XSL•FO
RenderX

laboratory settings, such as step counter accuracy tests, were excluded.
- Studies were required to report changes in walking-related indicators such as step count, walking frequency, walking distance, walking awareness, or achievement of step-based goals. Studies focusing exclusively on physical function tests, such as the Timed Up and Go Test or the 5-meter walk test, were excluded, as this review emphasized habitual walking behavior and associated intentions.
- Eligible study designs included experimental studies, quasi-experimental studies, and randomized controlled trials (RCTs).
- Studies published in English or Japanese between March 1, 2015, and February 28, 2025, were included.

Study Selection

Prior to the study selection, all authors discussed the inclusion and exclusion criteria based on the Population, Intervention, Comparison, and Outcome framework and reached a consensus. Study selection was conducted in 2 stages by three authors (HA, TI, and MH). The initial screening was conducted using Rayyan. Two authors (HA and TI) independently assessed the titles and abstracts according to predefined eligibility criteria. When a disagreement occurred, a third author (MH) served as the adjudicator. During the second stage, the same two authors independently reviewed the full texts of studies identified as eligible, and any conflicts were resolved through discussion with the third author (MH). To ensure consistency in study selection and data extraction, interrater agreement at each stage was assessed using Cohen kappa (κ) statistic [21].

Data Extraction

The following information was extracted from each of the included study: study identifiers (eg, author names and publication y), sample characteristics (eg, participant demographics, sample size, and health status), intervention duration, smartphone app details, and reported outcomes. All data were systematically organized and presented in tabular form.

BCT Classification

First, the lead author conducted an in-depth review of all 8 studies and generated a list of app functions and components. The second author subsequently cross-checked this list against the original articles to ensure accuracy. Finally, all authors reviewed the app functions and purposes described in the eligible studies and classified the corresponding BCTs accordingly. Classification was conducted using the BCT Taxonomy v1, which organizes 93 techniques into 16 clusters [11]. To visualize the relationship between the included studies and the identified BCTs, we created charts at the cluster level. In addition, to closely examine the mechanisms of behavior change, we mapped individual app functions to specific BCTs whenever possible. Any discrepancies were resolved through discussion until full consensus was reached.

Risk of Bias Assessment

To evaluate the risk of bias in the included studies, the National Institutes of Health Study Quality Assessment Tool was used. This tool is designed to assess the quality of observational cohort and cross-sectional studies involving human participants [22]. The tool comprises either 12 or 14 items, depending on the study design. The proportion of items rated “yes” was calculated for each study to determine overall methodological quality and potential risk of bias. Based on these percentages, categorical quality ratings were defined as follows: high (>70%), moderate (70% - 50%), and low (≤49%).

Results

Overview

Figure 1 illustrates the screening and selection process for this systematic review. A total of 296 records were identified through 4 database searches: PubMed (n=171), Cochrane Central (n=65), Igaku Chuo Zasshi (n=2), and CINAHL (n=58). A total of 71 duplicate records were collected. During the first screening of titles and abstracts, 4 conflicts between the authors were noted and resolved, and 199 articles were excluded, based on the inclusion criteria. The reasons for exclusion were as follows: incorrect outcomes (n=54), ineligible population (n=82), nonqualifying publication type (n=36), and irrelevant intervention (n=27). In the second screening stage, the full texts of 26 articles were reviewed without any reviewer conflict. Of these, 18 were excluded for the following reasons: incorrect outcome (n=3), ineligible population (n=5), nonqualifying publication type (n=5), irrelevant intervention (n=4), and non-English/Japanese language (n=1), resulting in 8 studies that met all inclusion criteria and were included in the final analysis. During the second screening stage, studies were excluded if the intervention involved smartphone apps for older adults but lacked walking-related outcome measures. For example, studies that assessed broader indicators such as overall physical activity [23] were excluded as having the wrong outcome. An interrater reliability analysis showed a high level of agreement between the authors. During the initial screening, the interrater agreement rate was 98.2%, with a Cohen kappa (κ) of 0.925, indicating almost perfect agreement. In the second screening, agreement reached 100%, with a κ value of 1.0, reflecting perfect concordance.

Study Characteristics

Table 2 presents an overview of the intervention study outcomes for smartphone apps promoting walking among community-dwelling older adults, along with their associated BCTs. The mean age (SD) of participants in the included studies ranged from 59.8 (6.4) to 78.0 (9.0) years. All participants were ambulatory, although several studies included older adults diagnosed with frailty, prefrailty, or heart failure. The duration of the interventions ranged from 2 weeks (excluding the empirical evaluation study by Zhong and Rau [24]) to 1 year. In terms of study design, none of the included studies used a full RCT. The studies comprised 4 controlled intervention studies, 2 observational cohort or cross-sectional studies, and 2 uncontrolled pre-post studies. The results of the risk-of-bias assessment for each study are presented in Multimedia Appendix 3.

		Activity Coach is an mHealth app developed to promote physical activity and reduce sedentary behavior in patients with heart failure. As an extension of the Optilogg self-management platform, it offers features like activity logging in 10-minute intervals, weekly goal setting, educational messages, and visual feedback. Users can define and track their own physical activities, such as walking or housework. The app provides daily educational messages during the first week to build beliefs in the benefits of activity, boost self-efficacy, and emphasize personal goal importance. Progress is displayed visually to support ongoing motivation and behavior change.			

[a]BCT: behavior change technique.

[b]The numbers of the types of BCT refer to the following meanings: 1=goals and planning; 2=feedback and monitoring; 3=social support; 4=shaping knowledge; 5=natural consequences; 6=comparison of behavior; 7=associations; 8=repetition and substitution; 9=comparison of outcomes; 10=reward and threat; 11=regulation; 12=antecedents; 13=identity; 14=scheduled consequences; 15=self-belief; and 16=covert learning.

[c]QA: quality assessment.

[d]IG: intervention group.

[e]CG: control group.

[f]LTCI: long-term care insurance.

[g]ESP: encouragement of social participation.

[h]ST: single task.

[i]DT: dual task.

[j]FW: fast walk.

[k]RMS: root mean square.

Among the 6 studies that reported physical outcomes [26-31], 2 demonstrated statistically significant effects of app use on walking behavior [28,30]. Four studies included comparison groups; however, none used a full RCT design. Among the 8 studies, 4 were identified as pilot studies [26,28,30,31] and only 2 of these [28,31] reported predetermined sample sizes sufficient for statistical analysis. Among the 6 studies reporting physical outcomes, 4 conducted statistical analyses [27-29,31]; however, 2 of these did not reach their target sample sizes [29,31].

According to the risk-of-bias assessment, 4 studies were rated as high quality [27-30], 3 as medium quality [24,26,31], and 1 as low quality [25].

App Features

Of the 8 studies, 1 used a commercially available app, while the remaining 7 used apps developed by the researchers. Six of the 8 apps were specifically designed to promote physical activity by monitoring step counts [24-28,31]. In contrast, 2 apps [29,30] were designed to promote not only physical activity but also social engagement. Six apps were intended for individual use [25-29,31,32], while 2 apps [26,30] incorporated group-based features that allowed users to interact on a shared platform.

Basic step-counting apps such as Pedometer Lite, Pedometer++, and WalkLogger [25] enable users to record and manage daily step counts. STARFISH [26] promotes increased physical activity among older adults by combining step tracking with animated feedback and group-oriented goal setting and reward mechanisms. The AEON Mall app [27] uses GPS to detect user visits to shopping malls and provides digital coupons when users exceed 1000 steps per day, thereby contributing to public

XSL•FO
RenderX

health initiatives aimed at restoring physical activity levels that declined following the COVID-19 pandemic.

ZTExApp [28], designed for patients with coronary heart disease, promotes simple, equipment-free exercises and provides educational content, self-assessment tools, and an activity diary. The ESP app [29], aimed at supporting social participation among older adults, records users' outings, step counts, and visited locations, classifies them into 4 participation levels, and provides weekly educational articles. Online Kayoinoba [30] integrates step goals, exercise videos, dietary tracking, social features, cognitive games, and health checks and uses a point-based system with multilevel rankings to enhance user engagement.

Among the more advanced monitoring tools, Pocket Gait [24] uses smartphone accelerometers to measure walking frequency, root mean square acceleration, regularity, symmetry, and variability, thereby supporting early detection of gait impairments. Activity Coach [31], developed for patients with heart failure, includes activity logs, weekly goal setting, educational messages, and visual feedback to reduce sedentary behavior and strengthen self-efficacy for maintaining physical activity.

The Effects of Walking Behavior and Intention to Walk by Using a Smartphone App Among Older Adults

Among the included studies, 5 assessed step count as a walking-related outcome, while 1 evaluated weekly walking time. Of these, 1 study reported a statistically significant increase in step count, and another observed a significant improvement in weekly walking time. Outcomes related to intention to walk were reported narratively in 2 studies, both of which indicated positive effects on walking motivation.

BCT Classification

Table 3 presents the relationship between the apps used in the reviewed studies and the corresponding BCT clusters. Based on the functional features of the apps, the number of BCTs identified per app ranged from 2 to 13 of the 93 techniques defined in the BCT Taxonomy. The smartphone apps incorporated BCTs from 1 to 7 of the 16 clusters defined in the BCT Taxonomy. All apps used techniques from cluster 2: feedback and monitoring. Improvements in walking motivation were also associated with BCTs from cluster 2: feedback and monitoring. Additionally, 4 apps included techniques from clusters 1: goals and planning, and cluster 10: reward and threat. Apps that demonstrated statistically significant effects on walking behavior consistently used techniques from clusters 1, 2, and 4: shaping knowledge. Conversely, 5 BCT clusters were not used in any of the reviewed apps: cluster 9: comparison of outcomes, 11: regulation, 13: identity, 14: scheduled consequences, and 16: covert learning.

XSL•FO
RenderX

Discussion

Overview

This systematic review investigated the effectiveness of smartphone apps on walking behavior and the intention to walk among community-dwelling older adults, based on 8 existing studies. Although the number of included studies was smaller than in comparable reviews (eg, Llopis et al [16]), this review distinctively focused on community-dwelling older adults, excluding those residing in institutions or hospitals, and explicitly evaluated both walking behavior and walking intention. Furthermore, by classifying the BCTs embedded in app functions, the review identified app-based intervention components that may effectively promote walking.

XSL•FO
RenderX

Does the Use of Smartphone Apps Improve Walking Behavior and Intention to Walk Among Older Adults?

The use of smartphone apps demonstrated positive effects on both walking behavior and walking intention [24,25,28,30]. Among the included studies, 6 measured physical outcomes (eg, step count or walking duration), while 2 assessed psychological outcomes such as walking intention. Although both studies reporting psychological outcomes relied on narrative data, indicating the need for further quantitative examination, the findings suggest that smartphone apps may have the potential to improve both physical and psychological outcomes related to walking.

The 2 studies that assessed psychological outcomes used apps that included step-monitoring functions. Previous research has demonstrated that activity tracker use can effectively increase step counts [33], suggesting that enabling older adults to self-monitor their walking behavior may also exert a positive influence on their walking intention.

Most smartphone app-based intervention studies targeting older adults have been pilot studies [34], a trend that is consistent with observations reported in previous systematic reviews [16]. Given this trend and the limited number of eligible studies, the conclusions of this review should be interpreted with caution. Nevertheless, some studies reported statistically significant improvements in walking behavior among community-dwelling older adults following app use, and narrative findings suggested psychological benefits as well [24,25].

Which BCTs Incorporated Into Smartphone Apps Are Effective in Promoting Walking Among Older Adults?

Among the studies included in this review, 2 smartphone app–based interventions [28,30] demonstrated statistically significant improvements in walking-related outcomes. Both of these apps implemented the following BCT clusters: (1) goal setting and planning, (2) feedback and monitoring, and (3) shaping knowledge. This overlap holds theoretical significance for the design of smartphone apps aimed at promoting walking among older adults. Gilchrist et al [13] demonstrated that interpersonal physical activity programs incorporating goal setting and self-monitoring effectively enhance physical activity levels, which aligns with the findings of this review.

Although the BCT Taxonomy provides a comprehensive framework for behavior change, this review suggests that, in the context of walking promotion among older adults, providing relevant knowledge, facilitating goal setting and planning, and enabling behavior monitoring may be especially effective. It is also important that apps designed for older adults maintain simplicity and minimize cognitive burden [35]. Because the number of implemented BCTs is not necessarily associated with increased physical activity [36], overly complex or multifunctional apps may impose unnecessary burden and hinder sustained use. Therefore, designing apps that focus on the specific BCTs shown to be effective is likely to lead to more desirable outcomes.

According to the BCT Taxonomy, all apps reviewed in this study incorporated cluster 2: feedback and monitoring, and positive effects were observed on both walking behavior and walking intention. These apps provided feedback related to walking behavior, such as step counts and activity levels. Smartphones are highly portable and are well-suited for real-time monitoring of physical activity [37], and health platforms such as Apple's HealthKit [38] and Android's Google Fit [39] allow developers to efficiently integrate feedback and monitoring functions via available application programming interfaces [40]. This not only facilitates the implementation of BCT-aligned features but also reduces development costs, offering advantages from both behavioral science and engineering perspectives.

In contrast, 5 of the 16 BCT clusters were not implemented in any of the reviewed apps. The absence of these techniques may reflect technological constraints inherent in app-based interventions. For instance, BCT 13.1 (identification of self as a role model) necessitates a high degree of self-reflection or interaction with professionals, making it challenging to implement in apps structured around predefined conditional logic [40]. Many of the reviewed apps were designed to deliver standardized, rule-based responses to user behavior, thereby limiting their capacity to offer context-sensitive or highly personalized feedback.

According to the scoping review by Panicker et al [41], smartphone apps were the most frequently used tools in interventions using wearable devices to promote physical activity, although wrist-worn and pendant-type devices were also used. Selecting hardware and software that supports user engagement and integrating them when appropriate may facilitate the implementation of a broader range of BCTs. Additionally, an RCT conducted by Lunde et al [42], which was excluded from this review due to population mismatch, reported a significant increase in step count when professional support was delivered via a smartphone app. This finding suggests that integrating smartphone apps with professional guidance may enable more personalized interventions and generate synergistic effects. Furthermore, with the rapid advancement of generative artificial intelligence in health care [20], large language models can now be integrated into mHealth interventions via application programming interfaces, thereby enabling more personalized and adaptive interventions [43]. This development may expand the capacity of mHealth systems to support a broader range of BCTs in the future.

Limitations

This study has several limitations that warrant caution when interpreting the findings. First, none of the included studies were full RCTs, so the review lacks high-level evidence on the effectiveness of smartphone apps for promoting walking among older adults. Second, many of the reviewed studies featured research designs that may be considered suboptimal, likely reflecting the challenge of keeping pace with the rapid evolution of ICT. This limitation could have resulted in the underestimation of the health effects of ICT-based interventions, potentially biasing the results of this review. Third, the operational definition of "older adults" varied across studies, introducing heterogeneity and potential bias. Moreover, older adults who are able to use ICT tend to be relatively younger and of higher sociodemographic status, reflecting a selection

XSL•FO
RenderX

bias. This inherent selection bias should be considered when evaluating the generalizability of our findings. Fourth, this review included only 8 studies, which is fewer than in reviews encompassing older adults with more diverse sociodemographic backgrounds [28]. Because this review focused exclusively on community-dwelling older adults rather than those residing in institutions or hospitals, its findings may not generalize to populations with different backgrounds. Finally, this type of research has inherent limitations that should be acknowledged, such as publication bias (the tendency for statistically significant studies to be published preferentially) [44] and selection bias (the possibility that eligible studies were not captured in the search) [45].

Conclusion

In this study, we conducted a systematic review of 8 studies examining the effects of smartphone app use on walking behavior among community-dwelling older adults. Several studies reported improvements in step counts and intention to walk. Despite the limited number of eligible studies, the findings suggest that apps incorporating features to support walking-related knowledge acquisition, goal setting and planning, and behavioral monitoring may be especially effective in promoting walking behavior and intention among older adults.

Acknowledgments

No generative artificial intelligence was used at any stage of the research conduct or manuscript preparation.

Abstract

Background: Heart failure (HF) is a prevalent condition among older adults in Canada, often leading to reduced quality of life and frequent hospitalizations. HF disease management interventions, particularly those delivered through telehealth, aim to improve care by fostering self-care and reducing readmissions. However, disparities in access to and use of HF telehealth services persist among vulnerable populations.

Objective: This study aimed to present the findings of a scoping review and a rapid realist synthesis of HF telehealth interventions for vulnerable groups of patients with HF. This review is underpinned by the metatheory of critical realism and intersectionality theory.

Methods: A rapid realist synthesis of the retrieved literature was undertaken to explore the underlying mechanisms and contexts that make HF telehealth interventions work or not work for marginalized groups of patients with HF.

Results: The realist review findings indicated that vulnerable patients require simple interventions. The findings also suggested that for effective use of telehealth and remote monitoring services, these patients require simplified training that could increase their confidence. The review findings further demonstrated that involving patients' family members in the delivery of telehealth interventions ensures success.

Conclusions: Future research with vulnerable populations should be underpinned by the critical realism and intersectionality theory and should apply the principles of intersectionality at all stages of the research process, including evaluation and analysis. This review also urges HF practitioners to apply the principles of intersectionality and health equity in clinical practice, such that interventions are simple and personalized, involve family members, include an in-person component, provide training for patients and health professionals, and integrate telemonitoring data.

Introduction

Background

Heart failure (HF) is a widespread health condition affecting many older adults in Canada. HF can significantly impair quality of life and is becoming increasingly common as populations age globally [1]. Heart failure disease management interventions (HFDMIs) aim to address these challenges by fostering self-care, enhancing well-being, and reducing recurrent hospitalizations and subsequent health care expenditure. These programs achieve this through patient education, ongoing follow-up, and improving care coordination, which in turn reduces emergency visits and promotes outpatient care [2,3].

HFDMIs encompass a wide range of interventions, including in-person interventions in hospitals, communities, or clinics, as well as remote interventions delivered through telehealth technologies, such as telephone, email, internet, text messages, telemonitoring, mobile health, video consultation, and wireless monitoring systems [4-9]. Despite its potential to improve chronic disease management, telehealth interventions are complex and multifaceted [10]. While telehealth technologies were introduced into HF management in 1998 [5], their

XSL•FO
RenderX

complexity as a health delivery model becomes evident when considering the various components and interactions involved and when compared with traditional face-to-face interventions [11]. Effective implementation of telehealth interventions requires harmonizing clinical protocols, leadership support, and technological factors, along with ensuring that patient and health care providers are confident in using technology through education and training [11]. As such, understanding the specific contexts and mechanisms that make telehealth interventions effective in managing HF becomes crucial.

This study details the findings of a rapid realist synthesis, which investigated the use of telehealth solutions for vulnerable patients with HF. The synthesis is framed within the approach of critical realism (CR) [12], aiming to explore the underlying mechanisms and contexts that contribute to the significance of telehealth interventions in improving HF management among vulnerable populations. Additionally, an intersectionality lens was applied to examine how the intersecting social identities of vulnerable groups with HF may affect their access to and use of telehealth services [13].

Intersectionality, Vulnerability, and Disparities—The Complex Interplay

Intersectionality highlights how different social identities, such as race, gender, age, culture, sexual orientation, socioeconomic status, and geographic location, combine to shape individual experiences [14-16]. These overlapping factors can either grant privilege or deepen inequalities, particularly in health care [14-16]. In the context of HF care, intersectionality plays a vital role in determining access to resources, medical treatment, and self-care support [14]. Patients from marginalized groups, including racialized minority groups and gender minority groups, rural residents, older adults, and people with disabilities, often struggle to receive adequate health care and telehealth services [17]. These disparities stem from systemic barriers such as economic hardship, geographic isolation, and implicit biases within health care systems [17]. The unfortunate reality is that those who require the most care often face the greatest barriers to accessing it, perpetuating health care inequities. These intersecting social identities may act as contextual factors or mechanisms that intensify disparities among marginalized populations and contribute to poorer health outcomes.

HF Telehealth Interventions—The Inherent Complexity

The use of telehealth has increased during the COVID-19 pandemic [18]. Nonetheless, telehealth adoption varies among demographic groups, with factors such as age, income, race, ethnicity, health literacy, digital skills, and language barriers playing significant roles. These disparities stem from challenges at multiple levels, including the patients themselves, health care systems, telehealth platforms, and overarching policies [18]. Recognizing and addressing these disparities is crucial to ensure fairness in telehealth services, optimize their impact on health care delivery, and ultimately promote telehealth equity [18].

The complexity of HFDMIs lies in the multifaceted nature of the condition, requiring innovative approaches to optimize patient outcomes. The adoption of telehealth interventions for vulnerable patients with HF is complicated by the overlapping social identities that can create barriers to accessing and using telehealth services. Although telehealth became widely accessible during the COVID-19 pandemic [19], these at-risk groups have still faced considerable barriers in making full use of telehealth options [20].

Current understandings of telehealth interventions for HF in vulnerable populations are hindered by 2 issues. First, there is a significant gap in research specifically addressing telehealth solutions tailored to marginalized patients with HF with intersecting identities, limiting insights into their effectiveness [21]. Second, addressing the complexities of telehealth in HF care for disadvantaged groups calls for advanced research methodologies, such as realist methods, that can unravel the contextual elements driving these challenges [22].

Rapid Realist Synthesis—Exploring Complexity

The use of theory-based research approaches to evaluate telehealth interventions has been urged in the literature [23]. There is increasing consensus that telehealth interventions should be evaluated using complexity-driven approaches [23]. In relation to such interventions, these approaches often bring complexity into various aspects, including the theoretical underpinnings of the research, the type of research questions posed, and the types of methods used. In recent years, the research review and synthesis field has seen an expansion in the variety of approaches used [24]. Among these approaches, realist synthesis has gained importance. Unlike traditional reviews that assess the effectiveness of interventions, realist synthesis aims to comprehend and analyze the underlying mechanisms that contribute to the success or failure of an intervention, offering explanatory insights rather than simple evaluations of its effectiveness [24,25]. Rapid realist syntheses are philosophically and theoretically underpinned by CR.

The CR Paradigm

CR focuses on uncovering the underlying mechanisms that generate outcomes, making it an explanatory rather than purely descriptive approach. It is particularly suited for addressing "why" questions about social and health phenomena. Within intervention research, this perspective shifts attention from simply assessing effectiveness to examining the reasons behind its effects. In other words, it asks what makes an intervention work in practice. This focus is not only practically valuable but also grounded in CR's ontological stance [12]. This study used a rapid realist synthesis approach that is underpinned by CR and intersectionality theory, which offers an in-depth understanding of how intersecting vulnerabilities, intervention components, and contextual health care factors interact to shape outcomes in HF telehealth delivery.

Methods

The search and screening methodology of this review has already been described in a previously published scoping review and intersectionality-based analysis titled "A scoping review and intersectionality-based analysis of heart failure telehealth interventions for vulnerable populations" [26]. The search strategy, screening process, and data extraction were identical

XSL•FO
RenderX

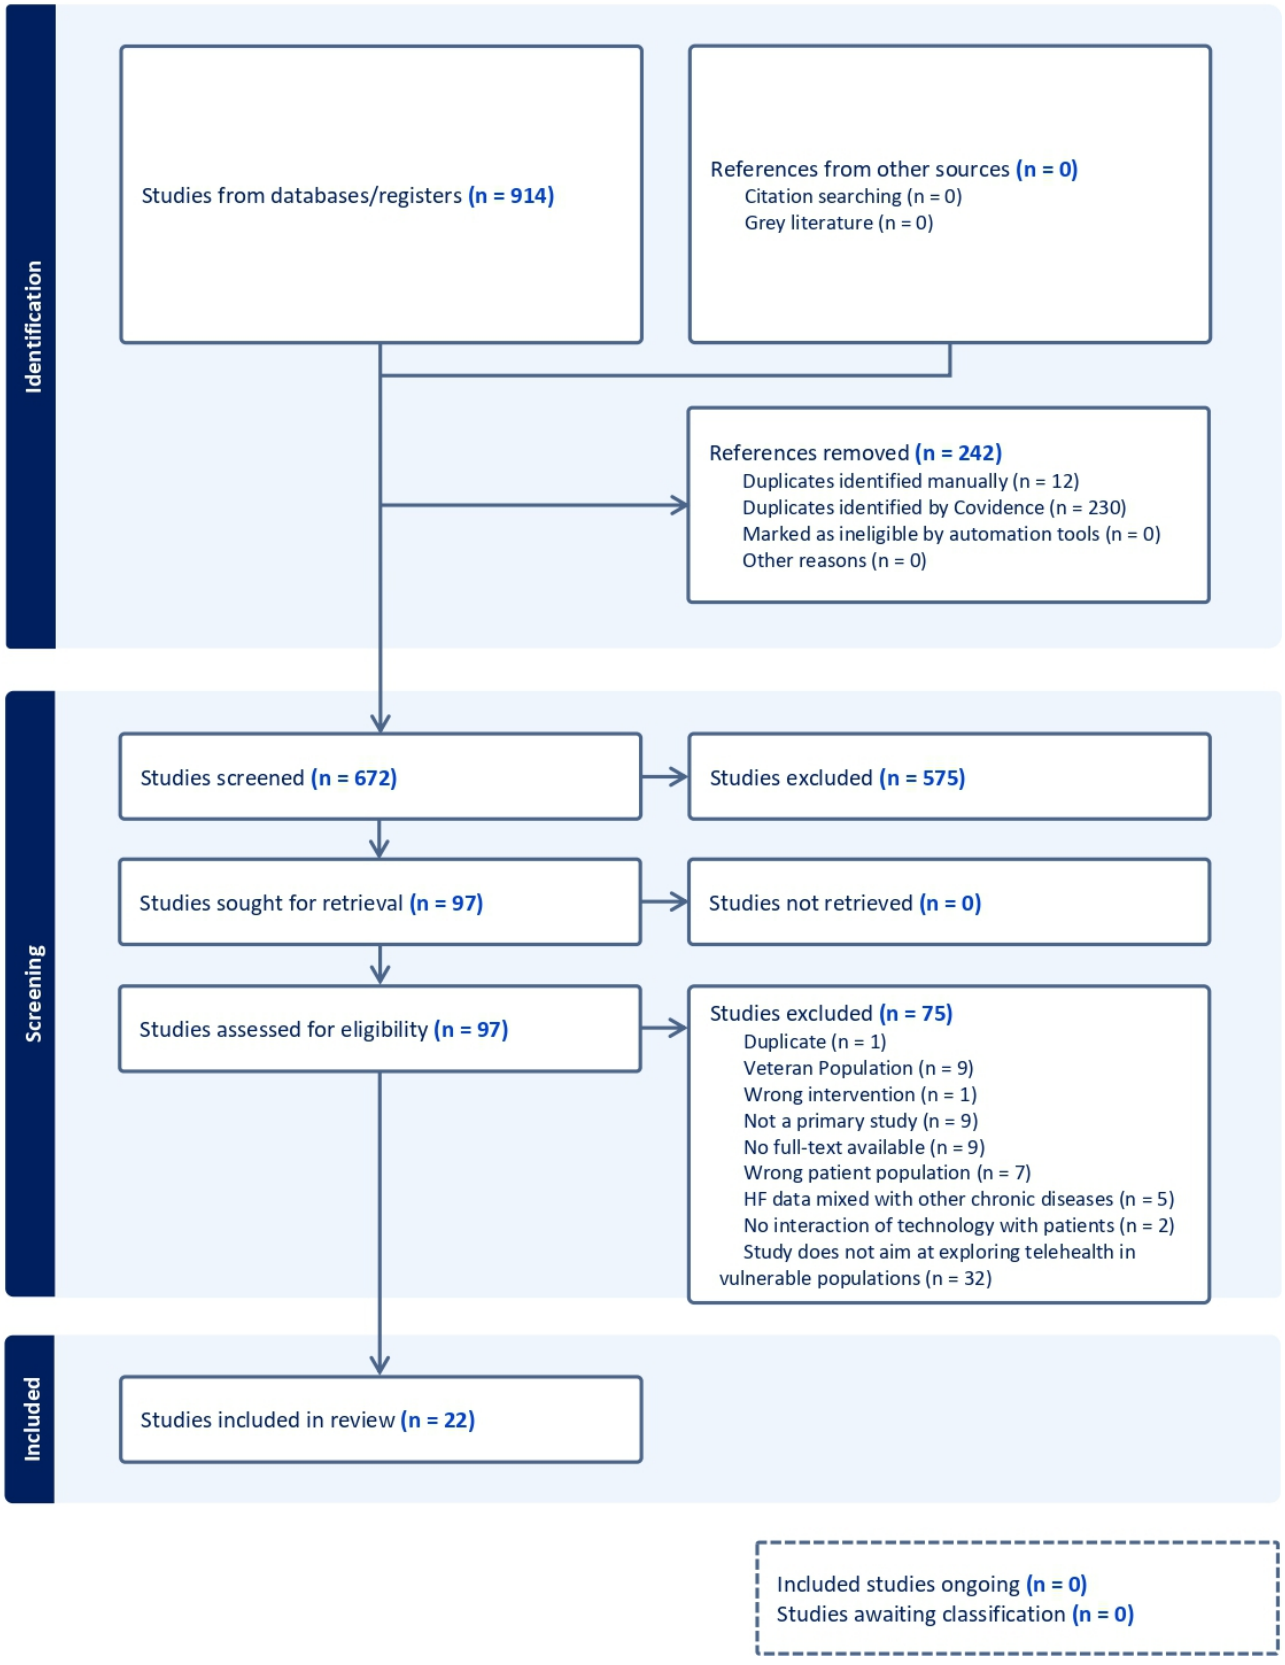
to this previous scoping review; full methodological details are previously published in the abovementioned scoping review paper [26]. However, the research questions and the subsequent analysis of data were completely different across the 2 papers. The previous paper reported the findings of a quantitative intersectionality-based analysis of the included studies [26]. However, this paper reports the findings of a rapid realist synthesis, which was undertaken to identify the contexts, mechanisms, and outcomes that make HF telehealth interventions work or not for vulnerable groups of patients with HF. This realist synthesis was important for understanding which HF telehealth interventions work for which vulnerable populations and why.

This scoping review was undertaken following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Checklist 1). To summarize the search strategy, a systematic search was conducted across MEDLINE, CINAHL, Scopus, and the Cochrane Central Register of Controlled Trials, with additional gray literature sourced via ProQuest Dissertations and Theses Global. Search terms included variations of “heart failure” and “telehealth,” combined with terms representing intersecting identities (eg, race, gender, income, and rurality) to capture studies involving marginalized populations. The screening process used a 2-step, independent, dual-reviewer approach using Covidence (Veritas Health Innovation Ltd), with conflicts resolved by a third reviewer. Studies were eligible if they examined telehealth HFDMIs involving marginalized patients with HF and/or their caregivers. Only full, English-language papers with primary data on the development, implementation, or evaluation of such interventions were included. Outcomes of interest included readmissions, mortality, quality of life, and self-care. Qualitative and mixed methods studies capturing patient, caregiver, or health care professionals’ experiences with telehealth were also considered. Data extraction was guided by a standardized form and included study characteristics, intervention details, and target populations. Study quality was appraised using the Mixed Methods Appraisal Tool.

This rapid realist synthesis was conducted following the Realist and Meta-narrative Evidence Syntheses: Evolving Standards (RAMESES) guidelines for realist reviews, using a theory-driven approach informed by CR and intersectionality theory [27]. Our aim was to uncover how and why HF telehealth interventions work, or do not work, for vulnerable populations by identifying contexts, mechanisms, and their outcomes from published literature.

Unlike stakeholder-engaged realist reviews that involve co-development of program theories through consultation, this rapid realist synthesis is document driven. We did not engage stakeholders in the formulation or refinement of program theories as it was a rapid realist review constrained by time and resources. Instead, the contexts and mechanisms were identified through analysis of peer-reviewed studies that were already mapped in a previously published scoping review [26].

We specifically searched for contexts and mechanisms, identified from the outcomes of the studies, in which HF telehealth interventions worked and did not work. Every study was thoroughly reviewed, analyzed, and summarized to identify these factors. To identify the underlying mechanisms and contexts from the included studies, retroduction was used. Retroduction is a method of analysis in which a pertinent observation or effect is first identified, and then, the researcher moves backward to understand the underlying mechanism or the causal reasoning [28]. Context- and mechanism-related data extracted from the included studies were synthesized by identifying the reoccurring themes across studies.



Results

Total Number of Studies Screened and Included

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram for this scoping review is shown in Figure 1, illustrating the number of studies included, excluded, and screened at each stage of the screening process (Checklist 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram. HF: heart failure.

Characteristics of the Included Studies

As assessed using the Mixed Methods Appraisal Tool, the studies included in this review were generally of high quality. A diverse range of methodologies and a relatively narrower geographical scope were identified among the 22 studies included in the review. The methodologies varied widely, with 8 (36.4%) studies using randomized controlled trials [29-36]. Other designs included 2 (9.1%) pretest-posttest studies [37,38], 3 (13.6%) cross-sectional or quantitative surveys [39-41], and 3 (13.6%) retrospective data collection and analysis [42-44]. The review also identified 2 (9.1%) feasibility trials [6,45], 2

XSL•FO
RenderX

(9.1%) qualitative studies [46,47], and 1 (4.55%) mixed methods study [48]. Notably, 1 (4.5%) study focused solely on developing and implementing a telehealth program for patients with HF [49]. The studies primarily examined vulnerable groups, including Black [6,29-32,35,42,44,46,47], Hispanic [30,31,33,35,39,42,47], rural [32,34,36,38,40,49], underserved [30,38,41,43], low-income [6,29,37,43-45,47], and low-education patients with HF [6,29,32,44,48]. Telehealth interventions varied, including telephone support [6,29,32,34,36,48], remote monitoring [31,38-40,42,43,45,46,48], video consultations [37,44,49], and combinations of remote monitoring and video consultations [30,47]. Other approaches included telephone case management [33] and a remote monitoring with symptom response system [35]. Among the included studies, 19 (86.4%) were conducted in the United States, indicating that the data predominantly originated from the United States. A total of 10 contexts and mechanisms were identified, of which 7 were contexts and 3 were mechanisms (Table 1).

XSL•FO
RenderX

Table . Characteristics of the included studies.

Study	Study design	Vulnerable population studied	Type of telehealth intervention
Bakitas et al [6]	Feasibility trial	African Americans, rural and urban population, and low educational level	Telephonic nurse coach sessions and monthly calls
Bakitas et al [29]	Randomized clinical trial	African Americans, rural and urban population, and low educational level	Telephonic nurse coach sessions and monthly calls
Newell et al [49]	Telehealth intervention design and implementation	Rural population	Video consultations
Pekmezaris et al [30]	Randomized controlled trial	Underserved Blacks and Hispanics	Remote monitoring and video consultations
Pekmezaris et al [47]	Qualitative study	Lower-income Blacks and Hispanics	Remote monitoring and video consultations
Dang et al [31]	Randomized controlled trial	Blacks and Hispanics	Mobile phone–based telemonitoring
Dionne-Odom et al [32]	Randomized clinical trial	African Americans, rural and urban population, and low educational level	Telephonic nurse coach sessions and monthly calls
Rosen et al [37]	Pretest and posttest design	Low-income patients	Video consultations
Riegel et al [33]	Randomized controlled trial	Hispanics of Mexican origin	Telephone case management, including decision support software and telephone support
Turchioe et al [39]	Cross-sectional feasibility study	English- and Spanish-speaking older adults	Mobile app to report symptoms
Heiney et al [46]	Qualitative study	African Americans	Mobile app for weight monitoring, health messages, and journaling
Jaana and Sherrard [40]	Cross-sectional study	Rural population	Remote monitoring via mobile phone
Bakhshi et al [45]	Feasibility trial	Low-income patients	Remote monitoring
Liu [41]	Quantitative survey method	Medically underserved urban population	Telemonitoring
Srisuk et al [34]	Randomized controlled trial	Rural population	Telephone support
Cabán [42]	Retrospective quantitative study	Hispanics, non-Hispanic Blacks, and non-Hispanic Whites	Home telemonitoring
Soran et al [35]	Randomized controlled trial	Older women, African Americans, and Hispanics	Telemonitoring and telephone-based symptom response system
Riley et al [38]	Pretest-posttest design	Underserved patients in rural communities	Remote monitoring
Krum et al [36]	Randomized controlled trial	Rural and remote communities of Australia	Telephone support
Lefler et al [48]	Mixed methods study	Low educational level	Remote monitoring and telephone support
Davis et al [43]	Retrospective cohort design	Underserved patients	Remote monitoring
Sammour et al [44]	Retrospective study design	African Americans, low-income, and low educational level	Video and telephone consultations

Contexts That Made HF Telehealth Interventions Work

Family Members' Involvement in Telehealth or Remote Monitoring Programs

The involvement of family members in training and implementing telehealth or remote monitoring programs was found to be crucial for the success of interventions. Studies by Riley et al [38] and Pekmazaris et al [47] demonstrated the positive impact of including family members in training and support. A study conducted in rural Thailand exclusively tested a family-based telehealth intervention and found it to be highly successful [34]. Similarly, Bakitas et al [6,47] and Dionne-Odom et al [32] tested palliative care interventions for patients with

XSL•FO
RenderX

HF that involved the active participation of family caregivers and demonstrated success.

Training of Health Professionals

The importance of training patients, family caregivers, and health professionals for telehealth programs has been emphasized in the review findings [6,31,35,37]. Bakitas et al [6] provided 20 hours of training to nurse coaches, focusing on effective communication and patient management through telehealth intervention. Dang et al [31] strongly recommended staff training based on their experience with telehealth interventions involving Black and Hispanic patients with HF. A different study observed that primary care physicians did not respond appropriately to clinical deterioration in remotely monitored patients with HF [35]. Accordingly, Soran et al [35] recommended training physicians and other health professionals involved in telehealth and remote monitoring interventions to ensure prompt and appropriate actions. In an interesting telehealth intervention by Rosen et al [37], social workers played a primary role in delivering the intervention. They received extensive training in health-related aspects of HF care while contributing their expertise in social aspects of care.

Significance of an In-Person Component Along With the Telehealth or Remote Monitoring Program

One of the significant findings of this review was that, in many studies, participants appreciated or requested at least 1 in-person meeting or interaction with their health care providers along with a telehealth or remote monitoring component. Those interventions that were a combination of both in-person and telehealth components were also found to be relatively more effective [6,32,34,37,43,47]. The in-person components, in most cases, were meant to build rapport with patients and support training or education. In the study by Pekmazaris et al [47], the Community Advisory Board, consisting of low-income Black and Hispanic patients, recommended arranging the first in-person meeting between patients with HF and the telemonitoring nurse. Comparing their study findings with other studies in this area of research, Soran et al [35] strongly suggested including a home visit, even if it was only possible once.

One Size Does Not Fit All—Personalized Tailoring of Telehealth Interventions

In this review, the importance of personalized and tailored interventions for vulnerable groups of patients with HF has been highlighted through several studies [31,33-35,39,43,46]. Riegel et al [33] conducted a trial of telephone case management with Hispanic patients with HF of Mexican origin, customizing the intervention to align with their cultural needs. Bilingual and bicultural health professionals, along with the integration of cultural values, trust, family inclusion, and problem-solving, were key components of this tailored intervention. Another example was the HF telehealth intervention by Srisuk et al [34] for rural Thai patients, which involved family caregivers at each stage of the intervention and incorporated cultural elements such as translated materials and culturally relevant content. Pekmazaris et al [47] used a community-based participatory research approach, involving Black and Hispanic patients with HF in developing a user-centered intervention through a Community Advisory Board. Patient feedback was used to modify the intervention delivery and equipment. Davis et al [43] recommended personalized, consistent feedback for patients with HF by telehealth providers (physicians, nurses, and allied health professionals involved in the delivery of telehealth services) based on their findings, while Dang et al [31] allowed patients to choose their preferred time and language for daily questions, emphasizing the importance of personalization. Heiney et al [46] involved African American patients in developing a mobile health intervention and ensured that the content was culturally relevant to their values. Pekmazaris et al [47] also emphasized the unique characteristics of vulnerable patients with HF, such as younger age and higher comorbidity rates, necessitating tailored telehealth programs considering cultural values, beliefs, and language.

Contextual Realities of Health Care Systems

Telehealth interventions are performed within the broader health care system; therefore, these are bound to be affected by the contextual realities of health care systems. In a study by Lefler et al [48], participants alluded to the unavailability of health professionals to respond to them or to unsatisfactory responses by them, when patients needed guidance on managing their symptoms. This could potentially lead to clinical deterioration and could result in the very outcomes that we are trying to prevent through the use of telehealth interventions. Dang et al [31] suggested using more health professionals and a variety of them (nurses, doctors, and dieticians) to be better able to support patients with HF via telehealth interventions.

Another very important contextual reality has been discussed by Soran et al [35]. They indicated the fact that a typical patient with HF is not seen by a cardiologist or a chronic care team; rather, such patients often present to primary care physicians in community settings. This holds true for most vulnerable patients with HF. However, most disease management programs, including telehealth interventions, are run in large academic centers [35]. To reach vulnerable patient populations, HF telehealth interventions need to be tailored accordingly and must be offered in community settings via primary care physicians' offices.

Soran et al [35] also alluded to another important fact that is part of the context. They indicated that when telehealth interventions are not integrated into workflow practices, it becomes difficult to run these interventions successfully. Riley et al [38] also made important recommendations in this regard. They suggested that to be useful, telemonitoring data must be incorporated in the care team's workflow, such that health care providers (physicians, nurses, and allied health professionals) know when and how to intervene based on the data received from patients via telemonitoring [38].

Equipment-Related Issues

As part of this review, some studies have highlighted the equipment-related issues that interfered with the delivery of telehealth interventions. Most often, these issues were highlighted by the patients with HF themselves. Some participants described setting up the equipment as a tough task,

XSL•FO
RenderX

such as leveling the weighing scale, setting up the iPad, etc [48]. In another study by Dang et al [31], Black and Hispanic patients with HF suggested having larger font sizes on screen, accurate translation of equipment names in Spanish, slowing down the speed of verbal instructions provided during telemonitoring, and decreasing the use of medical jargon.

Technical Issues

As telehealth and remote monitoring interventions largely rely on internet connectivity for virtual consultations and data transmission, internet connectivity problems emerged as one of the biggest technical issues that hampered the delivery of telehealth and remote monitoring interventions [38,47]. Riley et al [38] reported working proactively to ensure adequate network stability required for the transmission of patient data. Another important technical issue was discussed by Dang et al [31] based on their experience with web browser messaging. They suggested that text messages are not only more user-friendly than web browser messages but also require less data and therefore pose fewer connectivity challenges.

Mechanisms That Made HF Telehealth Interventions Work

Simplified Interventions Work vs Too Complex

Simplified interventions have been found to be more effective for HF telehealth interventions targeting vulnerable patient populations, considering their low levels of education, health literacy, and digital literacy [38,45,48]. Riley et al [38] emphasized the complexity of remote monitoring interventions for rural patients, while Lefler et al [48] highlighted the cognitive changes and poor health literacy among patients with HF. Bakhshi et al [45] advocated for simplicity in telehealth interventions, ensuring the automatic transmission of weight data for ease of remote monitoring.

Simplified Patient Training Increases Confidence for the Use of Telehealth and Remote Monitoring Equipment

Simplified patient training plays a crucial role in increasing confidence and proficiency in using telehealth and remote monitoring equipment [6,41,42,47]. Cabán [42] provided basic training to racialized groups, teaching them essential skills and electronic communication with health care providers (physicians, nurses, and allied health professionals). Dang et al [31] offered one-on-one instruction and visual manuals for participants with low educational attainment, while another study emphasized the need for more visual training materials [6]. Additionally, lower-income and racialized minority groups and gender minority groups with HF suggested increasing training time and offering in-person sessions to enhance the effectiveness of the telehealth program for these patients [47].

Sense of Security and Increased Comfort With Managing Symptoms Reinforces the Use of Telemonitoring

An increased sense of security and comfort in managing symptoms was reported as positive outcomes of telemonitoring interventions, reinforcing their use [41,43,48]. For instance, in a study by Lefler et al [48], a theme emerged, “watching over me,” whereby participants described a sense of confidence that emerged with telemonitoring. This confidence came from the feeling that someone experienced and knowledgeable in health care was watching over them, leading them to use telemonitoring more effectively. Participants in another study discussed a similar sense of security [43]. Another important theme in the Lefler et al [48] study was the increased comfort in managing HF symptoms and heightened awareness of one’s health experienced by patients who used telemonitoring regularly. This comfort and awareness reinforced their use of telemonitoring daily. Liu [41] suggested that patients with HF who are confident and proficient in using technology and who perceive it as easy to use are more likely to view telehealth interventions as useful.

Discussion

Principal Findings

As per the findings of the previous paper, there was a lack of integration of the intersectionality-based principles in the body of literature on HF telehealth use among vulnerable populations [26]. To build upon these findings, we wanted to explore which of these interventions worked or did not work for these vulnerable populations and how and why they worked or did not work. Therefore, a realist synthesis approach was used to build on the findings of the initial review. This rapid realist synthesis outlined important contextual factors, including family involvement, health professional training, in-person components, personalized tailoring, contextual realities and systems factors, equipment, and technical issues. The synthesis also highlighted mechanisms that can improve HF telehealth programs for vulnerable patient populations. It recognized the effectiveness of simplified interventions, including patient training, which can lead to positive outcomes such as (1) increased patient confidence and proficiency in using telehealth technologies and (2) enhanced sense of security and comfort in managing symptoms and overall health.

To further strengthen the analysis, we considered the application of intersectionality in designing, implementing, and evaluating HF telehealth programs for vulnerable populations. The review highlights the need for increased research attention to health inequities experienced by these populations, particularly in designing interventions across different countries and vulnerable or marginalized groups. This aligns with other research highlighting the importance of using various research methods, including qualitative, interpretive, or realist approaches, to comprehensively understand complexities and mechanisms of these interventions [12].

The analysis in this review indicates that while studies have focused on specific populations such as African Americans, Hispanics, and rural low-income groups, there is a need to include other vulnerable populations, including other racialized minority groups and gender minority groups, immigrants and refugees, women with intersecting social identities, and Indigenous peoples. Additionally, the review highlights the effectiveness of various telehealth interventions such as telephone support, video consultations, remote monitoring, and case management, emphasizing the importance of tailoring these interventions to meet the specific needs of vulnerable patients with HF.

XSL•FO
RenderX

Access and use inequities in telehealth services for vulnerable patients are significant, given their low educational, health literacy, and digital literacy levels [50]. Simplified interventions and training are essential to enhance their confidence and proficiency in using telehealth and remote monitoring equipment [50]. Family involvement, particularly in racialized minority groups and rural populations, is crucial for success, considering the cultural significance of family in patient care [33,34].

The review also highlights the importance of health professionals' training in delivering effective telehealth interventions [51]. Ensuring access to HF telehealth programs for vulnerable patients, particularly within primary care clinics in community settings, is essential to maximize their benefits [12].

In-person interactions and the personalization of interventions are valued by patients, emphasizing the significance of building rapport and tailoring interventions to cultural, linguistic, and contextual needs [52]. Integrating telemonitoring data into the care team's workflow enables prompt action and decision-making in case of clinical deterioration [12].

Communication-related issues, such as language translations, avoiding medical jargon, and using simple and understandable language, are crucial for effectively using telehealth interventions by racialized minority groups and individuals with lower health literacy [12]. The review also highlights the positive impact of telemonitoring interventions on patients' confidence, sense of security, and comfort in managing HF symptoms, reinforcing their use [12].

Strengths and Limitations

This review is notable for its originality, being the first to conduct a rapid realist synthesis in this research area, and its systematic search in multiple and multidisciplinary databases. However, it is limited by its reliance on published articles in English, the exclusion of gray literature, and the inability to collect primary data from key stakeholders, which could have enhanced the findings and theory generation.

Recommendations

The review findings offer valuable insights for improving HF telehealth interventions in clinical practice and research. Key practice-based recommendations include simplifying telehealth interventions for patients with lower education, health literacy, and digital literacy; providing tailored training; involving family members for support; training health care professionals; incorporating in-person components; personalizing interventions; offering telehealth in community settings; integrating telemonitoring data; building trust and acceptance for self-management; and using clear language and appropriate translations for racialized minority groups.

Conclusions

In conclusion, this scoping review highlights the need for greater incorporation of appropriate philosophical and theoretical foundations in research on HF telehealth interventions for vulnerable populations. While intersectionality principles have been applied in problem identification and intervention development, their application in evaluation stages needs to be improved. In addressing this, future research should adopt CR and intersectionality theory and apply intersectionality principles throughout the research process. The review emphasizes the importance of HF practitioners applying intersectionality and health equity principles in clinical practice by implementing simple, personalized interventions involving family members; including an in-person component; training patients and health professionals; and integrating telemonitoring data into care workflows. By fully implementing these findings, HF telehealth interventions can significantly improve care for vulnerable patients, addressing their specific needs; enhancing access, acceptance, and use of telehealth; and ultimately reducing health inequities.

Abstract

Background: Advances in data science and technology have transformed lifestyle research by enabling the integration of multimodal information and the generation of large-scale datasets. Despite the growing interest in machine learning (ML) within health behavior research, significant methodological gaps remain.

Objective: The study aims to systematically review the applications of supervised ML algorithms in the analysis of healthy lifestyle data, with a particular focus on the methodological approaches used. The specific objectives are to explore the types and sources of data used for health outcomes, examine the ML processes used, including explainable artificial intelligence (XAI) methods, and review the software tools used. Additionally, this review aims to provide practical guidelines to enhance the quality and transparency of future ML research in health.

Methods: Following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) recommendations, the search was conducted across PubMed, PsycINFO, and Web of Science, yielding 65 studies that met the inclusion criteria.

Results: Most studies (48/65, 74%) integrated multidomain data from physical activity, diet, sleep, and stress. Data sources were split between self-acquired data (33/65, 51%) and health repositories (32/65, 49%). Single-item measurements were common, particularly for physical activity, diet, and sleep. Although 40 of 65 studies used a multimodel approach, random forest was the most frequently applied algorithm. To improve explainability, 22 of 65 (33.84%) studies incorporated specific XAI methods, with 21 using Shapley Additive Explanation values and 1 using local interpretable model-agnostic explanations. R (R Core Team) and Python (Python Software Foundation) were the most widely used software tools, with variation in the libraries used.

Conclusions: This review highlights methodological gaps in the application of supervised ML to healthy lifestyle data. The ML workflow should span from data acquisition to explainability, using iterative steps to improve methodological rigor. Although multidomain data collection enhances the understanding of health issues related to lifestyle, representativeness remains limited due to methodological shortcomings in data acquisition. While random forest was the most commonly used algorithm, a multimodel approach is recommended for a comprehensive comparison. Lifestyle components consistently ranked among the top features in studies integrating XAI. Incorporating XAI methods into the ML pipeline can support personalized interventions, provided data collection is accurate. The R metapackage (tidymodels; Max Kuhn and Hadley Wickham) facilitates process evaluation through unified syntax, improving replicability. Methodological and reporting guidelines and a checklist are provided to enhance transparency and replicability in multidisciplinary ML research.

Introduction

There is a growing interest in understanding the effects of synergistic relationships among lifestyle behaviors and their effect on health outcomes [1,2]. Traditionally, healthy lifestyle (HL) research has primarily focused on physical activity and diet. However, recent studies increasingly include sleep and stress management as critical components of lifestyle [3,4]. For instance, stress has been shown to negatively influence physical activity, sleep, and dietary habits [5], which in turn have an

XSL•FO
RenderX

overall impact on health and well-being. This multidimensional perspective has gained attention in public health under the concept of lifestyle medicine, which incorporates physical activity, diet, sleep, and stress management as cost-effective interventions to prevent noncommunicable diseases, such as cardiovascular and metabolic diseases [6-8].

Technological advances, including wearable devices and lifelogging processes, have significantly enhanced the capability to collect multimodal, high-frequency, and ecological lifestyle data [9,10]. This wealth of data provides valuable contextual information and insights for researchers and users [11]. However, the vast amount and complexity of behavioral and physiological data expose significant analytical challenges. Traditional statistical models often struggle with the high dimensionality, heterogeneity, and nonlinearity typical of lifestyle studies. Recent progress in computational power and artificial intelligence (AI), particularly machine learning (ML), has contributed to addressing these limitations [12].

ML models are capable of analyzing complex data types and generating insights and knowledge to improve decision-making [13,14]. Furthermore, ML algorithms can flexibly handle nonlinear relationships among features and outcomes. While the boundary between classical statistics and ML is not clear, ML algorithms are recognized for their flexible data-driven approach, avoiding the imposition of a predetermined relational structure between variables [15-17]. Additionally, prioritizing algorithms that maximize generalizability to new data, often referred to as scalability in the big data context, is crucial to face new health challenges [18,19]. These characteristics make ML analysis a suitable methodology for predictive modeling and feature extraction in health-related lifestyle research.

ML models are broadly classified into supervised learning (SL) and unsupervised learning (UL). In SL, the model is trained with labeled data, where each observation has an associated response measurement, to predict known outcomes such as disease risk or behavioral adherence [19]. The goal of SL is to fit a model that can predict the response when applied to new data. When the response value is continuous, this is known as a "regression problem"; when the response is categorical, it is known as a "classification problem." In contrast, in UL models, the goal is to discover patterns rather than predict outcomes, since there is no associated response to the input, and the model seeks relationships and similarities between observations. In the health domain, where diagnosis and detection are key focuses, SL, and particularly classification tasks, are more prevalent due to their ability to evaluate these predictions [20,21]. Clinical applications of SL include triage systems, prognosis prediction, and disease classification using rapid testing [22]. Consequently, SL methods are standard in epidemiology to enhance clinical decisions based on input-output relationships [23]. Since prediction and explainability are central concerns in health research, this scoping review focuses specifically on SL methods.

Despite the growing attention to ML in health behavior research, there remain significant methodological gaps. Prior reviews have focused primarily on outcome effectiveness or AI chatbot interventions, often providing limited detail about the ML process involved [24]. A recent scoping review on ML methods used in health promotion and behavioral change found that the main interventions studied are those related to physical activity, while other crucial aspects of HL were overlooked, revealing an imbalance in this literature [25]. Similarly, Lai et al [26] reviewed the applications of large language models in exercise recommendations and physical activity, highlighting methodological limitations associated with these AI models. In sum, these studies underscore the need for a more comprehensive review to include a holistic concept of HL. Furthermore, methodological details such as data preprocessing, model evaluation, and explainability are often underreported, hindering transparency, reproducibility, and interdisciplinary collaboration.

To address the lack of explainability, explainable artificial intelligence (XAI) has emerged, which focuses on understanding AI algorithms and making them more transparent. XAI aims to provide human-understandable explanations for the decisions made by ML models [27]. In HL research, XAI can be directed to identify the set of behaviors that significantly influence health, thereby enhancing transparency and trust in AI. It is important to distinguish between interpretability and explainability in the AI context. While interpretability refers to understanding the influence of each feature in the original model, explainability involves deriving actionable human insights from the model's predictions [28]. Interpretability enables AI developers to delve into the model's decision-making to comprehend how algorithms reach their decisions. Conversely, explainability refers to the process for creating common meaning from model decisions and therefore provides human-readable explanations [28]. Therefore, reporting the explainability method used in ML projects is crucial not only to enhance the decision-making process of the end user but also to understand how lifestyle factors interact with health outcomes.

Therefore, this study aims to systematically review the applications of supervised ML algorithms in analyzing HL data, with a specific focus on the methodological aspects used in these studies, rather than their results. The specific objectives are to explore (1) the specific lifestyle data used in health outcome studies; (2) the sources and types of data subjected to analysis; (3) the characteristics of the ML models, including XAI methods; and (4) the programs and libraries used for ML implementation. Additionally, based on the findings of this scoping review, we aim to provide practical guidelines to enhance the quality and transparency of future ML research in lifestyle science. A scoping review is the type of systematized review (ie, systematic, transparent, and replicable) most appropriate for addressing these objectives [29].

Method

Overview

To maximize the reporting quality of this scoping review, we followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) recommendations [30] (checklist provided in Checklist 1). The protocol for this scoping review was registered with the International Platform of Registered Systematic Review and

XSL•FO
RenderX

Meta-Analysis Protocols (INPLASY) [31]. All data generated in this review are provided in Multimedia Appendix 1 and are accessible in the institutional repository [32].

Search Strategy

In this scoping review, we searched for primary studies in the 3 principal health databases: PubMed (National Center for Biotechnology Information), PsycINFO (ProQuest), and Web of Science (Clarivate). The search was restricted to medical and psychological databases to capture studies directly relevant to health outcomes. Consequently, studies primarily published in engineering or computer science, which may focus on algorithm development or sensor-based data processing, were not included. The search strategy followed the PRESS (Peer Review of Electronic Search Strategies) [33] and PRISMA-S (Preferred Reporting Items for Systematic Reviews and Meta-Analyses–Search extension) guidelines [34] and consisted of 2 groups of search terms referring to (1) HL and (2) ML. We also added a third group of terms preceded by the Boolean operator "NOT" to improve the specificity of the search strategy. This scoping review adopts a health-focused perspective, in which HL is treated as a multidimensional construct rather than the sum of isolated behaviors [6,35,36]. Therefore, the umbrella term HL was combined using the operator "OR" with an interaction block including (1) physical activity, (2) diet, (3) sleep, and (4) stress. This block is aligned with the multiple health behavior change and lifestyle medicine frameworks, in which the interaction between behaviors is a central construct [37,38].

The search strategy was adapted to the specific syntax of each database (Table S1 in Multimedia Appendix 1). The search was conducted on October 10, 2025, with language restrictions (English and Spanish) but without limitations on publication years.

Study Selection

Inclusion and Exclusion Criteria

Studies were included in or excluded from the review according to the following criteria provided in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Used supervised machine learning (ML) models for analyzing lifestyle data.
- Analyzed lifestyle behaviors as either inputs or outputs of the ML models.
- Used data from real individuals (not simulations).
- Published in English or Spanish.

Exclusion criteria:

- Focused on unsupervised learning (UL) without connection to supervised learning (SL) modeling.
- Focused on mathematical formulation or guidelines for implementing ML models in health.
- Used simulated data or aimed to develop a chatbot or app based on ML.
- Primarily addressed substance abuse, such as alcohol intake or smoking cessation.
- Focused exclusively on classical statistical regression algorithms, such as linear or logistic regression, which were not considered ML on their own in this review.

Justification of Exclusions

UL algorithms were excluded because they do not have an associated response to inputs, thereby lacking performance evaluation. Classical statistical regression algorithms, such as linear or logistic regression, were not considered in this review. While the boundary between classical statistics and ML is not clear, ML algorithms are recognized for their flexible data-driven approach, avoiding the imposition of a predetermined relational structure between variables [15-17]. Additionally, prioritizing algorithms that maximize generalizability to new data, often referred to as scalability in the big data context, is crucial to address new health challenges [18,19]. Consequently, studies focusing exclusively on this type of statistical algorithm were excluded. However, we acknowledge that the use of a model ensemble approach allows for the inclusion of these statistical algorithms to assess the performance of different algorithms during the evaluation step. Studies on substance abuse disorders were excluded as they involve distinct behavioral and neurobiological mechanisms that differ substantially from the domains of physical activity, diet, sleep, and stress, which are the core components of HL behaviors as defined in this review. In addition, substance abuse is categorized within the risk avoidance cluster, which is conceptually distinct from the other 4 behaviors examined in this review [3]. This distinction is well established in multiple health behavior theories, which differentiate behaviors that enhance health from those that reduce risk through avoidance. Therefore, its exclusion preserves the applicability of results to a multiple health behavior framework, as the selected behaviors are interrelated through shared psychological resources [2,39].

Two reviewers (TE and CA) independently screened titles and abstracts in the first phase and full texts in the second phase. Discrepancies were resolved by consensus, with the participation of a third reviewer (JML) when necessary. Agreement between reviewers during the selection process was analyzed by calculating Cohen κ.

XSL•FO
RenderX

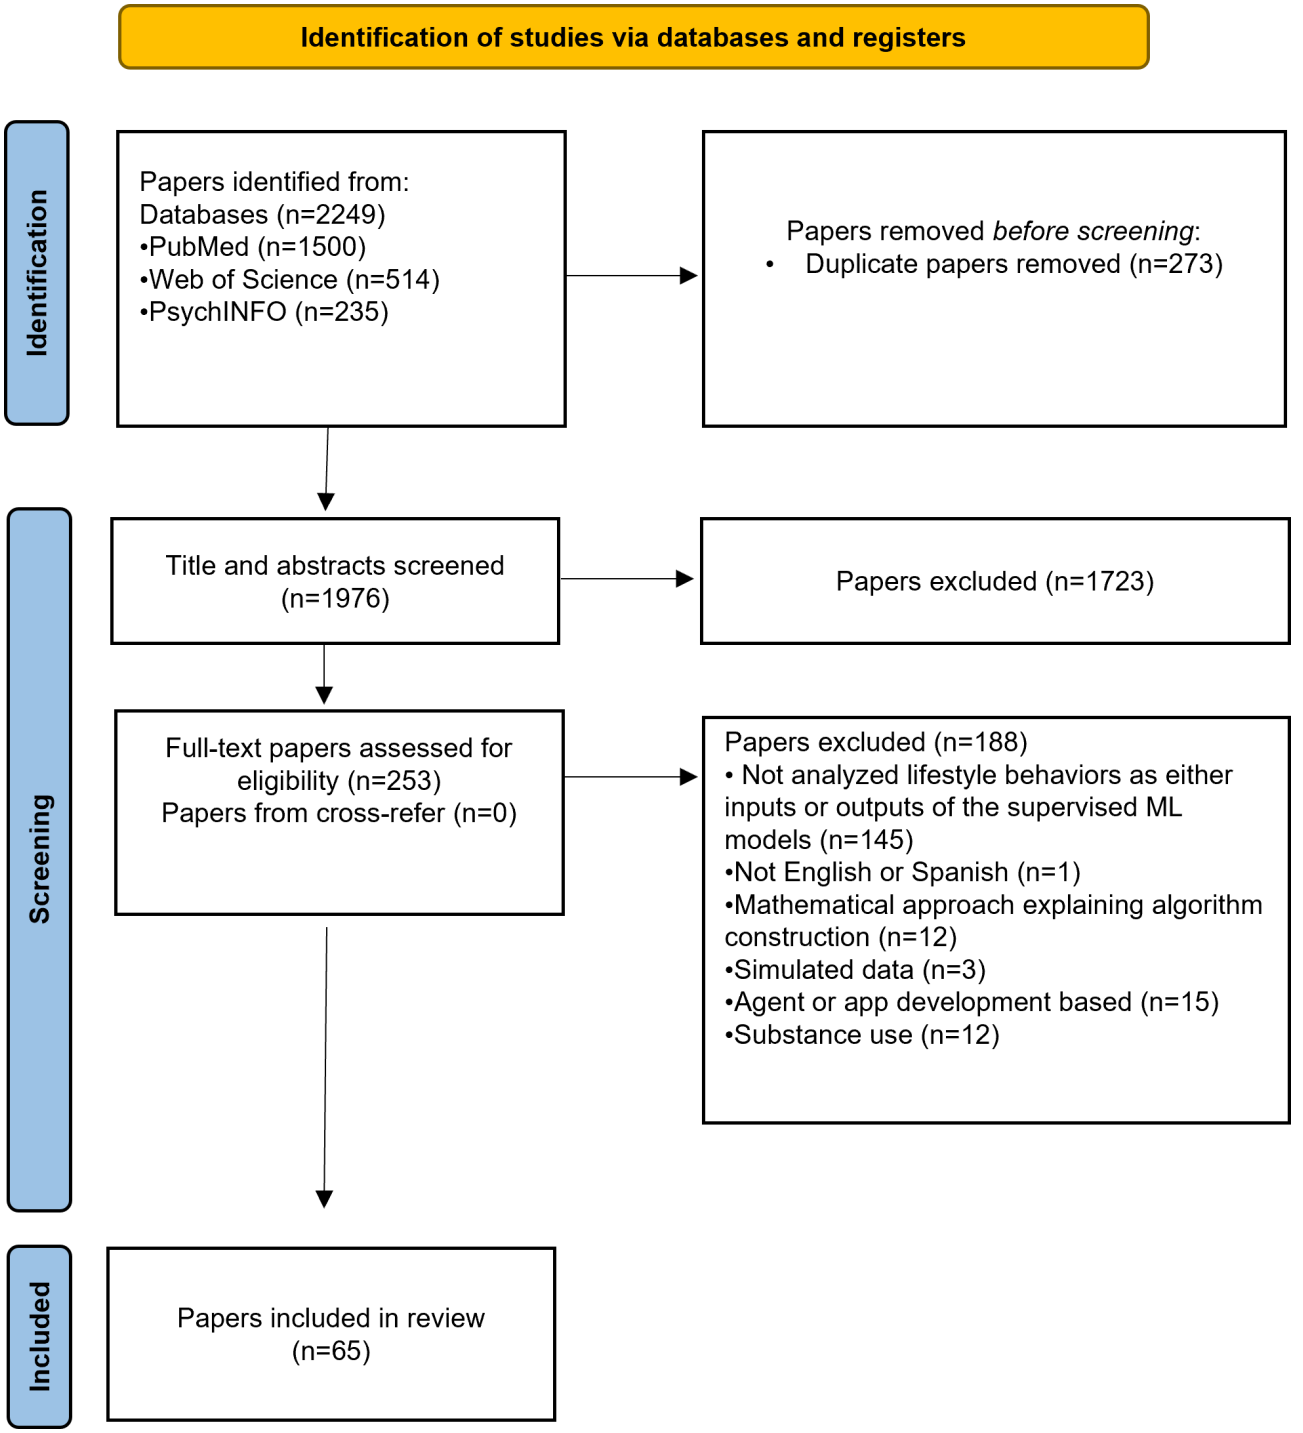
Data Management

Mendeley was used as reference management software; the results of the search strategy were entered, and duplicates were merged or removed. An ad hoc checklist was used to extract information from the included papers. The checklist was divided into 5 sections:

- General information: authors, title, year, and country of affiliation.
- Methodological data: type of study, aim, year of data collection, form of data acquisition, sample, and countries represented in the data.
- Study variables: health issues, lifestyle features, and the model's input and output variables.
- Software: statistical programming language, libraries, and packages.
- Model aspects: type of problem, stages of ML analysis, ML methods, model evaluation, evaluation metrics, and XAI methods.

Strategy of Data Synthesis

The review was presented as a narrative synthesis, and the information was summarized in tables and figures. The information extracted from the studies was divided into 3 blocks: type of data, ML process, and software. For data extraction, we focused on lifestyle components, health outcomes, data sources, acquisition methods, and data typology. Regarding the ML process, we focused on the whole process, consisting of preprocessing, modeling, validation, evaluation, and XAI methods. For model evaluation, only the procedures used for final performance assessment were extracted. When studies reported cross-validation, we classified it as the final performance estimation method unless authors explicitly stated its use for hyperparameter optimization. To identify the top-ranked lifestyle components in the XAI analysis, we systematically examined the figures and tables reported in each study. In this review, the term ranked refers to features that were highlighted by the XAI algorithm. In contrast, unranked indicates that appeared in the model but were not reported in the XAI visualization, while not available denotes features that were not included in the ML model. Software used in each study was also recorded.



Results

Overview

A total of 2249 papers were retrieved from the databases, and 65 studies met the eligibility criteria and were included in this scoping review (refer to Figure 1). There was very good agreement between reviewers during the selection process: 96% (n=52; κ=0.84, 95% CI 0.61-1.0) in the title and abstract screening and 94% (n=35; κ=0.88, 95% CI 0.71-1.0) in the full-text screening.

XSL•FO

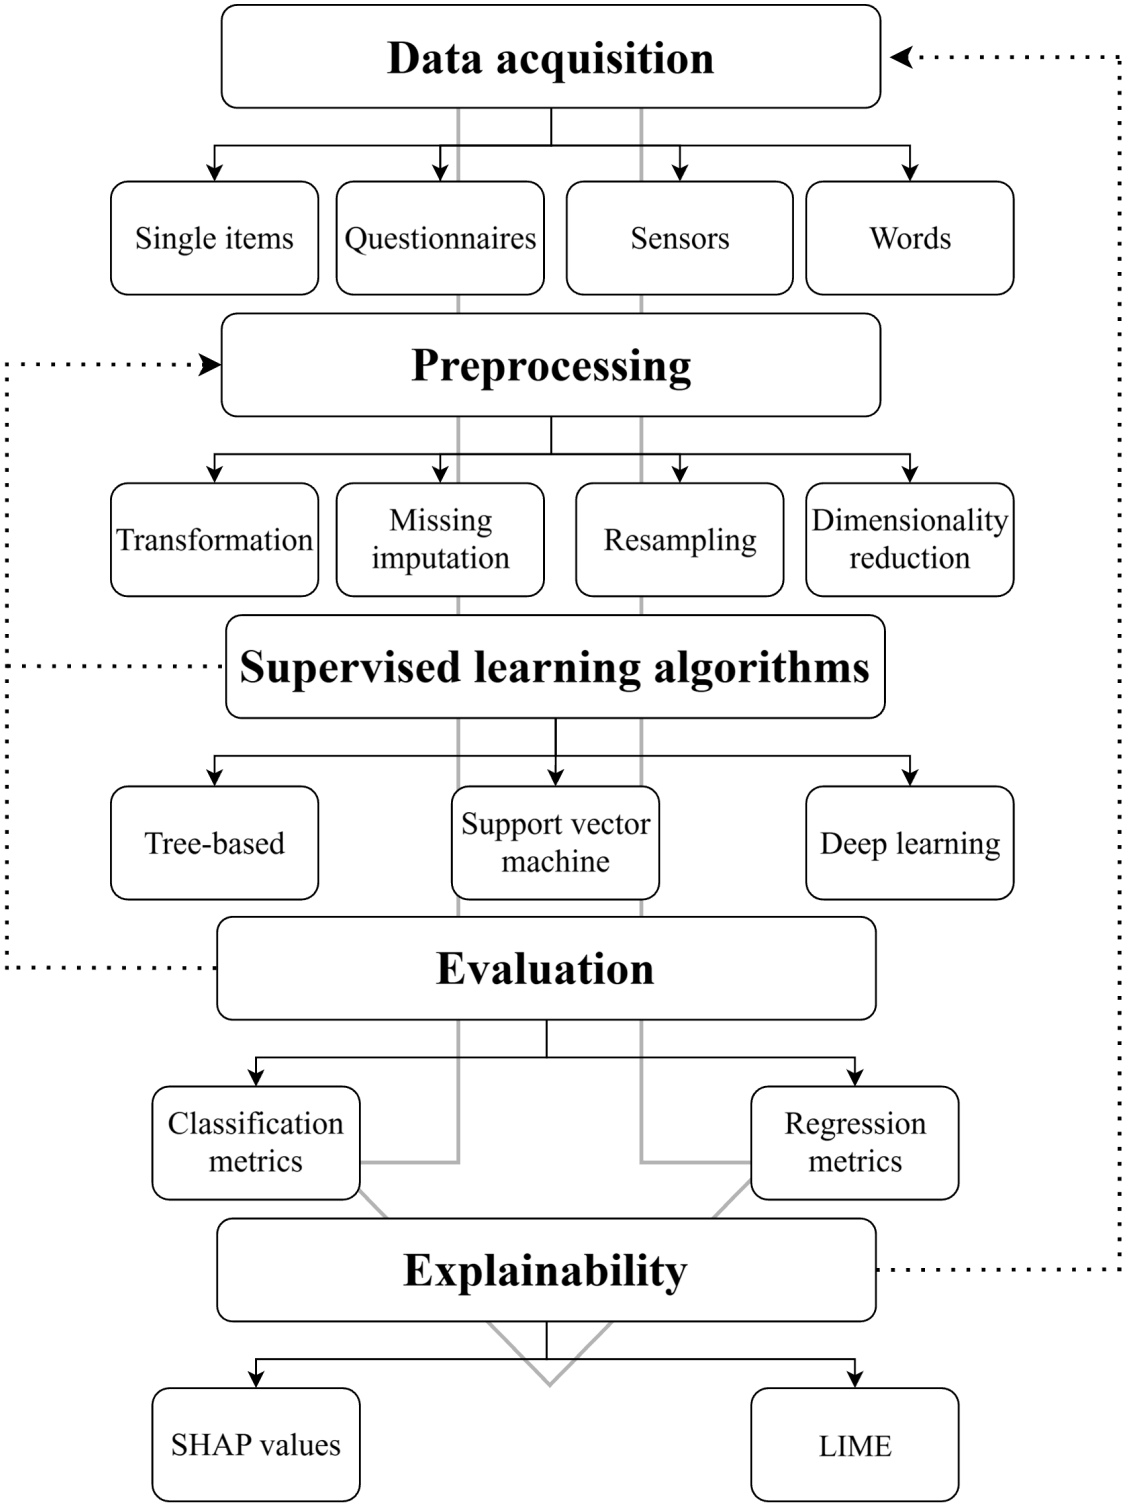

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the scientific literature search and selection. ML: machine learning.

From this point forward, the "Results" section is structured following the ML workflow depicted in Figure 2, which illustrates the 5 key steps in the ML pipeline. The process begins with data acquisition, followed by preprocessing to prepare the data. Then, SL algorithms are applied and evaluated to determine their effectiveness. Finally, explainability techniques are used to understand the models. The dashed lines indicate that modeling, evaluation, and explainability can improve earlier stages, making the process iterative. Each stage of the process corresponds to a subsection. Finally, we examined the software used throughout the entire process in the included studies.

Data Acquisition: Collection Modes, Data Typology, Lifestyle Variables, and Health Outcomes

The 65 papers included in this review were published between 2004 and 2025, with 57 (87.7%) published since 2019. Figure 3 shows the annual productivity output stratified by lifestyle components. The studies were carried out in several geographical regions across 4 continents (Table S2 and Figure S1 in Multimedia Appendix 1). The mean sample size was 29,905.14 participants, with the smallest study including 8 participants and the largest including 470,778 participants.

XSL•FO
RenderX

Figure 3. Bar graph showing productivity by publication year, with each line and dot representing a lifestyle component.

Four lifestyle domains were identified in the review: physical activity, diet, sleep, and stress. Most studies (48/65, 74%) integrated data from more than 1 lifestyle domain (refer to Table 1). The most studied component was physical activity, featured in 61 of 65 studies. Diet and sleep appeared in 33 of 65 (51%) and 34 of 65 (52%) studies, respectively, while stress appeared in 15 of 65 (23%) studies (refer to Figure 3). Only 17 of 65 (26%) studies focused exclusively on a single domain (15 on physical activity [40-54] and 2 on sleep [55,56]).

Regarding data sources, 33 of 65 (51%) studies relied on self-acquired data, while 32 of 65 (49%) studies used either private or public health datasets, such as UK Biobank [57]. Among the studies using self-acquired data, the mean sample size was 10,503.41 participants. Six studies focused exclusively on females [46,47,58-61], and 27 studies reported a female proportion ranging from 41% to 89.4%. Studies using health repositories exhibited a greater mean sample size of 80,406.38 participants. Nineteen studies reported a female proportion ranging from 41.33% to 70%, 12 did not report sex distribution, and 1 study focused exclusively on females.

Figure 4 summarizes the different data collection modes used for each of the 4 lifestyle domains identified (Table S3 in Multimedia Appendix 1 provides a detailed description of each measure). Single-item measures were used in 40 of 65 (61.5%) studies assessing physical activity, 18 of 65 (27.7%) studies assessing diet, and 22 of 65 (33.8%) studies assessing sleep. Despite the heterogeneity of these items, distinct categories emerged within each lifestyle domain.

For physical activity, the emerging categories included engagement in physical activities [47,50-52,54,58,62-66], intensity [10,42,49,57,67-71], frequency [43,44,60,72-86], and environmental factors [87,88]. Within the diet domain, categories included frequency of consumption [58,60,66,72,84], types of products [75,76,80,82], environmental factors [87], and consumption habits [59,62,65,68,70,71,86,89]. Regarding sleep, categories included sleep duration [57,60,62,66-68,70,72,77-79,81,82,84,85,87], perceived sleep quality [63,89], and sleep-related problems [69,80]. Finally, within the stress domain, the emerging category focused primarily on stress level [10,57,79,82,86,89,90].

Questionnaires were used to collect physical activity data in 13 studies. The standardized questionnaires included the Global Physical Activity Questionnaire (GPAQ) [53,72,91], the International Physical Activity Questionnaire (IPAQ) [92], the Lifetime Total Physical Activity Questionnaire (exercise and sport subscale) [93], the Nutritional and Social Healthy Habits (NutSo-HH) scale [94], the Indian Migration Study Physical Activity Questionnaire (IMS-PAQ) [95], physical fitness test [41], the Short Questionnaire to Assess Health-Enhancing Physical Activity (SQUASH) [73,74], the physical activity scale from the Active Living Index [88], the Pregnancy Physical Activity Questionnaire [61], and the Physical Activity Scale for the Elderly [96]. For diet assessment, 12 studies used the Food Frequency Questionnaire (FFQ) [57,73,74,83,88,91,92,95], the PrimeScreen questionnaire [61], the Mini Nutritional Assessment [97], the NutSo-HH scale [94], and a nonstandardized questionnaire consisting of items from different questionnaires [93]. The standardized questionnaires used to measure sleep were the Pittsburgh Sleep Quality Index [10,56,61,86,91,92,96,97], the NutSo-HH scale [94], the Munich Chronotype questionnaire and Sleep Disturbance Scale for Children [64], and the Epworth Sleepiness Scale [96]. To measure stress, the stress subscale of the Depression Anxiety Stress Scale (DASS) [92,93], the INTERHEART stress questionnaire [59], the Psychosocial Well-being Index-Short Form [91], the Perceived Stress Scale [61,64,88], and the Profile of Mood States [81] were used. Regarding data collection through sensors, most studies used wearable devices. One study used a smartphone to obtain points of interest related to physical activity and diet [98], and 1 sleep study used polysomnography [55]. Finally, 2 studies used words related to physical activity and diet, 1 derived from Google Trends [99] and the other from Twitter (Twitter, Inc) [100].

XSL•FO
RenderX

Concerning the modeled inputs, 56 of 65 (86.1%) studies used multimodal data. The input modalities were lifestyle (60/65, 92.3%), sociodemographic (49/65, 75.3%), clinical (29/65, 44.6%), anthropometric (14/65, 21.5%), psychological (20/65, 30.7%), physical (3/65, 4.62%), environmental (10/65, 15.38%), physiological (3/65, 4.62%), and behavioral (2/65, 3.07%). The model outcomes included lifestyle domains in 14 (22% studies; 5 physical activity [40,44-46,90], 5 sleep [10,48,86,97,101], 3 diet [62,66,94], and 1 stress [61]) and other health outcomes in 51 (75% studies; with mental health, cancer, cardiovascular diseases, and diabetes being the most frequent categories; refer to Table 1).

Cross-sectional data were acquired in 36 (55%) studies [42-44,51-53,56-58,60-62,65,66,71-74,77-80,84,85,89,92,94,95,97], longitudinal data in 18 (28%) [10,41,50,54,55,59,64,67-69,81,82,96] studies, time-series data in 7 (11%) [45,46,48,75,76,101,102] studies, combined longitudinal and time-series data in 1 study [90], textual data in 2 studies [99,100], and combined cross-sectional and geographical data in 1 study [103].

Preprocessing

The preprocessing phase was divided into variable transformation, missing imputation, resampling, and dimensionality reduction. At least one of these preprocessing phases was reported by 59 (90.76%) studies (refer to Table 1 and Table S4 in Multimedia Appendix 1 for more details).

There were 26 (40%) studies that reported normalization or other arithmetic or statistical transformations of variables before the modeling phase [40,41,45,48,50,51,53,58,59,62,64,67,69,73-75,79,81,83,84,89,91-94,102]. Six (9.23%) studies recoded categorical variables into quantitative variables, 5 used one-hot encoding [10,53,64,67,102], and 1 used principal component analysis with quantile transformer scaler [42].

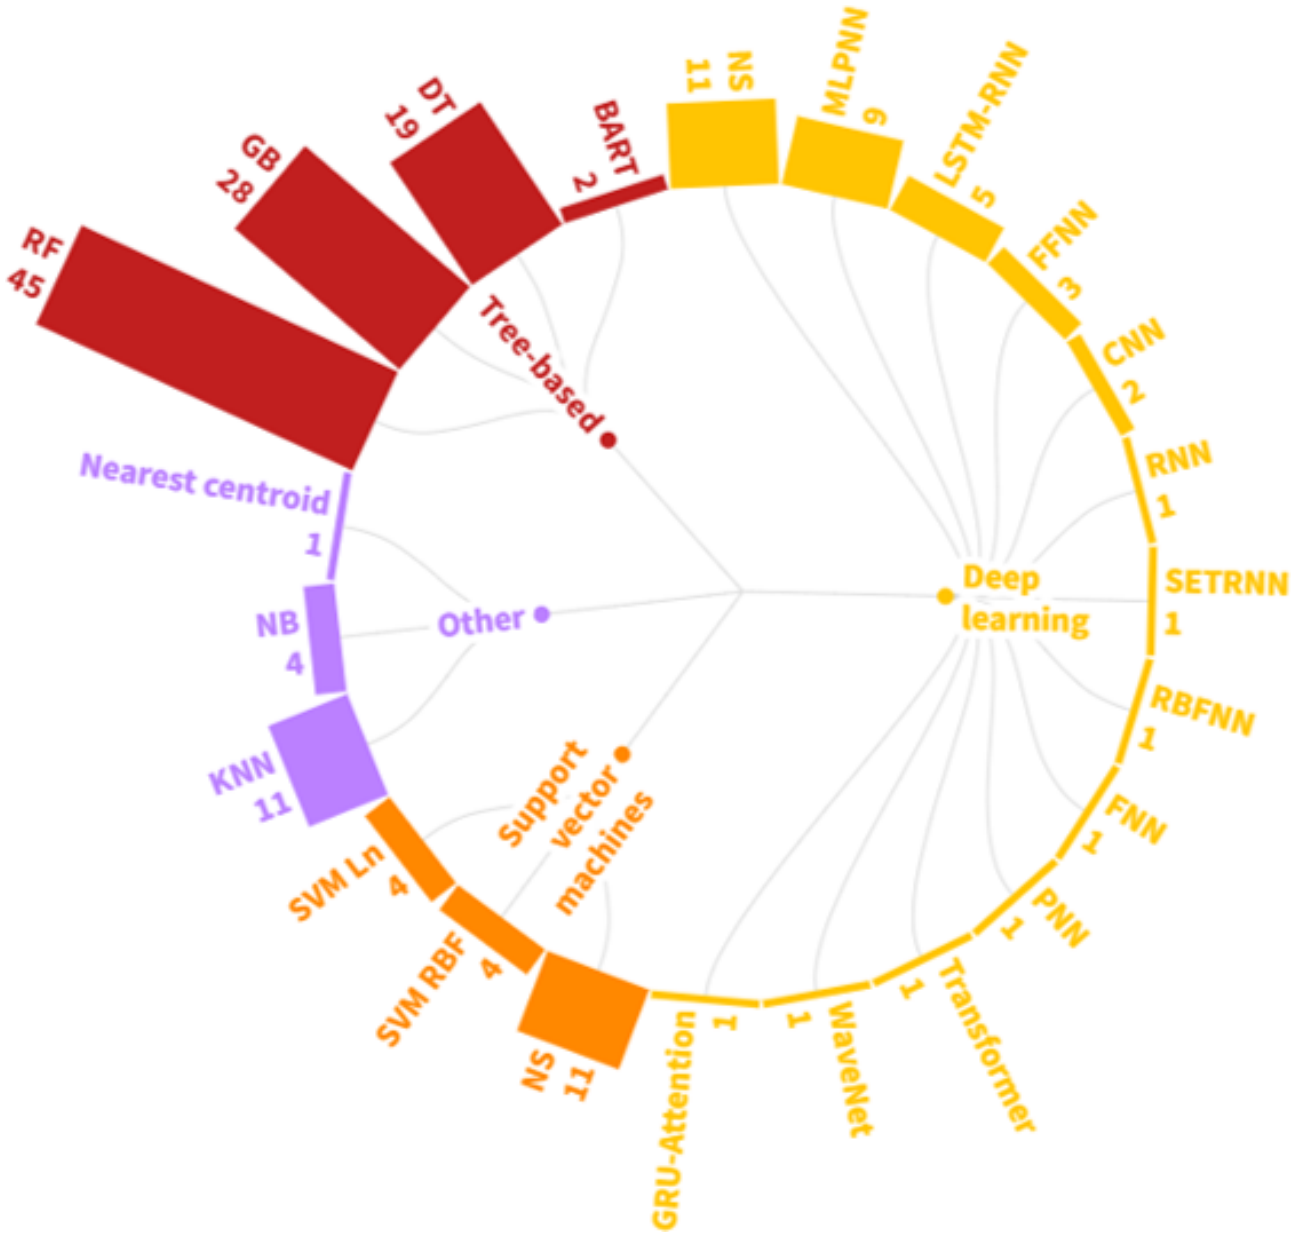
Missing data imputation was reported in 37 (56.92%) studies. Twelve papers simply removed cases with missing data [10,42-44,61,64,77,78,80,93,98,101], while others applied cutoff percentages for missing values (eg, 10% [87], 30 % [73], or >50% [58,72]), and 1 study removed observations with missing values in the output [102]. Techniques included single imputation (mean, median, or mode) [51,52,58,59,70,83,88,92], multiple imputation by chained equations [57,63,72,73], k-nearest neighbor [89,102], regression-based algorithm [57,81], random forest (RF)–based multiple imputation [55,69,84], the MissForest algorithm [67,68], imputation based on peers with similar health profile group [82], imputation using training data [104], and replacement of missing values with the last available data [75].

Resampling techniques were reported in 21 (32.30%) papers. Eighteen studies balanced the datasets using methods such as using the minority class as a reference, undersampling the majority class [42,61], or the synthetic minority oversampling technique (SMOTE) [43,44,52,60,63,67,71,72,84,86,89,91,94,95,97]. One paper compared the results of SMOTE against the adaptive synthetic algorithm [65]. Finally, 1 study stabilized variations in underrepresented outcome classes using bootstrap resampling [82]. Regarding cancer studies where cases were fewer than controls, 2 different strategies were applied to the same dataset: sample-size equalization by randomly grouping cancer-free participants based on the number of cancer survivors [74], while another study matched cases and controls by sex, age, and education level, then selected a random sample resulting in 50% cases and 50% controls [73].

Dimensionality reduction was used in 38 (58.46%) studies using 3 approaches. The first approach involved assessing the relationship between features and outcomes by removing redundant information [55,61,64,70,83,85,87,93,98,99]. Other methods included factor analysis [10] and principal component analysis [42,59,69]. The second approach optimized models to achieve lower prediction error [58,66,104]. The third approach involved automatic selection of predictors during model training [41,49,57,62,72-74,77,78,81,90,95,102]. For more information, refer to Table S4 in Multimedia Appendix 1.

SL Models

Models Overview



In this section, the core components of ML models are described, beginning with problem formulation and algorithm families, followed by evaluation components. Depending on the purpose of the ML analysis, papers were grouped as classification or regression when the objective was prediction, and as feature selection when the goal was explanation [19]. Most studies (46/65, 70.77%) focused on classification, 9

XSL•FO
RenderX

(13.83%) on regression, 2 (3.1%) on both classification and regression, and 8 (12.30%) on feature selection.

Six families of algorithms emerged from the studies: tree-based, deep learning, support vector machines, k-nearest neighbors, naïve Bayes, and nearest centroid. The approach adopted across 40 studies was a multimodel approach, with 29 of them incorporating algorithms from diverse algorithmic families. Figure 5 provides a comprehensive taxonomy of the specific algorithms implemented. The following subsections describe the application of specific algorithms within the 3 most used families (tree-based, deep learning, and support vector machines) in relation to the type of data used.

Figure 5. Machine learning families and algorithms taxonomy. BART: Bayesian additive regression trees; CNN: convolutional neural network; DT: decision tree; FFNN: feed-forward neural network; FNN: fuzzy neural network; GB: gradient boosting; GRU-attention: gated recurrent unit with attention; KNN: k-nearest neighbor; LSTM-RNN: long short-term memory recurrent neural network; MLPNN: multilayer perceptron neural network; NB: naive Bayes; NS: not specified; PNN: probabilistic neural network; RBFNN: radial basis function neural network; RF: random forest; SETRNN: simple Elman-type recurrent neural network; SVM Ln: support vector machine with linear kernel; SVM RBF: support vector machine with a radial basis function.

Tree-Based Algorithms

Tree-based algorithms were applied in 55 (84.61%) studies, covering all data types. RF was used in 45 (69.23%) out of 55 studies. Specifically, RF was implemented in 27 cross-sectional studies [40,43,44,47,51-53,56,60,65,70,72-74,77-79,84-87,89,91-95], 11 longitudinal studies [10,41,55,59,63,67,69,81,83,88,96], 3 time-series studies [45,76,102], 2 textual studies [99,100], 1 study with both cross-sectional and geographical data [98], and 1 study with both longitudinal and time-series data [90].

Different versions of the gradient boosting algorithm were performed in 28 studies, including gradient boosting machines, extreme gradient boosting, adaptive boosting, and light gradient boosting machine

XSL•FO
RenderX

[41,43,44,47,49,52,56,57,60,63-65,67,68,70,71,74,78,80,83,86,91,92,94,97,99,100,102]. Finally, decision tree algorithms were implemented in 19 studies [10,45,47,51,54,56,58-60,62,65,67,70,84,86,87,90,91,94], and Bayesian additive regression trees in 2 studies [77,78] (Table 1; Figure 5).

Deep Learning Algorithms

Neural networks (NNs) are considered the cornerstone of deep learning algorithms. Various NN architectures were applied in 24 (36.92%) of the reviewed studies. A multilayer perceptron neural network was used in cross-sectional [51,58,97], longitudinal [67,82], and time-series data [48,101,102]. Long short-term memory recurrent neural network was applied to longitudinal [50,63] and time-series data [75,101,102]. Feed-forward neural networks were used for cross-sectional data [42,66,94]. Convolutional neural networks were used to analyze time-series [101] and cross-sectional data [50]. Simple Elman-type recurrent neural networks were applied in a time-series study [101]. Radial basis function neural networks, fuzzy neural networks (FNNs), and probabilistic neural networks were used in a cross-sectional study [58]. In addition, Transformer, gated recurrent unit with attention, WaveNet, and RNNs were used to analyze longitudinal data [50]. In contrast, 11 studies did not specify the artificial neural network architecture used [41,45,47,70,72,75,83,86,88,89,98] (Table 1; Figure 5).

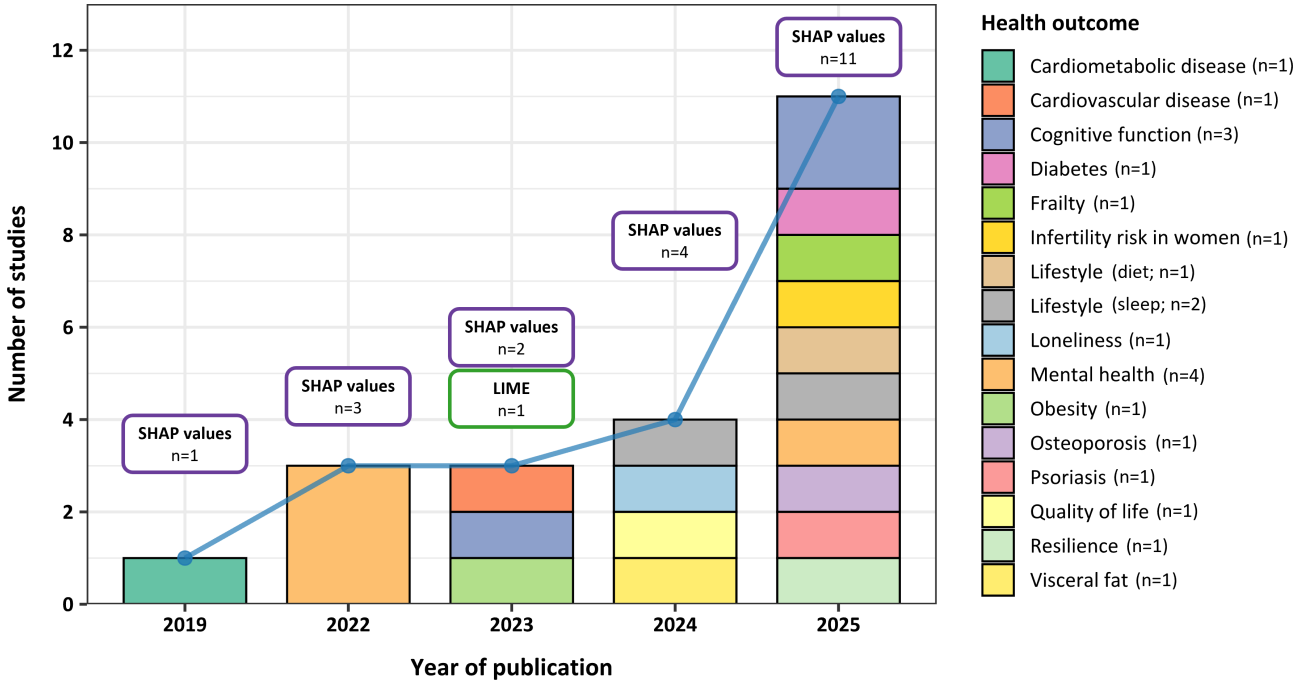
Support Vector Machine Algorithms

Support vector machine (SVM) algorithms were used in 19 (27.08%) studies, applied across various data types. SVM was implemented in 11 cross-sectional studies, 2 longitudinal studies, 3 time-series studies, and 2 studies that analyzed textual data. Configurations included support vector machine with a radial basis function [61,70,102,104] or a support vector machine with linear kernel [51,73,93,100]. Eleven studies did not report the type of kernel used [45,46,52,67,74,84,86,91,92,97,99] (Table 1; Figure 5).

Evaluation

Final model evaluation procedures were explicitly reported in 57 (87.69%) reviewed studies, with the hold-out test set being the most applied strategy. These included a hold-out test set [10,42,48,49,52,53,57,60,61,63,65-67,69,71-73,75,79,82-85,94,95,100,101], k-fold cross-validation (final evaluation) [40,41,43,44,47,50,51,58,68,70,74,78,81,87,88,91,92,97,98,104], nested cross-validation [64,93], leave-one-out cross-validation (for small datasets with n<150) [45,59,76]. Two studies used external datasets for model performance assessment [55,86]. For time-series data, 2 studies divided the dataset based on the time of acquisition, keeping an out-of-sample dataset for model evaluation [46,99], while 1 study [102] used 5-fold cross-validation in an offline setting followed by an online weighted resampling methodology to address drift.

Among the 11 studies that addressed regression problems, the reported evaluation metrics included mean absolute error [44,75,87,102], mean squared error [44,68,75], root-mean-square error [44,45,68,78,98,99,102], mean absolute percentage error [102], and coefficient of determination (R^2) [44,68,79,81,98,99].



For classification problems, reported evaluation metrics included specificity and sensitivity (recall) [41-44,47,48,58,63,66,72,76,82,85,86,91,93,95,104], precision and recall [40-43,48,61,70,80,86,100,101], the confusion matrix [42,48,80], error rate as the proportion of misclassified observations (1 – accuracy) [48,58,72,90], Cohen κ [58,72], F_1-score [41,43,49,59,70,80,86,91,100,101,104], and model training time [58]. The most frequently used metrics were accuracy [10,41-45,47-49,58,59,61,63,66,70,72,80,82,83,85,86,88,91,93,101] and area under the receiver operating characteristic curve [41-43,46-49,58,59,63,70,72-74,76,83,85,86,91,93,95,100,101,104] (Table S5 in Multimedia Appendix 1). Additionally, 1 epidemiologic study used the Brier score to assess cardiovascular mortality [53].

Explainability

To enhance explainability, 22 (33.84%) studies implemented specific XAI methods to clarify the contribution of each predictor and the direction of the relationship with the outcome. Of these, 21 studies used Shapley Additive Explanations (SHAP) values, while 1 used local interpretable model-agnostic explanations (LIME). As shown in Figure 6, XAI methods, particularly SHAP values, have been applied across different health domains, showing a remarkable increase in use in 2025. The most common visualization methods were beeswarm and bar plots, with the contribution of each feature ranked along the y-axis, placing the most important feature at the top of the plot. The number of features plotted ranges from 6 to 50, with 20 being the most common (refer to Table 2).

Because the nonlifestyle features included in each model vary substantially across studies, the ranking reported in Table 2 should be interpreted in relative terms. When a lifestyle behavior appears among the top-ranked features, this indicates that it contributed more strongly to the model than nonlifestyle variables included in the analysis. Conversely, lifestyle components appearing in lower positions acted as secondary predictors.

In a study on cardiometabolic disease [76], the ML solution was first explained at the individual participant level to provide specific behavioral feedback, and then at the group level to reveal the ranking of features for succeeding in behavioral changes. In both models, physical activity and diet variables were among the top contributors. However, in another study [65], neither regular physical activity nor diet habits were among the top 6 variables for predicting diabetes in adults.

In 4 mental health studies [64,67,80,85], SHAP values were used to rank the contribution of each feature. In 3 of the 4 studies, lifestyle variables were among the top contributors. In [80], physical activity and fruit and vegetable consumption; in [64], sleep variables were the top predictors of stress in young adolescents during the COVID-19 pandemic; and in [85], sleep duration was identified as important for predicting depression. However, in [67], the intensity of physical activity was unranked because it was excluded from the XAI analysis during a feature selection step prior to modeling. In the same study, sleep hours were the most important variable for predicting depression among adults. Regarding mental health studies, psychological resilience was assessed among medical students [56], with sleep disturbance being a key factor affecting their resilience.

Three studies focusing on older adults in China had cognitive function as their outcome [50,52,63]. In these studies, physical activity variables were ranked as top predictors. Additionally, in 1 of these studies [63], sleep quality was ranked as the eighth top feature out of 20. Furthermore, when loneliness was assessed among older adults from China [51], exercise was ranked as the seventh variable out of 15.

In a study predicting quality of life [91], stress, sleep quality, and physical activity emerged as the strongest predictors, with the eating index appearing in the top 15 variables.

Two studies focused on sleep as the specific outcome. In [86], the SHAP values ranked stress score, vegetable consumption, and sedentary time among the top 5 variables for predicting sleep disturbance. In [97], nutritional status was the third most important variable for predicting the risk of sleep disorders in older adults.

In [88], “favorable” food stores and global stress were identified as the top variables for predicting incidence of cardiovascular disease, with the availability of outdoor activities ranking in the top 5. In a longitudinal study investigating the association of diet with long-term reduction in waist circumference, SHAP values highlighted the importance of high-quality components in reducing visceral fat [83]. This study also measured exercise with a single item of frequency, which was not included in the top ranking. Regarding a diet study [94], the adoption of different diets in the Spanish population was assessed, with fish consumption positioned as the most important variable for all diets studied (Mediterranean, intermittent fasting, vegan, and vegetarian). In the same study, practicing sport was ranked among the top variables across the different diets. However, sleep quality was only included in the ranking for intermittent fasting and the vegan diet.

Physical inactivity emerged as the most important feature in explaining county-level obesity using LIME [87]. In this study, the food environment and insufficient sleep, both measured as single items, were not included as top predictors of obesity prevalence.

In a cross-national study assessing frailty [68], sleep variables were among the 20 most important variables across all the cohorts studied. Physical activity was included in the US and UK cohorts and was also ranked in the top 20 variables. In the UK cohort, fruit consumption was the 19th out of 20 key contributors to frailty.

One study on osteoporosis [84] used the Life’s Essential 8 scores for physical activity, diet, and sleep. Sleep and physical activity scores were among the 20 most important variables, but the diet health score was unranked. Similarly, the Life’s Essential 8 scores were used to determine infertility risk in women [60], with the diet score being the only one ranked among the top 10 variables.

Finally, 1 study combined lifestyle factors with metabolites associated with psoriasis [71], with physical activity intensity ranked among the 20 key factors out of 150 variables, whereas dietary habits were not ranked.

Software to Implement ML Models

Of the included papers in the review, 23 (35.38%) used R software (R Core Team) [105] for data analysis (Table 3). The R packages used were data.table for data manipulation, tidyverse [106] as a general package for data science, Multivariate Imputation by Chained Equations [107] for missing data imputation, missMDA for performing multiple imputation with principal component analysis, FactoMineR for exploratory data analysis and principal component analysis, Boruta [108] for feature selection through a wrapper algorithm, caret (Classification and Regression Training) [109] for creating models, randomForest for RF analysis, randomForestSCR for RF for survival, regression, and classification analysis, rpart for recursive partitioning and regression trees, xgboost for extreme gradient boosting, bartMachine for Bayesian additive regression trees, kernlab and e1071 for support vector machines, survival for survival analysis, lime for local interpretable model-agnostic explanations, and finally, SuperLearner [110] to choose the optimal learner for a given prediction problem with a k-fold cross-validation algorithm.

XSL•FO
RenderX

Table . Softwares used in the reviewed studies to perform machine learning (ML) algorithms.

Software used	Number of studies	Study references
R (R Core Team)	n=23	[41,45-47,49,54,55,69,72-74,77,78,80,87,90,93,95-97,99,101,111]
Python (Python Software Foundation)	n=24	[42,50,52,53,56,58,61,64,65,67,70,76,79,81,83,84,86,88,89,91,98,100,102,104]
R and Python	n=4	[57,63,68,71]
SPSS (IBM Corp)	n=2	[62,92]
MATLAB (The MathWorks Inc)	n=2	[48,66]
KNIME [112]	n=2	[43,44]

In contrast, 24 (36.92%) studies developed the models in Python (Python Software Foundation), using the following libraries: Scikit-learn, used in all studies for predictive data analysis; pandas, for manipulating tabular data; NumPy, for mathematical functions; Keras and TensorFlow, for implementing deep learning; lightGBM, for performing light gradient boosting machine; SHAP, to explain ML solutions; creme, for online ML; Bayesian optimization, as a global optimization package to find the maximum value of an unknown function in as few iterations as possible; imbalanced-learn, to combine either undersample or oversample methods; and TextBlob, emoji, nltk, and profanity, for processing and analyzing textual data.

Finally, 4 studies used both Python and R, and 6 studies used other software programs such as SPSS, MATLAB, and KNIME. Eight papers did not report the software used [10,40,59,60,75,82,85,94].

Discussion

Overview

This scoping review of 65 studies provides the current state of the application of supervised ML algorithms for the analysis of lifestyle data. The increase in studies in this field since 2019 indicates that it is a noteworthy area of study. The diversity in the sample origin, alongside the accessibility to new AI tools and novel methods for monitoring health outcomes (eg, wearables), denotes global attention to lifestyle. This section addresses the methodological shortcomings found in the reviewed studies.

About Data Acquisition

In relation to lifestyle data, we found that most studies adopted a multidomain approach, integrating more than just a single component. This strategy enhances and facilitates a more comprehensive understanding of health problems related to the 4 lifestyle domains considered in this review: physical activity, diet, sleep, and stress. The distribution of lifestyle domains identified here was similar to that reported in a previous scoping meta-review [113], although we observe that sleep has gained prominence in recent years, now reaching a level comparable to diet. Although these results highlight the growing recognition of the interrelated nature of lifestyle behaviors, the imbalance in the distribution of these factors limits the capacity of current studies to fully model and understand the interaction among the 4 lifestyle components and their combined effects on health.

Concerning the data acquisition process, over half of the studies acquired their own data. This acquisition process implies control over variables and reduces the time required for cleaning [114]. Interestingly, both self-acquired datasets and those sourced from private or public health repositories demonstrated gender parity in the analyzed datasets. However, we detected a major limitation in this part of the process regarding the data acquisition methodology. In most studies, data were collected through single items, such as regular physical activity (response “yes” or “no”) [58] or usual time of waking up and going to bed [62], resulting in low representativeness of the construct being measured. The result of this acquisition method is high heterogeneity in measures, which hinders their generalizability. Therefore, the quality of data must be one of the challenges to be addressed, and specifically, the consistency in measures [115,116].

Nevertheless, the current accessibility and precision of health sensors such as wearables [117] and the Internet of Things [118] may contribute to transferability and actionability in the population [119]. The growth in technology allows the integration of different data forms as well as more objective measures of lifestyle, substantially reducing the impact of retrospective bias by tracking real-time data in an ecological situation [120]. Therefore, merging questionnaires and sensor data may be the key to identifying relationships between lifestyle measurements and personalizing interventions or changes in specific behaviors. This integration would include physiological, psychological, and behavioral factors, which are the most common analysis types in the ML community to extract clinical insights [121].

About Characteristics of ML Models

Regarding the analysis of ML, 2 different approaches emerged in the reviewed studies: 1 focused on prediction through classification and regression problems, and the other focused on interpretability through feature selection. The first is already an acknowledged approach, while the second typically constitutes an important component of the ML process, specifically during the preprocessing stage. However, feature selection studies do not use model evaluation metrics, which can limit their statistical validity and the generalizability of results. Remarkably, the family of ML algorithms most closely related to feature selection is tree-based because it provides indices of the importance of each variable. Although most papers in this scoping review combined different families of algorithms and compared their results, the most common model family was tree-based, which was applied for each data typology identified.

XSL•FO
RenderX

Specifically, RF is the most used algorithm, which may be due to its robustness in handling missing values, the consideration of complex interaction in the data [122], and its lower sensitivity to variable scales [123]. Despite the benefits of RF, the underusage of DL algorithms represents a critical missed opportunity for robustly analyzing complex and multimodal data. In this review, DL algorithms were underused for lifestyle data. This result may reflect a gap in expertise or access to computational resources among lifestyle researchers, potentially limiting the application of more complex models. With ongoing advances in computational power and algorithmic efficiency, it is expected that the use of DL algorithms will become more widespread in the near future [124].

Regarding the preprocessing stage, most studies detailed some phases of the process, but there is no consensus on the description of this stage of ML. Variable transformation is a crucial step for certain algorithms, particularly for SVM and specific architectures of DL that exhibit sensitivity to the raw form of the variables. In this review, 12 out of 19 studies that performed the SVM algorithm, and 13 out of 26 studies focused on DL, reported variable transformation. Additionally, it is worth noting that these algorithms cannot handle missing values, requiring imputation before the modeling phase. Among the SVM studies, 11 out of 19 reported techniques for missing imputation, and 17 out of 26 DL studies explicitly addressed this. In contrast, tree-based algorithms are less sensitive to variable scales and missing values, yet incorporating these feature engineering steps could enhance model performance [123]. It is noteworthy that the preprocessing steps, specifically how missing values are addressed, have been identified as a potential concern for transparency. This procedural aspect could introduce sampling biases, thereby influencing the generalizability and comprehension of the dataset context [125].

Resampling techniques, aiming to balance the dataset, are commonly implemented in classification problems. SMOTE has been the most widely used technique in this review, especially because it achieves better results than a simple undersampling of the majority class. In the health domain, imbalanced datasets are common, and SMOTE oversamples the minority class with synthetic examples and randomly undersamples the majority class to balance the dataset [126].

Finally, dimensionality reduction enables capturing the most relevant information for the outcome while eliminating noise and redundant information. In this review, dimensionality reduction was the most frequent preprocessing step, appearing in 38 studies. Notably, not only could SVM and DL models benefit from removing irrelevant predictors, but also in tree-based algorithms, dimensionality reduction minimizes model complexity, resource consumption, and data acquisition costs [123].

The division of the original dataset is an essential step for assessing the performance of the ML solution. In this review, 8 studies did not report how they split their data to assess the model, which denotes a lack of generalization of their results. This omission represents a common issue in ML research that should be carefully addressed to minimize bias [127]. Train and test division, also known as “hold out,” is a method with considerable variability due to the use of a unique random data distribution [127]. Therefore, other methods might be more suitable. For example, leave-one-out cross-validation, which trains the model on “n – 1” observations and makes predictions on the remaining one. Although effective for small datasets, it is computationally intensive with large datasets [128]. K-fold cross-validation involves randomly dividing the original dataset into k groups. K-fold cross-validation not only offers computational advantage over leave-one-out, but also gives more accurate estimations due to the bias-variance trade-off [128]. In time-series data, only 1 paper [102] introduced a different form of data split, considering the dependencies of the entire series. Ideally, this type of data should be treated with a method called rolling forecast origin resampling, which estimates the model with historical data and evaluates it with the most recent data [129]. In other words, the training set should ideally comprise observations that occurred before those in the test set; however, this method was not found in this review.

Regarding the evaluation of ML models, the choice of metrics depends on the nature of the problem, whether regression or classification. Specific evaluation metrics tailored to each problem are crucial for correct evaluation, aligning with the priorities and needs of each field. For instance, in medical studies where the cost of treatment in terms of health is high, it becomes crucial to identify true patients over false positives. In contrast, if the treatment has minimal side effects and has demonstrated benefits, sensitivity might not be as important as specificity. It is worth highlighting that in the field of data science, precision and recall are more commonly used, whereas in medical fields, specificity and sensitivity are more prevalent [18]. These differences may cause misunderstandings between the 2 domains.

About Explainability Methods

Regarding model explainability, 22 studies incorporated a dedicated step in the ML process for explainability. SHAP values and LIME were the only XAI methods applied to lifestyle data, and these 2 methods were the most common in a recent systematic review on XAI methods [130]. XAI-related studies in this review were published since 2019, with a notable increase in the number of publications in 2025, comprising half of the papers. This exponential growth was also found in [27,28], where the trend in published papers occurred between 2016 and 2022. Thus, our review demonstrates this exponential distribution in the health and behavioral sciences, where XAI methods are gaining prominence.

Although tree-based algorithms, especially decision trees, are known for facilitating interpretation, SHAP values can be applied to any type of model [131]. The adoption of XAI in lifestyle studies remains low (33.84%). One possible explanation for this is that explainability algorithms are often not integrated into a standard ML pipeline, thereby increasing the technical complexity of the workflow. However, some efforts are being made by R and Python developers to incorporate XAI algorithms into pipelines using libraries such as H2O [132].

In this review, lifestyle components (physical activity, diet, sleep, and stress) consistently appeared among the top-ranked features in models using XAI techniques, highlighting their

XSL•FO
RenderX

substantive contribution relative to nonlifestyle variables. These findings align with prior research emphasizing the integration of diverse lifestyle components [133,134]. However, the level of interpretability achieved also depends on the quality of data used in the models, which in some studies did not meet expected standards. For instance, in a study where the focus was on obesity, the diet component was not among the top-ranked features [87]. In this county-level study, a food environment index was measured as a single item, potentially inadequately representing the diet component of lifestyle.

Therefore, integrating XAI methods into the ML process could enable tailored interventions based on model results, provided that measures are collected accurately. Furthermore, the adoption of XAI algorithms contributes to increased trust and verification of the fairness of the models. This approach can also facilitate the translation of findings to stakeholders and health systems, thereby enhancing transparency, promoting the adoption of models in society, and supporting informed decision-making [27].

About the Software for Implementing ML Models

Competition between Python and R for ML software dominance in data science is currently intense. Both Python and R are freely distributed, object-oriented software with large and active communities. Python, as a programming language, offers specific implementations through libraries tailored for statistical analysis, including ML and DL. In contrast, R is a statistical software that integrates fundamental statistics into its base functionalities. While Python requires libraries for each stage of analysis, its well-established libraries streamline the process. On the other hand, R faces challenges due to its heterogeneous libraries, which hinder replicability and require expertise in varying syntax across packages. To address this concern, the meta-package tidymodels (Max Kuhn and Hadley Wickham) resolves these issues by integrating all necessary packages for each ML step, using a unified syntax. Additionally, tidymodels integrates user-friendly interfaces and promotes good methodological practice, thereby preventing user errors [135]. Conversely, Python presents a preferable environment for DL with the TensorFlow and PyTorch frameworks. In this regard, the possibility of developing ML projects on powerful computational cloud-based platforms, such as Google Colaboratory (also referred to as Google Colab) [136], offers Python a remarkable advantage over R local environments.

Methodological and Reporting Guidelines and Checklist

Based on the review's results and to enhance transparency and replicability in multidisciplinary sciences [137], we provide comprehensive methodological and reporting guidelines and a checklist for ML projects. Although various studies have proposed guidelines and checklists [138,139], the rapid expansion of ML algorithms in health domains necessitates iterative evaluation to incorporate new steps into the ML research workflow. The guidelines and checklist (Checklist 2) are based on the 5 stages of the ML workflow, as depicted in Figure 2, with added software tools.

Data Acquisition

The integration of multidomain data enhances the comprehension of real-world problems. Using appropriate methods to collect data ensures representativeness. We recommend the use of standardized questionnaires and validated sensors. Regarding health repositories, we recommend providing information about data characteristics such as gender distribution, sample size, and variable descriptions [140].

Preprocessing

Reporting the preprocessing methods used in the data analysis is particularly crucial for ensuring replicability. While preprocessing contributes to improving data quality, different preprocessing methods can lead to different results. We propose the following recommendations for each preprocessing step, although not all steps need to be performed in every ML project.

Transformation

Categorical data should be encoded using methods such as one-hot encoding and dummy variables. Continuous data should be transformed using normalization or rescaling of features with different units to ensure algorithm performance, particularly for those sensitive to the raw form of variables [123].

Missing Imputation

Some algorithms cannot handle missing data and require imputation before modeling. Depending on the number of observations and the data distribution, imputation with the mean, median, or mode is typical. For time-series data, imputation with the last or next observation is preferred, though rolling statistics imputation or interpolation may offer better solutions [141].

Resampling

Imbalanced datasets can bias models, resulting in poor performance on underrepresented classes [142]. While SMOTE is an effective technique for handling imbalanced datasets, it is not without its limitations. However, when the class imbalance ratio is extremely high, SMOTE can potentially bias the model performance by overfitting the minority class. This issue is particularly pronounced in datasets containing noise, as synthetic observations may replicate these artifacts. To mitigate these challenges, recent studies have proposed tree algorithms, which have shown effectiveness in handling class imbalance [143]. Furthermore, due to their robustness, the use of tree-based algorithms is increasingly recommended when working with class imbalance [144].

Dimensionality Reduction

Removing noise from the dataset and retaining features directly related to the outcome can enhance both data acquisition and modeling efficiency. Removing correlated features is particularly beneficial [123].

Modeling

Our guidelines focused on SL algorithms for classification and regression problems. The choice of algorithms depends on the measurement of the outcome. We recommend using multiple algorithms to compare results and select the best fit, given that there is significant variability across problems [145].

XSL•FO
RenderX

Additionally, comparing different families of algorithms is also advisable, as some improvements exist within the same family. When it comes to replicability and transparency, reporting algorithm hyperparameters is crucial in ML problems, as different configurations can yield varying results [146].

Evaluation

Avoiding overfitting requires dividing the original dataset appropriately. This step is fundamental in ML implementation and should be considered in every study to ensure that the extracted insights are reliable and generalizable. This division depends on data typology; we identified 3 different typologies relevant at this stage, defined by whether time is an implicit factor in the data acquisition process.

Cross-Sectional

Data are collected at a single point in time, with no temporal dependencies. Leave-one-out cross-validation is effective for small datasets (n<150) typically seen in life sciences; the computational complexity increases [147]. K-fold cross-validation is recommended for large datasets to balance the bias-variance trade-off [128]. Cross-validation with bootstrap resampling can also be used to evaluate the performance of the models and estimate CIs of performance metrics [148].

Longitudinal

In longitudinal studies, researchers collect repeated measures, potentially with dependencies between observations and high correlation that can bias the model [135]. Data should be divided by grouping individual participants' information. The methods used are similar to those for cross-sectional data, but with consideration of partitioning.

Time Series

Time series data are a sequence of data points in chronological order. Rolling forecast origin resampling is suitable for this data [129]. The training set should include observations occurring before those in the test set.

Evaluation Metrics

Appropriate metrics should be selected based on the type of ML problem (regression or classification) [149] and the characteristics of the study field [18]. It is also recommended to compute evaluation metrics repeatedly across cross-validation samples and to apply nonparametric tests, such as the Wilcoxon signed-rank test and the Friedman test, to assess model performance [149]. For imbalanced datasets, performance metrics such as balanced accuracy and F_1-score are recommended. For example, in an imbalanced dataset, a model may achieve high accuracy by predominantly predicting the majority class. In contrast, balanced accuracy assigns equal weight to each class regardless of its frequency, providing a more informative evaluation of model performance [150].

Explainability

Explainability Overview

Reporting the method of explainability used in the ML projects is essential. It is important to distinguish between interpretability and explainability. While explainability refers to understanding the effect of each feature on the original model, interpretability involves deriving actionable insights from the model's prediction. Although tree-based methods include importance metrics, they do not indicate the direction of relationships with the outcome. Incorporating explainable resources such as SHAP values [151] or LIME [152] enhances the interpretability of the results, providing both actionability and transparency, and transforming black boxes into glass box models. The H2O package in R offers XAI algorithms that are compatible with the framework tidymodels, enabling a unified workflow for modeling and explainability. For a more detailed taxonomy of XAI packages in R, we refer the reader to [153].

Additionally, the choice of appropriate visualization methods and the number of features displayed are crucial for ensuring comprehensive results and supporting fine-grained decision-making. Regarding the number of features, we recommend visualizing at least the top 20 features whenever possible, as this allows a broader understanding of the contribution of the most important variables. Furthermore, future studies should report all model features used in the ML analysis, not only the top-ranked ones, to ensure full transparency and allow readers to verify which HL components were excluded or had low impact in the model. Based on SHAP values, we propose the following XAI visualization techniques [94,154]:

Beeswarm Plot

This is the most common summary plot, where features are ranked on the y-axis from most to least contribution by their mean absolute SHAP value. The x-axis represents the SHAP values, which express the change in the log-odds (or model output), resulting in a positive or negative contribution for a specific observation. Each dot represents an observation in the dataset, and the color is indicative of the original value for that observation. Higher values are displayed as red and lower values as blue. The vertical dotted line represents the zero SHAP contribution. Contributions to the right assign a positive effect, and those to the left assign a negative effect.

Dependency Plots

Scatter plots that show the effect a single feature has on the model's predictions. Each point represents an instance's feature value and its corresponding SHAP value. This plot provides a detailed and clear explanation of the direction and magnitude of the relationship (whether linear or nonlinear) between the feature and the outcome.

Bar Plot

This plot provides information on the global feature importance. Features are ordered on the y-axis from the highest to the lowest average contribution to the outcome.

Waterfall Plot

This plot is a local explanation that illustrates the contribution of each feature in transforming the expected value E[f(x)] into the final prediction f(x) for a specific instance. Each row represents a feature's contribution; positive contributions are red, while negative contributions are blue.

XSL•FO
RenderX

Force Plot

This plot is a local explanation that shows the effect and the direction of the most impactful features for a given observation.

Software

Python and R were the most widely used software in the review. However, the variety of libraries can complicate the process. To address this, the metapackage "tidymodels" provides unified syntax, enhancing replicability [135]. For DL, Python offers a more powerful environment thanks to PyTorch and TensorFlow frameworks and the possibility of developing analyses on cloud services such as Google Colab. Furthermore, we encourage researchers to make their code publicly available in open repositories such as GitHub.

Limitations

At the level of the review itself, some limitations emerge. Although time-series data were frequently used in the analysis of lifestyle behaviors, the primary focus of this review was on the methodological framework of supervised ML, rather than on specific time-series modeling approaches. Future research should specifically address this gap by examining the current use of time-series models applied to wearable data to better capture human behavior. Moreover, the exclusion of UL algorithms limits the scope of ML algorithms covered in this review. For example, cluster analysis has been used to classify children according to their eating behaviors and identify features related to obesity [155], with findings suggesting that interventions such as reducing eating speed may help prevent childhood obesity. This scoping review focuses on supervised ML approaches, but future research could examine the current application of UL in lifestyle data. Finally, a further limitation of this review is that the search strategy prioritized studies using the umbrella term "healthy lifestyle." While this approach captured a representative sample of research explicitly conceptualized as HL, it may have excluded multidimensional studies examining combinations of physical activity, diet, sleep, or stress that did not use this terminology. Although an interaction block was incorporated to address the interconnectedness among these domains, we acknowledge that some multidomain research may not have been retrieved due to the specificity of the search string.

Conclusion

This review has identified several limitations within the studies reviewed that need to be addressed. First, ensuring data quality remains a significant challenge that must be addressed by carefully selecting data acquisition methods to build reliable and robust models. Second, the evaluation process is crucial for preventing overfitting, and using hold-out cross-validation can lead to high variance partitioning. Therefore, it is recommended to implement k-fold cross-validation at various stages, such as during validation; for time-series data, rolling forecast origin resampling is recommended [129].

In conclusion, this scoping review provides a comprehensive analysis of lifestyle using ML models and serves as a guideline for future research. While the relationship between lifestyle and health is well-established, ongoing efforts are needed to refine how we measure lifestyle to create robust models. It is essential to focus not only on model performance but also on data representativeness, which is closely related to the granularity established during data collection. Although RF algorithms are prominent in lifestyle data analysis, it is recommended to compare their performance with other algorithms within and across families. Future research should also incorporate SHAP values to enhance interpretability within the ML workflow. Additionally, the *tidymodels* metapackage (R software) with H2O for XAI can assist researchers in evaluating process quality with unified syntax, thereby contributing to replicability.

Abstract

Background: Electronic health records (EHRs) play an essential role in modern health care, enabling data sharing and improving patient safety; however, even though vendors must adhere to International Organization for Standardization–related usability standards for EHR certification, persistent usability issues continue to undermine efficiency, contribute to clinician burden, and increase the risk of preventable errors.

Objective: This scoping review synthesizes existing research on EHR adoption and usability, emphasizing theoretical models, measurement approaches, factors, and analytic methods used to assess or predict usability. We identify gaps and opportunities for integrating predictive analytics and artificial intelligence (AI) to advance research and improve the usability of EHRs.

Methods: Following Joanna Briggs Institute and PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, we systematically searched MEDLINE, Web of Science, IEEE Xplore, and Scopus library databases for studies published between January 1, 2009, and April 9, 2025. Inclusion criteria focused on empirical research using predictive methods or models related to EHR usability. Data were charted and synthesized thematically.

Results: Of the 2323 screened papers, 47 studies met inclusion criteria. Most research examined or predicted EHR adoption (not usability) using dominant frameworks, such as the technology acceptance model, unified theory of acceptance and use of technology, and the information system success model, which comprised usability. Factors related to usability—particularly perceived usefulness, perceived ease of use, effort expectancy, and facilitating conditions via the EHR adoption models—appeared frequently. Regression-based methods and structural equation modeling were the most common analytic techniques. No studies applied predictive modeling or AI to predict EHR usability.

Conclusions: The focus of this study on the prediction of EHR usability and adoption for the past 15 years is distinctive in the literature. It extends prior usability reviews (mostly focusing on adoption, not prediction of usability). Predictive modeling for EHR usability remains underdeveloped throughout 2009 to 2025. Dominant frameworks in the EHR literature continue to prioritize predicting adoption over operational usability. These models rely heavily on self-reported, cross-sectional measures captured at a single postimplementation time point, embedding systematic bias and obscuring longitudinal usability dynamics. Despite the application of increasingly sophisticated predictive techniques—primarily variants of regression and structural equation modeling—usability has remained analytically subordinate to adoption and acceptance constructs for more than 15 years. As a result, widely used models, such as the technology acceptance model and unified theory of acceptance and use of technology, position usability merely as an antecedent to intention or use, rather than as an independent, system-level property that can be empirically measured, modeled, and predicted. Therefore, there is substantial opportunity to integrate predictive analytics, AI, and longitudinal usability measures to build dynamic models.

artificial intelligence; electronic health records; perceived usefulness; predictive analytics; technology acceptance model; usability

Introduction

Electronic health records (EHRs) are central to modern health care delivery, enabling real-time access to patient information, supporting continuity of care, and enhancing clinical decision-making. However, persistent usability challenges continue to increase cognitive workload, reduce user satisfaction (US), and contribute to patient safety risks [1-5]. Usability can be defined as the extent to which a system can be used efficiently, effectively, and satisfactorily by specified users in

XSL•FO
RenderX

a specified context (International Organization for Standardization [ISO] 9241‐11) [6]. In contrast, adoption refers to the extent to which users accept and implement technology [7]. Usability can directly influence the uptake of the system; however, it is not the same as adoption.

Studies show that inadequate usability contributes to data entry errors, inefficient workflows, increased cognitive burden, and user frustration, thereby limiting the potential benefits of EHRs [8,9]. While EHR vendors adhere to certification processes, these often fail to capture human factors that shape system utility and usefulness [10,11]. Reliable measures of the usability of EHRs—particularly those that can predict performance before and after go-live—remain scarce, and even fewer studies have examined usability over extended durations post implementation of ≥1 year [12].

Over the past 2 decades, theoretical frameworks, such as technology acceptance model (TAM), unified theory of acceptance and use of technology (UTAUT), and the DeLone and McLean (D&M) information system success (ISS) model, have been widely applied to understand EHR adoption and acceptance. Core determinants in the constructs of these theoretical frameworks, such as perceived usefulness (PU) and perceived ease of use (PEOU), consistently predict user intentions and behaviors [13,14]. However, these adoption models often rely on cross-sectional surveys to collect data to run the model and do not comprise any ISO or industry standards, offering limited insight into how the EHR system performs, as usability evolves over time. Hill et al [7] concluded that despite the widespread adoption of EHR systems, a very small number of research papers analyzed the use, impact, and weaknesses of existing search functions for clinical tasks. Moreover, EHR usability changes dynamically with user experience and across the software development life cycle [15,16], which EHR adoption frameworks do not capture.

Many EHR interfaces remain cluttered, nonintuitive, and difficult to navigate, requiring ongoing training [1]. Such design limitations increase cognitive workload, prolong documentation time, and contribute to alert fatigue and workflow interruptions [17-19]. Physicians spend nearly half of their workday interacting with EHRs [20]. Alert fatigue, task switching, and interoperability failures further reduce usability standards and compromise care coordination [21,22].

A range of methods has been employed to assess usability. Heuristic evaluations allow for comparisons of EHRs against usability principles [23,24], while clinician-based testing highlights workflow inefficiencies and inadequate training [25]. Surveys reveal widespread dissatisfaction, with 70% of physicians citing usability concerns [26]. PU indicators include improved performance, productivity, and effectiveness [27], whereas PEOU indicators include learnability, clarity, flexibility, and ease of becoming skillful [28]. The D&M ISS model extends these perspectives with constructs such as system quality (SQ) and information quality (IQ) [29-31]. However, these models typically lack task-level analyses, despite evidence that inefficient task flows waste time, increase errors, and reduce physician satisfaction, altering the behavior, intent, and acceptance of adopting the EHR workflow [32-35].

Audit logs and system metadata provide opportunities to quantify usability through measures such as task completion time, error rates, system usability scale (SUS) scores, National Aeronautics and Space Administration-Task Load Index (NASA-TLX) scores for cognitive load, clickstream and keystroke logs, US surveys, and eye-tracking data [24,36,37]. Yet these metrics are not captured by EHR adoption models and are rarely used to predict specific usability problems or outcomes.

Emerging approaches in data mining, human-computer interaction (HCI), and artificial intelligence (AI) offer new opportunities for predictive modeling of usability. Techniques such as logistic regression, decision trees, random forests, gradient boosting (eg, XGBoost), support vector machines, and neural networks—including recurrent neural networks, convolutional neural networks, and long short-term memory networks—have been applied to analyze system logs, classify sessions, and model usability [38-40]. Predictors such as interaction complexity (eg, clicks per task), alert fatigue, workload peaks, demographic variables (eg, age and digital literacy), and prior EHR training have also been identified [19,21,25,31,37]. Integrating such factors into dynamic feedback loops could enable continuous monitoring and improvement for safety-enhanced design with vendors and end users in clinical settings. However, the extent to which these approaches have been systematically applied in EHR usability research remains to be fully studied.

Given the large datasets (eg, Office of the Coordinators Certified Health Product List dataset of usability testing results for EHR certification [41] that had been collecting data on EHR usability from 2014 until the present), this knowledge could be useful for predicting and anticipating potential usability problems with specific EHRs. Additionally, the data could be mined and used for supporting, selecting, and procuring usable EHRs for health care organizations that match their contexts, as well as for predicting and anticipating usability issues that may occur over time.

To address these gaps, we conducted a scoping review to examine any existing research that predicts the usability of EHRs with special emphasis on postimplementation. The main research objective was to examine and identify gaps in the literature on the prediction of EHR usability that could follow how theoretical frameworks, usability metrics, and analytic methods have been applied. By doing so, we aimed to critique existing models and highlight opportunities for predictive factors in EHR usability research and any further development of dynamic approaches to predict usability. These insights into the usability of EHRs over time and across systems are of value to health care organizations, system designers, EHR vendors, government certification bodies, and clinicians.

Methods

Design and Framework

Methodology and Data

This scoping review began on February 10, 2023. Our review followed the Joanna Briggs Institute (JBI) scoping review

XSL•FO
RenderX

methodology and adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) reporting guidelines (Checklist 1) [42]. The sequential steps defined by Arksey and O'Malley [43] were applied: (1) identifying the research question, (2) identifying relevant studies, (3) selecting studies for inclusion, (4) charting the data, and (5) collating, summarizing, and reporting the results.

Four electronic databases were searched: MEDLINE (Ovid), Web of Science, IEEE Xplore, and Scopus. The MEDLINE database was selected because it comprises operational research on EHRs in clinical settings, nursing, health care, and related fields from 1946 to the present. Similarly, the Web of Science database was selected because it contains research on EHR usability in clinical settings, HCI journals, implementation science, and human factors research on EHRs across sciences, social sciences, arts, and humanities. The IEEE Xplore database was selected because it contains papers about HCI with EHRs and technical considerations of implemented EHRs related to usability across computer science, engineering, and electronics. Finally, the Scopus database was selected because it contains human factor research across scientific and technical fields (health, physical, and social science) plus arts and humanities.

Step 1: Identifying the Research Question

The research questions were as follows:

1. What is the state of the literature relevant to the prediction of EHR usability?
2. What studies have been conducted that predict or model EHR usability?
3. What factors are used to predict EHR usability?
4. Which methodologies have been used to evaluate or predict EHR usability?

Step 2: Protocol Registration, Screening Reliability, and Data Charting Procedures

This scoping review was conducted in accordance with the JBI methodology and reported using PRISMA-ScR guidelines. A formal review protocol defining the research questions, eligibility criteria, search strategy, and data charting framework was developed a priori and finalized prior to database screening. To ensure screening reliability, 3 independent reviewers (DC, EMB, and AK) conducted both title/abstract and full-text screening, with conflicts resolved through structured consensus meetings. Interreviewer agreement was monitored throughout the screening process, and discrepancies were discussed until full agreement was achieved, thereby strengthening internal validity. The reviewers AW, EMB, AK, AT, and DC have published and worked with EHRs, and all have experience and expertise as content experts and as methodological experts.

Data charting followed a structured extraction framework that systematically captured study design, theoretical models, analytic methods, usability metrics, predictors, and outcomes. Charting was conducted iteratively and audited across multiple cycles to ensure internal consistency and completeness. Inclusion and exclusion criteria were defined a priori with a clear rationale grounded in the study objective of identifying predictive—not purely descriptive—approaches to EHR usability, thereby justifying the exclusion of studies focused solely on organizational acceptance, vendor reports, non-EHR systems, or clinical outcome prediction without a usability construct. These safeguards ensured methodological transparency, reproducibility, and commitment to JBI and PRISMA-ScR standards.

Step 3: Identifying Relevant Studies

Eligibility criteria were defined using inclusion and exclusion rules that determine whether a study was relevant to the research question (Table 1). Inclusion and exclusion criteria were established before the first screening was carried out. The criteria specified study characteristics, such as publication timeframe, focus on usability, predictive methods, and EHR/electronic medical record (EMR) context for inclusion.

XSL•FO
RenderX

Table . Inclusion and exclusion criteria in the search strategy.

Domain	Inclusion criteria	Exclusion criteria
Modeling frameworks	• Adoption- or sociotechnical-related factors linked to usability • Regression analyses or modeling approaches aimed at predicting usability • Analytic approaches and measurable usability in EHR[a] adoption frameworks	• Papers describing organizational-level acceptance only • Papers linking usability to safety only • Health information technology (HIT) only
Electronic records	• EMR[b] and EHR, or broader health information system contexts • EMR and EHR adoption	• Dental systems, medication systems, and pharmacy • Personal health record • General information systems, eye care, and radiology • Surveillance • Laboratory information systems
EHR adoption and usability	• Technology acceptance or sociotechnical models relevant to usability • User-centered design, tasks, social-technical • User acceptance, patient safety • User satisfaction, human-computer interaction • Safety-enhanced design • Cognitive task load	• Usability survey only • Usability of other systems • User experience only
Informatics and data used in the model	• Usability data modeled • User experience data modeled • EHR adoption	• EHR data, Public Health Informatics • Patient data and EHR phenotyping • Medical conditions • Health information exchange • Clinical data
Artificial intelligence	• Data mining, regression, confirmatory analysis, hierarchical regression, and exploratory factor analysis • Text mining • Algorithm • Machine learning and deep learning	• Pattern recognition and large language models
Context	• Prediction or analysis EHR or EMR	• Clinical or solely clinical context
Time frame	• From January 2009 to April 9, 2025	• Published before 2009
Study design	• Usability research studies • Qualitative and quantitative analyses • Cognitive load with the EHR usability model • Usability data analysis of EHRs	• No literature reviews, commentary, or opinion • Papers without full text • EHR data analysis for medical outcomes • No technical reports • No position or opinion viewpoints • No vendor-based reports

[a]EHRs: electronic health records.

[b]EMR: electronic medical record.

These inclusion criteria were defined to capture studies using quantitative, qualitative, or mixed methods approach that assessed, modeled, or predicted aspects of EHR usability, EHR adoption, or sociotechnical factors primarily. The exclusion criteria removed research papers that were not related to EHRs, studies focused on usability but not prediction, and excluded literature reviews, opinion papers, or technical reports. All papers included were in English only.

Search Strategy

A comprehensive search was conducted across 4 databases—MEDLINE (Ovid), Web of Science, IEEE Xplore, and Scopus—to identify studies evaluating or predicting EHR usability. All searches were limited to English-language publications from January 1, 2009, to April 9, 2025. Keyword strategies incorporated terms related to usability, prediction or analytics, and EHRs.

XSL•FO
RenderX

The search strategy included combinations of controlled vocabulary terms and keywords related to usability ("usability," "user experience," "human factors," "human-computer interaction"), prediction ("predict*," "regression," "data mining," "machine learning"), and EHR ("EHR," "electronic health record," "EMR").

Search strategies for each of the 4 databases were as follows:

1. IEEE database ((((usability OR user OR "human factors" OR "human-computer interaction")))) AND (("predict*" OR "classif*" OR forecasting OR "data mining" OR "text mining" OR "regression*" OR "confirmatory factor analy*") AND (EHR OR "electronic health record*" OR EMR OR "electronic medical record*")).
2. Web of Science (usability or user or "human factors" or "human-computer interaction") AND (predict* or classif* or forecasting or "data mining" or "text mining" or "regression*" or "confirmatory factor analy*") AND (EHR or "electronic health record*" or EMR or "electronic medical record*").
3. MEDLINE (Ovid) ((usability or user or "human factors" or "human-computer interaction")).tw,kf. AND (("predict*" OR "classif*" OR "data mining" OR "regression*" OR "confirmatory factor analy*" OR algorithm*)).tw,kf. AND (EHR or "electronic health record*" or EMR or "electronic medical record*").tw,kf.
4. Scopus (TITLE-ABS ((usability OR user OR "human factors" OR "human-computer interaction")) AND TITLE-ABS (("predict*" OR "classif*" OR "data mining" OR "regression*" OR "confirmatory factor analy*")) AND TITLE-ABS (ehr OR "electronic health record*" OR emr OR "electronic medical record*")) AND (LIMIT-TO (LANGUAGE, "English")) AND (LIMIT-TO (SRCTYPE, "j") OR LIMIT-TO (SRCTYPE , "p")).

Screening, Data Extraction, and Analysis

Step 4: Study Selection

Title and abstract screening were completed by 3 reviewers, namely EMB, AW, and DC. Each reviewer independently screened the titles and abstracts of papers, with conflicts resolved by consensus during regular review meetings via Covidence. Title and abstract screening established the study section as a quick review of papers that the reviewers deemed included or excluded based on the inclusion and exclusion criteria. For papers that met the eligibility criteria, the papers were analyzed using a conventional content analysis approach to review the papers, chart the data, and identify themes.

For papers that did not meet the criteria, the reviewers noted this. Once the first screening was completed, the second full-text screening was then conducted to determine final eligibility. Studies were excluded during screening if they did not address usability or EHR-related usability via EHR adoption models; did not include predictive or analytic methods; did not directly examine EMR/EHR usability; lacked empirical methods or analytic rigor, or had the wrong study design.

The screening workflow ensured that only studies with explicit relevance to usability measurement, modeling, or prediction were retained.

Data extraction was carried out using a structured template. Extracted variables included study design, country and year, models or frameworks used, adoption determinants, usability-related metrics or instruments, analytic methods (eg, regression, SEM), main predictors examined, and key findings. Extraction fields were defined a priori to ensure consistency and comprehensiveness across studies.

Steps 5 and 6: Charting, Collating, and Reporting with AI Method Utilization

Study characteristics were manually charted by the research team. These characteristics included country of study, publication year, keywords, study design, analytic method, and predictive or explanatory techniques.

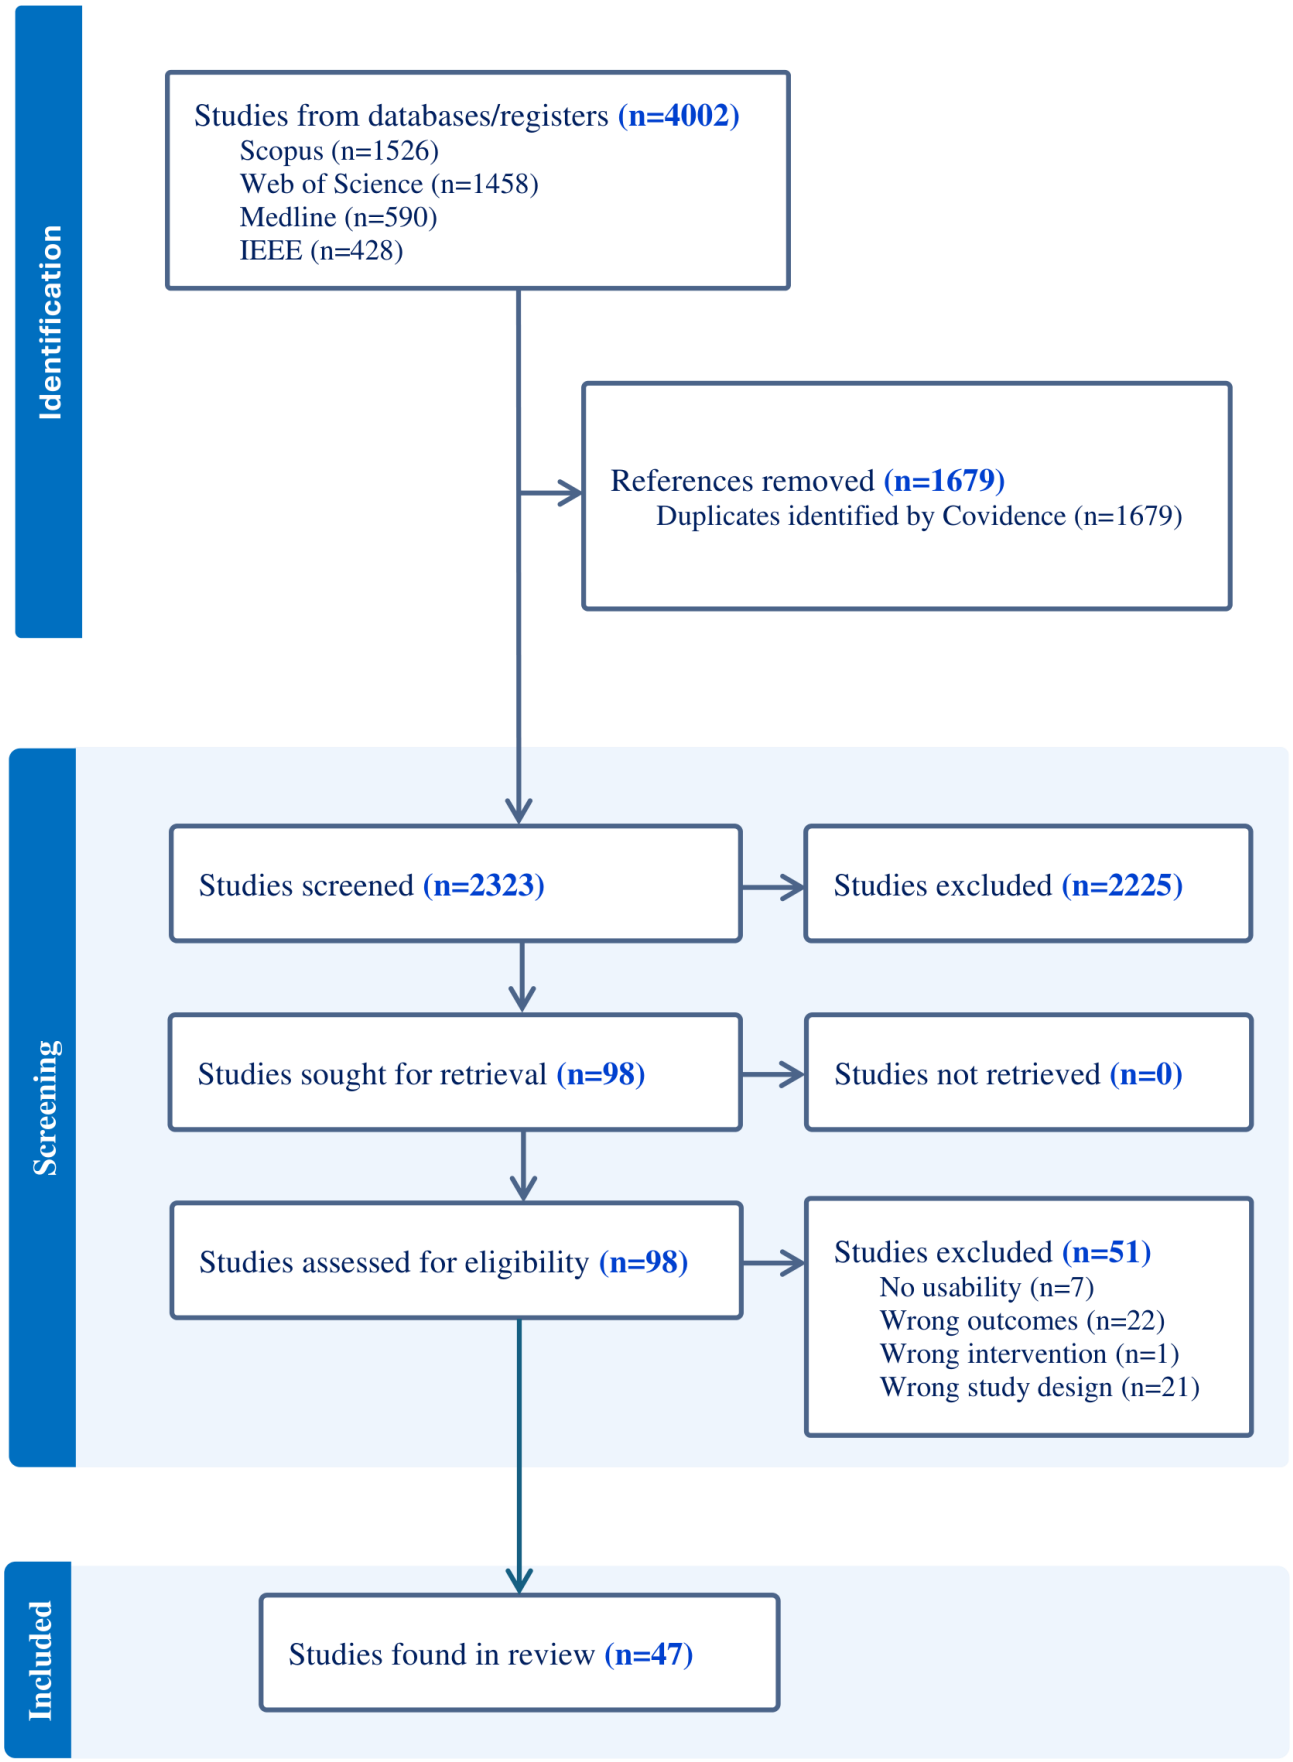
Extracted variables and categorizations were cross-checked using ChatGPT (GPT-5) to identify inconsistencies, ensure terminology alignment, and cross-check study characteristics. It should be noted that GPT-5 was used after manually updating the critique of the 47 journal papers (2009-2025) in Table S1 in Multimedia Appendix 1. It did not reproduce that table. For each of the papers selected for full review, GPT-5 was prompted with the instruction "summarize the study design, models, factors, significant findings and overall critique" to cross-check the content of the table's columns of models, factors, and critique. The response from GPT was mostly consistent, with only a few discrepancies found between GPT-5 and the human researcher. Any discrepancies were manually reviewed and updated thereafter. GPT-5 was only used for checking human processes in the review and critique of the papers found. GPT-5 was also used to obtain frequency counts for categories of predictive techniques in the papers. This was also cross-checked with frequency counting by the human researcher, with any discrepancies in the categories and the counts resolved through further analysis by the human researcher.

Ethical Considerations

This study was reviewed by the University of Victoria Human Research Ethics Board (UVic HREB) Chair and determined to be exempt from formal human research ethics review because the research does not involve human participants and is limited to the analysis of existing, publicly available documents and/or datasets. The determination was made in accordance with the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans (TCPS2 2022) and the University of Victoria Board of Governors Research Policy RH8100 and University of Victoria Board of Governors Regulations for Research Involving Humans RH8105. The UVic Human Research Ethics Chair concluded that the activities described in this study fall outside the scope of research requiring institutional ethics review because they do not involve human participants, human biological materials, or identifiable private information. The work is limited to the analysis of publicly available documentation and datasets.

Results

Study Selection and Characteristics



The included studies were drawn from 4 major databases: Scopus (n=1526), Web of Science (n=1458), MEDLINE

XSL•FO
RenderX

(n=590), and IEEE (n=428). Database searches yielded 428 papers in IEEE Xplore, 1458 in Web of Science, 590 in MEDLINE (Ovid), and 1526 in Scopus. After the removal of duplicates (n=1679), a total of 2323 records underwent title and abstract review in the first screening (Figure 1). A total of 98 full-text papers were assessed during the full-text screening. In the full paper screening, 51 records were excluded because of wrong outcomes (n=22), wrong study design (n=21), studies that did not address usability (n=7), and wrong intervention (n=1). Thus, a total of 47 studies met the full screening eligibility and were retained for analysis.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

From 2323 records screened, 47 studies met the inclusion criteria. The majority were cross-sectional surveys that applied TAM, UTAUT, or ISS frameworks to evaluate EHR adoption and US. Common predictors included PU, PEOU, effort expectancy (EE), and facilitating conditions (FCs).

XSL•FO
RenderX

Cross-sectional designs were the most common (31/47), followed by survey-based studies (26/47) (Multimedia Appendix 2). Almost all studies were conducted postimplementation. Data collection methods most frequently included direct data capture (36/47) and questionnaires (31/47). Regression analysis was the most common modeling approach (26/47).

Study Characteristics, Metrics, and Data Sources

Across the 47 included studies, EHR adoption was most commonly predicted with usability measures that were predominantly subjective, relying on surveys and self-reported satisfaction. Objective indicators—such as task completion time, error rates, and audit log data—were rarely incorporated, and no study combined task-based HCI data with predictive analytics for longitudinal monitoring.

The reliance on survey-based methods, with limited integration of task-level or objective usability metrics, was a consistent finding. Acronym use across the studies (Table S1 in Multimedia Appendix 1) reflects a synthesis of 47 studies from 26 countries (2009 - 2025), largely dominated by TAM, UTAUT, and D&M ISS frameworks. Analytic approaches included regression, SEM, and in a small number of studies, machine learning or decision trees. While nearly every study examined adoption or acceptance, very few explicitly focused on prediction even with the EHR adoption constructs with significant determinants.

Model Applications

TAM and UTAUT frameworks in many studies were evaluated using regression and SEM. Some studies used confirmatory factor analysis (CFA) and exploratory factor analysis to validate constructs. A small number integrated machine learning or neural networks with SEM, but no study applied AI to predict EHR usability.

Regression was the most commonly applied predictive analytic method, followed by SEM, which was the most frequently applied analytic methods, supplemented by ANOVA, multivariate ANOVA, CFA, and exploratory factor analysis in 13 studies [18,44-55].

Common Determinants and Constructs

Table S1 in Multimedia Appendix 1 presents 26 reported adoption-related determinants and model constructs such as TAM, tripolar model of technology acceptance, theory of planned behavior, UTAUT, and Systems Engineering Initiative for Patient Safety (SEIPS) that had usability aspects of EHR/EMR that included (1) PU, PEOU, performance expectancy (PE), user behavior (UB), and US; (2) behavioral intention (BI), EE, FCs, and job relevance; (3) IQ, IT support, organizational culture, SQ, and service quality (SRQ); (4) broader usability frameworks and scales, such as the NASA-TLX, National Usability–Focused Health Information System Scale (NuHISS), and SUS.

Frequency of Metrics

Metrics were grouped into nine categories: (1) attitudes and social aspects, (2) behavioral and intention-related factors, (3) IQ, (4) organizational and environmental factors, (5) PU, (6) SRQ, (7) SQ, (8) US and perceived usability, and (9) work efficiency and productivity.

FC, defined as the degree to which an individual believes that an organization and its technical infrastructure exist to support the use of the system [56], was the most frequently measured determinant construct, or predictor variable, followed by PEOU, PU, and attitude. In total, more than 50 unique usability-related metrics were reported across the 15-year span of literature.

Temporal and Geographic Distribution

The studies spanned 16 years from 2009 to 2025, with 12 published before 2015 (Multimedia Appendix 3). Study duration was, on average, less than 1 year and ranged from 2 months to 14 years. No clear temporal trend was observed, though extending the screening into 2023 to 2025 revealed an increasing number of studies. However, databases searched in 2025 only included papers published in that year up to April 9.

Geographically, the 47 studies originated from 26 countries (Multimedia Appendix 4). The United States (10 studies) and Finland (5 studies) contributed the largest number of studies found. North American studies more often employed the D&M ISS model compared to other countries, while nursing-focused studies frequently adopted the UTAUT framework.

Keywords and Clusters

Most frequent keywords across studies were EHR, usability, TAM, and UTAUT (Multimedia Appendix 5).

Across all studies published between 2009 and 2025, no study directly predicted EHR usability using computational or longitudinal modeling techniques. Most research examined adoption outcomes, satisfaction ratings, or intention-to-use constructs rather than usability performance or workflow-based usability metrics. Psychometric determinants (eg, PU, PEOU, EE, and FC) were frequently evaluated across adoption frameworks.

Regression and SEM techniques predominated, supporting cross-sectional inferences but offering limited value for forecasting usability over time. Although FCs often emerged as a significant predictor of intention-to-use EHRs, they were rarely examined within dynamic contexts, task-based assessments, or sequential workflows that reflect actual clinical use.

There were 95 predictive techniques of analysis across 12 technique categories found, with many studies using multiple techniques (Multimedia Appendix 6). Regression-based methods dominated (40/95) [15,17,18,27,44,45,47-49,51,55,57-73] (Multimedia Appendix 7) followed by SEM (26/95) [50-55,74-77]. Furthermore, there were several regression and SEM variants in the studies found.

Only a limited number of studies incorporated AI-related techniques, but these were used for prediction of EHR adoption and not for usability. Almarzouqi et al [78] used neural networks with SEM to predict adoption, Alsyouf and Ishak [79] used decision trees with heuristic evaluation and UTAUT, and Sachdeva et al [74] used decision trees to discover behavior patterns. Cluster analysis was used to predict general BI [79] and evaluate EHR use in primary care providers [70]. Four studies used principal component analysis for dimensionality reduction and feature extraction [44,45,70,74].

XSL•FO
RenderX

Discussion

Key Findings

Across 47 studies, regression and SEM dominated, indicating minimal methodological progression toward predictive, automated, or real-time usability modeling.

This scoping review found that EHR adoption models dominated studies identified using usability and prediction-related keywords. However, adoption is not synonymous with usability, despite often being treated as interchangeable in the literature. As noted by Shachak et al [80], models such as TAM and UTAUT reduce complex sociotechnical properties of health information technology to individual perceptions and intentions, privileging acceptance over system-level performance and postimplementation use. Consequently, usability was assumed through adoption intent rather than directly measured or predicted.

The predominance of EHR adoption models in the reviewed studies underscores the need to address postimplementation system success. EHRs are complex sociotechnical systems in which usability emerges from interactions among interface design, configuration, organizational context, and user roles, making post hoc evaluation insufficient for meaningful intervention.

The continued use of TAM, UTAUT, and D&M ISS models highlights an enduring emphasis on explaining acceptance and satisfaction rather than modeling or forecasting usability performance in clinical practice. Developing predictive models could shift usability research from reactive post hoc assessment to proactive identification of inefficiencies, workflow burdens, and potential contributors to clinician burnout.

This scoping review highlights that although the TAM, UTAUT, and D&M ISS provide useful foundations for understanding adoption, they offer limited ability to capture evolving usability patterns with task complexity or changes in user interaction over time. Poor usability (clunky interface and workflow disruption) hinders adoption and satisfaction, causing burnout, whereas good usability (intuitive design and efficient workflows) drives adoption and better patient outcomes, even if a system is technically adopted. Thus, an EHR can be widely adopted but still have terrible usability that leads to frustration and workarounds. Therefore, predicting usability adds value to adoption and more insight as the system becomes operationalized.

The predictive focus distinguishes this study. Zhang and Walji [12] conceptualized EHR usability as a balance between intrinsic complexity (reflecting the work domain's inherent demands) and extrinsic difficulty (stemming from interface and workflow design). Their TURF framework—task, user, representation, and function—offers a roadmap linking usability determinants such as usefulness, satisfaction, and efficiency. Despite its potential, none of the included studies applied TURF to predictive modeling of EHR usability. EHR metadata, including audit or task logs, could serve as the foundation for predictive models of usability and clinician workload or burnout [34]. Significant predictors, such as PEOU and PU, highlight opportunities for AI-driven approaches that integrate adoption constructs with task-level metadata to advance predictive usability research.

Across the 16-year period reviewed (2009 - 2025), very few studies attempted to predict EHR usability directly, regardless of model sophistication. The facilitating conditions, such as the predictor variable of EHR adoption, appeared to be significant and impacted the intent to use EHRs. The FC determinant is defined as "the degree to which an individual believes that an organization and its technical infrastructure exist to support the use of the system" [56]. This psychometric determinant was deemed to be a useful metric for predicting adoption.

FCs have a direct positive effect on the intention-to-use, but this effect often diminishes after initial system use, suggesting its relevance may shift toward sociotechnical factors affecting learnability and decision-making. That is, the FCs would have linkages to sociotechnical aspects related to learnability, which is one of the factors in usability as defined by Nielsen [81]. The implications for understanding HCI and clinical decision-making suggest that survey-based constructs may insufficiently capture deeper usability determinants rooted in workflow, cognitive processes, and task structure, as mentioned by Kushniruk et al [82]. The review showed that several countries represented in their use of EHR adoption models over the past 15 years to find success or failure in the actual or intended use of EHRs postimplementation.

None of the reviewed models predicted EHR usability. In addition, no models incorporated detailed task-level inputs (eg, time-on-task, error rates, and interaction complexity) into predictions of intended or actual system use. Instead, many studies focused on PEOU or PU as attributes of usability and not tasks. Nevertheless, these attributes are important to establish (eg, easy to learn, efficient use, easy to remember, few errors, and subjectively pleasing) as recognized core usability attributes in the concept of usability engineering in the 1990s as defined by Nielsen [81]. Therefore, this result from the literature review makes it clear that predicting EHR adoption based on BI and actual use is still under investigation, with very limited modeling related to EHR usability. Importantly, the models used in the papers did not state that categories or aspects of usability and their usefulness could be dynamically utilized postimplementation.

Logistic regression or hierarchical regression via SEM with many predictive variables and hypotheses was studied in several of the papers. However, these approaches generally reflect relationships among perceptions rather than true indicators of usability performance. Aspects of task completion or failure appear directly related to usability, yet they were rarely used to establish predictive usability metrics. Furthermore, SEM in the studies [48,50-54,59,64,75,76,78,83-86] showed complex networks of hypotheses linked through latent constructs. This highlights the need for more evidence connecting specific usability issues (eg, coded problems from video-based testing [82]) with operational real-world EHR use, which takes time, and predictive models of EHR usability could reduce the burden of large and extensive usability testing.

XSL•FO
RenderX

Interpretation of Findings

The literature indicates an increasing sophistication in applying TAM, UTAUT, and D&M ISS constructs by researchers, often through SEM. Many predictive analytics applied within these models reflect the complexity of usability-related factors. Researchers frequently tested 10 to 15 hypotheses of TAM, UTAUT, or ISS in the analysis, demonstrating rigorous statistical approaches. However, the extensive statistical testing often highlighted variability in the acceptance or intention to use the system postimplementation rather than convergence toward models capable of predicting usability. A major trend was the use of TAM or UTAUT with SEM to evaluate multiple factors—even though many of these factors could, in principle, support predictive usability modeling, for example, by linking task-based observations with survey responses.

SEM's prominence reflects its origins in psychology and social sciences, where latent constructs such as attitudes and intentions have long been modeled through survey-based items. The Task–Technology Fit framework has also been used in SEM to assess alignment between tasks and IT [87]. CFA was commonly employed to evaluate usability parameters within hierarchical regression models [48]. However, the reviewed studies modeled adoption, satisfaction, or BI, which are important and should be done in unison with usability testing to evaluate its efficiency with UB and acceptance.

Global Distribution and Framework Use

The 47 studies, representing 26 countries, indicate global interest in EHR adoption research. Regional differences were minimal, although the D&M ISS model was used more frequently in North America. In 2024, Rihayha and Ismaili [52] proposed a modified human–organization–technology fit model for resource-limited settings, integrating SQ, IQ, and SRQ via SEM. Hyppönen et al [48] proposed adoption predictors, including user friendliness, perceived benefits, technical problems, and cooperation metrics, applying NuHISS in Finland. Welchen et al [88] applied NuHISS in Brazil through a star-schema confirmatory analysis. Even though NuHISS is very detailed, it lacks objective usability measures such as error rates and time-on-task. The use of NuHISS across multiple countries was a major finding, though no multicountry comparative studies were identified.

TAM and Its Determinants

Studies have updated versions of the TAM [16,50,57,58,69,76,79,89], TAM2 [66,84], and TAM3 (a hybrid of TAM and UTAUT) [63,66,78,86]. Important TAM usability determinants included PEOU and PU [16,44,48,50,54,57,58,60,63,64,66-68,70,78,83,85,89,90]. PU and PEOU can significantly predict health care professionals' intentions to use health information systems [13,14,58,73]. Additionally, subjective norms, relevance, and computer anxiety predict intentions beyond PU and PEOU [87,88]. One study showed that PEOU was influenced by computer self-efficacy, external control perceptions, anxiety, and enjoyment [55]. Chi and Ku [61] showed that voluntariness affected determinants of actual use, with EE increasing in importance as voluntariness decreased. Despite their importance, PU and PEOU may be undervalued in their significance for predicting BIs, especially when contextualized within newer constructs.

UTAUT Framework and Critique

UTAUT consistently demonstrated stronger predictive performance than TAM. Shiferaw and Mehari [53] reported that UTAUT explains up to 70 % of the variance in the intention-to-use technology. However, Bagozzi [91] critiqued the model in that it coheres the "many splinters of knowledge" to explain decision-making and its subsequent extensions, stating "UTAUT is a well-meaning and thoughtful presentation," but "it presents a model with 41 independent variables for predicting intentions and at least 8 independent variables for predicting behavior." Furthermore, Li et al [92] argued that UTAUT's reliance on moderators complicates model interpretation and may artificially inflate R^2 values. They also criticized construct labeling practices that combine disparate items into a single psychometric measure.

Nevertheless, UTAUT adds self-efficacy, social influence, and FCs, replacing TAM's PU and PEOU with PE and EE. For example, one research paper found that self-efficacy was a significant predictor variable in comparing urban, rural, and remote settings in the Philippines [49], indicating that one's ability to succeed or accomplish a task significantly and positively increased the intention to use an EHR in that setting. FC is a direct and commonly significant determinant of UB in the UTAUT framework with many subfactors [91-95].

EHR Usability and Related Frameworks

Several tools and frameworks have been developed to assess EHR usability. A few papers use the SUS and NASA-TLX [69,79]. However, this review identified no studies that incorporated ISO-based frameworks [96] as evaluation or predictive factors for EHR usability or adoption.

There was mention of the Health Information Technology Usability Evaluation Scale. This scale is specifically designed for evaluating the usability of health IT applications, including EHRs. It includes subscales for measuring PU, PEOU, and user control, among others [37]. Additionally, Carayon et al [97] proposed the SEIPS model, which provides a framework for understanding the relationships between technology, work processes, and patient outcomes in health care settings. This review identified a study by Alsyouf and Ishak [79] that used SEIPS to predict and evaluate the usability of EHR systems by identifying potential mismatches between the technology and the users' workflows.

The regression model by Butler and Johnson [60] did not predict EHR usability but rather productivity, which may be related to usability. Butler and Johnson [60] used an estimation framework for a productivity index based on physician characteristics, EMR functions, and vendors. Another study by Sulley and Ndanga [71] predicted US among physicians and different EHR system types or vendors and found that the EHR system type was significant. In addition, this study suggests that some EHR vendors can have higher satisfaction levels, which could be linked to the Butler and Johnson estimation of productivity using EHR. Moreover, Yin et al [73] used a logistic regression model and found that participants who are more likely to

XSL•FO
RenderX

consider EHR portals as valuable tools were those who found EHR portals useful for information.

Therefore, a regression model of productivity with usability factors and EHR components across vendors could be an alternative for predicting usability instead of adding external usability variables to more common EHR adoption frameworks, such as constructs of TAM, UTAUT, and D&M ISS models. Furthermore, cognitive aspects, such as the theory of reasoned action, theory of planned behavior, and a user's motivation to use IT, are influenced by the system features and capabilities in TAM, UTAUT, or D&M ISS model constructs. Further investigation is needed to predict EHR usability based on productive HCIs, the incorporation of aspects of EHR adoption frameworks, and other related models, such as Health Information Technology Usability Evaluation Scale, human factors engineering, SEIPS, and many more.

Future Work

Emerging technologies, such as AI, machine learning, and advanced data mining, offer opportunities to extend these models and utilize large datasets. There is almost no research using AI with TAM, UTAUT, and D&M ISS.

The EHR adoption models initially emerged several decades ago. AI algorithms could add feedback loops or feedforward recursive networks to adjust to different data over time, for example, sequences of tasks, usability, and actual use of EHRs under different scenarios. Aspects of EHR usability could be added to the TAM and UTAUT models with training and test datasets via machine learning potentially integrated within SEM and CFA frameworks. Machine-learning techniques have been applied to the usability of health information systems [98].

Integrating audit log data, clickstream analyses, and HCI measures can enable predictive modeling of usability performance, informing adaptive design and proactive system improvements. There is evidence of increasing use of EHR audit log files as evidence for the macrostructure of EHR work completed [99]. Furthermore, there is a viewpoint that there are emerging domains for measuring health care delivery with EHR metadata: (1) team structure and dynamics, (2) workflows, and (3) cognitive environment [100]. These domains contain modified index or scoring, continuity index, comprehensiveness index, conformity score, undivided attention, and task switching [100].

Furthermore, Rule et al [34] stated that metadata from EHR from audit logs can be used to predict physician burnout, which could be considered a usability metric. Moreover, even if there are more recent studies that utilize metadata from EHR system logs, a major limitation is the absence of explicit task-level variables via large datasets to predict usability over time. There is, nevertheless, capacity to include such task measures in SEM-based models as determinants of PE, self-efficacy, EE, and traditional TAM constructs such as PU and PEOU.

Therefore, researchers should consider combining established adoption frameworks with continuous usability monitoring and predictive analytics. Predictive approaches—leveraging design attributes, certification data, usage patterns, and organizational indicators—could enable early identification of usability risks, when redesign and mitigation remain feasible. Furthermore, predicting EHR usability could be used for analyzing large datasets now being collected on EHR usability, anticipating usability problems with specific systems and supporting selection and procurement decisions for acquiring more usable EHRs. The work in this paper could form the groundwork for establishing future efforts in analyzing and predicting usability. Future work could develop feedback loops that link UB, system tasks, and usability outcomes, providing actionable insights for EHR vendors and health care organizations.

Conclusion

No study in this review developed a predictive model for EHR usability postimplementation only, and very few studies used AI to predict adoption. To advance both EHR adoption and EHR usability sciences, researchers could bridge gaps between static adoption models and dynamic human factors engineering by integrating AI, audit log analysis, and real-time usability testing.

Acknowledgments

The authors declare the use of generative AI in the research and writing process. According to the GAIDeT (Generative AI Delegation Taxonomy), the following tasks were delegated to GAI tools: quality assessment. The GAI tool used was ChatGPT-5. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

The authors declared no financial support was received for this work.

Conflicts of Interest

AK is Editor-in-Chief of *JMIR Human Factors* and EMB is Editor-in-Chief of *JMIR Nursing*. AK and EMB were not involved in the journal's review process or editorial decision-making for this paper. All remaining authors declare no conflict of interest.

Abstract

Background: The digital divide constitutes a growing form of social inequality, influencing access to, use of, and benefit from digital health technologies. Accurate assessment of this phenomenon requires psychometrically sound measurement instruments, especially in health care contexts.

Objective: This systematic review aimed to identify and evaluate the psychometric properties of instruments developed to measure the digital divide, with a particular focus on their application in health-related settings.

Methods: A systematic review was conducted following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 and COSMIN (Consensus-Based Standards for the Selection of Health Measurement Instruments) guidelines. Literature searches were performed in PubMed, Scopus, Dialnet, and Web of Science for studies published between 2015 and 2025. Inclusion criteria required studies to report a psychometric evaluation of instruments measuring the digital divide.

Results: Four studies met the inclusion criteria (ranging from 875 to 1337 participants). The identified scales primarily measured digital skills and capital. All studies reported adequate internal consistency, with Cronbach α coefficients ranging from 0.70 to 0.94. Structural validity was confirmed through factor analysis in all studies. However, data on temporal stability and responsiveness were absent.

Conclusions: Existing instruments show potential for assessing digital inequality in health, but further psychometric validation and cultural adaptation are required. Nursing professionals are encouraged to lead efforts in developing and validating context-sensitive instruments to promote digital health equity.

KEYWORDS

digital divide; psychometric properties; measurement instruments; digital health; health inequalities; systematic review; nursing

Introduction

Digital transformation has profoundly altered the way in which individuals interact with information, communication, and self-management of their health [1]. However, this evolution has not been uniform across all citizens. While some have benefited from these new digital tools, others have been left behind. This inequality is known as the digital divide, a multidimensional phenomenon encompassing disparities in access, use, digital skills, and benefits derived from technology [2].

This multidimensional concept involves not only inequalities in access to devices or connectivity (first-level divide) but also limitations in the competencies required to use technologies effectively (second-level divide) and disparities in the actual benefits obtained, such as improvements in health outcomes (third-level divide) [2,3]. Consequently, the digital divide acts as an emerging social determinant, disproportionately affecting

XSL•FO
RenderX

older adults, individuals with low educational attainment, socioeconomically disadvantaged groups, and those with limited digital literacy [4,5].

Within the health care sector, the digital divide compromises access to digital services such as telemedicine, mobile health apps, self-management tools, and eHealth resources. This situation hinders the implementation of technology-based interventions and limits the effectiveness of public policies aimed at promoting equity [6-8]. These limitations particularly impact older adults, individuals with lower educational levels, those in vulnerable socioeconomic situations, and individuals with cognitive impairments [5]. This digital gap critically undermines the efficacy of telehealth interventions as patients lacking necessary digital skills or capital cannot effectively engage with virtual care models, thereby exacerbating existing health inequities [4,5,7].

In this regard, the COVID-19 pandemic exacerbated exclusion when a substantial portion of health care services transitioned to virtual environments. These difficulties in health care delivery were particularly evident among groups with low digital literacy or communication disabilities [6].

Despite the growing interest in this phenomenon, the measurement of the digital divide remains a challenge. Although scales and instruments assessing digital literacy or technological competencies exist, their specific psychometric validity, comprehensive structural approach, and cross-cultural applicability are not always ensured [7,8]. This situation undermines comparability across studies, limits accurate assessment of disparities, and hampers the design of evidence-based interventions [9].

Research conducted by Kayser et al [5] and Mota [10] relied on instruments focused on assessing digital literacy, attitudes, or knowledge regarding technology; however, these tools fail to adequately address the structural dimensions of the digital divide. Moreover, in several studies, such as that by Jongebloed et al [7], questionnaires lacking proper psychometric validation were used, thereby compromising the reliability of findings and restricting their utility in future research. Consequently, the guidelines proposed by Beaton et al [8] and the COSMIN (Consensus-Based Standards for the Selection of Health Measurement Instruments) checklist developed by Mokkink et al [9] are essential for the robust evaluation of measurement properties.

The availability of psychometrically sound instruments adapted to diverse sociocultural contexts is crucial to quantify the digital divide [5], understand its implications for health, and guide effective strategies for its reduction, particularly within nursing and public health, which play key roles in fostering digital equity.

In this context, this study aimed to conduct a systematic review of scientific literature to identify and analyze the psychometric properties of instruments designed to measure the digital divide, with special emphasis on their applicability in health care settings and their potential use in Spanish-speaking populations.

Methods

Study Design

This study was designed as a systematic review of scientific literature conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines and the COSMIN framework [9,11] with the objective of comprehensively analyzing the scales used to measure the digital divide, with a particular focus on the health care context. The review protocol was registered in the PROSPERO database (registration number CRD420251068347).

The review focused on the structural and methodological dimensions of the instruments, as well as on their key psychometric properties, encompassing reliability, validity in all its forms (content, construct, convergent, discriminant, and predictive or concurrent), and structural fit assessed through exploratory factor analysis (EFA) and confirmatory factor analysis (CFA), in addition to the Rasch item response model [12].

The rigorous application of the PRISMA and COSMIN guidelines ensured process transparency, minimized methodological bias, and guaranteed quality in the selection and analysis of the relevant scientific literature [9,11].

Search Strategy

The search strategy was designed to ensure a broad and exhaustive retrieval of scientific literature related to instruments measuring the digital divide.

A systematic search was conducted across 4 scientifically recognized databases—Scopus, Dialnet, PubMed, and Web of Science—aimed at covering both English-language literature and studies conducted in Spanish-speaking contexts. The databases were searched with the time window set from 2015 to 2025. The final search across all databases was executed on January 15, 2025.

Boolean search strings were constructed by combining controlled and free-text terms primarily in English. These terms were organized into 3 blocks interconnected using the Boolean operators “AND,” “OR,” and “NOT.” The first block referred to terms related to the digital divide (“digital divide” and “digital inequality”), the second referred to instruments or related tools (“scale,” “instrument,” and “tool”), and the third referred to the measurement of psychometric properties (“psychometric properties,” “validity,” and “measurement properties”).

Document retrieval and bibliographic management were performed using the RefWorks software (Clarivate Analytics). This information is summarized in Table 1, which details the databases searched, the specific Boolean strings applied, the total number of documents identified, and the number of documents ultimately selected for this research.

(“digital divide” or “digital gap”) and (“scale” or “measure”) and (“validity” or “reliability” or “psychometric properties”)	32	3

[a]WOS: Web of Science.

Selection Criteria

The selection of studies included in this review was conducted through a careful, coherent, and progressive process. Studies published in English or Spanish, available in full text, and published within the time frame of 2015 to 2025 were included, coinciding with the increased research on the digital divide over the last decade, particularly following the acceleration of digitalization triggered by the COVID-19 pandemic.

Eligible articles were required to focus on the development, validation, adaptation, or application of structured instruments designed to measure the digital divide and provide data on their psychometric properties, including reliability, validity, internal consistency, or factor analysis.

Articles that did not directly address the measurement of the digital divide through psychometric instruments, as well as narrative reviews, opinion papers, and similar works, were excluded. Studies focusing exclusively on digital literacy without addressing digital inequalities or lacking psychometric data were also excluded. Selection was based on these inclusion and exclusion criteria following a detailed review of titles, abstracts, and full texts of articles meeting the eligibility requirements.

Effect Measures

The psychometric properties of the identified scales were assessed using the COSMIN guidelines [9]. Effect measures included indicators of reliability (Cronbach α coefficient, ω coefficient, Kuder-Richardson Formula 20, and intraclass correlation coefficient [ICC]); content, construct, convergent, discriminant, and predictive or concurrent validity; factor analysis (EFA and CFA); and estimates derived from the Rasch item response model [12].

Unlike classical test theory, which focuses on total scores and sample-dependent statistics, item response theory (IRT) and Rasch modeling allow for the evaluation of individual item properties independent of the specific sample. Consequently, Rasch analysis is preferred for its ability to verify measurement invariance and transform ordinal data into linear interval

XSL•FO
RenderX

measures, offering a more rigorous validation than classical test theory alone [9,12]. Each property was qualitatively classified according to the criteria by Terwee et al [13] as sufficient (+), insufficient (−), or indeterminate (?). This categorization facilitated the assessment of the methodological robustness of the instruments included in the review and supported the narrative synthesis of the findings [13].

Study Selection Process

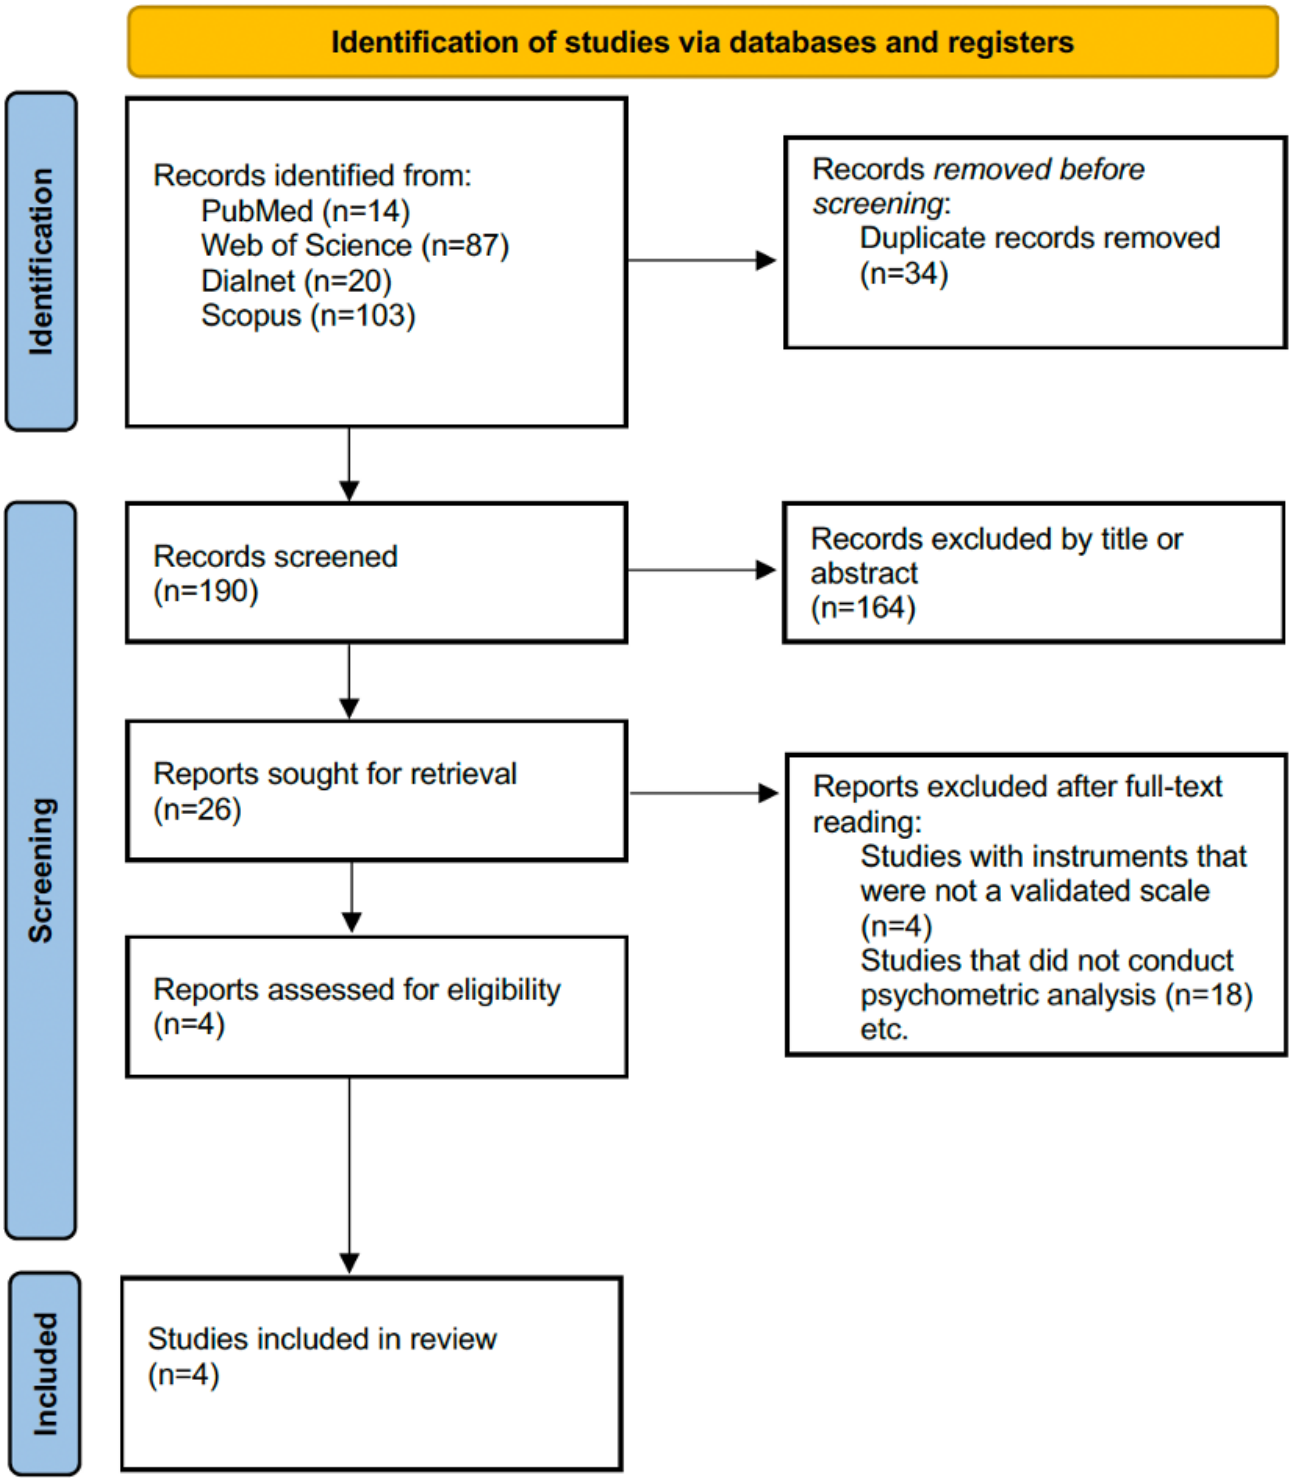
Studies were included if they were relevant to the research question, met the inclusion criteria, and demonstrated adequate methodological quality. Two reviewers (AM-S and CR-T) independently screened the titles and abstracts of retrieved documents to identify potentially eligible studies. The full texts of these studies were then independently assessed by 2 other reviewers (CR-T and NN-E). Discrepancies were resolved through discussion, with a third reviewer (AM-S) consulted when necessary. Interrater agreement was measured using the ICC.

Study Selection and Data Extraction

Evaluated aspects included risk of bias, methodological design, and reporting quality. The PRISMA and COSMIN frameworks were applied to assess study quality. Data were identified, verified, and extracted independently by 2 authors (CR-T and NN-E). Extracted variables included author, year, country, instrument name, target population, number of items, reported psychometric properties, and applied statistical methods [9,11].

Data Summarization

Results were synthesized narratively and organized into descriptive tables detailing the main characteristics, psychometric properties, and scientific quality of the identified instruments. Findings were grouped according to property type and corresponding evaluations.



Results

Overview

Through a systematic bibliographic search across scientific databases, 224 records were initially identified. Of these 224 records, after removing 34 (15.2%) duplicates using RefWorks, 190 (84.8%) remained. Title and abstract screening resulted in the exclusion of 86.3% (164/190) of the remaining studies for not meeting the inclusion criteria. Consequently, 26 studies were selected for full-text review, of which 22 (88.5%) were excluded due to lack of instruments, absence of psychometric analysis, or limited thematic relevance. Ultimately, 4 studies met the inclusion criteria and were included in the systematic review, as illustrated in the PRISMA flow diagram (Figure 1). The ICC between reviewers was 0.80 (95% CI 0.68 - 0.88).

XSL•FO
RenderX

Figure 1. Selection process flow diagram.

Studies Included

The 4 studies analyzed were published between 2015 and 2023. These investigations were conducted in the United Kingdom [14], the Netherlands [2,14], the United States [15], and Italy [16]. Two studies focused on samples of students or young individuals [2,15], whereas the remaining 2 administered questionnaires to representative adult populations [14,16]. The sample sizes in all included studies were adequate according to COSMIN standards (N>100), with respondent-to-item ratios ranging from 35 to 127, ensuring robust conditions for the factor analyses performed [2,14-16]. All included studies used a cross-sectional design.

Identified Scales and Instruments

The 4 instruments evaluated different dimensions of the digital divide, as shown in Table 2. Each instrument was developed by the original authors and culturally adapted to the country where it was applied. The tools measured aspects such as digital competencies, digital capital, technological adaptability, and functional digital skills, with particular emphasis on the

XSL•FO
RenderX

psychometric properties of the measurement tools used [2,14-16].

Table . Studies included in the systematic review.

Study	Study type	Measuring instrument	Language	Objective	Population	Cross-cultural adaptation
van Deursen et al [14], 2015	Cross-sectional study	ISS[a]	English	Develop a tested instrument for measuring internet skills	Adults from the UK[b] and the Netherlands (N=1337)	No

Puckett [15], 2022	Cross-sectional study	Digital Adaptability Scale	English	Measure digital adaptive capacity as a dimension of digital inequality	University students in the United States (N=897)	No
Addeo et al [16], 2023	Cross-sectional study	Digital Capital Index	Italian	Validate a composite index of digital capital in the original population	Italian adults (N=1016)	No

[a]ISS: Internet Skills Scale.

[b]UK: United Kingdom.

[c]IoTSS: Internet of Things Skills Scale.

The instruments were based on diverse theoretical frameworks, ranging from models focused on the collection and storage of digital resources [16] to self-assessment scales of performance in technological contexts [15] and European regulatory frameworks on fair competition [2]. All were administered through online surveys and underwent psychometric analysis.

Psychometric Properties Assessed

Table 3 presents the analysis of the psychometric properties of the instruments identified in the 4 studies included in this review. Regarding factor analysis, Puckett [15] applied a 1-stage EFA, whereas van Deursen et al [14], Addeo et al [16], and van Deursen et al [2] conducted both EFA and CFA to verify the internal structure of their scales.

Table . Psychometric properties of the measurement instruments included in the review.

Study	Measuring instrument	Items, n	Reliability, Cronbach α	Factor analysis	Reported validity
van Deursen et al [14], 2015	ISS[a]	35	0.83-0.94	EFA[b]+CFA[c]	Content and construct validity
van Deursen et al [2], 2022	IoTSS[d]	25	0.89-0.92	EFA+CFA	Construct validity: convergent and discriminant
Puckett [15], 2022	Digital Adaptability Scale	12	0.77	EFA	Construct validity: convergent and discriminant
Addeo et al [16], 2023	Digital Capital Index	8	0.701-0.946	EFA	Content and construct validity

[a]ISS: Internet Skills Scale.

[b]EFA: exploratory factor analysis.

[c]CFA: confirmatory factor analysis.

[d]IoTSS: Internet of Things Skills Scale.

All studies reported Cronbach α values exceeding 0.70, indicating at least adequate internal consistency. This suggests that the items in the questionnaires consistently measured the same construct. However, it should be noted that none of the studies reported data on temporal stability (test-retest reliability) or interrater reliability, which limits the assessment of the instruments' consistency over time [2,14-16].

Validity analysis demonstrated that the instruments accurately measured the intended concepts. van Deursen et al [14] and Addeo et al [16] assessed both construct and content validity, whereas Puckett [15] and van Deursen et al [2] examined convergent validity (similarity to previous tests) and discriminant validity (ensuring that the test does not measure unrelated concepts).

XSL•FO
RenderX

In reviewing the instruments used to assess digital skills and thereby measure the digital divide, 4 scales with robust psychometric evidence were identified in the included studies. The Digital Adaptability Scale [15] and the Digital Capital Index [16] were developed as new instruments, whereas the Internet of Things Skills Scale (IoTSS) [2] sought to validate its structure based on the preexisting Internet Skills Scale (ISS) [14] and additional items related to the Internet of Things.

The internal consistency reliability of the instruments was assessed using the Cronbach α coefficient. The interpretative thresholds were as follows: excellent (Cronbach α≥0.90), good (Cronbach α=0.80 - 0.89), acceptable (Cronbach α=0.70 - 0.79), moderate (Cronbach α=0.60 - 0.69), poor (Cronbach α=0.50 - 0.59), and unacceptable (Cronbach α<0.50) [17]. These thresholds align with established psychometric standards for the evaluation of internal consistency in health measurement instruments.

The factor structure of the instruments was analyzed using 2 primary approaches. First, EFA was used in studies where no a priori theoretical structure was assumed. This method is typically used during the development of new instruments or when the dimensionality of the construct is unknown. Regarding CFA, it was used in studies with a predefined hypothesis about the number of factors and the item-factor relationships based on existing theory or prior empirical evidence. Some studies applied a combined approach, initially exploring the underlying structure and subsequently confirming it in a separate analysis or sample [9].

The ISS [14], consisting of 35 items, demonstrated high internal consistency (Cronbach α=0.83 - 0.94) and underwent both EFA and CFA, providing evidence of content and construct validity. Subsequently, the IoTSS [2], comprising 25 items with similarly elevated reliability coefficients (Cronbach α=0.89 - 0.92), was validated through EFA and CFA, with construct validity specifically supported by convergent and discriminant evidence. Similarly, the Digital Adaptability Scale [15], consisting of 12 items and yielding a Cronbach α of 0.77, was validated via EFA, demonstrating construct validity through its convergent and discriminant relationships with other variables. Finally, the Digital Capital Index [16], which includes 8 items, exhibited a wide range in internal consistency (Cronbach α=0.701 - 0.946) as a result of a 2-stage EFA and provided evidence of both content and construct validity. Collectively, these instruments exhibit adequate levels of reliability and validity, making them valuable tools for measuring digital competencies in various contexts.

Methodological Quality Assessment

The risk of bias of the included studies was assessed using the COSMIN Risk of Bias tool, which evaluates the methodological rigor in the design, development, and application of measurement instruments (Table 4). Overall, the studies appropriately defined the construct to be measured and justified its theoretical relevance. However, recurring weaknesses were observed in the preliminary phases, particularly regarding the design of pilot-testing and the evaluation of item comprehensibility from the perspective of the target population.

Table . Assessment of the level of bias in tool design according to the COSMIN (Consensus-Based Standards for the Selection of Health Measurement Instruments) Risk of Bias tool.

Study	PROM[a] (design)	PROM relevance and comprehensiveness	Pilot test design	Comprehensibility of the pilot test	Comprehensiveness of the pilot test	Final assessment (the lowest qualitative score obtained)
van Deursen et al [14], 2015	Very good	Very good	Very good	Very good	Very good	Very good
van Deursen et al [2], 2022	Very good	Very good	Very good	Very good	Very good	Very good
Puckett [15], 2022	Adequate	Adequate	Doubtful	Doubtful	Doubtful	Doubtful
Addeo et al [16], 2023	Adequate	Adequate	Doubtful	Doubtful	Doubtful	Doubtful

[a]PROM: patient-reported outcome measure.

The studies by van Deursen et al [14] and van Deursen et al [2] received a “very good” final rating, having systematically met the COSMIN criteria, including a well-designed and adequately reported pilot phase. In contrast, the studies by Puckett [15] and Addeo et al [16] showed limitations in the implementation and reporting of comprehensibility testing and cognitive interviews, leading to reduced methodological transparency and a final rating of “adequate.”

The quality of the psychometric properties of the instruments was assessed according to the criteria proposed by Terwee et al [13], classifying each property as sufficient (+), insufficient (–), or indeterminate (?; Table 5). Regarding reliability, all 4 studies reported adequate levels, with Cronbach α coefficients exceeding 0.70, indicating sufficient internal consistency (+). Structural validity was also rated positively in all cases as EFA and/or CFA were applied, thus meeting the established standards (+).

XSL•FO
RenderX

Table . Evaluation of psychometric properties.

Study	Reliability	Structural validity	Content validity	Convergent validity	Discriminant validity
van Deursen et al [14], 2015	+[a]	+	+	?[b]	?
van Deursen et al [2], 2022	+	+	+	+	+
Puckett [15], 2022	+	+	+	+	+
Addeo et al [16], 2023	+	+	+	?	?

[a]Sufficient.

[b]Indeterminate.

In terms of content validity, all 4 instruments were grounded in solid theoretical frameworks and developed based on prior literature or expert review, leading to a sufficient rating (+). With respect to convergent and discriminant validity, only the studies by van Deursen et al [2] and Puckett [15] provided clear empirical evidence supporting these aspects of construct validity and, therefore, were rated as sufficient (+). In contrast, the studies by van Deursen et al [14] and Addeo et al [16] did not report enough information to determine the presence of these forms of validity and, thus, were rated as indeterminate (?).

Finally, none of the reviewed instruments used advanced measurement models such as Rasch analysis or IRT, which represents a limitation in terms of more rigorous psychometric evaluation.

Summary of the Most Relevant Results

The 4 studies contributed recent, culturally contextualized instruments for measuring various dimensions of the digital divide. Notably, they reported adequate reliability levels and validated their structures through factor analysis. However, aspects such as convergent and discriminant validity, as well as the use of advanced measurement models, were less frequently addressed.

From a methodological perspective, all studies defined their theoretical content, but limitations were noted in the studies by Puckett [15] and Addeo et al [16] regarding the implementation of pilot-testing and the detailed evaluation of item comprehensibility, which may affect instrument validity in certain contexts [2,16].

Despite these limitations, the validated instruments—particularly the ISS by van Deursen et al [14] and the IoTSS by van Deursen et al [2]—represent valuable tools for analyzing digital inequality in social and health care settings. These tools may be further strengthened in future research through broader validation efforts.

Discussion

Principal Findings

This study is framed within the growing interest in assessing the digital divide arising from unequal access to, use of, and benefit from health technologies, particularly following the rapid digital transformation of recent years accelerated by the COVID-19 pandemic. The digital divide has been widely recognized as a social determinant that conditions equitable access to health care in increasingly digitized environments. This inequality has driven the development of measurement instruments for various contexts, along with the assessment of their corresponding psychometric properties [2,18].

Although the digital divide has 3 levels, as described in the Introduction section, the instruments identified in this review predominantly map onto the second level (digital skills and use) and third level (digital capital and tangible outcomes). Specifically, the scales by van Deursen et al [14] and Puckett [15] operationalize the transition from technical competencies (second level) to social and economic benefits (third level). This focus is crucial for health contexts as it moves beyond mere physical access (first level) to measure effective engagement with digital health resources. The review findings reveal measurement instruments for the digital divide that demonstrate adequate reliability levels and validated structures through factor analysis. However, methodological limitations persist in some studies, such as those by Puckett [15] and Addeo et al [16], including the absence of pilot-testing, inadequate evaluation of item comprehensibility, and a lack of complementary analyses—such as Rasch modeling—that could strengthen scale validity and robustness [2,16]. These gaps complicate cross-study comparisons and limit applicability across diverse contexts.

A critical issue identified is the limited cross-cultural adaptation of the analyzed instruments. None of the included studies [2,14-16] carried out formal translation or linguistic validation processes for use beyond their original context, which restricts their cultural applicability and relevance to Spanish-speaking populations. Nevertheless, the ISS [14] and IoTSS [2] evaluate general competencies, facilitating potential cross-cultural adaptation.

The IoTSS by van Deursen et al [2] stands out as one of the instruments with the strongest psychometric properties and high applicability among young populations, with potential utility in Spanish-speaking educational and health care settings. Its use could promote international result comparisons and inform the design of more context-specific interventions [2].

Adapting measurement tools for vulnerable populations represents a pressing need in public health and clinical research. Sociodemographic factors such as advanced age, migrant status, or rural residence influence access to health care services, health literacy, and psychosocial well-being [19,20]. For instance, research conducted in China by Tang et al [19] demonstrated

XSL•FO
RenderX

that the digital divide negatively impacts quality of life and mental health among older adults in rural areas, primarily due to limited information seeking skills. This finding underscores the importance of culturally adapting measurement instruments by incorporating variables that reflect the social, technological, and educational conditions of diverse population groups.

Despite progress in the design of health-related measurement instruments, there is limited integration of validated scales in cross-sectional studies involving vulnerable populations. Evidence shows that phenomena such as the "grey digital divide" described by Mubarak and Suomi [21] significantly affect older adults, who face technological and social barriers that hinder access to essential services, including health care. The scarcity of cross-sectional studies using validated scales restricts the generation of comparable data and limits the planning of evidence-based interventions [21].

Nursing, due to its central role in health promotion and patient education, should lead cross-cultural validation and adaptation processes for measurement instruments in vulnerable settings. This leadership aligns with nursing practice, characterized by a holistic approach and close ties to community environments. Nurses also possess the necessary competencies to ensure that measurement tools are not only linguistically translated but also adapted to the cultural, social, and educational specificities of target populations, taking into account literacy levels, access to IT, and social support networks [19].

The COVID-19 pandemic critically highlighted structural inequalities, particularly those related to the digital divide and its impact on vulnerable groups. In education, Golden et al [22] documented how the transition to online learning amplified preexisting disparities among racialized and socioeconomically disadvantaged youth, affecting their academic performance and access to mental health resources. Similar inequities are observed in digital health care access, impacting older adults, rural residents, and migrants.

Furthermore, Meka'a et al [23] demonstrated that digital technology use significantly increased the likelihood of youth employment in a Cameroonian population, indicating that information and communications technologies can play a protective role in socioeconomic well-being. However, the lack of internet access or digital devices creates structural gaps that are difficult to overcome [23,24]. Therefore, measurement scale adaptation must consider these sociocultural variables to ensure valid and clinically useful results [22].

The limited integration of measurement instruments into intervention studies or public policies compromises the evaluation of strategies aimed at reducing the digital health divide. Without valid, reliable, and culturally adapted tools, there is a risk of perpetuating—or even exacerbating—inequities in access to digital health technologies, undermining the effectiveness of health care digital transformation [19,21]. Recent research [19,21,25] highlights that insufficient technology access and low digital literacy deepen social and health inequalities. Moreover, without the systematic application of culturally adapted scales, it becomes difficult to identify the actual barriers faced by vulnerable populations and design policies that effectively promote health equity..

Limitations

The predominant use of cross-sectional designs in the included studies limited the assessment of temporal stability and responsiveness. Longitudinal studies are needed to evaluate how digital divide metrics evolve over time. The limited number of fully validated instruments also restricts the availability of evidence regarding the cross-cultural validity of these scales rather than the generalizability of the systematic review findings themselves [8,9]. Additionally, the limited number of studies conducted across diverse demographic or cultural contexts restricts the assessment of broader scale applicability.

Implications for Nursing Practice

Nurses should not only apply validated instruments but also actively engage in their cultural adaptation, ensuring that assessment tools are understandable and relevant for the most vulnerable social groups. For rural populations, older adults, or communities with low digital literacy, it is essential that instruments are accessible and tailored to the cognitive, technological, and sociocultural capacities of participants, thereby addressing the impact of digital exclusion on access to health care and well-being.

In clinical practice, these instruments can serve as screening tools during nursing admission assessments. By identifying patients with low digital capital or skills, nurses can tailor education strategies (opting for nondigital alternatives or providing guided assistance for telehealth use), thereby preventing exclusion from care pathways.

Future Research

From a practical perspective, the analyzed instruments provide a useful foundation for developing new public policies, digital literacy programs, and interventions focused on digital equity. However, their applicability in real-world settings remains challenging due to the need for further strengthening of psychometric properties, particularly sensitivity to change, external validity, and cultural adequacy.

Conclusions

The instruments identified in this review represent a significant advancement in the structured measurement of the digital divide, showing adequate internal reliability and factorial validation. Nonetheless, a critical analysis of their psychometric properties reveals common methodological limitations such as insufficient assessment of convergent and discriminant validity, lack of pilot-testing, and absence of the use of advanced analytical models such as Rasch or IRT.

Moreover, none of the instruments have undergone cross-cultural adaptation for use outside their original linguistic contexts. Despite these limitations, the reviewed tools hold substantial potential for use in health care, particularly if their validation and adaptation processes are strengthened.

Finally, there is a clear need to expand research in this area in terms of both the number of studies and their methodological quality to develop robust instruments capable of accurately and contextually assessing the digital health divide. Future studies should prioritize validation in vulnerable groups, use advanced analytical models, and incorporate cross-cultural adaptation and

XSL•FO

uniform scale validation to enable a more precise, inclusive, and comparable evaluation of the digital divide in health.

Abstract

Background: Navigation programs for patients with cancer improve access and continuity of care, yet their digital transformation is often limited by poor usability and inadequate uptake. Applying user-centered and human-centered design (UCD/HCD) principles may close this gap, but the extent to which such design methods are used and evaluated in oncology navigation tools remains unclear.

Objective: This scoping review identifies how UCD/HCD principles have been, and should be, applied in developing and implementing digital health tools for navigation for patients with cancer.

Methods: A scoping review was conducted following PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) and Joanna Briggs Institute guidance. A total of 7 databases (PubMed/MEDLINE, Scopus, IEEE Xplore, Web of Science, Embase, ACM Digital Library, and CINAHL) were searched for English-language articles published between January 2015 and July 2025. Eligible studies reported original, peer-reviewed research on digital or mobile health interventions linked to cancer navigation and documented at least 1 UCD/HCD activity. Two reviewers independently screened records and charted data on context, target users, functions, tool modality, design phase, methods, and outcomes. Findings were synthesized descriptively and thematically.

Results: A total of 36 studies met the inclusion criteria. Findings were organized into 4 domains: study characteristics, navigation functions and digital modalities, design processes and methods, and UCD/HCD application. Iterative prototyping and usability testing were the most common, while participatory design and implementation evaluation were underused.

Conclusions: UCD/HCD approaches enhance usability and patient relevance of digital cancer navigation tools. However, their application remains limited across cancer types, regions, and functions. Broader stakeholder participation and evaluation beyond usability are needed to strengthen coordination, equity, and sustainability in cancer care.

Introduction

Cancer remains a leading health challenge, with an estimated 35 million new cases to be diagnosed globally by 2050 [1]. Given ever-aging and evolving populations, the intricate nature of cancer care can pose significant challenges to patients and those caring for them [2]. Patient navigation strategies have emerged to eliminate barriers and improve access to care [3]. Community-based patient navigation programs provide personalized support to patients, families, and caregivers across the cancer care continuum [3,4].

Navigation programs improve care engagement, enhance adherence and treatment completion, reduce diagnostic delays, support survivorship care, and improve overall patient quality of life and satisfaction. Moreover, these programs can help patients overcome language barriers, schedule care appointments, and respond to social needs (ie, lack of transportation, childcare, etc). Patient navigation programs also empower patients by helping them better manage their own medical information and promote active participation in their care, including the power to make informed decisions [4,5].

Despite these benefits, patient navigation program design and delivery vary widely and lack standardization. This complicates multidisciplinary care coordination and introduces additional challenges to already complex health care systems, including financial sustainability concerns that may present an unmanageable burden for many care centers [5]. Addressing these issues requires a comprehensive understanding of the sociotechnical aspects of current technologies and workflows. To optimize the reach and effectiveness of patient navigation programs, there is growing interest in leveraging digital health technologies, including mobile health (mHealth) solutions.

Digital health broadly refers to the use of information and communication technologies to support health care delivery, including web-based platforms, mobile apps, telehealth systems, remote monitoring tools, and data-driven decision support technologies [6]. In oncology, digital health tools supporting patient navigation span multiple modalities, such as web portals, mobile apps, hybrid systems, and, increasingly, artificial intelligence–enabled or conversational tools [7]. Defined by the World Health Organization as “medical and public health practice supported by mobile devices,” mHealth encompasses a wide range of tools, including mobile apps, wearables, sensors, and communication platforms designed to improve health outcomes and promote patient-centered care [8]. In oncology settings, mHealth interventions have been used to deliver real-time patient alerts, streamline manual administrative tasks, and improve communication between patients and care teams [9]. Accordingly, this review adopts a broad digital health lens, situating mHealth within a wider ecosystem of technologies used to support navigation for patients with cancer.

Qualitative studies have found that oncology navigators particularly value digital features that reduce administrative workload and facilitate timely intervention (ie, automatic appointment reminder systems, real-time patient messaging, etc). The findings emphasize the importance of care coordination for patients with cancer undergoing chemotherapy and the critical role of technology in improving this process by enhancing communication and access to information for patients [9]. However, many digital tools fail to simultaneously meet the needs of patients and care teams due to poor design, low usability, and a lack of user engagement. Patients often disengage from apps that are not intuitive, while care navigators may find systems incompatible with clinical workflows. To address these issues, there is increasing recognition of the importance of user-centered design (UCD) and human-centered design (HCD).

UCD is a design philosophy that focuses on placing the end user at the center of the design process [10]. In some contexts, the terms HCD and UCD are used interchangeably. However, HCD is often used to emphasize a broader consideration of impacts on various stakeholders, beyond just the direct users. A UCD/HCD approach, which focuses on understanding user needs, engaging stakeholders, and creating tailored solutions [11], can help address these complexities and improve care delivery [12]. These approaches prioritize the needs, preferences, and lived experiences of end users (ie, patients, caregivers, and providers) through iterative, participatory design processes that foster usability, engagement, and real-world applicability [13,14].

Specifically, cancer care is a complex and emotionally demanding process that involves not only patients but also caregivers and clinicians. Patients often face multiple treatments, fluctuating symptoms, and interactions with numerous health care professionals across different systems. Caregivers experience emotional stress and logistical burdens, while clinicians manage heavy workloads and complex decision-making demands. These challenges can lead to physical strain, emotional distress, cognitive fatigue, and variable energy levels, all of which influence how each group engages with digital tools. Therefore, designing tools that are intuitive, accessible, and emotionally supportive is essential for all stakeholders, as this can enhance usability, encourage sustained engagement, and foster coordinated cancer care.

Given the potential for UCD and HCD to improve their effectiveness, there is a need to systematically map the literature on how these design principles have been applied in this context. This scoping review aims to identify and characterize how UCD and HCD approaches have been applied across the development and implementation of digital health and mHealth tools to support navigation for patients with cancer. Rather than assessing effectiveness, the review examines how UCD/HCD has been operationalized across four interrelated dimensions: (1) study characteristics, (2) navigational functions and digital modalities, (3) design processes and methods, and (4) UCD/HCD application. These dimensions were selected because design choices influence not only usability, but also stakeholder inclusion, workflow integration, scalability, and equity. By evaluating current practices against these dimensions, this review seeks to clarify where UCD/HCD efforts have been concentrated, where gaps remain, and how future digital navigation tools might better align with the complex realities of cancer care.

Methods

Overview

This review was guided by the Joanna Briggs Institute methodology [15] for scoping reviews and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines (Multimedia Appendix 1) [16]. Ethical approval was not applicable to this study, as it involved secondary analysis of previously published, peer-reviewed literature and did not include human participants.

Search Strategy

A comprehensive literature search was undertaken to map how UCD and HCD principles have been used when developing or implementing digital and mHealth tools for navigation for patients with cancer. The search strategy was developed iteratively by the study team; no formal librarian consultation was conducted. The review incorporated peer-reviewed studies that were identified from 7 electronic databases (PubMed/MEDLINE, Scopus, IEEE Xplore, Web of Science Core Collection, Embase [Ovid], ACM Digital Library, and CINAHL [EBSCO]) and were published between January 1, 2015, and July 30, 2025. The search was conducted on July 30, 2025, and the strategy combined the following three concept blocks joined by the Boolean operator AND: (1) cancer navigation terminology ("cancer navigation," "patient navigation," "care coordination," "care transitions," "cancer care pathway," "cancer journey support"), (2) digital and mHealth terminology ("digital health," "mobile health," "mHealth," "eHealth," "mobile application," "wearable," "remote monitoring," "telehealth," "teleoncology," "health technology"), and (3) UCD/HCD terminology ("user-centered design," "human-centered design," "UCD," "HCD," "participatory design," "person-centered care" combined with design, "usability testing"). Database-specific controlled vocabulary (eg, Medical Subject Headings and Emtree) was incorporated where available, and search strings were adapted to the syntax of each platform.

Full, database-specific search strategies and dates of execution are provided in Multimedia Appendix 2.

Eligibility Criteria

Studies were included for review if they met all of the following criteria: (1) published between January 1, 2015, and July 30, 2025, (2) described the development or implementation of 1 or more cancer care navigation-related functions, including care coordination, access facilitation, communication between patients and care teams, appointment management, psychosocial support, financial or logistical assistance, or guidance across the cancer care continuum, (3) reported at least 1 UCD or HCD component (ie, needs assessment, co-design workshop, iterative prototyping, and formal usability testing), (4) involved patients with cancer of any age, their caregivers, or navigation personnel, (5) were original, peer-reviewed research articles or design case studies, and (6) were available in the English language. Studies were excluded if they evaluated oncology digital tools unrelated to navigation, lacked any description of UCD/HCD processes, examined nononcology populations, or appeared as conference abstracts, dissertations, protocols, commentaries, or other gray literature.

Study Selection

All search results were imported into Covidence [17] for screening. Duplicates were removed automatically and confirmed manually. The screening process was conducted in two sequential stages: (1) a primary title and abstract screening followed by full-text review of potentially eligible studies and (2) a secondary bidirectional snowballing process, which involved recursively pursuing relevant references cited in the retrieved literature (backward snowballing) as well as identifying studies that cited the included articles (forward snowballing).

Two reviewers (SK and BMW) independently screened titles and abstracts to assess relevance to the eligibility criteria; disagreements were resolved through discussion, with a third reviewer available for arbitration if needed. Studies meeting the inclusion criteria were advanced to the full-text review stage, where the same dual-review procedure was applied.

Definitions and Conceptual Framework

In this review, digital health refers broadly to the use of information and communication technologies to support health care delivery, including web-based platforms, mobile apps, telehealth systems, remote monitoring tools, and data-driven decision support technologies. mHealth represents a subset of digital health technologies supported by mobile devices.

UCD and HCD are design approaches that emphasize the active involvement of end users and stakeholders throughout the design process to ensure that technologies align with user needs, values, and contexts. In this review, UCD/HCD applications were examined across multiple design phases, including discovery, design, prototyping, evaluation, and implementation.

Design methods refer to specific activities or techniques used to engage users or stakeholders, such as interviews, focus groups, co-design workshops, or usability testing. These design methods may be applied at different design phases and are not mutually exclusive.

Participatory methods are defined as design approaches that involve users or stakeholders as active contributors to the design process rather than solely as subjects of evaluation.

Implementation, as used in this review, refers to the deployment and integration of digital navigation tools within real-world care settings, including considerations related to feasibility, workflow integration, training, and sustainability.

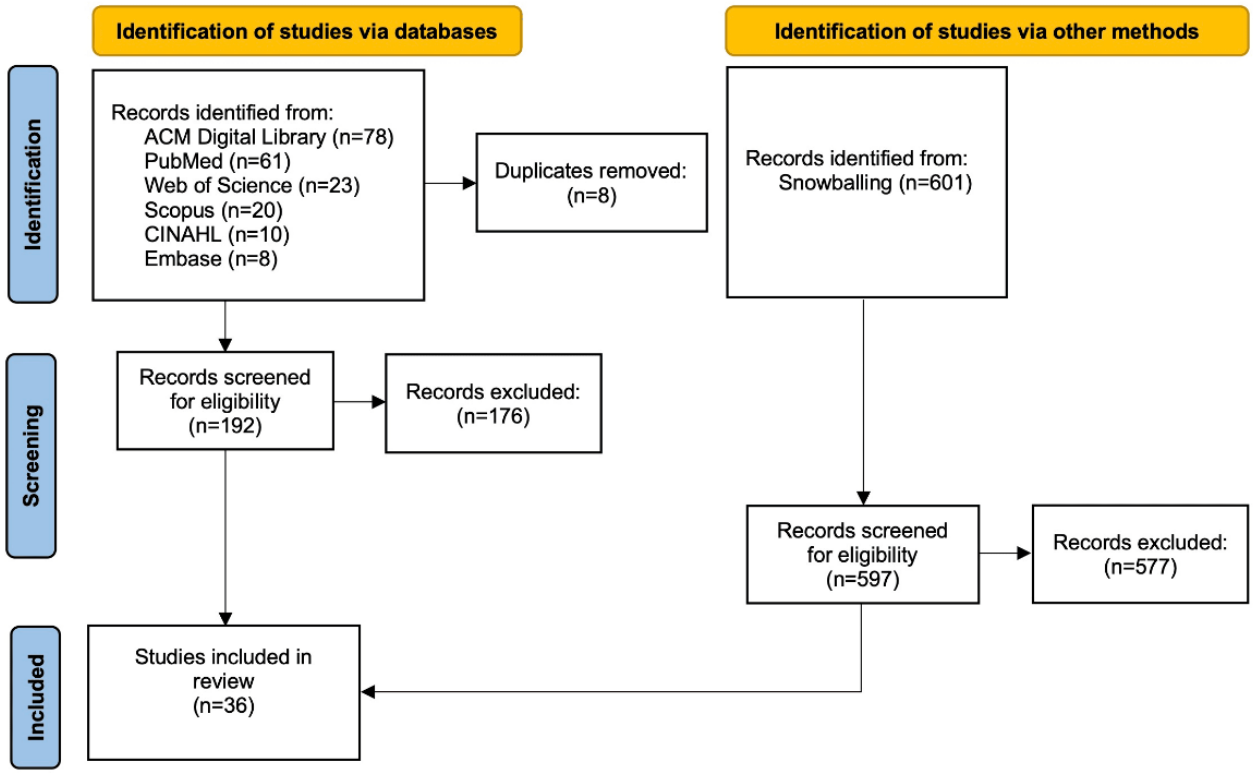
Data Extraction

Data were extracted using a pilot charting form in Microsoft Excel. Two reviewers (SK and BMW) independently recorded bibliographic details (author, year, country, and journal), study design and methods, participant characteristics (cancer type, age range, and navigator role), digital tool attributes (platform, functionality, and stage of deployment), UCD/HCD activities undertaken, navigation tasks supported, and reported outcomes (usability measures, patient engagement, navigator workload,

XSL•FO
RenderX

and clinical indicators). Discrepancies were reconciled by consensus.

Data Analysis



Thematic analysis was conducted through a qualitative synthesis of the studies presented in Table S1 in Multimedia Appendix 2. Each article was reviewed in full to identify key concepts, use cases, and reported outcomes relating to the application of UCD/HCD in digital cancer navigation. An inductive approach was used to identify patterns emerging directly from the data, which were then organized into the following four overarching domains reflecting the clinical and methodological dimensions of UCD/HCD: (1) study characteristics, (2) navigation functions and digital modalities, (3) design processes and methods, and (4) conceptualizations of cancer navigation through UCD/HCD. Domains were refined iteratively until they provided a coherent, nonoverlapping structure for grouping the findings. Alongside the qualitative synthesis, quantitative frequencies (publication year, geography, cancer type, and digital modality) were summarized in descriptive tables and figures to map the landscape of evidence.

Results

Overview

A total of 36 studies met the inclusion criteria for review, as shown in Figure 1. Of the 192 records screened for inclusion through the primary title and abstract review, 176 records were excluded for failure to meet the eligibility criteria. In total, 16 studies met the inclusion criteria and were retained for qualitative synthesis. Bidirectional snowballing of these records resulted in the inclusion of 20 additional articles.

Figure 1. PRISMA-ScR flow diagram of literature search and screening.

Study characteristics are summarized in Table S1 in Multimedia Appendix 2. Below, findings are organized around 4 domains that emerged from qualitative synthesis of the extraction matrix.

Table 1 presents a high-level synthesis of the thematic findings from the included studies, summarizing reported UCD/HCD design processes, functional scope, and digital modalities, and evaluation approaches and impacts in oncology patient navigation tools. The table highlights commonly used methods, dominant functional focuses, and key gaps identified across the literature. Descriptive study characteristics, such as cancer types, geographic distribution, and study settings, are provided separately in the text and Table S1 in Multimedia Appendix 2 to contextualize the evidence base.

XSL•FO
RenderX

Table 1. Summary of key findings on user-centered design (UCD)/human-centered design (HCD) for digital patient navigation in oncology.

Domain	Key themes	Key findings
Design processes (UCD/HCD phases, design methods, and stakeholder engagement)	• Iterative prototyping and usability testing were most common. • Discovery and implementation phases rarely included. • Interviews and surveys were most frequently used, few participatory or co-design workshops. • Engagement was largely patient-only; minimal involvement of clinicians, navigators, or caregivers.	• UCD applied primarily to midcycle for usability evaluation. • Participatory methods underused, limiting innovation and sustainability.
Functional scope of tools (navigation purpose and digital modality)	• Web portals and mobile apps were overwhelmingly used; focused primarily on education and communication. • Limited coverage of financial, logistical, or psychosocial barriers. • Few integrated or multimodal systems.	• Tools improved patient knowledge and engagement. • Narrow functional range; informational focus was most common. • Opportunities to integrate financial, transportation, and emotional-support features remain.
Evaluation and impact (navigation outcomes and author reflections)	• Usability and satisfaction were the most used metrics. • Few studies assessed navigation effectiveness, coordination, or clinical outcomes. • Equity, timeliness, and continuity rarely evaluated. • Some studies conceptually broadened navigation toward empowerment and communication.	• Tools perceived as usable but with limited real-world evidence of improved care continuity. • Shift needed from acceptability to system-level effectiveness. • UCD reframes navigation as multidimensional (communication, coordination, and empowerment).

Study Characteristics

Across the 36 included studies, most focused on all adult cancers (n=16, 44.4%) or specifically on breast cancer (n=8, 22.2%). Fewer addressed pediatric populations (n=3, 8.3%), lung (n=3, 8.3%), or prostate cancer (n=2, 5.6%), while single-study contexts included brain, cervical, chronic myeloid leukemia, colorectal, esophageal, head and neck, melanoma and renal cell carcinoma, and multiple myeloma (n=1, 2.8% each). This distribution reflects a strong emphasis in the current literature on adult and breast cancer contexts, with limited representation of other cancer types and life stages.

Regarding target user groups, most digital tools were designed for patients (33/36, 91.7%) and clinicians or providers (25/36, 69.4%), while caregivers (6/36, 16.7%) and patient navigators (2/36, 5.6%) were considered in just 2 studies. This distribution highlights a strong emphasis on patient-facing tools in the current literature, with comparatively limited attention to caregivers and patient navigators. For example, OncoKompas [13], an app codeveloped with cancer survivors, enables users to monitor their quality of life through patient-reported outcomes and receive automated, personalized feedback and supportive care recommendations, illustrating how tools are often designed directly with patients in mind to provide personalized self-management support.

Geographically, nearly half of the studies were conducted in the United States (17/36, 47.2%), followed by the Netherlands (7/36, 19.4%) and Canada (3/36, 8.3%). Fewer studies were conducted in Africa, Germany, and Sweden (2/36, 5.6% each), and from Australia, Iran, Norway, and Taiwan (1/36, 2.8% each). The predominance of studies from North American and European settings underscores a need for more geographically diverse applications of UCD/HCD approaches to enhance their generalizability and global relevance in cancer navigation.

Navigation Functions and Digital Modalities

Navigation Purpose

According to our findings, navigation functions were most frequently conceptualized as education and information provision (23/36, 63.9%). Closely following were overall care system navigation or access to care and patient-to-provider communication (21/36, 58.3% each), along with care coordination (20/36, 55.6%). Less frequently, studies reported functions related to emotional or psychosocial support (11/36, 30.6%) and appointment scheduling and tracking (7/36, 19.4%). Additionally, functions included patient-to-patient communication (3/36, 8.3%), symptom management (2/36, 5.6%), and financial or insurance navigation, medication support, and transportation or logistics (1/36, 2.8% each).

These results show a predominant focus on education, system navigation, and communication functions, with limited attention to supportive services, financial or logistical navigation, and peer interaction. For example, Mendu et al [18] created and tested a culturally tailored virtual patient educator for Hispanic women to improve cervical cancer and human papillomavirus education using an iterative, UCD. The *CMyLife* platform presented by Ector et al [14] was codeveloped to help patients interpret their own test results and take action across their care journey, reframing navigation as patient empowerment rather than simple wayfinding. Similarly, digital personal health network systems supported chemotherapy patients by enhancing communication with providers and improving care coordination, while usability studies identified needed refinements in data entry and connectivity [9,19]. Moreover, interventions such as *iNNOVBC* presented by Mendes-Santos et al [20] highlighted the underexplored potential of navigation tools to provide psychological support, positioning digital navigation to address care gaps in survivorship.

XSL•FO
RenderX

Type of Digital Tools

Web platforms were the most common type of proposed digital tools, reported in 18 (50%) studies, closely followed by mobile apps (17/36, 47.2%). A smaller proportion presented only a conceptual design without testing a specific tool (3/36, 8.3%), while software prototypes and telehealth or video tools were each reported in a single study (1/36, 2.8%).

This distribution suggests that research has largely concentrated on familiar digital formats (ie, web platforms and mobile apps), with comparatively limited integration of newer modalities such as conversational agents or artificial intelligence–driven chatbots, which were categorized as digital health modalities within this review. For example, the *MijnAVL* [21] platform was iteratively developed with survivor input as a patient-facing web portal to enhance usability and provide accessible educational content. Similarly, the *StressProffen* [22] platform illustrates the use of mobile apps to deliver psychosocial support. Broader approaches also emerged, such as a human-centered mobile and web application (*mPCL*) [23] in Tanzania, which extended functionality beyond patient-facing use to support coordinated palliative care among patients, caregivers, and local health workers.

UCD/HCD Phase and Methods Used

Across studies included, UCD/HCD approaches were reported at multiple phases of the design cycle, including discovery, design and prototyping, testing, and implementation. Rather than following a linear or standardized sequence, most studies reported applying UCD/HCD selectively at 1 or more phases, with considerable variability in timing and depth.

In this review, discovery refers to early-stage activities aimed at understanding user needs, care contexts, and system requirements through methods such as interviews, focus groups, and needs assessments. Design and prototyping encompass the iterative creation of low- to high-fidelity solutions, including wireframes, mock-ups, and functional prototypes, often developed through co-design with stakeholders. Testing includes usability evaluations and pilot studies conducted to assess feasibility, acceptability, and workflow fit in controlled or limited real-world settings. Implementation indicates the deployment and integration of a digital navigation tool into routine clinical workflows or operational care settings, where real users engage with the system as part of care delivery. Distinguishing these phases allowed us to examine the maturity of UCD/HCD application across studies and identify gaps in extending user-centered practices into real-world deployment.

Discovery-phase activities, such as needs assessments, contextual inquiry, and early exploration of user workflows, were reported in fewer than half of the studies (17/36, 47.2%). These approaches were typically used to identify barriers to care coordination, information gaps, or workflow challenges faced by patients, caregivers, or clinicians. As examples in early discovery, Carr et al [12] examined barriers in the workflows of patient navigators supporting patients with breast cancer and explored how an mHealth app could help improve their care delivery and coordination, Ankrah et al [24] interviewed childhood cancer survivors and caregivers to explore survivorship experiences and offered sociotechnical design insights to better support young survivors, and Lau and Loiselle [25] examined oncology nurses' views of an evidence-based eHealth tool, highlighting that incorporating their perspectives makes eHealth tools valuable for patient care and nursing practice.

Design and prototyping phases were more frequently represented (19/36, 52.7%), often involving the development of functional prototypes and working systems. Studies such as *CMyLife* [14] and *iNNOVBC* [20] illustrate how patient-centered platforms were developed and iteratively refined through user feedback, leading to improvements in navigation, personalization, and care coordination features. These examples highlight the use of UCD/HCD primarily to refine near-functional systems and support real-world implementation.

Evaluation and testing activities were the most consistently reported component of UCD/HCD application. Testing was used in 63.8% (23/36) of studies, reflecting a strong emphasis on evaluating and refining tools once developed. As an example in usability testing, the *ASyMS* platform developed by Moradian et al [26], a remote monitoring system, underwent think-aloud usability testing with patients to refine symptom reporting functions before moving toward broader clinical use.

Implementation was the least represented phase (7/36, 19.4%), indicating that relatively few studies extended user-centered approaches into deployment, integration, or evaluation of digital navigation tools within routine clinical workflows. Studies such as Mittal et al [27] and Nabelsi and Plouffe [28] demonstrated that user feedback during implementation revealed system-level challenges, including training needs and resource constraints. These findings underscore the importance of extending UCD/HCD beyond development and evaluation into real-world deployment contexts.

Overall, UCD/HCD approaches were mostly used in prototyping and evaluation phases, with less frequent attention to early discovery and downstream implementation in cancer navigation. Their potential for shaping problem definition and ensuring sustainable implementation remains less frequently explored in available literature.

A variety of UCD/HCD design methods were reported across the included studies, with 80% (29/36) of the studies reporting the use of more than 1 method across the design process. Interviews were the most frequently used approach (25/36, 69.4%), followed by usability testing (16/36, 44.4%). End-user feedback sessions and surveys were reported in 22.2% (8/36) of studies, while focus groups appeared in 13.9% (5/36). Less commonly reported design methods included content analysis, scenarios, stakeholder consultations, and thematic analysis (2/36, 5.6% each). Participatory design sessions (2/36, 5.6%) and co-design workshops (1/36, 2.8%) were comparatively rare. Other approaches, such as direct observation, field trials, iterative design, journey mapping, pilot-testing, and system usage data, each appeared only once (1/36, 2.8% each).

Several cases illustrate this methodological skew toward consultative rather than collaborative techniques. *OncoKompa* [13] and *MijnAVL* [21] primarily drew on survivor interviews

XSL•FO
RenderX

and usability testing to refine prototypes, while *ASyMS* [26] relied on structured usability evaluations, including think-aloud protocols, to improve device navigation. These approaches ensured tools were aligned with patient needs but often stopped short of deeper participatory design. By contrast, studies such as *StressProffen* [22] integrated stakeholder perspectives more systematically, combining evidence-based principles with design thinking methods to produce a culturally sensitive psychosocial intervention. Likewise, the *mPCL* [23] project in Tanzania demonstrated the value of participatory methods by actively involving patients, caregivers, and local health workers in shaping the platform, ensuring contextual relevance and cultural appropriateness.

In summary, researcher-led design methods that capture user perspectives were predominant across the included studies, while collaborative and participatory approaches were less common. Only a small number of studies reported using co-design workshops, journey mapping, or multistakeholder sessions. This indicates that participatory techniques aimed at involving users and stakeholders throughout the design process remain limited in current cancer navigation research.

Conceptualizations of Cancer Navigation Through UCD/HCD

Overview

Across included studies, UCD/HCD approaches were most often applied as practical design strategies rather than overarching frameworks for navigation. Based on our findings from currently available literature, their use has been concentrated to three main functions: (1) evaluating usability and satisfaction outcomes as markers of navigation success, (2) centering patient perspectives as the primary driver of design decisions, and (3) using iterative cycles of prototyping and testing to refine tools. For example, O'Malley et al [29] developed and tested the *e-EXCELS* eHealth tool for cancer survivorship follow-up care.

Usability testing revealed concerns about patient burden, tool fatigue, timing of introduction, relevance, and privacy, underscoring the importance of using a UCD process.

Less frequently, studies broadened participation to include caregivers, clinicians, or navigators, or leveraged design methods to reconceptualize navigation itself as a process of information exchange, communication, and coordination.

In summary, UCD/HCD approaches in cancer navigation were mainly used to ensure that patient-facing tools are usable and acceptable. Fewer studies applied these approaches to address system-level outcomes, involve multiple stakeholders, or support implementation in real-world settings.

Outcomes as Navigation Constructs

Across included studies, outcomes most often reflected usability (28/36, 77.8%) and user satisfaction (26/36, 72.2%), with these measures commonly serving as proxies for the overall success of cancer care navigational tools. Navigation effectiveness was reported less frequently (17/36, 47.2%), while patient engagement appeared in just over one-third of studies (13/36, 36.1%).

Broader outcomes such as clinical use (9/36, 25%), design or strategy insights (8/36, 22.2%), and health professional engagement (6/36, 16.7%) were less assessed. For example, Ho et al [23] evaluated a digital case management platform for community-based palliative care in sub-Saharan Africa by gathering clinicians' perspectives on its impact on care delivery, showing that it improved access, enabled remote symptom management, and supported more efficient patient prioritization. Even more rarely, studies addressed feasibility and implementation logistics (5/36, 13.9%), collaboration and coordination (3/36, 8.3%), or educational value (2/36, 5.6%). For example, Nikkhah et al [30] applied role theory to understand how parents act as caregiving teams in children's hospitals, emphasizing the need for design features that support coordination and shared responsibilities. As another example, Womack et al [31] engaged patients in conceptualizing clinic processes and digital health tools aimed at raising awareness and supporting education on integrative oncology services.

These findings reveal a strong emphasis on usability and user satisfaction in cancer navigation tools, illustrating how UCD/HCD has been applied primarily to ensure tools are acceptable and easy to use, rather than to measure their long-term effectiveness or system-level impact. For instance, *StressProffen* [22] and *Enable* [32] demonstrated high usability and satisfaction among survivors, underscoring the success of iterative, user-centered refinements. Similarly, *ASyMS* [26] usability testing revealed strong patient motivation to engage with symptom monitoring, even as participants called for a more attractive design and expanded features. Ahmadi et al [33] developed a mobile app for self-care management in Iranian women with breast cancer, and usability testing confirmed that its content and functions were appropriate and satisfactory. Moving beyond usability, tools such as *OncoKompas* [13] and *mPCL* [23] illustrate a shift toward evaluating navigation effectiveness and feasibility in real-world contexts, whether through tailoring survivorship resources or coordinating palliative care across diverse settings.

Overall, the reviewed studies primarily measured outcomes related to usability and user satisfaction, with fewer examining broader aspects such as navigation effectiveness, coordination, or sustainability. Only a limited number of studies assessed system-level or implementation-related outcomes, such as timeliness, collaboration, or equitable access. Toward this direction, Geerts et al [34] developed and evaluated *MM E-Coach*, a patient-centered eHealth application designed to support patients with multiple myeloma and health care professionals by improving treatment management, usability, and communication through an iterative, user- and stakeholder-driven design process. They further initiated a randomized clinical trial to evaluate its clinical effectiveness.

Similarly, Morse et al [35] designed, developed, and tested mPCL, a human-centered mobile and web application that supports outpatient palliative symptom assessment, care coordination, and pain control among Tanzanian patients with cancer by connecting patients, caregivers, local health workers, and palliative care specialists. Their findings emphasized the need for further evaluation to assess the tool's effectiveness and sustainability, particularly in remote and resource-limited

XSL•FO
RenderX

settings. Mittal et al [27] also designed and deployed *SCOPE*, a platform for technology-enhanced collaborative care combining a patient-facing mobile app with a provider-facing registry. They deployed *SCOPE* for 24 months for actual care in 6 cancer clinics.

Levels of Stakeholder Engagement in UCD/HCD

Across included studies, stakeholder engagement in UCD/HCD processes varied in scope and depth. Most studies engaged patients as the primary voice in the design process, often through semistructured interviews and surveys. This strong emphasis on patient perspectives reflects the value of empathy and coproduction, which are central principles of UCD/HCD as shown by Hou et al [36] and Womack et al [31]. Schadewaldt et al [37] also suggested that applying evidence and stakeholder input through a UCD/HCD approach can inform implementation strategies that reduce the risk of digital health failure.

In line with these findings, Glaser et al [38] evaluated the *CAPABLE* prototype for immunotherapy patients, showing that involving target users improved perceived usefulness and revealed critical symptom–reporting issues that would have gone unnoticed without their participation. Tools such as *OncoKompas* [13] and *MijnAVL* [21] exemplify this approach, with cancer survivors directly involved in iterative prototype testing to refine content, navigation features, and overall functionality. *CMyLife* presented by Ector et al [14], developed for individuals with chronic myeloid leukemia, equipped patients with tools to track and interpret their results while aligning design decisions with survivor priorities identified during participatory sessions. Similarly, *SmartSurvivor* by Baseman et al [39] explored mHealth options for survivorship care, explicitly embedding patient perspectives into the functionality and usability of the tool.

Although most included studies centered on participation of patients with cancer in UCD/HCD processes, a smaller but important subset extended participation to include health care providers, clinicians, caregivers, and navigators [40,41]. These examples demonstrate how human-centered approaches can extend beyond individual patients' needs to reflect the complex, multiactor systems that shape cancer care. For example, Salako et al [42] brought together researchers, clinicians, and technology developers to review remote symptom monitoring for palliative cancer care in Africa. They described 3 approaches from different countries, highlighting delivery models, outcomes, and implementation experiences. The study concluded that codeveloping and adapting these tools with local stakeholders is feasible, with user-centered insights guiding future scale-up.

Nabelsi and Plouffe [28] engaged nurse navigators and interfacility teams to refine a web-based coordination platform designed to improve oncology and nononcologic thoracic surgery care pathways. Similarly, the *mPCL* project by Ho et al [23] incorporated local health workers in Tanzania to co-design a mobile platform for palliative care, ensuring cultural and contextual relevance in a low-resource setting. Aronoff-Spencer et al [43] also described a human-centered participatory design approach that engaged patients, caregivers, and community stakeholders to support rural patients experiencing distress during cancer treatment. Patel et al [44] interviewed 20 caregivers of children with cancer to explore potential design solutions. They identified 4 caregiving coordination technology archetypes at diagnosis and showed how caregivers' preferences evolved over time.

Across the reviewed studies, inclusion of diverse stakeholders such as clinicians, caregivers, and navigators was less common compared to patient-only approaches. Studies that incorporated multiple stakeholder groups identified additional factors affecting navigation design, including workflow alignment, caregiver responsibilities, and infrastructure limitations. Overall, most studies maintained a primary focus on patient perspectives, with fewer addressing the broader system-level context of care delivery, such as organizational workflows, care coordination processes, technological infrastructure, and institutional constraints that shape how navigation services are implemented and sustained.

Iteration and Responsiveness

Across included studies, UCD/HCD was frequently operationalized as an iterative cycle in which prototypes were tested and refined in response to user feedback. This responsiveness ensured that navigation tools were grounded in real-world needs and experiences.

For example, tools such as *StressProffen* [22] and *CMyLife* [14] demonstrated how usability testing can identify challenges with data entry and workflow guidance, which directly informed revisions to interface design and content presentation to improve navigation pathways. Likewise, iterative development of *MijnAVL* presented by Kuijpers et al [21] led to usability improvements, including the addition of FAQs and hyperlinks to improve patient experience. Similarly, an iterative development process of a cancer prevention web application by Carrera et al [45] and the prevention-focused web application described by Anders et al [32] incorporated repeated cycles of feedback that shaped tutorials and interactive features, supporting its potential to enhance risk understanding and healthy behavior.

Redefining Navigation Through Design

Beyond creating tools for discrete functions, several studies applied UCD/HCD approaches to reconceptualize what "navigation" means in cancer care. Rather than limiting navigation to scheduling or wayfinding, studies framed it as a broader process of information exchange, communication, and care coordination.

For example, Basch et al [46] leveraged patient-reported outcomes to enhance communication between patients and clinicians, transforming symptom monitoring into a navigation mechanism for timely intervention and treatment adjustment. Similarly, Donawa et al [47] co-designed a mobile tool for distress management in rural communities, positioning navigation as an integrated support system that addressed emotional, informational, and logistical barriers simultaneously. *Interaktor*, presented by Langius-Eklöf et al [48], also broadened navigation by increasing patients' sense of security and self-reflection, thereby embedding psychosocial support directly into routine symptom monitoring.

XSL•FO
RenderX

Discussion

Principal Findings

This scoping review synthesizes how UCD and HCD principles have been applied in the development and implementation of digital cancer navigation, while also identifying gaps that limit broader impact. Overall, UCD/HCD was most often applied to patient-facing tools during prototyping and usability evaluation, with comparatively less attention to early discovery phases and downstream implementation in routine care settings. These efforts appear to have improved alignment between navigational tools and patient needs; however, fewer studies addressed system-level barriers, equity, cancer-specific navigational needs, and global applicability. Future research and development should consider deliberately extending UCD/HCD across a wider variety of cancers, diverse geographic contexts, multistakeholder design processes, and outcomes that measure more than usability. To support interpretive clarity, we distinguish between findings derived directly from the reviewed studies and forward-looking implications intended to inform future research, design practice, and implementation.

Findings demonstrate that UCD/HCD in cancer navigation has been applied most extensively to adult cancers in high-income settings. Pediatric and rare cancers were comparatively underrepresented, as were studies conducted in low- and middle-income settings, despite the substantial coordination demands often present in these contexts. Addressing these gaps may be important for improving the generalizability and equity relevance of digital navigation research. As an illustrative scenario, in a pediatric oncology ward in sub-Saharan Africa, co-design workshops with caregivers could reveal the daily burdens of medication access and transportation [23]. Embedding those insights into a navigation app might prioritize transportation support (eg, ride-share scheduling or community volunteer coordination) alongside education, addressing barriers that may influence treatment continuity. Without attention to these barriers, digital navigation may risk reproducing existing inequities rather than mitigating them.

At the stakeholder level, most tools were developed directly with patient input, demonstrating the strength of UCD/HCD in capturing and centering lived experience. However, caregivers, navigators, and clinicians were rarely included, which may leave workflow and coordination barriers underexplored. Caregivers and patient navigators can play pivotal roles in access, treatment timeliness, and continuity of cancer care, while clinician engagement at each iterative stage of UCD/HCD is critical for integration into workflows and sustained adoption [2,30]. Limiting participatory design primarily to patients could risk overlooking system-level and workforce perspectives needed for real-world implementation. To address this gap, design processes could prioritize multistakeholder participation. For instance (as an illustrative example), in developing a survivorship platform for rural patients, engaging nurse navigators could identify how symptom alerts fit within clinical workflows, while caregiver voices could flag gaps in home-based support. This approach may shift tools from stand-alone patient tools toward integrated systems designed to bolster continuity of care.

Current tools focus heavily on education and information provision, with limited attention to psychosocial, financial, or logistical barriers. These functions may improve self-efficacy and patient activation [49], but they may be insufficient for addressing the psychosocial, financial, or logistical barriers that many patients face [50]. While UCD/HCD approaches have supported the development of education and communication functions responsive to patient needs, future applications could also extend to the broader spectrum of navigation services that shape equity, access, and continuity of care. This pattern reflects how UCD/HCD has been applied primarily to informational and communicative aspects of navigation, while more complex or resource-intensive functions remain underexplored.

Strengths and Limitations

This review offers one of the first comprehensive maps of how UCD/HCD principles have been applied to digital and mHealth tools for navigation for patients with cancer. A comprehensive search strategy was applied across 7 major databases, combining controlled vocabulary and free-text terms to capture diverse design approaches and navigation functions. However, several limitations should be noted. Despite the breadth of databases searched, the review was limited to English-language publications between 2015 and 2025, potentially excluding relevant studies in other languages or earlier foundational work. While the dual-review process enhanced rigor, inclusion criteria required explicit mention of UCD or HCD, which may have excluded studies using participatory approaches under different terminology. Although descriptive and thematic analysis revealed important patterns, no formal quality appraisal was conducted, in keeping with scoping review methodology. Given this, the strength of evidence underlying individual findings could not be assessed. Moreover, most studies were conducted in high-income countries and focused on adult cancer populations, limiting generalizability to low- and middle-income settings or underrepresented cancer types.

Future Directions

Overall, the review's comprehensive scope provides a foundation for future research. The implications outlined below are forward-looking and intended to inform future research and practice; several examples are illustrative and were not directly evaluated in the reviewed studies. Subsequent systematic reviews should incorporate quality appraisal frameworks, cross-cultural analyses, and longitudinal evaluations to further examine the effectiveness, equity impact, and sustainability of UCD/HCD in cancer navigation.

Moving forward, developers should also consider expanding navigation functions to directly address psychosocial, financial, and logistical barriers identified in the literature. For example, a survivorship tool could embed a financial navigation module where patients track insurance claims and receive cost-of-living support resources, similar to the Wheeler et al [51] model. Likewise, a peritreatment app might integrate transportation (ie, ride-share) scheduling to reduce missed appointments in gynecologic oncology. Designing and implementing these

XSL•FO
RenderX

functions may require moving beyond informational features toward more complex domains with potential system-level impact.

Most reviewed studies relied on traditional UCD/HCD design methods (ie, interviews, surveys, and usability testing applied midcycle) with limited reporting of upstream discovery or downstream implementation. Discovery and routine care implementation were rarely discussed, which may limit both innovation and sustainability. This pattern reflects broader digital health literature, where many interventions are tested in laboratory- or pilot-type settings, very few report robust real-world deployment, maintenance, or adoption over time [52]. Overreliance on consultative design methods risks capturing only surface-level usability preferences while overlooking systemic challenges such as workflow misalignments, caregiver burdens, or sociotechnical barriers [53]. These observations and gaps carry important public health policy implications, as insufficient integration of UCD/HCD across the design-to-implementation continuum can undermine investments in digital oncology infrastructure, limit scalability, and hinder equitable access to effective navigation technologies. Health systems and policymakers should prioritize frameworks that embed UCD/HCD into digital health standards and implementation incentives.

Additionally, a shift toward embedding participatory and iterative design methods from start to finish is needed. Journey mapping at the discovery stage could uncover bottlenecks in care transitions (ie, from surgery to rehabilitation), guiding more effective tool design. Co-design workshops and multistakeholder field trials during implementation could then test how tools integrate into routine care, adapt across cancer contexts, and endure beyond pilots into real-world applications [54-57].

Correspondingly, outcomes were dominated by usability and satisfaction, while far fewer studies assessed navigation effectiveness, care coordination, or clinical use. Moreover, even fewer included measures of equity, timeliness, or continuity of care. This narrow scope risks producing tools that are usable but not transformative for access, coordination, or sustainability. Evaluation frameworks must expand to capture system-level outcomes. Pairing implementation outcomes with theory-informed, causally grounded evaluation approaches can help assess not only acceptability, but whether proposed mechanisms (eg, improved coordination leading to fewer delays) are supported by observed data rather than usability proxies alone [58].

One example could include comprehensive trials to assess whether navigation apps reduce treatment delays across racial groups, improve communication between community hospitals and tertiary centers, or decrease financial burden for patients and families. Embedding these outcomes would help ensure UCD/HCD advances are judged by their tangible contribution to health equity and system performance, and not just whether users like the interface.

Finally, UCD/HCD approaches may contribute to broadening the conceptualization of navigation from wayfinding toward communication, coordination, and empowerment. Tools such as *StressProffen* [22] and *CMyLife* [14] illustrate how iterative design can expand navigation beyond tracking to include psychosocial support and relational care. For practice, this shift underscores the importance of embedding patient perspectives alongside those of clinicians, navigators, and caregivers, ensuring tools align with real-world workflows. Scaling this orientation across cancer contexts and diverse health systems could transform navigation from a patient app to a core function of oncology care delivery. For research, future studies should move beyond single-site, short-term evaluations toward longitudinal and multicountry designs that capture not only usability but also system-level outcomes. By expanding participatory approaches and testing tools in diverse contexts, UCD/HCD has the potential to transform navigation into a durable, equity-sensitive component of cancer care delivery.

Conclusions

UCD and HCD approaches have demonstrated value in shaping digital cancer navigation tools that are usable, acceptable, and responsive to patient needs; however, their current application remains narrow, concentrated in adult cancers, high-income settings, and informational functions. While these contributions are notable, relatively few studies address the broader coordination, equity, and implementation challenges that define navigation in real-world oncology settings.

The evidence from this review suggests that UCD/HCD has been most impactful when applied iteratively, embedding patient perspectives to refine tools that improve engagement, communication, and self-management. At the same time, caregiver, navigator, and clinician voices remain underrepresented, participatory methods are underused, and outcomes largely privilege usability over system-level effectiveness. These patterns may limit both the scalability and sustainability of current tools. To more fully realize the full potential of UCD/HCD in cancer navigation, future research and practice should extend beyond interface refinement toward the development of equitable, context-sensitive systems. This includes deliberate inclusion of a wide variety of cancers and low- and middle-income settings, broader stakeholder engagement across patients, caregivers, and providers, and systematic use of participatory and co-design methods that span discovery through implementation.

Equally, evaluation frameworks should extend beyond usability to capture coordination, timeliness, continuity, and equity as essential markers of navigation success. These findings underscore that UCD/HCD should both refine cancer navigation tools and redefine what navigation means within oncology. An integrated process of empowerment, communication, and coordination across diverse care contexts is warranted. By embracing inclusivity, methodological innovation, and system-level evaluation, the next generation of digital navigational tools can move beyond promising prototypes to sustainable solutions that improve outcomes and reduce disparities in cancer care delivery.

Abstract

Background: Implementing digital mental health interventions (DMHI) for those with psychosis is a persistent challenge. A process evaluation, or studies conducted alongside trials, is one research method that may address this issue. However, a synthesis of process evaluation data in this area is missing.

Objective: This study aimed to understand what is known about context, implementation, and mechanisms of impact by synthesizing process evaluation data from trials evaluating DMHIs used by people with psychosis.

Methods: A scoping review using a 2-phase search strategy underpinned by the Medical Research Council (MRC) process evaluation framework was conducted. Database searches of Cochrane Central Register of Controlled Trials and PsycInfo in 2024 and 2025 first identified an index sample of peer-reviewed trials predominantly conducted in the United Kingdom (≥50% of samples from the United Kingdom in multicountry studies). Next, papers linked to the index sample were retrieved and included if they reported process evaluation data as operationalized in the MRC framework. Two authors independently screened references, extracted summary data, and assessed the quality of index trials. One author qualitatively synthesized process evaluation data using a deductive framework synthesis approach using the MRC framework. Findings were triangulated with senior authors and presented as a narrative synthesis.

Results: Searches identified 14 DMHIs and 45 papers reporting process evaluation data, though only 2 were labeled as such. Qualitative syntheses of process evaluation data generated five themes aligned with the MRC framework: (1) enhancing fit and supporting delivery (implementation strategies); (2) DMHI implementation varied across users, staff, and delivery settings (implementation outcomes); (3) helping users to respond in more helpful ways (mechanisms); (4) addressing perceived and actual implementation factors (context); and (5) limited impact of user characteristics on DMHI outcomes (context).

Conclusions: There is preliminary evidence that DMHIs can be delivered to people experiencing psychosis within trial settings, although use varied between individuals. Future implementation efforts may benefit from addressing contextual factors influencing DMHI use, including users' treatment needs and preferences, everyday demands, and staff availability for blended interventions. Future research could evaluate implementation strategies, validate how and for whom DMHIs work, and embed process evaluation in trials.

Introduction

Psychosis is characterized by strongly held unusual beliefs and often distressing sensory experiences, such as hearing voices [1], and can cause difficulties in many aspects of life, including interpersonal relationships, reduced quality of life, and increased risk of early death due to poorer health outcomes [2]. In the United Kingdom, clinical practice guidelines recommend psychological interventions, such as cognitive behavioral therapy or family interventions, for individuals with psychosis [1]. However, access to these therapies remains below recommended levels [3,4].

Given these persistent access challenges, attention has increasingly turned to digital mental health interventions (DMHIs), or technology-based treatment designed to improve users' mental health [5], as a potential way to expand psychological support. Notably, a 2024 early value assessment by the National Institute for Health and Care Excellence in the United Kingdom highlighted DMHIs could be a promising treatment mode for those with psychosis [6]. Although evidence suggests DMHIs can reduce mental health symptoms experienced by those with psychosis [7,8], implementing these interventions in practice remains a persistent challenge [9-11].

To help bridge this DMHI evidence-practice gap, an international commission from Lancet Psychiatry in 2024 recommended adopting methods that embed implementation work throughout the research process [12]. One such research method is a process evaluation, or studies that are often embedded in randomized controlled trials (RCTs) that explore how, for whom, and where interventions work [13]. The most recent process evaluation guidance was published by the Medical Research Council (MRC) in the United Kingdom in 2015 [13]. Process evaluation in the MRC framework explores 3 outcomes (Textbox 1) [13].

Textbox 1. Medical Research Council process evaluation components [13].

- Context: external factors that influence how an intervention is implemented or functions.
- Implementation: the quantity and quality of, and processes required for, intervention delivery.
- Mechanisms of impact: how an intervention produces an effect.

Some studies have used process evaluation to evaluate DMHIs used by those with psychosis [14-17]. Existing evidence highlights that digital treatments may work by empowering users or facilitating self-reflection [14-17], and has identified some barriers to implementation, including user-level (eg, competing life demands) [17] and service-level (eg, staff turnover) [16] factors. However, no review has synthesized process evaluation findings for DMHIs used by those with psychosis. Further, process evaluation is often underused [18] or inconsistently labeled as such [19,20], meaning relevant data may be difficult to identify. Consequently, the breadth, nature, and gaps in the available evidence base are currently unclear.

A scoping review is therefore warranted to understand what is currently known in this area and to identify key evidence gaps to inform future research, evaluation, and implementation efforts. In line with methodological recommendations [21,22], our review focuses on research conducted in the United Kingdom, as differences in health care systems and psychosis care pathways can limit comparisons between countries. Our research question was, "What is currently known about the context, implementation, and mechanisms of impact from RCTs predominantly conducted in the United Kingdom used by people with psychosis?"

Methods

Design

This review followed the Joanna Briggs Institute methodology for scoping reviews [23] and is reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [24] and Enhancing Transparency in the Reporting of Syntheses of Qualitative evidence [25] checklists (Tables S1 and S2 in Multimedia Appendix 1). The protocol was preregistered and can be accessed at PROSPERO (International Prospective Register of Systematic Reviews; CRD42024439117). No amendments were made to the protocol.

Search Strategy and Eligibility Criteria

A 2-phase search strategy, supported by Covidence software, modeled on a prior review of process evaluation [19], was used to first identify relevant RCTs, then associated papers (Figure 1 adapted from French et al [19]). This approach helped address inconsistent use of the term "process evaluation" [19,20] and is recommended for retrieving such studies [20].

Phase 1 identified DMHIs used by people with psychosis that were evaluated in an RCT (index RCTs) using preplanned database searches of PsycInfo and Cochrane Central Register of Controlled Trials on January 31, 2024, and October 22, 2025 (Table S1 in Multimedia Appendix 2). Studies included in phase 1 met the following requirements:

- Population: participants aged >14 years with psychosis established by either (1) a diagnosis of a psychotic disorder using a validated tool, or (2) a score on a standardized psychosis measure (indicating psychotic symptoms are the primary presenting difficulty), or (3) receipt of care from a specialist psychosis service.
- Intervention: digitally delivered, targeting a mental health difficulty.
- Studies: the main outcome paper (the first peer-reviewed paper publishing the prespecified primary outcome data) of peer-reviewed predominantly RCTs based in the United Kingdom (≥50% of samples in the United Kingdom in multicountry studies with comparable health care systems).

Phase 2 systematically identified peer-reviewed publications associated with index RCTs that reported process evaluation

XSL•FO
RenderX

data. Following Cochrane guidance [26], process evaluations were identified using the 2015 MRC framework [13], irrespective of how the studies were labeled. Definitions and coding rules are provided in Table 1. Studies in phase 2 met the following requirements: reporting at least 1 process evaluation outcome from the 2015 MRC framework (context, implementation, or mechanisms of impact) [13] using qualitative, quantitative, or mixed methods, and being clearly linked to the main RCT (via trial registration or program grant).

In phases 1 and 2, masked reviewers (CH, SD, CF, and ALT) independently screened search results in Covidence using eligibility criteria on titles and abstracts, then the full text. Agreement between reviewers was calculated using Cohen κ for both screening stages in Covidence, and discrepancies in inclusion were resolved through discussion, with senior team members (PJ and CD) consulted where appropriate.

Figure 1. Method overview. MRC: Medical Research Council; RCT: randomized controlled trial.

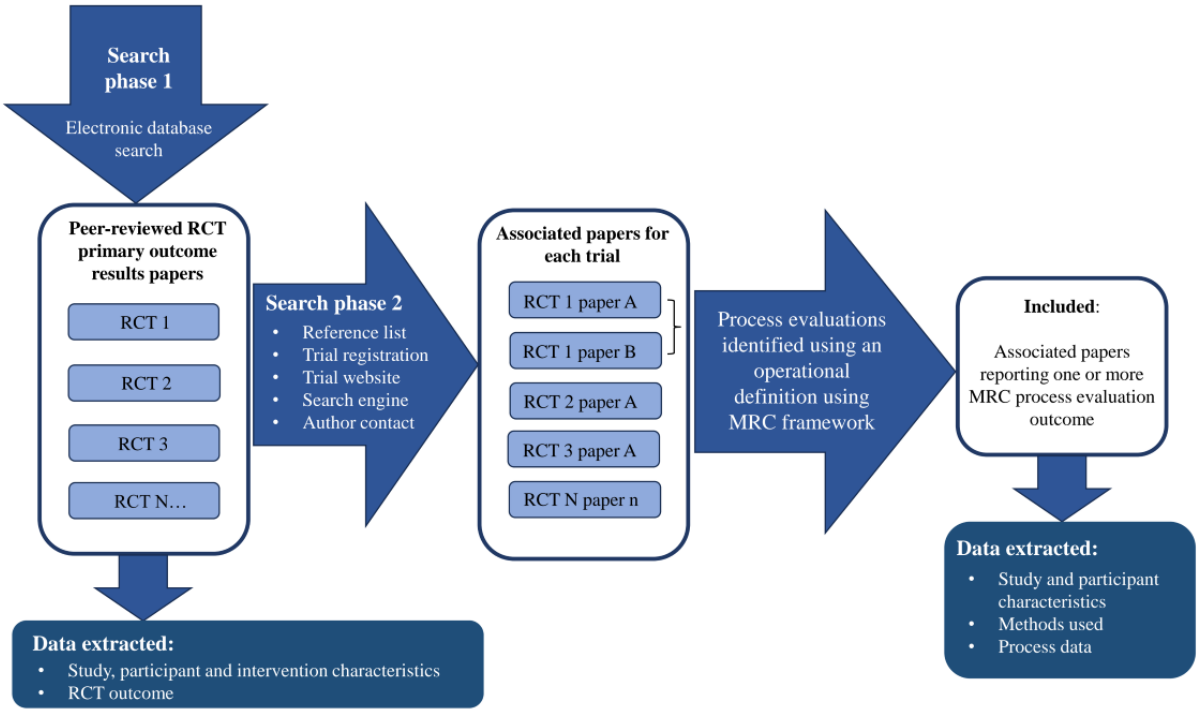

Table 1. Coding framework operationalizing process evaluation components [13].

Component and definition	Coding rules
Context	
• External factors that influence intervention implementation or functioning in a trial.	• Code data about factors that are external to the intervention and its components. • For intervention implementation, code data that influences how the intervention delivery or components are carried out. • For intervention functioning, code data that influences the purpose or desired effect of interventions.
Implementation	
• How much and/or how well an intervention is used and/or delivered in a trial (implementation outcomes) [27].	• For implementation outcomes, code data about any of the following: who participates in, uses, or delivers the intervention, how much the intervention is implemented, and the degree to which the intervention is implemented as intended.
• How delivery is achieved in a trial (implementation strategies) [28].	• For implementation strategies, code data about the actions taken by researchers to enable or support delivery in a trial.
Mechanisms of impact	
• How interventions bring about change in a trial.	• Code data about the intermediate structures between the intervention and the outcomes that produce an effect. Data can include intended and unintended mechanisms.

Data Extraction and Critical Appraisal

Relevant data were electronically extracted in Covidence to reduce bias. Masked reviewers (CH, SD, and ALT) extracted summary characteristics from index RCTs (study, participant, and intervention characteristics and RCT outcome [positive/negative]) and process evaluation studies (study and participant characteristics and methods used). CH extracted process evaluation data using a predefined coding guide (Table 1). Missing data were not sought from the authors. The methodological quality of associated publications was not assessed because a validated tool for process evaluations has not been developed [20], and inclusion of all studies in qualitative syntheses is recommended [29]. Index RCTs were independently assessed by masked reviewers (CH and RT) using the Cochrane risk-of-bias 2 tool, evaluating five domains: (1) randomization procedures, (2) deviations from intended interventions, (3) missing outcome data, (4) measurement of the outcome, and (5) selection of the reported result [30]. As scoping reviews do not typically exclude studies based on methodological quality, these assessments were conducted to provide contextual information on the included evidence rather than to inform study inclusion.

Data Synthesis

We used a constructivist approach [31] with a critical realist perspective [32]. A convergent data-based synthesis design, supported by NVivo (Lumivero), was used to qualitatively synthesize process evaluation data deductively [33]. Framework synthesis, using the 2015 MRC process evaluation framework [13], guided analysis in five stages: (1) familiarization, (2) framework selection, (3) indexing, (4) charting, (5) mapping and interpretation (Figure 2) [34]. Process evaluation data were indexed using the coding framework outlined in Table 1. To enhance the interpretability of findings, data coded within the implementation domain in the MRC framework were categorized into implementation outcomes using relevant domains from the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework, which includes 5 outcomes relevant to evaluating implementation [27]. Data were also coded as implementation strategies (actions taken to support delivery) from the Expert Recommendations for Implementing Change (ERIC), which includes 73 defined implementation strategies that have been ranked by implementation experts [28]. These are established implementation science frameworks that are commonly used to structure and evaluate implementation processes and outcomes in health care research [35,36], and, therefore, organized data using terminology consistent with the implementation science field. CH was the primary analyst, iterated stages as necessary, and triangulated findings with senior researchers (PJ and CD; Figure 2). Results are presented as a narrative synthesis. To enhance synthesis clarity, we applied a frequency criterion adapted from Graham-Rowe and colleagues [37], whereby the number of studies associated with themes was considered in the narrative synthesis. The coding tree is reported in Multimedia Appendix 2.

Figure 2. Framework synthesis overview.

Reflexivity Statement

The authors have experience in intervention delivery and implementation and DMHI projects. The team includes a PhD candidate completing a doctorate on the implementation of a DMHI for paranoia (CH), clinical psychologists with experience delivering interventions to service users experiencing psychosis (PJ and ALT), an expert in psychosis research who has conceptualized a DMHI for paranoia included in our review (CBM-pa; JY) [38], researchers involved in evaluating an adapted version of this DMHI in an RCT (CH, SD, CF, ALT, and RT) [39], and a senior researcher with experience implementing health interventions (CD). We recognize that our professional and research backgrounds and interest in DMHI implementation may have influenced analyses. Our combined clinical and research experience may have provided a nuanced understanding of RCT implementation processes and mechanisms of impact. Direct engagement with DMHI participants provided insight into end user perspectives, which may have informed attention to the relational and practical aspects of implementation. Involvement of senior authors not directly engaged with DMHI users (PJ, CD, and JY) provided an external perspective that may have counterbalanced potential biases. Bias was also mitigated in quality assessment and interpretation, as JY was not involved in the quality rating of CBM-pa or the analysis of intervention findings.

Results

Overview

The search results are summarized in Figure 3. Phase 1 initially identified 1039 papers, 914 of which were excluded after deduplication, primarily because they were protocol papers, were conducted outside of the United Kingdom, or were not primary outcome papers. In phase 1, a total of 14 index RCTs were included. Agreement in phase 1 was moderate to substantial for title/abstract screening (k=0.55-0.72), and substantial to perfect (k=0.62-1) at full text screening. Phase 2 screened 77 papers for process evaluation data (14 were index RCTs included in phase 1, and 63 papers were systematically identified in phase 2). From this, 10 duplicates and 22 papers (mostly protocol papers and papers not reporting process evaluation data) were excluded. In phase 2, a total of 45 papers reporting process evaluation data were included (13 index RCTs and 32 associated papers). Agreement in phase 2 was perfect for title/abstract screening (k=0.87-1) and substantial at full text (k=0.75).
