Abstract

Background: Clinical trials of psychological therapies such as cognitive behavioral therapy typically show sustained posttreatment effects. However, less is known about individuals' outcomes following treatment in routine practice, and additionally, patient representatives have highlighted a need for better postdischarge support.

Objective: The "Paddle" app aims to address these issues. Paddle allows patients to store their therapy materials, reflect on sessions, and monitor their well-being during and after treatment, completing outcome questionnaires and monthly reviews.

Methods: Study 1 evaluated patients' use of Paddle during treatment in routine practice. Patient and therapist surveys explored feasibility, acceptability, and helpfulness. Study 2 examined the feasibility of using the app post discharge, inviting users to submit monthly questionnaires for 6 months, and seeking feedback via survey.

Results: Our findings indicate that Paddle was feasible to implement with few technical problems. Although not all patients wanted to use an app in Study 1, uptake was 66% (111/168) and users found it acceptable and helpful for organizing and remembering therapy information. Most reported using the app on a weekly or fortnightly basis. In Study 2, a total of 321 patients downloaded and used the app at least once, of whom 49% (156/321) submitted follow-up data. Of those who reliably improved during treatment, 73% (86/118) remained so throughout the 6-month follow-up period. Among all users, 20% (31/156) showed further reliable improvement at least once compared to their end-of-treatment score. We introduce the concept of "reliable relapse," which occurred for 36% (32/89) of users who had reliably recovered during treatment, highlighting that some experience fluctuations or deterioration. Feedback highlighted Paddle's value in helping people self-monitor and prioritize their well-being after treatment, with 81% (50/62) suggesting a postdischarge follow-up period longer than 6 months would be helpful.

Conclusions: These preliminary findings suggest that Paddle shows promise in supporting patients to collate therapy resources and monitor their well-being during and after treatment. It may help to improve rates of follow-up data collection, which warrants further investigation.

KEYWORDS

anxiety; app; cognitive behavioral therapy; depression; NHS Talking Therapies; outcome measurement

Introduction

Psychological therapies, such as cognitive behavioral therapy (CBT), have a strong evidence base demonstrating their efficacy in the treatment of anxiety and depression [1-3]. They are recommended as first-line treatment options by health guidance organizations such as the National Institute for Health and Social Care Excellence [4,5], due to there being stronger evidence for sustained gains compared to other treatments such as medication [6]. Evidence from randomized controlled trials suggests that, on average, the clinical gains made during treatment are well-maintained after treatment ends, with studies typically showing sustained effects in follow-up assessments 12-24 months posttreatment [7-9]. However, although improvements are maintained on average, some people show further gains, and some people show deterioration during the follow-up period.

Services providing such therapies within routine clinical practice are often limited in their ability to provide posttreatment support to patients, and to monitor the outcomes of those after they have been discharged. In England, data from the National Health Service Talking Therapies programme for anxiety and depression (NHS TT) in 2022-2023 showed that only 1.3% of patients received a follow-up appointment after they had been discharged [10]. This is perhaps not surprising because these services are not commissioned to collect follow-up data, but it does highlight that we know little about how such patients progress after leaving treatment, and that efforts to increase postdischarge data collection may be valuable for our understanding of the maintenance of treatment gains in routine practice.

A small number of studies have examined posttreatment relapse rates in cohorts of patients who had recovered following low-intensity CBT. Observed relapse rates included 29% in the first 9 months [11] and 53% within 12 months [12]. Factors increasing the likelihood of relapse have included residual depression symptoms at the end of treatment, younger age, unemployment, and nonlinear treatment responses [12,13]. Such studies provide helpful indications about which patients may be at greater risk of relapse. They also highlight areas where further research is needed. For example, studies to date have focused only on low-intensity treatment, so our understanding of posttreatment outcomes across whole services (which include high-intensity treatments and sequential low- and high-intensity interventions) is limited. Studies to date have focused only on patients who recovered during treatment, meaning less is known about those who showed reliable improvement in symptoms but did not fully recover. Finally, the time-to-relapse analyses used in most studies to date place less focus on what happens after a relapse, suggesting there is more to understand about the duration of relapses and the frequency of fluctuating symptom trajectories in this period. Furthering our knowledge of patient outcomes in the posttreatment period is an important step toward better tailoring of treatments or developing targeted posttreatment support to those who may particularly benefit. This might reduce the need for patients to return to services [14], enhancing clinical effectiveness and the efficient use of services' resources.

Importantly, the need to improve posttreatment support and prevent relapse has also been identified as a priority by patients. Patient and public involvement (PPI) on this topic in the Thames Valley region led to the development of the "Staying Well" guidance and support package that has been recommended for use as a component of low-intensity interventions in NHS TT services (materials available at Oxford Centre for Anxiety Disorders and Trauma, 2024) [15]. PPI contributors also highlighted that therapies such as CBT often result in a large number of materials, such as worksheets, diaries, flashcards, pictures, and diagrams, and that it can be challenging to organize and store these in ways that are accessible and useful both during therapy and afterward. Many had kept a folder or notebook but found that if they were out or away from home, they were not able to remind themselves of the key points or reminders they had generated from treatment. As one contributor put it, "a folder is no good if you are having a panic attack on the bus."

These discussions led to the development of an app ("Paddle"; Global Initiative Ltd) as a collaboration between PPI contributors, regional services, clinicians, and software developers [16]. Digital tools have been suggested as a helpful method to enhance the delivery of psychological therapies [17] and their role in preventing relapse has been identified as a priority research area [18]. Paddle is a secure, personal storage app in which a patient can add and organize their materials from therapy, as well as keep notes or reflections about their sessions. The app also includes easily accessible emergency and crisis information. Finally, Paddle allows patients to complete routine outcome measures within the app, sending these results directly to services, and presenting graphs and information about these questionnaires to the patient, to support them in monitoring their own well-being both during and after treatment. It is hoped that Paddle represents a useful and effective adjunct to standard psychological therapy interventions, which may support patients in organizing, accessing, and remembering their therapy materials during and beyond treatment.

This paper reports the findings of 2 studies evaluating the use of Paddle as part of routine service provision in 3 NHS TT services. The research questions were as follows:

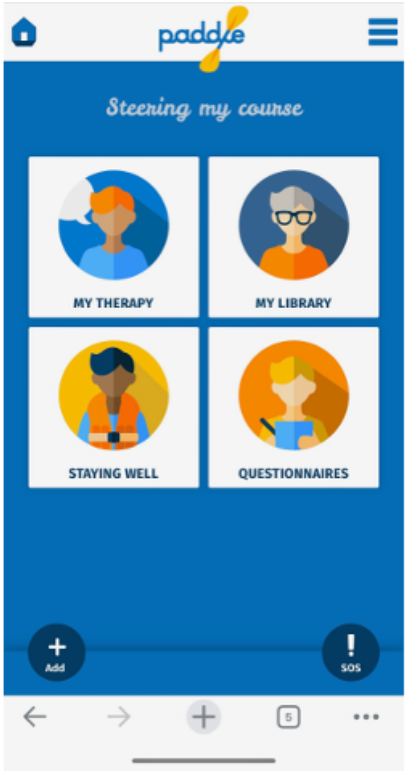
1. Is Paddle feasible to use alongside standard psychological therapy interventions?
2. Do patients and therapists find the app acceptable?
3. Is it feasible to use Paddle to collect outcome data following the end of treatment?
4. What are patients' views on using Paddle to monitor their own well-being after discharge?

XSL•FO
RenderX

Study 1

Methods

Design



This was a survey-based study of participants starting treatment in the participating NHS TT services (Berkshire, Buckinghamshire, and Oxfordshire) whose therapist introduced and discussed Paddle with them. Both low- and high-intensity interventions were included.

App Description

Paddle is a prescribed (invite-only) app available to patients receiving treatment for anxiety and/or depression in NHS TT services. It is designed to be used solely by the patient as an adjunct to their psychological therapy intervention at low or high intensity, allowing them to add, organize, and store their therapy-related information in one secure location. These materials are then easily accessible for the patient both during treatment and afterward. It does not therefore deliver therapy content but is an adjunctive tool designed to support psychological interventions such as CBT. Paddle meets all relevant technical and data security standards (DCB0129 of the NHS Data Coordination Board, ISO [International Organization for Standardization] 9001, and ISO 27001). Since the completion of the studies described here, Paddle has been approved and registered as a Class I medical device.

During Study 1, the app allowed patients to upload information to 3 areas: "My Therapy," where patients could enter notes, actions, reflections, and materials from their sessions; "My Library," where patients could develop a bespoke set of resources, including images, audio files, documents, websites, and telephone numbers; and "Staying Well," where patients could add information and resources for emergencies, setbacks, or difficult moments (eg, a safety plan, relapse prevention plan, or other key points to remind themselves of during and after treatment). In addition, an "SOS" section of the app allows patients to easily access their most important resources when needed. Figure 1 shows a screenshot of the app homepage [16].

Figure 1. Screenshot of a phone showing the Paddle app home page.

Participants

A group of 18 therapists (12 psychological well-being practitioners and 6 CBT therapists) across the 3 participating services attended a half-day in-person training session to learn about the aims, features, and functionality of the app, how to introduce Paddle to their patients, and how to generate an app invite for patients.

These therapists then discussed Paddle with eligible patients on their caseload. The only exclusion criteria were patients using an internet-based platform to undertake treatment, for example, SilverCloud (SilverCloud Health) [19], iCT-SAD (internet-delivered cognitive therapy for social anxiety disorder) [20] or iCT-PTSD (internet-delivered cognitive therapy for posttraumatic stress disorder) [21], or those attending a brief psychoeducation-only group.

Paddle was discussed with 203 patients, and 168 (83%) agreed to be sent an invite to download the app. Of these, 111 (66%) downloaded and logged into the app at least once.

Procedure

Therapists from the participating NHS TT services who attended the training were asked to introduce the Paddle app to each new patient during the first or second treatment session between

XSL•FO
RenderX

October 2019 and February 2020. Patients were signposted to the Paddle website for further information and sent a sheet of frequently asked questions about the app. Therapists then asked patients if they wished to be sent an invite to download and use the app. Those who agreed and downloaded the app were then able to use it as they wished for the duration of their treatment. Therapists were not required to prompt discussion or use of Paddle but could do so if clinically relevant.

At the point of discharge from treatment, the therapist invited the patient to complete an online survey (using the Qualtrics survey platform; Qualtrics LLC). All 203 patients were invited. A branching survey design was used to present questions relevant to respondents. For those who had requested an invite to download Paddle, questions were asked about their use of and experience with the app. For those who declined to be sent an invitation, they were invited to share feedback about their reasons for doing so. Response types on the survey therefore included Likert and frequency response scales, multiple choice, and free-text questions.

At the end of the study period, the participating therapists were also invited to complete an online survey to gather their impressions of Paddle based on their interactions with patients, and record any technical issues they had experienced when sending invites.

Data Analysis

Responses to both the patient survey and therapist survey were analyzed descriptively.

Ethical Considerations

The study was registered and approved as a pilot service evaluation project with the research and development departments of the participating NHS trusts (Oxford Health NHS Foundation Trust and Berkshire Healthcare NHS Foundation Trust). Ethics approval was sought and granted for this process within the University of Reading (Reference UREC 19/02). All participants provided consent to participate and for their data to be used to support service evaluation and improvement. Any identifiable data was removed prior to analysis. Compensation was not provided.

Results

Patient Survey

A total of 68 responses were received, giving an overall response rate of 33% (68/203). Respondents comprised 51 people who had logged in at least once and 17 who declined to be invited to Paddle. The response rate of those who had logged in was therefore 46% (51/111), and of those who declined was 49% (17/45). There were no responses from patients who had received an invite to download the app but had not logged in.

The age range of Paddle users, as self-reported on the survey, was 16-59 years, with the most common reported age range being 20-29 years. The age profile of nonusers was older, ranging from 20 to 69 years, with the most common reported age range being 60-69 years. Overall, 70% of this sample were 50 years or older, compared with 10% of the sample who had chosen to download the app.

Paddle users all reported using other apps in everyday life, with 69% (35/51) using other health-related apps. On average, they rated their confidence in using health-related apps as 78/100 (SD 11.61). In contrast, only 12% (2/17) of the nonusers group reported using other apps, with only one person using a health-related app. Mean confidence was 10/100 (SD 2.89).

The majority (45/51, 88%) of Paddle users indicated that they had downloaded the app because their clinician had recommended it, and 63% (32/51) because they wanted to have their therapy materials together and to hand. Paddle nonusers gave 2 main reasons for declining to use the app: a lack of confidence with this type of technology and concerns about information security.

Paddle users reported using all sections of the app, including “My Therapy” (46/51, 90%), “My Library” (36/51, 71%), and “Staying Well” (40/51, 78%). Most reported using the app on a weekly (29/51, 57%) or fortnightly (12/51, 24%) basis during treatment, which likely reflected use in relation to each therapy session. Some users used the app more than once per week (8/51, 16%) and some less than fortnightly (2/51, 4%). Users’ agreement ratings with statements about Paddle are shown in Table 1. These reflected positive feedback regarding the feasibility, acceptability, and helpfulness of the app. Free-text comments indicated that users liked that this app had been developed by patients for patients, and that everything was in one place to refer back to. Various comments indicated the app had also been helpful in organizing users’ thinking: for example, “Summarising the sessions in the app helped me to focus and remember the techniques,” “It was really helpful writing a summary from each session to get my thoughts together,” “It’s helped me to organise my thoughts, I can look back on this when I need to,” “It helped me to think about what I needed to focus on and what I’d learnt.” Comments also indicated that users felt the app will be a helpful resource to use following the end of treatment.

XSL•FO
RenderX

Table 1. Number of Paddle users agreeing with statements about the app.

Statement	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
Paddle has helped me make the most of treatment	0	1	13	20	17
Paddle has been useful to me	0	1	12	19	19
Paddle has been straightforward to use	0	0	13	22	16
I've liked using Paddle	0	1	14	19	18
I plan on using Paddle now treatment has ended	0	5	12	23	11
I would recommend Paddle to others having treatment for anxiety or depression	0	1	14	21	15

Therapist Survey

Eleven responses to the therapist survey were received, a response rate of 61%. Responses came from 7 psychological well-being practitioners and 4 CBT therapists. Therapists' comments highlighted patients' interest in the app and willingness to receive an invite to download it. They noted the value of discussing it together with the patient ("Explaining about Paddle in the session is helpful – especially if there are questions"). Consistent with findings from the patient survey, age and technological confidence were reported as factors that might be associated with not wanting to use the app ("They might not be used to using apps"; "It's been my older clients who are more hesitant"). No major technical problems or barriers to use were reported. Therapists' impressions of their patients' experiences using the app alongside treatment were positive ("I had one client who said how useful it was to have a place to store everything together," "Clients seem to like it and are finding it useful," "I've had very positive feedback about it," "Clients were definitely using it between sessions to record info and help them prepare for subsequent sessions").

Discussion

Principal Findings

The findings of this study provided an initial indication that it was feasible for therapists to introduce and discuss Paddle with their patients, and for patients to download and use the app during treatment. No major technical issues were observed. Acceptability was indicated by the high rate (168/203, 83%) of those willing to receive an invite to the app, and of those who downloaded and used the app at least once (66% of those invited, 111/168). Most patients reported using the app regularly during treatment. The positive feedback provided an initial indication that the app was valued and perceived as helpful by the majority of respondents, though we cannot say whether nonrespondents had similar views. The findings also suggest that not everyone found the idea of using an app alongside therapy to be helpful, which may be associated with technological confidence and concerns about information security.

These initial findings that the app could be implemented during treatment and that it could be a helpful tool for patients indicated that progression to the next phase of development was warranted. This involved adding the functionality to complete outcome questionnaires within the app.

Study 2

Methods

Design

This was a single-cohort observational study, examining (1) whether the app could be used to collect outcome data following discharge and (2) whether users found using the app helpful to self-monitor their well-being in this phase. Unlike in Study 1, we invited patients at the point of discharge to download and use Paddle to support their posttreatment well-being. All features of the app were available, including the functionality to complete routine outcome measures within the app. Patients were invited to complete these questionnaires on a monthly basis for the first 6 months following discharge.

App Description

The app was identical to that used in Study 1, with the addition of a "Questionnaires" area, which allowed users to complete the same routine outcome measures they had used during treatment. It also provided users with a brief explanation of each questionnaire and what it measures. After completing a set of questionnaires, users could view graphs and tables of their scores over time, allowing them to compare these with their scores at the start and end of treatment. Based on the trajectory of the 3 most recent scores on each questionnaire, and the current score in relation to the standard clinical caseness threshold for that measure (described in National Collaborating Centre for Mental Health, 2018) [22], Paddle provided brief feedback and using short question prompts, encouraged users to reflect on what had been going well or less well and to continue building on strategies they were finding helpful, referring to their "Staying Well" materials as required.

Users' submitted questionnaire data were automatically integrated with the electronic care record used by the relevant NHS TT service. It was explained to users that because they were not currently under the care of the service (having been discharged), the scores they submit to the service were for information only, and if they wanted to access additional support, they should contact the service or other health care providers as normal.

One of the routine outcome measures, the Patient Health Questionnaire 9-item version (PHQ-9) [23], contains an item relating to risk of suicide or self-harm. It was agreed with services that in the course of looking to improve follow-up data collection after discharge, there is a responsibility to respond

XSL•FO
RenderX

appropriately if significant risk is indicated. Based on discussion with clinicians, service managers, and patient representatives, we established the following procedure for this study. If any risk was indicated on the PHQ-9 (ie, a response >0 on the self-harm and suicidality item), the app presented 4 brief additional questions to the user, exploring plans, preparations, behavioral intent, and protective factors. All PHQ-9 data, plus any responses to the additional questions, were sent directly to the relevant service. A nominated clinician in each service reviewed these on a regular basis in conjunction with the clinical notes. Based on their clinical judgment and local service procedures, the clinician would contact the patient if necessary to conduct further risk assessment and management. Users were informed that services are not able to respond to mental health crises and provided with a list of emergency and crisis service details for them to contact if needed.

Participants

Patients were eligible if they reported a main problem of depression or an anxiety disorder and had received at least 2 therapy sessions, at low- or high-intensity. NHS TT services deliver National Institute for Health and Care Excellence (NICE)-recommended therapies, most commonly CBT but also approaches such as counselling or interpersonal therapy. They were not eligible if their last course of treatment prior to discharge used an internet-based treatment platform, because these treatments typically allow users to continue to access the treatment material for a fixed period after discharge. Patients were also not eligible if they were being referred on for further treatment in another service.

Across the 3 participating NHS TT services, 7714 patients were discharged within the 13-week study recruitment period (October 2021 to January 2022), of whom 4063 were eligible and invited to participate. Of these, 321 patients (8%) downloaded and used the app at least once.

Procedure

All clinical staff received a brief training webinar explaining about Paddle and how to introduce it to eligible patients. Where possible, the treating therapist introduced and explained Paddle during the final treatment session and sent the invitation to download the app. However, in most cases, this was not possible, so a designated clinician in each service reviewed the list of recently discharged patients and sent the app invite by email.

Paddle users were free to use all areas of the app as they wished. They received a monthly email invitation to submit their questionnaires, with a reminder 1 week later. At the end of their 6-month period post discharge, anyone who had logged into Paddle at least once was invited to complete a feedback survey via the Qualtrics survey platform. Questions focused on the use of the questionnaire area of the app, and the experience of using Paddle post discharge.

Data Analysis

App usage, clinical outcomes, and user feedback were analyzed descriptively. The demographic and clinical representativeness of app users was analyzed using 2-tailed *t* tests and chi-squared tests.

Measures

As is standard in NHS TT services, all participants were given standardized and well-validated measures of depression (PHQ-9; Kroenke et al [23]), generalized anxiety (Generalized Anxiety Disorder 7-item version; GAD-7; Spitzer et al [24]), and general functioning (Work and Social Adjustment Scale; WSAS; Mundt et al [25]). Where a participant's treatment focused on a specific anxiety disorder, Paddle administered a relevant additional measure, matching that which was used during treatment. Anxiety disorder specific measures (ADSM) used in this study were Health Anxiety Inventory [26], Obsessive Compulsive Inventory [27], Posttraumatic Stress Disorder Checklist for *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) [28], Panic Disorder Stress Scale [29], Patient Health Questionnaire 15 item [30], and Social Phobia Inventory [31]. These measures are also well validated and used as standard within NHS TT services [22]. Participants were also asked to provide their employment status and indicate their use of health care services in the past month.

Classification of Clinical Outcomes

Clinical outcomes were categorized following standard NHS TT definitions, which are calculated based on changes in the PHQ-9 and GAD-7 scores. Where ADSM scores are available, these are used in place of the GAD-7. Reliable improvement is indicated where scores on the PHQ-9 and/or GAD-7/ADSM decrease by an amount greater than the reliable change index for the measure, and neither measure shows a reliable increase. Reliable deterioration is indicated by an equivalent increase in scores, with neither measure showing a reliable decrease. Reliable recovery is indicated where a patient starts treatment above the clinical caseness threshold on the PHQ-9 and/or the GAD-7/ADSM, shows reliable improvement, and has an end score below caseness on both measures. For further details, see the NHS TT manual [22].

For this study, we developed the concept of "reliable relapse," which is the conceptual opposite of reliable recovery. Reliable relapse is indicated where a patient is below caseness on both PHQ-9 and GAD-7/ADSM, shows reliable deterioration, and has an end score that is above caseness on either or both measures. By requiring that scores must have shown a deterioration that is clinically meaningful and more than might be expected by measurement error alone (ie, reliable deterioration), this definition avoids classifying a small change from just below to just above the clinical cutoff as a relapse.

Ethical Considerations

The study registration and ethical considerations were identical to Study 1. The study was registered and approved as a pilot service evaluation project with the research and development departments of the participating NHS trusts (Oxford Health NHS Foundation Trust and Berkshire Healthcare NHS Foundation Trust). Ethics approval was sought and granted for this process within the University of Reading (Reference UREC 19/02). All participants provided consent to participate and for their data to be used to support service evaluation and

XSL•FO
RenderX

improvement. Any identifiable data were removed prior to analysis. Compensation was not provided.

Results

Use of the App to Complete Questionnaires

Of the 321 patients who downloaded and used the app at least once, 156 (49%) submitted at least one set of questionnaires and thus provided follow-up data. No major technical problems occurred. Patterns of data completion across the 6-month follow-up period were variable: 30 (19%) users provided data in all 6 months, 17 (11%) provided data on 5 occasions, 19 (12%) on 4 occasions, 17 (11%) on 3 occasions, 20 (13%) on 2 occasions, and 53 (34%) on 1 occasion. ADSMs were used by 17% of those who submitted questionnaires.

A total of 487 PHQ-9 questionnaires were completed during the study, of which 78 (16%) included a score of 1 or more on the risk item, and 23 (5%) showed an increase in score compared to the last available datapoint. Upon review of the PHQ-9 and additional risk questions by the designated clinician in each service, seven users were contacted for further risk assessment and management as appropriate.

Representativeness of App Users

We compared the demographics of Paddle users with those who were invited but did not log in. No significant differences were observed with respect to age (t_{4060}=–0.031; P=.98, or gender: χ^2_2=1.5; P=.47). The proportion of those from non-White ethnic backgrounds (ie, selecting options other than “White British,” “White Irish,” and “White Other”) was lower among Paddle users (10.26%) compared to nonusers (14.36%; χ^2_1=3.9; P=.049). The same pattern of results was shown when comparing Paddle users with all other people who were discharged within the study recruitment period: age (t_{7711}=–0.084; P=.93; gender: χ^2_2=1.8; P=.41; ethnicity: χ^2_1=6.5; P=.01).

To compare treatment characteristics between Paddle users who submitted follow-up data and those who did not, we compared the number of treatment sessions received. Users who provided follow-up data had received a greater number of sessions (mean 15.05, SD 10.89) compared to those who did not (mean 11.64, SD 7.85; Mann-Whitney U=9858.50; P=.004).

Clinical Outcomes

Clinical outcomes were explored for the 156 Paddle users who submitted follow-up questionnaires. We started by examining their clinical outcomes during treatment. The rate of reliable improvement during treatment was 76% (118/156), and reliable deterioration was 4% (7/156). Reliable recovery was shown by 61% of users during treatment (89/146 users who started treatment above caseness). The mean PHQ-9 score was 14.45 (SD 5.66) at the start of treatment, and 7.24 (SD 5.18) at the end of treatment. The mean GAD-7 score was 12.47 (SD 4.97) at the start of treatment, and 6.21 (SD 4.57) at the end of treatment.

An average of the PHQ-9 and GAD-7 scores provided by each user during the 6-month follow-up period was calculated as an indicator of symptom severity across this phase. The mean PHQ-9 score during follow-up was 8.40 (SD 5.21), and the mean GAD-7 score was 7.31 (SD 4.99). Paired t tests indicated that the follow-up scores were an average of 1.2 points higher on the PHQ-9 compared to the end of treatment (t_{155}=–3.81; P<.001, Cohen d=0.31) and 1.1 points higher on the GAD-7 (t_{154}=–3.85; P<.001; Cohen d=0.31). Although significant, the observed effect sizes suggested these increases were considerably smaller than the decreases seen when comparing the follow-up scores to the start of treatment scores (PHQ-9 t_{155}=13.62; P<.001; Cohen d=1.09; GAD-7 t_{154}=12.01; P<.001; Cohen d=0.96).

We then looked at individual change trajectories over the follow-up period, comparing each monthly follow-up score to the start of treatment score. First, we examined the 118 users who had reliably improved during treatment. This showed that 86 (73%) users stayed reliably improved across the 6-month period, 26 (22%) had at least one score that no longer reflected reliable improvement, and 4 (3%) showed reliable deterioration at at least one point. Two users (2%) had insufficient data for this analysis. The results also showed that of the 29 people in this group who had reliably improved but not reliably recovered during treatment, 5 (17%) went on to demonstrate reliable recovery during the follow-up.

Second, we examined those who had not reliably improved during treatment (n=38). We found that 7 users (18%) went on to reliably improve or reliably recover and remained so throughout follow-up. Three (8%) users showed reliable improvement or reliable recovery that was not sustained. Nine (24%) users showed no reliable changes in score throughout follow-up, and the remaining 19 users (50%) showed reliable deterioration at any point.

Third, we examined the group of users who had reliably recovered during treatment (n=89). There were 46 (52%) users who remained reliably recovered throughout the 6-month period, and a further 20 (22%) who remained either reliably recovered or reliably improved at each follow-up timepoint. Conversely, 18 (20%) users had at least one score that no longer reflected reliable improvement, and 4 (4%) showed reliable deterioration at at least one follow-up occasion. One (1%) user had insufficient data for this analysis. For this group, we also examined rates of reliable relapse by comparing each monthly follow-up score to the end-of-treatment score. This showed that 32 users (36%) showed a reliable relapse at any point during follow-up. In 9 of these instances, subsequent available data showed that the relapse was not sustained.

Finally, we examined changes within the follow-up period by comparing each monthly follow-up score to the end-of-treatment score for all cases (n=156). This showed that compared to when users ended treatment, 11 (7%) showed reliable improvement at every available timepoint during follow-up. Nine users (6%) showed a series of follow-up scores that reflected either reliable improvement or stability (ie, no reliable change compared to the end of treatment). Moreover, 72 (46%) showed stability at each available timepoint. In addition, 29 (19%) showed a series of follow-up scores that reflected either stability or reliable deterioration, and 23 (15%) showed reliable deterioration at

XSL•FO
RenderX

every available timepoint during follow-up. There were 11 (7%) users with a fluctuating series of scores that included both reliable improvement and reliable deterioration, and 1 (1%) user with insufficient data for this analysis.

Employment and Health Care Use

There were 109/156 (70%) Paddle users who were in employment at the start of their treatment. Of these, 102 (94%) remained employed across the treatment and follow-up period (1 moved to sickness or disability benefits, 2 experienced a temporary period of unemployment, 2 became students, 1 retired, and 1 was unemployed at the end of follow-up). There were 11/156 (7%) users who were unemployed at the start of their treatment, 7 (64%) of whom moved into employment by the end of treatment, and remained in employment or study throughout the follow-up period.

Of the 153 users who provided information on their health care use at any point during follow-up, 45 (29%) reported accessing further health care services in the month prior to completing the questionnaire. Examples included general practitioner support, voluntary helplines, private psychological therapy, or other postdischarge support from NHS TT, such as online peer support (Browne et al [32]) or an additional booster session.

Patient Survey

Of the 321 people who had used Paddle at least once, 62 (19%) responded to the feedback survey. Most reported they had downloaded Paddle because they thought it might be a helpful tool to store their information, reflect on progress, and stay well following treatment. Nearly all respondents had used Paddle to check their latest scores on the questionnaires (95%), with the majority also checking how their scores had changed over time (89%), and reviewing their progress using the monthly prompt questions (61%). Three respondents reported minor technical problems experienced when logging into the app, but noted these were eventually resolved. No other technical problems were reported. When asked about the duration of the follow-up questionnaire period, 19% of respondents felt that 6 months was appropriate, 47% said they would prefer 12 months, and 34% felt the monthly questionnaire prompts should continue indefinitely.

Users' agreement ratings with statements about Paddle are shown in Table 2. These reflected positive feedback regarding the feasibility, acceptability, and helpfulness of the app. Free-text comments highlighted the app's role in supporting users to monitor their well-being, for example: "It helped me to keep an eye on myself following the end of therapy by completing the same questions I'd done beforehand," "It's helped me to check in regularly when life's been busy and make sure the new habits I'd built in therapy had stuck," "It's been a great resource to keep my mental health a top priority," "The app has been really helpful – and I am of the older generation who didn't grow up with the internet and this technology, so that's really a tribute to the Paddle app."

Table 2. Number of Paddle users agreeing with statements about the app.

Statement	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
Paddle has been straightforward to use	0	1	16	25	20
Paddle helped me to stay well	0	1	19	26	16
I would recommend Paddle to other people who've had treatment for anxiety or depression	0	1	16	27	18

General Discussion

Principal Findings

Taken together, the 2 studies reported here demonstrated preliminary evidence that the Paddle app is feasible to implement and acceptable to patients, with good potential to support patients during and after treatment and collect postdischarge outcome data. Feasibility was indicated by the successful use of Paddle within NHS TT services, with minimal technical problems evident across the stages of inviting participants, downloading and using the app, submitting data and integrating this with services. The app was also feasible from a risk management perspective, with services only needing to respond to indications of risk on 7 occasions.

Acceptability was indicated in Study 1 by the high uptake rate (66%) and use of the app as evidenced by patient and therapist feedback. Study 2 focused specifically on the postdischarge period, and thus invited participants at the point of discharge. Although appropriate for the study aims, this design meant participants had not been using the Paddle app to develop a set of useful therapy resources during treatment. They were therefore not familiar with the benefits of Paddle before being asked to use it to submit outcome data post discharge. Perhaps as a result, uptake was low (8%). However, despite the nonoptimal conditions for starting to use Paddle, 49% (156/321) of users submitted outcome data on the app and feedback suggested they found it acceptable to help monitor their well-being after treatment.

These studies provide an initial indication of the ways in which the app may have a positive impact on patients, though further studies are needed to examine this in more depth. Feedback highlighted the potential role of the app in supporting patients to organize and remember their thoughts from each session, keep their therapy materials together, and help patients to self-monitor their well-being after treatment had ended. Using the observed uptake rate of 66% (111/168) at the start of treatment, and the follow-up data collection rate of 49% (156/321), a tentative estimate would be that if used in routine practice, the app would be collecting follow-up data on around 32% of patients in NHS TT services. This is considerably higher than typically collected in the participating services (10%) and in these services nationally (1.3%). Although the findings demonstrate that not all patients will choose to use an app or to

XSL•FO
RenderX

complete questionnaires after discharge, this suggests Paddle may offer a helpful route to improve follow-up data collection and understand more about how patients do after treatment.

Analyses indicated that the cohort of app users was representative of patients using the participating services regarding gender and age, though users from White ethnic backgrounds were overrepresented. The group of app users had an average of 13 treatment sessions and a good, reliable recovery rate (89/146, 61%), indicating the sample may have overrepresented those who did well in treatment. Although this provided a greater opportunity to demonstrate reliable relapse in the present study, future research could explore ways to broaden the use of Paddle to reach those who received fewer sessions and those from a wider range of ethnicities.

Although the present follow-up period of 6 months in Study 2 was slightly shorter than in other studies, the observed 36% relapse rate among those who reliably recovered during treatment is consistent with previous literature, falling between existing estimates of 29% [11] and 53% [12]. When analyzing all Paddle users together, regardless of their outcomes during treatment, 40% (63/156) showed reliable deterioration at any point during the follow-up phase. The data suggested that some of these increases in symptoms were not sustained, resolving later during follow-up, but this was only possible to explore where a subsequent timepoint was available. It does suggest, however, that some observed relapses or symptom deteriorations are short-lived, and may reflect natural fluctuations that are qualitatively different from more sustained relapses where additional support may be more beneficial.

We also found considerable evidence of posttreatment stability in Study 2, with a total of 74% (66/89) of those who reliably recovered during treatment remaining reliably recovered or reliably improved across the 6-month follow-up period. Similarly, among the cohort of patients who had reliably improved during treatment, 73% (86/118) remained so across the follow-up period. These findings are in line with the broader CBT literature, suggesting clinical gains are well-sustained following treatment [7-9]. It is also notable that 5 cases who reliably improved during treatment went on to reliably recover during follow-up, and in total, 20% (31/156) of all cases showed reliable improvement at one or more follow-up timepoints compared to their end-of-treatment scores. This demonstrates that further clinical gains can occur after treatment ends.

Employment data indicated that most Paddle users were in employment at the start of treatment and remained so throughout follow-up. Only 11 were unemployed at the start of treatment, but the majority of these moved into employment by the end of treatment and remained so across follow-up. These findings are therefore promising given the association between employment and well-being [33], though the extent to which they directly relate to NHS TT support is unclear and larger studies are needed.

Limitations

These initial studies have some limitations to consider when interpreting the findings. First, although we made good efforts to elicit feedback from those who chose not to use Paddle, the extent of data here was limited, despite providing informative findings. Second, the uptake of the app in Study 2 was low when considered as a proportion of the total number of people invited. However, low uptake rates can be common among health apps with many contributing factors [34], and as discussed earlier, it is possible that, having completed treatment, patients were reluctant to start using the app to collect all their therapy materials together. A helpful next study would recruit participants at the start of treatment as per Study 1, allow users to build their therapy resources through treatment, then explore the rates of continued use and questionnaire completion post discharge. Third, although the sample of app users included people from a range of ethnic backgrounds, those from White backgrounds were overrepresented. Further work to support greater diversity among app users is needed. Fourth, the classification of clinical outcomes was only possible based on the available data. Although data availability was good, with 53% of users providing at least 3 datapoints, it is possible that certain evidence of stability or fluctuations in scores could not be demonstrated. Finally, as it was not possible to include a control group in Study 2, we cannot quantify the extent to which patients' scores in the follow-up period were influenced by using Paddle to self-monitor their well-being, though participant feedback did suggest that Paddle was helpful in this regard. More broadly, it would be beneficial for studies in this area to examine postdischarge employment outcomes in greater detail alongside clinical outcomes. It would also be valuable to use methods that more clearly distinguish temporary lapses from more sustained episodes of relapse. The metric of reliable relapse developed for this study may offer a useful starting point for this.

Conclusions

Overall, the results suggest that Paddle could offer a promising route toward improving support for patients both during and after treatment. Refinements such as further streamlining the risk management procedure are now possible due to the app having medical device status, and based on patient feedback, extending the follow-up period to 12 months may be appropriate. Future studies could helpfully explore users' experience of the app in greater detail and examine factors associated with reliable deterioration or reliable relapse that may guide the provision of further support for these patients.

Abstract

Background: Many veterans who served in the Gulf experience Gulf War Illness (GWI), a chronic multisymptom condition associated with fatigue, pain, gastrointestinal problems and respiratory issues, mood/cognitive issues, and sleep difficulties. These symptoms contribute to decreased function, increased mental health needs, and poor quality of life. The Veterans Affairs War Related Illness and Injury Study Center in New Jersey developed a 26-week virtual health coaching intervention to support symptom management for veterans with GWI. In 2023, a consumer-grade smartwatch was added as part of an activity monitoring program to complement this program.

Objective: The purpose of this project was to assess the feasibility and acceptability of including a smartwatch-based activity monitoring component to complement a virtual health coaching program for veterans with GWI.

Methods: Twenty-four veterans enrolled in the health coaching program were invited to participate in the activity monitoring component. Participants attended a virtual orientation to set up the smartwatch, and verbal consent to share data through a Health Insurance Portability and Accountability Act (HIPAA)-compliant platform was obtained. Program feasibility was assessed by evaluating wear-time percentage and duration of use. Acceptability was assessed using two items from a monthly survey and through a midprogram semistructured interview. Quantitative data were summarized descriptively, and qualitative data were analyzed using a coding scheme adapted from Sekhon et al's Theoretical Framework for Acceptability (TFA).

Results: Twenty veterans agreed to participate in the program (mean age 49 years; 7/20, 35% female; 19/20, 94% non-Hispanic White; 11/20, 55% first-time smartwatch users). Twelve participants (60%) wore the watch for the full 26 weeks. Among participants who completed 26 weeks, median daily wear-time completeness exceeded 80% for 25 weeks. Most participants (12/20, 60%) reported that wearing the smartwatch helped them achieve their wellness goals, and the majority (16/20, 80%) said they would recommend using the smartwatch for activity monitoring to other veterans. Qualitative findings supported acceptability across TFA domains. One adverse event was reported (minor skin irritation that resolved after changing the smartwatch band to a hypoallergenic watch band).

Conclusions: Within this clinical program, pairing a smartwatch with virtual health coaching for veterans with GWI was feasible and acceptable. Activity monitoring integrated into an existing intervention may support symptom self-management and augment patient education and engagement. As no prior activity monitoring programs specific to veterans with GWI have been described, these findings could inform future program development and implementation within this population.

KEYWORDS

smartwatch; digital health; feasibility; Gulf war illness; HIPAA

Introduction

An estimated one-third of veterans who served in the 1990-1991 Persian Gulf War experience chronic multisymptom illnesses, commonly referred to as Gulf War Illness (GWI) [1,2]. Veterans with GWI often report a range of symptoms, including fatigue, pain, gastrointestinal problems, respiratory issues, mood/cognitive issues, and sleep difficulties that may be related to exposures during their deployment [1,3]. These chronic health concerns and symptoms contribute to decreased function, increased mental health needs, and poor quality of life [1,3]. Because the etiology of GWI remains poorly understood, treatment for GWI has largely focused on managing and alleviating symptoms [3]. Prior interventions targeting physical activity, pain, cognition, gut health, and mindfulness have shown mixed results [4].

In 2021, the Veterans Affairs (VA) War Related Illness and Injury Study Center in New Jersey (WRIISC-NJ) developed a virtual 26-week health coaching intervention to support individualized symptom management for veterans with GWI [5]. The program combines group-based sessions for peer support with individual health coaching tailored to participants' symptom profile. In 2023, a smartwatch-based activity monitoring component was added to support physical activity and sleep tracking as part of this program.

Consumer-grade smartwatches are now widely available and are used by a substantial proportion of US adults [6]. Veterans' interest in and use of smartwatches has increased in the past few years [7]. These devices use accelerometers and optical sensors to capture physical activity and heart rate. While smartwatches are not used for diagnosis, the information provided can serve as "baseline" for the individual, which can lead to greater awareness of health behavior patterns [8,9]. When paired with behavioral interventions, smartwatches may offer participants added support toward achieving personal health goals such as weight loss, reduced sedentary behavior, and increased physical activity [9,10].

Assessing feasibility and acceptability is a critical early step in the development of digital health interventions. Using definitions from Proctor et al's [11] implementation outcomes framework, feasibility refers to the extent to which an intervention can be successfully performed within a given setting, and acceptability reflects the degree to which the intervention is perceived as satisfactory or agreeable [11,12]. Acceptability and feasibility are closely linked, as an intervention may be feasible to deliver but not acceptable to participants or acceptable but difficult to implement [13,14]. In a resource-limited environment, assessing feasibility and acceptability helps determine whether an intervention is a reasonable use of time and effort before broader implementation or scale-up. These evaluations identify key facilitators and barriers based on participant feedback and willingness to engage in intervention activities, and findings can be used to refine program design and delivery [15]. Consistent with behavior change theories such as the Theory of Planned Behavior [16], sustained engagement with digital health tools is essential for the intervention to have any practical impact. Understanding feasibility and acceptability is particularly important for veterans with GWI, given their high symptom burden and complex care needs.

The purpose of this project was to assess the feasibility and acceptability of including a smartwatch-based activity monitoring component to complement a virtual health coaching program for veterans with GWI. From a human factors perspective, feasibility and acceptability reflected veterans' perceptions of how the technology fit into their daily routines and use capabilities in real-world settings. Since there is no known activity monitoring program for veterans with GWI, evaluating feasibility and acceptability is critical to future implementation of any activity monitoring program for this population.

Methods

Ethical Considerations

This quality improvement study aimed to inform the development of an activity monitoring program to complement a clinical intervention for veterans with GWI. The VA New Jersey Healthcare System Institutional Review Board determined that this quality improvement project met criteria for quality improvement and was considered non-research; therefore, formal institutional review board review was not required. The CONSORT (Consolidated Standards of Reporting Trials) extension for pilot and feasibility studies was used for reporting (Multimedia Appendix 1) [17,18].

Study Participants

Veterans with GWI who completed a comprehensive evaluation at the WRIISC-NJ were invited to participate in a 26-week virtual health coaching intervention program. Two cohorts were enrolled: April 2023 to September 2023 and October 2023 to March 2024. GWI diagnosis was determined clinically through WRIISC-NJ specialty evaluation.

Procedures

Participants received a smartwatch (Fitbit Sense 2) as part of a VA device distribution initiative [19] as well as a user guide. A videoconferencing orientation provided an overview of device setup, smartwatch capabilities (eg, tracks physical activity and heart rate), program expectations, risk mitigation (ie, taking breaks from wearing the smartwatch to mitigate skin irritation), and data privacy and sharing through a third-party Health Insurance Portability and Accountability Act (HIPAA)-compliant platform (Fitabase). Verbal consent for data sharing was obtained. Participants did not receive monetary compensation but could keep the smartwatch after program completion. Feasibility and acceptability were assessed using

XSL•FO
RenderX

smartwatch wear-time data, monthly electronic surveys, and a semistructured interview.

Activity Monitoring Program

Participants were instructed to wear the smartwatch, keep it charged, sync data using the manufacturer's mobile app at least once every 7 days, and agree to share data with the project team. These procedures were intended to reflect typical real-world use rather than impose artificial workflow constraints on participants. No additional instructions were provided regarding when or how long to wear the device beyond wearing it as tolerated. The program was designed to capture participant behavior in a free-living environment. A nurse educator reviewed battery status and "last synced" data twice per week and contacted participants if more than 6 days had elapsed without data syncing. During the postprogram session with the clinical director, participants were presented with a report summarizing their average weekly step count and sleep duration.

Quantitative Data Collection

Program feasibility was assessed using the number of participants recruited and enrolled, average daily wear-time percentage, and duration of smartwatch use (weeks) prior to discontinuation. Adverse events related to smartwatch use were recorded. Program acceptability was assessed using two items from the monthly Qualtrics survey: (1) the extent to which the smartwatch has helped them achieve their wellness goals (0=not at all; 10=definitely) and (2) the likelihood of recommending the program to another veteran by using a modified 1-item net promoter score (0=not at all likely; 10=extremely likely) [20].

Qualitative Data Collection

Questions focused on smartwatch use, perceived benefit, and anticipated continued use. These questions were loosely adapted from interview guides from other interventions conducted by the senior researchers (GA, SM) that had included questions about acceptability of technology use. Questions included, "How do you use your Fitbit?" and "Do you think you'll keep wearing the watch after the program has ended? Why or why not?" A nurse educator (author PM) trained in motivational interviewing contacted the participants by phone after the program midpoint to conduct a semistructured interview regarding smartwatch use. Two attempts were made to reach each participant. Interviews were scheduled to coincide with other program evaluation activities when possible. Interviews lasted approximately 10 minutes, and responses were recorded using a Microsoft Teams form.

Data Analysis

Survey Data

The number of completed surveys was recorded. For each survey item, the range and frequency of the final response were summarized. Group net promoter score was calculated by subtracting the percentage of detractors (scores 0-6) from promoters (scores 9-10); scores range from –100 to 100, with scores above 0 considered favorable [21].

Smartwatch Data

Step count and heart rate data were downloaded as Microsoft Excel files and stored on a VA secure server accessible only to the project team. Data were accessed by authorized project staff through the Fitabase platform and exported manually for analysis. Twenty-four-hour wear time, defined as the presence of a heart rate signal, was calculated as a weekly percentage for each participant. Weekly group distributions were visualized using box plots. Anomalous days (eg, steps recorded without heart rate signal) were excluded (~1%). All analyses were conducted using Microsoft Excel.

Semistructured Interviews

Interview data were analyzed using the Theoretical Framework for Acceptability (TFA) [22]. Sekhon et al [22] developed TFA as a comprehensive guide to assess this multifaceted measure. Six constructs were applied: affective attitude, burden, perceived effectiveness, intervention coherence, opportunity costs, and self-efficacy (Table 1).

Ethicality was excluded because no ethical or moral issues were identified in this context. Data were transferred from a Microsoft Teams form to Microsoft Word and then uploaded into Atlas.ti (version 23.2.1) for further analysis [23]. Two team members (SM, GA) piloted the coding scheme on 4 documents together. After minor revisions to the coding scheme, the same researchers coded subsequent documents independently and reconciled conflicts with team discussion.

XSL•FO
RenderX

Table 1. Coding scheme adapted from Sekhon et al's [22] Theoretical Framework of Acceptability (TFA).

Construct of acceptability	Definition of construct	Notes
Affective attitude	• How a new smartwatch user feels about using the smartwatch • How an individual with previous experience using a smartwatch feels about using the program-issued smartwatch compared to another brand's smartwatch	Whether a participant has had previous experience with another smartwatch will likely affect his/her perception of using a smartwatch
Burden	• The perceived amount of effort that is required to use the smartwatch	Comments may provide insight into barriers that should be addressed before a large-scale trial/future implementation of program
Intervention coherence	• The extent to which the participant understands how to use the smartwatch and how it can continuously collect various forms of data passively	Whether participants understood that the smartwatch should be worn "continuously" to allow for collection of data continuously will affect smartwatch wear time. Device wear time is often a proxy for an acceptability.
Opportunity costs	• The extent to which benefits, profits, or values must be given up by using the smartwatch	Comments may provide insight to barriers that should be addressed before a large-scale trial/future implementation of program
Perceived effectiveness	• The extent to which using the smartwatch is perceived as likely to achieve its purpose	Our interview questions proposed two purposes of the smartwatch: (1) whether the smartwatch has helped the participant achieve his/her wellness goals and (2) whether participants reviewed the data collected by the smartwatch.
Self-efficacy	• The participant's confidence that they can perform the behavior(s) required to use the smartwatch • The participant's confidence that they can perform the behavior(s) required to use the smartwatch led to actual use of the smartwatch's tracking function	Self-efficacy is central to technology acceptance because it reflects whether a user believes they can successfully use the device. The degree of confidence will affect actual use.

Results

Participant Characteristics

Twelve individuals enrolled in each of the two cohorts (n=24). Three later withdrew from the health coaching program, and 1 declined to participate in the activity monitoring program, resulting in a final sample of 20 participants (mean age 49 years; 7/20, 35% female; 19/20, 94% non-Hispanic White; 11/20, 55% first-time smartwatch users; Table 2). Nineteen participants completed at least one of the 6 monthly surveys, including 11 who completed all 6 surveys, 4 who completed 5 surveys, and 4 who completed 2-4 surveys. All participants completed a semistructured interview.

Table 2. Participant characteristics (N=20).

Demographic characteristics	Values, n (%)
Sex	
Female	7 (35)
Male	13 (65)
Age group (y)	
30-40	3 (15)
41-50	6 (30)
51-60	11(55)
Race/ethnicity	
Non-Hispanic White	19 (94)
Declined to answer	1 (6)
First-time smartwatch user	11 (55)

Survey Responses

Eighteen participants responded at least once to the question, "To what extent did the Fitbit program help you achieve your wellness goals?" Final responses ranged from 0 (not helpful at all; n=1), 1-5 (n=5), 6-8 (n=9), to 9-10 (very helpful; n=3). Among the 17 participants who completed at least two surveys,

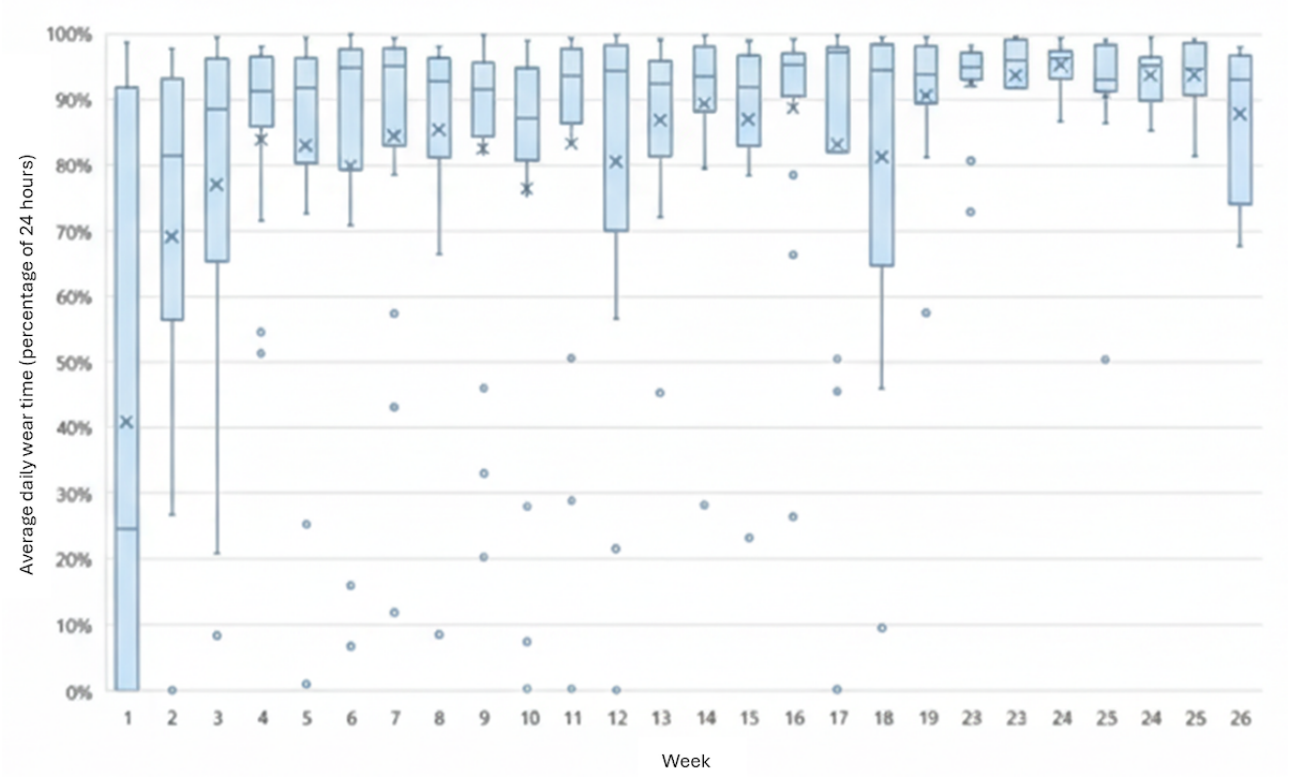
XSL•FO
RenderX

the largest observed change was from 3 to 10. All but one participant showed an increase from baseline to final response.

Nineteen participants responded at least once to the recommendation question. Final ratings ranged from 0 to 6 (n=4), 7 to 8 (n=8), and 9 to 10 (n=7). The final net promoter score was 15.8, indicating a favorable score. All but 4 participants reported increased recommendation scores over time.

Twelve participants who rated the device as helpful (rating greater than 5) also indicated they would recommend the smartwatch to other veterans (rating greater than or equal to 7). Four of 6 participants who did not rate the device helpful would still recommend the device to other veterans.

Wear Time



Total wear time ranged from 8 weeks to 26 weeks (median 26, IQR 18-26). Twelve participants (60%) wore the smartwatch for the full 26 weeks. The remaining 8 participants discontinued use between 8 and 12 weeks (n=3), 16 and 18 weeks (n=4), and 23 weeks (n=1).

Average daily wear-time completeness ranged from 10% (2.4/24 hours) to 96% (23.0/24 hours) across participants. Among those who completed 26 weeks, daily completeness ranged from 76% to 96% (18.2-23.0/24 hours; mean 87% [20.9 hours], SD 6% [1.0 hours]). Prior to device discontinuation, 6 participants demonstrated similarly high completeness (mean 85% [20.0 hours], SD 8% [2.0 hours]).

First-Time Smartwatch Users

Of the 11 first-time smartwatch users, they were more likely to be younger than 50 years (8/11, 73%) and female (5/11, 45%). First-time users showed higher rates of early discontinuation (6/11, 55%) and low daily completeness (2/11, 18%). Figure 1 shows the weekly distributions of daily wear-time completeness across participants. In most weeks, wear-time distributions were negatively skewed, with a subset of participants demonstrating substantially lower wear time than the group median. By approximately week 18, this pattern diminished as participants who discontinued use had stopped contributing data. The remaining 12 participants who wore the smartwatch for the full 26 weeks generally maintained consistently high weekly wear time.

Figure 1. Wear time by week of program. The blue box is the IQR and represents the middle 50% of wear time for the group. The bars indicate typical range (1.5 times IQR). Dots indicate outlier points (outside 3 times IQR), horizontal dash indicates median, and X indicates mean. Participants who stopped wearing smartwatch altogether (between 8 and 12 weeks [n=3], between 16 and 18 weeks [n=4], at 23 weeks [n=1]) are excluded at the point of discontinuation.

Adverse Events

There was one adverse event reported. One participant reported minor skin irritation related to the watch band, which resolved after switching to a hypoallergenic watch band.

Semistructured Interviews

Findings from the semistructured interviews are organized below by domain from TFA. Representative quotes are provided in Table 3.

XSL•FO
RenderX

Table 3. Illustrative quotes.

Construct of acceptability	Quotes
Affective attitude	• …In general, I do not like the Fitbit anywhere near as much as my Apple iWatch v3 Bluetooth. The Fitbit's Bluetooth disconnects constantly throughout the day, won't allow me to change the temperature measurement from Celsius to Fahrenheit, rings for an entire minute after I pick-up my phone, has less apps capability, but [it] does have better sleep monitoring and battery life. [Participant 8] • …I like it more and more, especially for the sleep monitoring because it has helped me attend to my sleep. [Participant 12] • …I love it! I would recommend it to others. [Participant 14] • …I stopped wearing it. It doesn't help me with my needs. I'm just not comfortable wearing it. I can't explain. Intrusive comes to mind but I don't know if that is the right word? Inconvenient? [Participant 3]
Burden	• …I thought it would be difficult to wear but it's not. [Participant 15] • …I don't even notice I'm wearing it anymore. [Participant 6] • …I do wear it except for when I'm showering and charging. I [sometimes forget] to put it on after charging, but I do wear it almost all of the time. [Participant 20]
Intervention coherence	• …I wear it all the time and look at my activity and my steps. [Participant 9] • …I wear it during the day and at night. I take it off to charge or take a shower. [Participant 11] • …I wear it in the day and when I sleep. I take it off to charge or when I shower. [Participant 15] • …I'm wearing it because I'm in the [health coaching] program. [Participant 19]
Opportunity costs	• …I had to adjust to wearing it all the time in the beginning but I am used to it now. [Participant 20] • …I was using a Garmin to affect the way I do things so I'm wearing the Fitbit to do that now. [Participant 11] • …I'm wearing [the Fitbit] every day, but I prefer my Garmin. [Participant 10]
Perceived effectiveness	• …I like it more and more, especially for the sleep monitoring because it has helped me attend to my sleep. [Participant 12] • …I use it for everything…I've lost weight! I watch my food intake. [Participant 14] • …I use the step counter, it saves the weekly reports so I look at those, heart rate and exercise, calorie counter and running heart rate checker if I'm feeling stressed…I also don't use the watch as a phone. I use it to track my health. [Participant 14] • …I use it to track my sleep but it doesn't always show up. The sleep isn't accurate with tracking…According to the watch I'm not sleeping. [Participant 15]
Self-efficacy	• …Yes. I look at my steps and my sleep. Sometimes when I look at the data I'm surprised by how many I have moved around. I recently got a penguin badge for all the walking I did when I visited the zoo with my niece a few weeks back - almost 6 miles! Even this morning I was surprised at how far I walked with the dogs. I didn't think it was that far. [Participant 7] • …I think it causes me to move more and makes me want to hit more steps. I set a goal of 10K steps but sometimes I do more. I'll do more as it goes on. I joined a gym since I started the program and I walk on the treadmill there. [Participant 15] • …I look at it more now to track my steps, sleep, and HR. I started looking at the other apps available now that I'm more familiar with the watch. [Participant 6] • …I like to look at the data and track my activity and progress. I'll look and see I haven't been as active as I thought, and so I will take the dogs for another walk so I can reach my goal of 8k steps. [Participant 1]

Affective Attitude

Most participants reported a positive overall attitude toward using the smartwatch, with many noting good usability and low interaction burden during daily activities. Some expressed immediate enthusiasm for the device, while others, particularly first-time smartwatch users, became more comfortable over time as they learned its features. Participants with prior smartwatch experience often compared devices and expressed brand preferences; however, these preferences did not appear to limit the continued use of the program-issued smartwatch, suggesting that acceptability of activity monitoring was not driven by brand alone. One participant discontinued use, citing discomfort and inconvenience with wearing the device.

Burden

The perceived effort required to use the smartwatch was generally described as low. Participants most commonly cited routine charging and remembering to put the watch back on after charging as minor inconveniences. These issues did not appear to substantially interfere with ongoing use. Only one participant reported skin irritation, which resolved with a band change.

Intervention Coherence

Participants demonstrated a clear understanding of how the smartwatch fit within the larger health coaching program. Participants consistently articulated that wearing the device, syncing data, and sharing information with the program team were expected components of participation. There was little

XSL•FO
RenderX

evidence of confusion regarding device purpose or data collection.

Opportunity Costs

There were only a handful of comments related to the idea that wearing the smartwatch caused the participant to give up something else. No individual was overly concerned about loss of time related to managing the device. One participant shared that while he preferred another brand of smartwatch because it tracked his runs better, he gave up wearing the other watch and wore the program-issued smartwatch instead while participating in the health coaching program.

Perceived Effectiveness

Most participants provided specific examples about functionalities of the smartwatch. They mentioned “steps,” “sleep,” “heart rate,” and one participant mentioned “water intake” and “calories.” They reported that the act of monitoring increased their awareness of physical activity and encouraged them to be more active or pay closer attention to sleep habits. While participants generally described the smartwatch data as useful for self-monitoring, several expressed mixed views about the perceived accuracy of certain metrics, particularly sleep data.

Self-Efficacy

Participants uniformly expressed confidence in their ability to use the smartwatch. Particularly for those with previous experience using another smartwatch, they leveraged their previous experience to use the program-issued smartwatch, and some reported tinkering with the applications. The majority of the participants recognized that the smartwatch can be used to track some health behaviors and reported independently reviewing their data to inform daily activity choices.

Discussion

Principal Findings

In this program, smartwatch-based activity monitoring was incorporated into a virtual health coaching program for veterans with GWI with sustained use and participation. High rates of sustained participation and daily wear-time completeness indicate that most participants were willing and able to engage with activity monitoring over an extended period. Favorable survey scores and qualitative feedback further support the acceptability of this approach. From a human factors standpoint, the combination of sustained wear, low reported burden, and high self-efficacy suggests that the device-user interaction was well aligned with participants’ capabilities and daily workflows. Program observations support the feasibility and acceptability of incorporating activity monitoring into health coaching programs for veterans with GWI.

This paper presents findings from the first known activity monitoring program specifically for veterans with GWI. Prior studies have shown that wearable activity trackers can be implemented in populations with chronic disease and are commonly used to support physical activity and self-monitoring, which is consistent with the patterns observed in this program [24-28]. Using a smartwatch for activity monitoring may help inform the design of personalized symptom-management strategies and may provide signals regarding treatment response. This may be applicable for veterans with GWI with decreased cognitive function, since the smartwatch may serve as a cognitive support tool to reduce tracking burden, create accountability, increase awareness of how behavior can affect health, and prompt discussions with care team [27].

Assessing feasibility and acceptability are conventional practices for researchers when introducing new program components, particularly in unique clinical populations such as veterans with GWI who have complex and variable health needs. A feasibility pilot would also explore barriers and pain points related to technology use prior to broader implementation. Technology acceptance frameworks such as the Technology Acceptance Model describe how perceived usefulness and perceived ease of use shape attitudes toward technology and influence actual use [29]. Although our qualitative analysis was guided by TFA, these constructs align conceptually with the Technology Acceptance Model and helped clarify why participants did or did not accept the activity monitoring program.

Prior studies have identified factors such as social features and engagement strategies that influence the acceptability of mobile health components, including social connectivity [30], gamification [31], and ability to choose among available devices [32]. Device-agnostic platforms may increase flexibility and user choice; however, they can also introduce challenges related to data integration and standardization across devices [32,33]. Issuing a single device to all participants can simplify data management and support consistent clinical feedback, but it may also introduce tension for participants who prefer another brand of smartwatch. Our findings reflected this complexity. Several participants expressed loyalty to other smartwatch brands; however, most continued to wear the program-issued device, suggesting that brand preference alone did not determine acceptability of the activity monitoring program. Similar to prior digital health programs, sustained engagement tends to decline over time in app-based and wearable-based interventions [34,35].

Acceptability in this program appeared to be multifaceted and strongly shaped by clinical context. Survey results suggested that perceived helpfulness was closely aligned with willingness to recommend the program, supporting overall acceptability. At the same time, qualitative data indicated that some participants viewed the smartwatch as less useful, preferred a different brand, or questioned specific device features. Despite these reservations, many continued to wear the program-issued device because it was embedded within the larger health coaching program. For these participants, participation in the core health coaching intervention and their commitment to the program appeared to outweigh dissatisfaction with the specific device. This suggests that acceptability of the activity monitoring component was influenced not only by the smartwatch itself but also by veterans’ motivation to fully engage in the broader health coaching program.

Limitations

This quality improvement project was designed to assess feasibility and acceptability rather than effectiveness; therefore,

XSL•FO
RenderX

causal inferences cannot be made. Smartwatch data were collected in an uncontrolled free-living environment and could not be independently validated. Although the sample size was modest, it was sufficient to detect common feasibility challenges in pilot work [36]. Participants were recruited from a single VA center, which may limit generalizability to the broader population of veterans with GWI. Because activity monitoring was implemented as part of a health coaching program, our findings may not generalize to a standalone activity monitoring program or to other populations.

Conclusions

The growing availability of smartwatches creates an opportunity to support symptom self-management for veterans with GWI. In this program, activity monitoring was implemented to complement a 26-week virtual health coaching program. The program demonstrated high feasibility and acceptability within this clinical setting, supporting activity monitoring as a feasible way to augment patient education and ongoing support for veterans with GWI. Program acceptability appeared to be influenced by both the usability of the device and its integration within the existing health coaching program.

When conducting feasibility work, programs should be designed to reflect the specific setting and population of interest. Collecting both quantitative and qualitative data provides important context for understanding use and engagement. Assessing feasibility and acceptability can then be used to inform implementation strategies tailored to supporting sustained participation in the program.

Acknowledgments

The authors would like to thank Elijah Sacra, Clarissa Kussin, and Sandhya Bandi for their support of the program. Carolyn Alish of Sterling Medical Communications LLC provided editorial support. The views expressed in this article are those of the authors and do not necessarily represent the views of the US Department of Veterans Affairs or the United States government. Generative artificial intelligence (AI) tools were used solely to assist with grammar and style editing. No AI tools were used to generate substantive content. The authors reviewed all edits and take full responsibility for the final text.

Funding

No funding was received for this study. However, GIA's time was supported by the National Institute of Diabetes, Digestive, and Kidney Diseases of the National Institutes of Health under a mentored research scientist development award (K01DK129441).

Data Availability

The data that support the findings of this study are available on request from the corresponding author.

Authors' Contributions

Conceptualization, formal analysis, methodology, visualization, writing – original draft: SSM, GIA
Data collection: PM, SG, SSM, GIA

Abstract

Background: The rising popularity of apps that sync with continuous glucose monitors (CGMs) reflects growing interest in on-demand, personalized care. These platforms combine real-time glucose biofeedback with self-monitored behaviors to optimize metabolic health among individuals with and without diabetes. However, little is known about user characteristics, engagement patterns, or factors associated with sustained use of CGM-integrated digital health apps in real-world settings.

Objective: This study aimed to describe user demographics, CGM usage patterns, and food logging behaviors among Vively app users and to identify characteristics of sustained engagement with CGM wear and food tracking.

Methods: We conducted a retrospective observational study of Vively app users between August 2021 and February 2025. Vively is a commercial digital health app that integrates with Abbott FreeStyle Libre CGMs to deliver personalized nutrition guidance. Users with at least 1 day of CGM wear were included. Primary outcomes were CGM wear duration (total days) and food logging engagement. Factors associated with engagement were identified using negative binomial regression for CGM wear and hurdle negative binomial models for food logging, adjusting for age, sex, BMI, baseline glucose, and device connectivity; the food logging model additionally adjusted for CGM wear category.

Results: The analytical sample included 7647 users (4782/6905, 69.3% female, mean age 44.4, SD 10.9 years, mean BMI 27.8, SD 6.1 kg/m²). Users wore CGMs for a median of 15 (IQR 14-30) days, with 42.7% (3263/7647) completing one full wear period (13-15 days) and 30.3% (2315/7647) completing 2 or more wear periods (≥28 days). Most users (7013/7647, 91.7%) logged food at least once, with a median of 47 (IQR 18-91) food entries over 12 days. Food logging declined progressively during CGM wear (mean 63.2%, SD 8) and dropped sharply after sensor removal (mean 2.4%, SD 1.1). In multivariate models, higher baseline glucose was associated with longer CGM wear (incidence rate ratio [IRR] 1.15, 95% CI 1.13-1.17) but fewer food logging days (IRR 0.96, 95% CI 0.94-0.98). Connected device syncing showed the strongest association for both CGM wear (IRR 1.32, 95% CI 1.28-1.37) and food logging (IRR 1.45, 95% CI 1.39-1.51). Older age and female sex were associated with higher engagement in both behaviors.

Conclusions: This large-scale analysis reveals distinct engagement patterns with CGM-integrated digital health applications. Food logging was largely concurrent with active CGM wear, dropping dramatically in CGM-free periods. The divergent associations of baseline glucose levels, with longer CGM wear but reduced food logging, may reflect different motivational drivers for passive monitoring versus active behavior tracking. These findings have important implications for designing sustainable digital health interventions that maintain user engagement beyond periods of biological feedback, though replication in more diverse samples and studies accounting for diabetes status and socioeconomic factors is needed.

Introduction

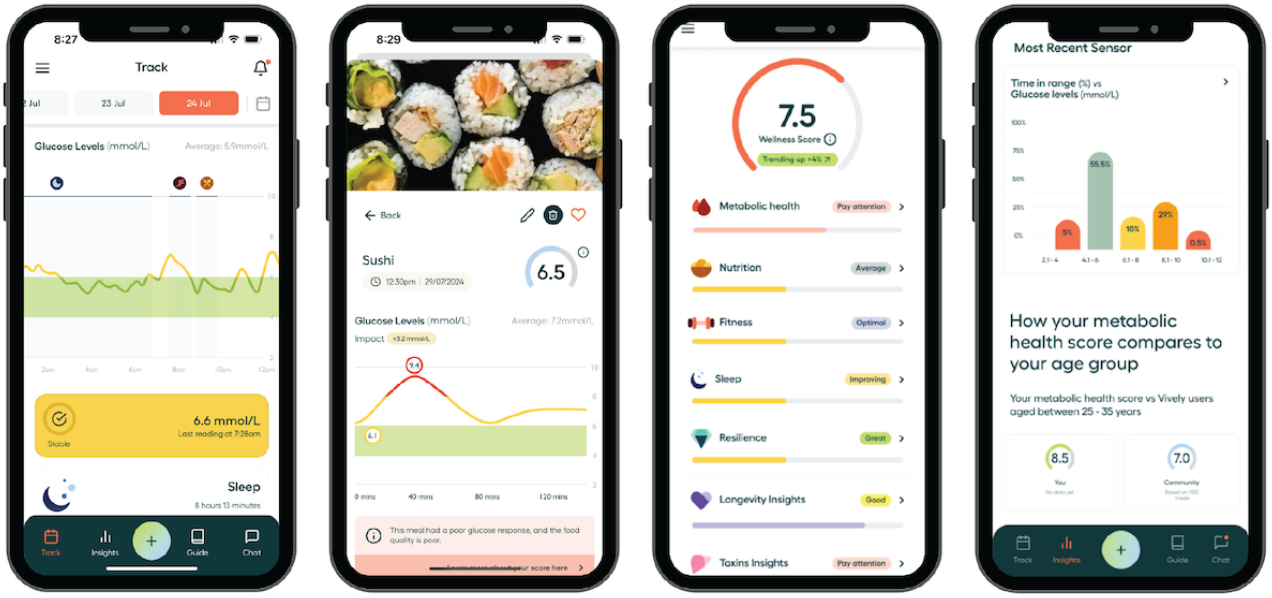
In recent years, a growing number of companies have begun offering direct-to-consumer web- or app-based programs that are paired with continuous glucose monitors (CGMs) to optimize well-being and improve metabolic health. These programs represent an emerging application of precision nutrition: a technology-enabled approach that leverages individual variability in genetic, metabolic, phenotypic, and behavioral factors to optimize dietary recommendations and health outcomes [1,2]. By providing real-time, CGM-based biofeedback on glucose responses to meals and lifestyle behaviors, these platforms are increasingly marketed to individuals without diabetes as tools for metabolic optimization. Users are encouraged to adjust their diet, meal timing, and physical activity based on their personalized guidance to promote weight loss and glycemic stability, an indicator of metabolic health [3]. Early clinical trials have begun to demonstrate the effectiveness of combining CGM with personalized nutrition therapy on health outcomes among people without diabetes [4-6].

Advances in CGM technology and artificial intelligence, the precision health movement, and increasing device accessibility [5] have driven the expansion of commercial CGM-integrated apps. While CGMs were originally developed for insulin-dependent diabetes management, manufacturers have expanded access by releasing over-the-counter versions in several countries, enabling broader use among health-conscious consumers. Paired with mobile apps that translate sensor data into behavioral insights, CGMs are being positioned not only as medical devices but also as tools for health behavior change [6-9]. Yet most existing research on CGM-integrated apps has focused on diabetes management populations [10-12], with less attention to predominantly nondiabetic consumers using intermittent wear patterns for metabolic optimization. Despite the increasing interest in CGM-based mobile health apps, there is little empirical evidence describing who uses these tools, how they are used in everyday, nonclinical settings, and which factors are associated with sustained engagement. Most commercial platforms do not publicly report user characteristics or behavioral engagement metrics, leaving a critical gap in real-world evidence that limits both scientific understanding and the design of effective, scalable interventions.

This study addresses this gap by leveraging large-scale observational data from real-world users of the Vively app (Vively Health Pty Ltd), a commercial, CGM-integrated platform focused on personalized nutrition and lifestyle modification. We characterize user demographics, CGM usage patterns, and food and activity tracking, and identify associations with sustained engagement. In doing so, this work provides rare, real-world insight into how individuals interact with CGM-based feedback tools in consumer settings, with implications for the design and evaluation of precision digital health interventions.

Methods

Study Design



This was a retrospective observational study of Vively app users. The cohort entry window included users who initiated app use between August 2021 and November 2024. The follow-up window extended through February 2025, ensuring all users had at least 3 months of potential engagement data for analysis. Users were eligible for inclusion if they had at least one day of CGM sensor wear during the study period. The final analytical sample included 7647 users. This study followed STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for reporting observational research [13] (Multimedia Appendix 1).

Vively CGM Program

The Vively app is a commercially available digital health application that integrates with the 14-day Abbott FreeStyle Libre 2 and 3 CGM. It delivers real-time glucose feedback, meal scoring, and behavioral guidance to support metabolic health, weight management, and disease prevention. Designed for users with and without diabetes, the app combines CGM data with self-reported food and activity logs, allowing users to observe how lifestyle factors affect glucose levels (Figure 1).

XSL•FO
RenderX

Figure 1. Screenshots of the Vively app.

Vively includes meal-level scoring based on both nutrient quality and postprandial glucose responses. Users are encouraged to log meals during and between CGM wear periods to receive personalized feedback and track changes over time. The app can also sync with wearable devices to capture data on physical activity, sleep, and stress. Optional support from a registered dietitian is available as a paid add-on, offering one-on-one feedback for users seeking additional guidance.

Users typically begin their Vively experience by wearing a CGM sensor for 14 days to establish a baseline of glucose patterns and responses to food, activity, and lifestyle factors. During this period, users are encouraged to log meals and workouts to help the app generate personalized insights. After this initial wear period, users may continue to engage with the app without wearing a sensor. During these times, users can still log meals and receive guidance based on their previous CGM data and overall dietary patterns. Users are advised to repeat CGM wear approximately every 3 months as a refresher and to receive updated feedback. This intermittent approach is intended to balance the benefits of biological feedback with long-term usability and cost.

Study Outcomes

User engagement was assessed using 2 outcomes: daily food logging and CGM wear duration. Daily food logging was treated as a continuous variable (total food logging days) and as a binary outcome indicating whether a user ever logged food. CGM wear duration reflects the total number of days with CGM data. In addition to modelling total CGM wear duration, we categorized wear duration to reflect the intended, intermittent, CGM use pattern (2 weeks, every 3 months): less than 1 full wear duration (<13 days), 1 full wear duration (13-15 days), 1 to 2 wear durations (16-27 days), and 2 or more wear durations (≥28 days). A CGM wear duration of 13-15 days will herein be referred to as 1 CGM wear, and a CGM wear duration of 15 or more days will be referred to as 2 (or more) CGM wears. Food logging served as our primary measure of app engagement, since users received feedback mainly on this behavior, while CGM sensor wear was used as a secondary measure of engagement.

Diet quality and diet glucose scores, as derived by the Vively app, were extracted as indicators of the average nutritional and glycemic quality of meals logged over the cumulative CGM wear and food logging duration. The diet quality score (range 0-10) reflects the nutritional composition of meals, including macronutrient distribution, degree of food processing, and whether the food contained alcohol. The diet glucose score (range 0-10) is derived from CGM data and captures postprandial glucose responses over a 2-hour window following each reported meal, and includes area under the curve, time-in-target range, and peak glucose levels. For each user, average scores were calculated across all eligible meals to summarize how meals aligned with the app's metabolic goals. Higher scores for each diet-related outcome are more favorable.

Physical activity data were extracted from the Vively app as steps or workouts. Users with physical activity data were those who synced a connected device, such as a smartwatch or smartphone, to the Vively app. Step counts were inferred from any non-null step data linked to a third-party source (eg, Apple Health, Garmin). Workout data were collected from both third-party sources and user-logged events and were analyzed descriptively as a proxy for physical activity engagement.

Statistical Analysis

We used descriptive statistics to summarize user characteristics, CGM wear, and app usage, reporting mean (SDs) or median (IQRs), as appropriate for the data distribution. Diet scores, step counts, and workout frequency were summarized descriptively and not included in modelling. Step counts were restricted to a plausible daily range of 500-100,000 steps. The lower bound was chosen to exclude days likely reflecting nonwear rather than genuine sedentary behavior, as very low counts are implausible for a full wear day [14]. Days with step counts more than 3 SDs below an individual's mean were additionally

XSL•FO
RenderX

removed; only below-mean outliers were excluded, as high step counts remain physiologically plausible.

CGM wear and food logging were the outcomes of interest, modeled separately as correlates of app engagement. Daily food logging rates were calculated across the first 14 days of the first CGM wear period and the first sensor-free period following it. The analytical sample on each day was restricted to users who had reached that wear day or break day. For wear days, users with shorter initial wear periods were excluded from subsequent days' calculations. For break days, users who initiated a second sensor wear were excluded from subsequent days' calculations, as their first sensor-free period had ended. To identify factors associated with food logging, we used a hurdle, negative binomial model. The hurdle model accounts for zero inflation and overdispersion in the count of logging days by modelling two components: (1) a logistic regression estimating the odds of ever logging food (≥1 day vs none), and (2) a zero-truncated negative binomial regression estimating the number of logging days among users who logged at least once. To reduce the influence of extreme values, food logging days were winsorized at the 99th percentile (111 days) prior to modelling, retaining all users in the analysis while reducing the influence of the 76 users (1%) with extreme logging durations [15]. Variables in both components included age, sex (reference: female), BMI, baseline mean glucose, and connected device use. The CGM wear category was included in the food logging model as an adjustment variable to account for the association between wear duration and food logging opportunity. As the CGM wear category represents a study exposure rather than a user characteristic, its coefficients are not presented in the regression forest plot.

Total CGM wear days were modeled using a standard negative binomial regression, using the same set of variables. Food logging days were excluded from this model to avoid adjusting for a potential downstream behavior. All continuous variables were modeled linearly and checked for collinearity. Exponentiated coefficients are reported as odds ratios or incidence rate ratios (IRRs), with corresponding 95% CIs. All regression models estimate associations between variables. As this is an observational study without randomization or experimental manipulation, findings should be interpreted as descriptive associations rather than causal effects.

User characteristics and engagement outcomes of interest were compared across the predefined categories of CGM use using pairwise tests. For continuous variables, pairwise independent 2-tailed *t* tests were conducted; for categorical variables, pairwise Fisher exact tests were used. All *P* values were adjusted for multiple comparisons using the Bonferroni correction. Effect size was calculated using Eta-squared (η^2) for continuous variables and Cramér V for categorical variables. Users with missing values for any of the variables were excluded from regression models; no imputation was performed. Missing data were observed for age (n=274, 3.6%), BMI (n=293, 3.8%), and baseline mean glucose (n=218, 2.9%), resulting in 502 users (6.6%) excluded from both regression models, leaving an analytical sample of 7145. All analyses were conducted in R (version 4.2.2; R Foundation for Statistical Computing), using the *pscl* and *MASS* packages for count models.

Ethical Considerations

The Georgetown University Institutional Review Board reviewed the study and determined this secondary analysis of deidentified data to be exempt (STUDY00008558). On account creation, Vively users agree to the Health Privacy Policy, which explicitly permits the use of deidentified operational data for research purposes. Users may withdraw consent at any time by opting out within the app or by contacting Vively support. Data extraction was performed by Vively prior to transfer in accordance with their privacy policy and the terms of the data-sharing agreement, which governed how opt-out requests were handled. Data were deidentified before transfer. Data were transferred via a secure file transfer protocol under a formal data-sharing agreement that specified permissible uses, storage requirements, and publication rights, and prohibited reidentification. No direct identifiers were available to investigators. No compensation was provided. Vively provided deidentified data exports under a data-sharing agreement and had no role in study design, analysis, interpretation, or the decision to submit. Investigators retained full control of the analytic code and results.

Results

Vively User Characteristics

The analysis included a total of 7647 individuals who used Vively with at least 1 day of CGM sensor wear (Table 1). The cohort was predominantly female, with roughly equal proportions in the normal (2555/7354, 34.7%), overweight (2518/7354, 34.2%), and obesity (2164/7354, 29.4%) BMI categories. Age ranged from 18 to 88 years. Most users were based in Australia (7091/7571, 93.7%), where Vively Health is headquartered.

[a]Effect size calculated using Eta-squared (η^2) for continuous variables and Cramér V for categorical variables. These reflect different types of association and are not directly comparable.

[b]For η^2: small ≈ 0.01, medium ≈ 0.06, large ≈ 0.14.

[c]For Cramér V (df=3): small ≈ 0.06, medium ≈ 0.17, large ≈ 0.29.

[d]Not applicable.

[e,f,g,h]Values with e, f, g, h superscript letters indicate statistically significant differences in pairwise comparisons between CGM wear categories (<1, 1, 1-2, ≥2 wears) based on 2-sided independent *t* tests or Fisher exact tests with Bonferroni correction.

[i]Calculated from hours 24 to 96 of continuous glucose monitor wear.

[j]A high diet quality score indicates better nutrient composition and less food processing.

[k]A high diet glucose score indicates a more stable and controlled glucose response, while a low score suggests potentially more rapid and significant spikes in blood sugar.

CGM Wear Patterns

Users wore a CGM for a median of 15 (IQR 14-30) days. There were 2 peaks in total wear durations: 42.7% (3263/7647) of users had 1 CGM wear (13-15 days), and 30.3% (2315/7647) of users had 2 or more CGM wears (≥28 days; Figure 2). For those with 2 CGM wears (either partial or full wears, 16-30 days; 1583/7647, 20.7%), the median number of days between CGM wears was 31 (IQR 6-85) days, and patterns varied widely (Figure 3). There were 141 users (1.8%) with 10 or more CGM wears (≥140 days). Reasons for partial CGM wear (<14 days; 2069/7647, 27.1%,) were not recorded.

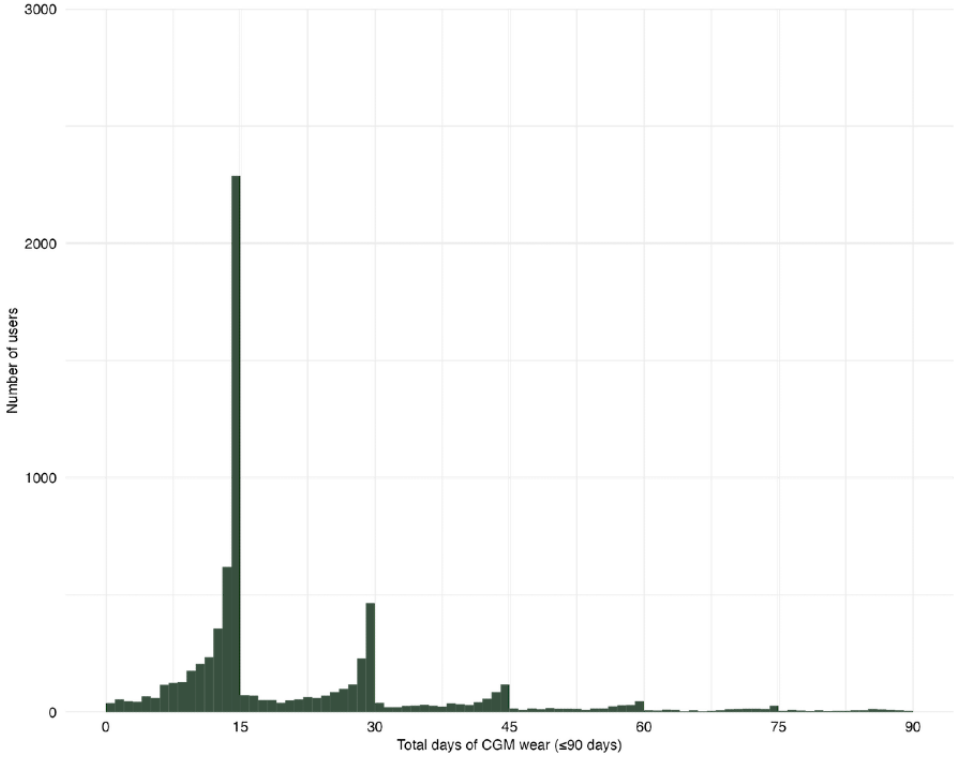
Figure 2. Distribution of total continuous glucose monitor wear days per user (N=7647). CGM: continuous glucose monitor.



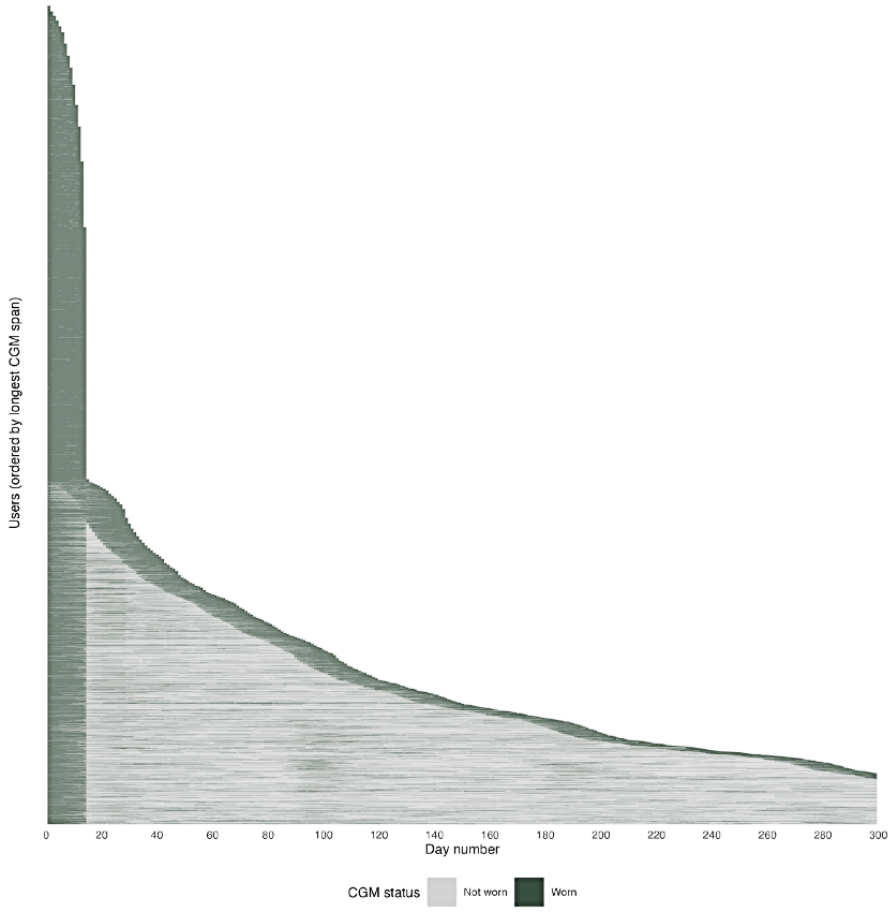


Figure 3. Continuous glucose monitor wear patterns among users over 300 days (N=7647). Each row represents an individual user, ordered by the longest span of CGM wear. Green tiles indicate days with continuous glucose monitor wear, and grey tiles indicate days without continuous glucose monitor wear. CGM: continuous glucose monitor.

XSL•FO
RenderX

Food Logging

Most users (7013/7647, 91.7%) logged at least 1 food item. The median number of entries was 47 (IQR 18-91) items over a median of 12 (IQR 6-19) days. One hundred users logged on for at least 100 days, and 8 users logged food on more than 300 days. As with CGM wear, the most common cumulative food logging duration was 13-15 days (960/7647, 12.6%). On days with food entries, users reported an average of 3.5 (SD 1.4) meals per day.

Food logging declined progressively during CGM wear and dropped sharply after sensor removal. During the first 14 days of the initial CGM wear period, daily food logging rates averaged 63.2% (SD 8), declining from 72.3% (5519/7638) on the first wear day to 50.7% (2500/4934) on the 14th wear day. After sensor removal, daily food logging rates averaged 2.4% (SD 1.1), declining from 5.4% (415/7636) on the first day after sensor removal to 1.6% (95/6091) on the 14th day after sensor removal.

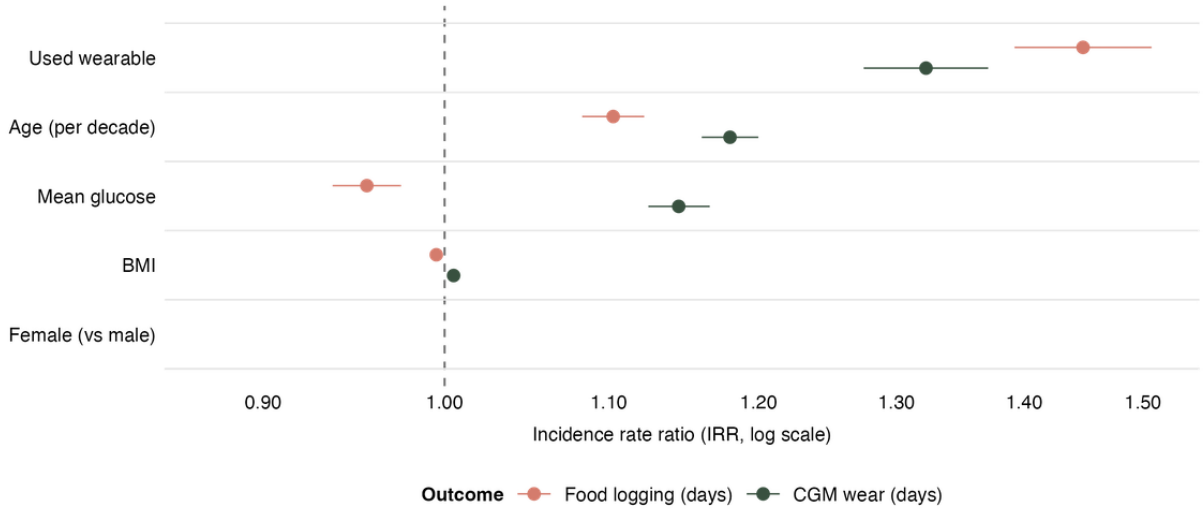
Diet scores were presented to users for each logged meal and were scored from 0 to 10, with higher scores suggesting better food choices. Diet quality scores, which were based on nutrient composition and degree of food processing, were available for 77.5% (421,418/543,476 meals) of logged meals across 6876 users. To receive a score, a meal needed to contain at least one ingredient with nutrient information. The cumulative, per-user mean diet quality score was 8.1 (SD 0.7). Diet glucose scores, based on postprandial glucose response, were available for 86.3% of logged meals (469,279/543,476 meals) across 6917 users. The cumulative, per-user mean diet glucose score was 8.7 (SD 0.8).

Vively User, Engagement, and Behavioral Characteristics Across CGM Wear Categories

When comparing Vively users, engagement, and behavioral characteristics across CGM wear categories, most between-group differences were small in magnitude ($\eta^2 \leq 0.03$; Cramér V ≤0.13) and should be interpreted cautiously given that statistical significance is expected across nearly all comparisons at this sample size (Table 1). Compared to users with 1 total CGM wear, users with 2 or more CGM wears were older (47.0 (SD 10.6) years vs 43.8 (SD 11) years, $P<.05$), they had the highest mean baseline CGM glucose, they reported fewer meals per day (on average), and had slightly higher Vively diet quality scores. Users with 1 total CGM wear also had the highest proportion of CGM days with food logging (62.9%, SD 34.6), with users in all other wear categories logging on a smaller proportion of their CGM days (50.1%-50.7%). Users with less than 1 CGM wear were the youngest users; they were least likely to have a connected device synced with Vively, they reported the fewest number of meals per day, and had the lowest Vively diet quality score. Users with 1-2 CGM wears were not markedly different from users with 1 CGM wear or 2 or more CGM wears.

Steps and Workouts

Most users (4668/7647, 61%) connected Vively to a third-party device. The most common devices were the Apple Watch (3026/7647, 39.6%) and the Garmin watch (625/7647, 8.2%). Among those with connected devices, step counts were recorded on average for 80.6 (SD 79.2) days, with a mean daily step count of 3831 (SD 4024). Exercise logging was high, with 78.8% (6029/7647) users logging at least one workout. The number of workouts per user varied widely (median 28, IQR 7-93).



Factors Associated With Food Logging and CGM Wears

Regression analyses examined associations between measured user characteristics and engagement, but could not control for unmeasured factors such as diabetes status, medications, or socioeconomic circumstances.

Figure 4 depicts the factors associated with app engagement, measured as food logging (total days) and CGM wear duration (total days). Baseline mean glucose showed divergent associations across outcomes, with higher glucose associated with greater CGM wear but reduced food logging. Device syncing, older age, and being female were associated with higher engagement for both outcomes. Associations with BMI were small and inconsistent across models.

XSL•FO
RenderX

Figure 4. Factors associated with engagement behaviors. Incidence rate ratios with 95% CIs from negative binomial models of food logging days and continuous glucose monitor wear days. Incidence rate ratios are shown on a log scale; values >1 indicate positive associations. CGM: continuous glucose monitor; IRR: incidence rate ratio.

Among the 7013 Vively users (91.7% of 7647) who logged food at least once, females logged 14% more days than males (IRR 1.14, 95% CI 1.09-1.19). Each additional decade of age was associated with an 10% increase in logging days (IRR 1.10, 95% CI 1.08-1.12), and each 1 mmol/L higher mean glucose was associated with 4% fewer logging days (IRR 0.96, 95% CI 0.94-0.98). Users with a connected device logged 45% more days than those without (IRR 1.45, 95% CI 1.39-1.51). Logging days were marginally lower with higher BMI (IRR 0.995, 95% CI 0.992-0.998).

CGM wear duration was positively associated with baseline glucose (IRR 1.15, 95% CI 1.13-1.17). Similar to food logging, use of a connected device was associated with more CGM days (IRR 1.32, 95% CI 1.28-1.37). CGM wear days were 8% higher among women than men (IRR 1.08, 95% CI 1.04-1.12) and were slightly higher among users with higher BMI (IRR 1.01, 95% CI 1.00-1.01) and older age (IRR 1.18 per decade, 95% CI 1.16-1.20).

Discussion

Principal Results

This large-scale observational analysis of Vively users offers a rare window into real-world use of a digital health app that integrates CGM with self-tracked behaviors. The cohort of 7647 users was predominantly female and middle-aged, with a broad range of BMIs and mostly normoglycemic glucose levels. Most users wore a CGM for 15 days, with distinct peaks in wear duration at 13 to 15 and 28 to 30 days, reflecting 1 or 2 sensor periods, respectively. Users with repeat CGM use (2 or more wears) tended to be older and had higher baseline glucose levels, though differences in user characteristics across CGM wear categories were generally small in magnitude. Food logging, used as an indicator of app engagement, was largely confined to periods of active CGM wear, declining progressively during the wear period and dropping sharply after sensor removal. Several user characteristics were associated with engagement, with some variation by outcome. Higher glucose levels were linked to longer CGM wear but fewer food logging days. Consistent associations of greater engagement across both behaviors included device syncing, older age, and identifying as female. BMI showed small and inconsistent associations with engagement.

The level of engagement among this cohort of Vively app users, specifically in food logging, was notable, even when accounting for potential self-selection bias. The observed level of self-directed adherence suggests a motivational factor, likely driven by the immediacy and personal relevance of glucose feedback. This aligns with prior research showing that combining food logging with self-monitoring of behavioral outcomes, such as self-weighing during weight loss efforts, is associated with higher engagement and greater goal attainment [16]. Other studies have found that personalized feedback independently improves adherence to food logging [17-19]. CGM-based feedback may provide particularly salient motivation, as it offers immediate, personalized insights into the physiological consequences of food choices. While our observational design cannot determine whether CGM feedback directly causes increased engagement or whether highly motivated individuals are more likely to both wear CGMs and log food consistently, previous research has shown that self-monitoring diet is itself a key behavior in achieving health goals and has been identified as one of the strongest predictors of weight loss [16,20-22]. Nevertheless, food logging dropped sharply after CGM removal, even though the Vively app continues to provide personalized dietary feedback in the absence of sensor wear, suggesting that engagement with active self-monitoring behaviors is closely tied to the availability of real-time biological feedback.

Several factors were consistently associated with overall engagement with the app, including both food logging and CGM wear. Device syncing emerged as one of the strongest relationships across both outcomes, suggesting that integration of multiple data sources may be associated with higher engagement by providing more complete and rewarding feedback. Previous research has found that integrating

XSL•FO
RenderX

third-party devices, such as wearables, into interventions has been associated with improved engagement [23] and enhanced physical activity outcomes [24,25]. As wearable technology becomes more sophisticated and apps increasingly integrate multiple devices and data streams, the role of device connectivity in sustaining user engagement warrants further investigation. Understanding both how users interact with digital health technologies and whether that interaction supports behavior change is essential for designing effective interventions [26]. Older age was also associated with higher engagement in our sample, though this relationship is inconsistently observed across studies of nutrition app use [27]. Women were more likely to engage in both food logging and CGM wear. However, as is common in behavioral research, our sample included a greater proportion of women, which may have influenced these findings.

We found that baseline glucose showed divergent effects on engagement. While users with higher glucose were more likely to persist with CGM wear, they were paradoxically less likely to log food, potentially reflecting lower motivation for active diet tracking or greater burden of behavior change. Users with higher glucose levels may perceive greater value in the sensor data itself, focusing on monitoring rather than on modifiable behaviors such as dietary tracking. While these patterns suggest potential mechanisms, such as passive monitoring requiring less effort than active logging, or users with higher glucose prioritizing observation over intervention, our cross-sectional, observational design prevents us from determining the directionality or causality of these relationships. Longitudinal experimental studies would be needed to test these hypothesized mechanisms.

Comparison With Prior Work

Our findings are consistent with emerging evidence on engagement patterns in CGM-integrated digital health applications. The divergent associations between baseline glucose and engagement behaviors, with higher glucose associated with greater CGM wear but reduced food logging, echo patterns observed in other studies. Kumbara et al [11] reported that diabetes management app users with baseline mean glucose >10 mmol/L (180 mg/dL) were substantially less likely to log food intake, exercise, sleep, and medication use. This suggests that elevated glucose may signal lower capacity or motivation for active self-monitoring despite greater clinical need. Dehghani Zahedani et al [10] reported similar engagement patterns, with nondiabetic participants showing better adherence to food and activity logging during a 10-day CGM intervention. While their superior metabolic outcomes (91.7% of nondiabetic participants improving time in range compared to 58.3% with type 2 diabetes) could reflect better engagement, metabolic differences and medication use likely contribute substantially to these outcome differences independent of engagement behavior. The consistent pattern of reduced engagement among those with elevated glucose nevertheless suggests that metabolic dysregulation may create barriers to effortful self-monitoring, whether through competing priorities, psychological burden, or lower self-efficacy.

Our results also support the expected finding that passive monitoring requires less sustained effort than active tracking. Böhm et al [12] documented this pattern in a diabetes management app, where users engaged more consistently with automated data entry, such as CGM, compared to manual input like food and medication logs. More recent real-world evidence confirms that CGM adherence patterns predict glycemic outcomes, with higher adherence associated with greater hemoglobin A_{1c} improvements [28]. We observed similar dynamics, with CGM wear showing more sustained engagement than food logging, particularly after the initial sensor period. While the lower effort required for passive monitoring compared to active tracking is self-evident, passive data collection methods also eliminate recall bias and reduce administrative burden compared to manual self-monitoring [29], which may explain their superior adherence patterns. Quantifying this difference in real-world commercial settings provides empirical support for prioritizing low-burden technologies in intervention design, particularly for individuals managing chronic conditions or elevated health risks who may have limited capacity for intensive self-monitoring.

Our study contributes to this evidence base by examining engagement in a predominantly nondiabetic, commercial app context. While prior research has focused primarily on clinical diabetes management platforms, we demonstrate that these engagement dynamics also occur in consumer-oriented precision nutrition applications targeting metabolic optimization. The progressive decline in food logging from an average of 63.2% during wear to 2.4% after sensor removal underscores how strongly engagement depends on the presence of immediate biological feedback. This pattern emerged even among self-selected, paying users presumably motivated to improve their health, which has implications for designing sustainable digital health interventions that must maintain user engagement beyond periods of wearable sensor use.

Strengths and Limitations

As an observational study without a control group, randomization, or experimental manipulation, our findings represent associations rather than causal relationships. We cannot determine whether CGM feedback directly drives engagement behaviors or whether unmeasured factors influence both CGM adoption and self-monitoring behaviors. Additionally, we cannot establish temporal ordering, for example, whether baseline glucose influences subsequent engagement, or whether pre-existing engagement patterns predict glucose levels. To assess whether differential follow-up time could explain engagement differences across CGM wear categories, we compared available follow-up time across groups. Median follow-up time was broadly comparable across categories (45-70 weeks), and the correlation between follow-up duration and total wear days was negligible (Spearman ρ=0.06), suggesting that observed differences in wear reflect true engagement rather than observation time.

The dataset lacks information on diabetes status, medications, comorbidities, and socioeconomic status, factors that may influence both glucose levels and motivation to engage with health tracking technologies. These unmeasured factors could

XSL•FO
RenderX

confound observed associations. As an observational dataset of paying users of a commercial wellness app, the sample is self-selected and skewed toward women and Australian residents, likely representing health-motivated early adopters of CGM technology rather than typical patients or the general population. While we characterize this as "real-world" data because it reflects naturalistic, voluntary app use in commercial settings (as opposed to controlled research conditions with prescribed protocols), findings may not generalize to nonpaying users, clinical populations, men, or other geographic regions. Furthermore, step count was based on data from users' smartwatches or phones, without confirmation that devices were worn continuously, leading to potential underestimation when devices were removed or worn inconsistently.

However, the study's strengths include its large sample size and ecological validity, providing rare insight into real-world use of a CGM-integrated digital health app outside of research or clinical settings. The availability of granular engagement data across both passive and active behaviors also enables a nuanced understanding of how users interact with biological feedback tools. While future studies with comprehensive health and socioeconomic data and more diverse samples are needed to enhance generalizability and disentangle these relationships, the current findings offer important baseline information about engagement patterns among early adopters of CGM-integrated wellness technology for hypothesis generation and intervention design.

Conclusions

The rising popularity of apps that sync with CGMs reflects growing interest in on-demand, personalized care. This large-scale analysis of a commercial CGM-integrated app in naturalistic use underscores how user characteristics and engagement patterns among self-selected, paying users can inform the design of mobile-enabled tools that move healthcare beyond traditional models. While these findings reflect engagement among health-motivated early adopters, they provide important insights into the behavioral dynamics of CGM-integrated digital health interventions. As sensors become more affordable and longer-lasting [30], future research should explore not only how to sustain engagement beyond CGM use but also how long sensor wear continues to influence behavior. Identifying the behavioral drivers and specific features that support sustained engagement will be essential for developing interventions that are both scalable and effective [31-34]. This work should also expand to other apps and digital health platforms that use biofeedback to support personalized nutrition [35], to understand which tools and contexts most effectively promote lasting dietary behavior change. While our findings are associational and cannot establish causation, they provide valuable descriptive evidence of real-world usage patterns that can inform hypothesis generation for future experimental research. Gaps in our data, particularly the absence of diabetes diagnoses, medication information, comorbidity data, and socioeconomic indicators, highlight the need for future studies to comprehensively assess these factors to better understand how health status and social determinants influence CGM engagement patterns. Translating lessons from early adopters to broader, more diverse populations will require attention to access, usability, and behavioral support [33,36], especially for those who may benefit most from metabolic feedback but are less intrinsically motivated to actively self-monitor. Frameworks for understanding technology implementation, adoption, and sustainability can help guide efforts to scale these interventions across diverse settings and populations [37,38].

Abstract

Background: Support, Monitoring, and Reminder Technology for Mild Dementia (SMART4MD), a customized tablet app, was developed to improve or maintain the quality of life of people with mild cognitive impairment (MCI) and their informal caregivers.

Objective: This study conducts an 18-month economic evaluation of the SMART4MD app, in addition to standard care, compared with standard care alone in Sweden and Spain, from a health care provider perspective.

Methods: In a pragmatic randomized controlled trial, people with MCI and their informal caregivers were randomized to the intervention and control groups. Health care costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratios (ICERs) were measured in 345 Swedish people with MCI and their informal caregivers, and in 347 Spanish people with MCI.

Results: The analysis showed higher incremental costs and lower QALYs for Swedish people with MCI than for controls, whereas higher incremental costs and higher QALYs were observed for Spanish people with MCI. The intervention was not found to be cost-effective for Swedish informal caregivers, with an ICER of €78,000/QALY (€1=US $1.16).

Conclusions: The differing findings regarding cost-effectiveness for people with MCI in Sweden and Spain highlight the need for further research with extended follow-up, ideally involving a larger sample size and conducted across different national contexts.

Trial Registration: ClinicalTrials.gov NCT03325699; https://clinicaltrials.gov/ct2/show/NCT03325699

Introduction

Memory loss, or a decline in cognitive abilities such as language and spatial skills, is an early sign of diminishing mental abilities, referred to as mild cognitive impairment (MCI). MCI is a condition characterized by cognitive decline that exceeds what is typical for a person's age and education level, yet does not significantly impact daily activities [1]. This condition has the potential to progress into dementia over time. Approximately half of the people with MCI develop dementia within 3 years [2]. Dementia imposes a substantial financial burden on the health care sector, as well as emotional and financial stress on close relatives. The annual incidence of dementia in Sweden is estimated at 25,000 cases, with a corresponding societal cost of €45,000 (€1=US $1.16) per person [3]. The age-adjusted incidence rate of dementia among individuals aged 65 years or older in Spain is reported to be 6.66 per 1000 persons [4]. The total societal cost of dementia in Spain was reported to be €8268.5 million in 2018 [5]. According to the Dementia in Europe Yearbook 2019 [6], the prevalence of dementia in Sweden and Spain by 2050 is projected to be approximately 2.63% and 3.99% of the total population, respectively. Research further demonstrates that people with dementia incur higher health care costs up to 10 years before diagnosis compared with those without dementia [7].

MCI poses challenges to activities of daily living. People with MCI need active assistance from informal caregivers, for example, with taking medication, keeping medical appointments, and managing other daily activities. Caregiving responsibilities increase as the cognitive abilities of people with MCI decline over time [8]. This is expected to lead to emotional and mental stress among informal caregivers and affect the quality of life (QoL) of both people with MCI and their informal caregivers [9].

Smartphone/tablet apps have been suggested as useful tools to assist people with MCI in performing activities of daily living [10]. Regular use of smartphone/tablet apps by people with MCI may help them develop routines that become even more important, and thus beneficial, with increasing cognitive decline. Maintaining autonomy is expected to ease the burden on informal caregivers and improve the well-being of both people with MCI and their informal caregivers. Based on this notion, the tablet-based app Support, Monitoring, and Reminder Technology for Mild Dementia (SMART4MD) was developed to improve or maintain the QoL of people with MCI and their informal caregivers [11]. A pragmatic randomized controlled trial (RCT) was conducted in 3 European countries (Sweden, Spain, and Belgium) to study the effectiveness of the app in comparison with standard care over an 18-month period, from December 2017 to September 2020 (ClinicalTrials.gov registration number NCT03325699).

Our findings regarding the efficacy of the SMART4MD app over the 18-month trial period indicated a significant improvement in the quality of life at 6-month (measured as quality-adjusted life-years [QALYs]) of informal caregivers and dyads in the intervention group (authors' unpublished observations). Economic evaluations of such interventions can assist health policy makers and reimbursement agencies in making informed and transparent decisions. A short-term economic evaluation of the SMART4MD intervention, based on 6-month trial data, has previously been published. The results indicate that the intervention might yield benefits for informal caregivers in terms of reducing caregiving burden and improving their QoL [12]. However, the short follow-up period is not expected to fully capture the effects on health and QoL. Therefore, the purpose of this study is to assess the 18-month cost-effectiveness of the SMART4MD tablet-based intervention, in addition to standard care, compared with standard care, from the perspective of the health care provider in the Swedish and Spanish settings.

Methods

Study Design and Reporting Standards

This economic evaluation was conducted following the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) guidelines (see Multimedia Appendix 1), using data from the SMART4MD trial [13].

The SMART4MD Trial

SMART4MD aims to improve or maintain the quality of life of people with MCI and their informal caregivers. SMART4MD is a customized mobile health (mHealth) app for tablets, adapted for people with MCI. The app was developed by Healthbit Ltd [14] in consultation with people with MCI, their informal caregivers, and health care professionals. The app's primary features include medication and health care appointment reminders, cognitive support activities such as games and photos, and a health information feature that allows users to share their daily health status or health-related issues with others. The idea was to support people with MCI while also helping establish a routine in their daily lives that could be maintained as the disease progressed.

The SMART4MD trial was conducted at 4 sites in Sweden, Spain, and Belgium: (1) Blekinge Institute of Technology (BTH), Karlskrona, Sweden; (2) Consorci Sanitaria de Terrassa (CST), Barcelona, Spain; (3) Servicio Andaluz de Salud, Málaga, Spain; and (4) University College Leuven-Limburg, Belgium. One of the Spanish sites (Servicio Andaluz de Salud) was excluded from the analysis due to the unavailability of cost data, whereas the Belgian site was excluded due to insufficient participants (5 dyads) and the unavailability of both cost and effect data. However, we performed a scenario analysis for people with MCI from 1 Spanish site (CST), where inpatient and outpatient cost data were available only for people with MCI. Thus, this study conducted the primary analysis using complete 18-month trial data for both people with MCI and informal caregivers from the Swedish site (BTH), and a scenario analysis only for people with MCI from the Spanish site (CST).

The recruitment of participants was carried out through primary care and secondary care services (memory clinics), as well as outpatient clinics, day hospitals, specialist mental health care units, geriatric medicine units, and neurology service units. Older adults (≥55 years) who could administer their own medication and had a Mini-Mental State Examination (MMSE)

XSL•FO
RenderX

score ranging from 20 to 28 were eligible for inclusion. Further inclusion criteria were that participants were physically fit to use the app, had an informal caregiver, and had experienced impaired cognition for more than 6 months. Older adults were excluded if they scored above 11 on the 15-item Geriatric Depression Scale, indicating severe depression [15], or if they had a life expectancy of less than 3 years due to a life-limiting illness. A research nurse used information collected at the baseline visit and from participants' medical records to assess life expectancy.

A total of 345 dyads (people with MCI and their main informal caregiver) were randomized to either the intervention or control group, resulting in 173 dyads in the intervention group and 172 dyads in the control group. In addition, 347 people with MCI (intervention group, n=174; control group, n=173) participated from the Spanish site (CST). Participants randomly assigned to the intervention group received the SMART4MD app on data-enabled tablets, along with standard care. The intervention group also received a 1.5-hour training session, led by a research nurse, to demonstrate the functions of the app and was instructed to use the app daily, with assistance from their informal caregiver if needed. As data-enabled tablets and training were provided to trial participants, no technical prerequisites regarding familiarity with, or ownership of, smartphones or tablets were required for participation.

Participants in the control group received only standard care. Standard care in Sweden includes an annual in-person or telephonic visit to a physician for routine checkups and the renewal of drug prescriptions, as well as necessary laboratory tests, if required. Standard care in Spain includes a visit to a health center, where patients receive diagnostic, therapeutic, and preventive services and are potentially referred to specialists if necessary [16]. As all dyads continued to seek health care as needed, the extent of health care contacts varied between participants due to differences in general health, comorbidities, and health-seeking behavior. Further information on the SMART4MD app and the trial is described in detail elsewhere [11].

Ethics Considerations

The study was conducted in accordance with the ethical principles of the Declaration of Helsinki (World Medical Association, 2013). Ethical approval for the SMART4MD trial was obtained from the Regional Ethical Review Board in Sweden (LU numbers 650-00 and 744-00) and the local research ethics committee in Spain (approval number 02-16-107-029). Before participation, all older adults received comprehensive oral and written information about the study, including its objectives, data protection measures, and the voluntary nature of participation. Written informed consent was obtained from each participant before enrollment and reaffirmed at each data collection point.

Resource Use Measurement and Estimating Costs

A health care provider's (regional council's) perspective was adopted; thus, only costs incurred by the health care provider were included. Costs related to community, social, and home support services were not included, as these costs fall on municipalities rather than the health care provider. All costs were estimated in Swedish kronor (SEK) and reported in 2020 euros (€), using an exchange rate of 10.4867 SEK/€ [17].

All types of health care utilization for both inpatient and outpatient care were included in the study. Outpatient care includes both primary care and specialized outpatient clinics. Costs arising from the intervention include the purchasing cost of tablets, mobile data, and the time of the research nurse who provided training on how to use the app. All managerial costs related to the development and execution of the RCT were classified as research costs and were therefore excluded from the analysis.

Health care utilization and costs were collected from the Blekinge regional council health care registers [18], where costs were assigned to each health care episode using diagnosis-related groups [19]. In cases of missing outpatient health care costs, the average costs of visits in primary care and in each specialized outpatient clinic, stratified by type of health care personnel, were used (Table S1 in Multimedia Appendix 2). In a few cases, both cost and type of health care personnel were missing; in these instances, the average cost for each type of visit in specialized clinics was used. In cases where inpatient care costs were missing, the average daily cost was used.

Measurement of Effectiveness

EQ-5D-3L Index Score

The EQ-5D-3L questionnaire is a preference-based instrument that includes 5 attributes: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. Each attribute can be rated at 3 levels: no problem, some problem, and extreme problem, creating a total of 243 possible health states [20]. These health states are translated into a score ranging from 0 (equivalent to dead) to 1 (perfect health), based on population preferences [21]. The EQ-5D-3L questionnaire was collected for both people with MCI and informal caregivers at baseline and at 3 follow-up points (6, 12, and 18 months). EQ-5D-3L utilities [20] were estimated using the Swedish experience-based tariff [22].

Quality-Adjusted Life-Years

QALYs were included as the primary outcome measure for both people with MCI and informal caregivers, based on the EQ-5D-3L index score. The change in QALYs was estimated using the area-under-the-curve approach [23]. QALYs were calculated for each follow-up assessment at 6, 12, and 18 months. A 180-day window, with a tolerance of +18 or –18 days, was designated for each visit in the SMART4MD trial. However, as is common in trials, some participants' visits occurred outside this 180-day period. Consequently, QALYs were calculated using the actual number of days between visits instead of the fixed 180-day intervals. To determine the total QALYs for the entire 18-month trial period, the QALYs from each follow-up assessment were summed, and participants who missed any follow-up assessments were excluded.

Quality of Life in Alzheimer's Disease Scale

Quality of Life in Alzheimer's Disease Scale (QoL-AD) measures disease-specific quality of life and comprises 13 items

XSL•FO
RenderX

covering interpersonal, environmental, functional, physical, and psychological aspects of people with dementia [24]. Scores of 1 (poor), 2 (fair), 3 (good), and 4 (excellent) were combined to yield a total score, with higher totals indicating better quality of life [25]. We employed both self-rated and proxy-rated versions of QoL-AD. People with MCI were interviewed to obtain QoL-AD scores, while informal caregivers completed a self-administered questionnaire. Following Logsdon et al [26], we combined the 2 ratings into a weighted composite QoL-AD score, in which the rating of people with MCI was given 2 times the weight of the informal caregiver's proxy rating.

Mini-Mental State Examination

The MMSE score measures cognitive functioning [27]. It is a standardized assessment tool used to evaluate the cognitive abilities of people with MCI. This test focuses on memory, attention, orientation, and language skills, with a maximum score of 30 [27]. A higher MMSE score suggests a more positive outcome, while a score below 24 indicates the presence of dementia. However, there is no agreed-upon cutoff score for the MMSE to define MCI in the scientific literature [28].

Short-Form 12-Item Zarit Burden Interview

Caregiving burden was included as a secondary outcome measure for informal caregivers and was estimated using the short-form 12-item Zarit Burden Interview (ZBI-12). This self-reported instrument contains 12 items measuring the effect of caregiving activities on the informal caregiver's leisure time and overall health. A 5-point Likert scale (0=never to 5=nearly always) was used to score each question. The maximum score of the ZBI-12 is 48 points, where a score of less than 17 represents no burden [29]. To align with other outcome measures, we inverted the ZBI-12 score so that a higher score indicates a more favorable outcome. Thus, a score equal to or above 31 represents no burden.

Analysis of Cost-Effectiveness

The results are presented as an incremental cost-effectiveness ratio (ICER), which is the ratio of between-group differences in costs and effects, measured from baseline to the end of follow-up (18 months). According to the Swedish National Board of Health and Welfare, an ICER above 500,000 SEK (€48,876) is considered a high cost per QALY gained and is therefore used as the willingness-to-pay (WTP) threshold in this study [30]. Thus, if the estimated cost per QALY was below this threshold, the use of the SMART4MD app was considered cost-effective from a health care provider's perspective, compared with standard care. We also expressed the results in terms of net monetary benefit (NMB), which is calculated as follows: (incremental benefit × WTP) − incremental cost. The NMB provides results in monetary terms with a known threshold value of benefit. A positive NMB indicates that the tablet-based app is cost-effective compared with standard care. Some advantages of calculating NMB are that it is linear, has a simple sampling distribution, and is more stable than the ICER in cases of marginal differences in effectiveness between the intervention and comparator [31]. As both Swedish and Spanish guidelines recommend using a 3% discount rate in economic evaluations, we applied this rate to discount both QALYs and costs for the last 6 months of the trial [32].

The uncertainty around the cost-effectiveness results was explored using 5000 bootstrap resamples of the ICER, presented graphically on a 4-quadrant cost-effectiveness (CE) plane [33]. A cost-effectiveness acceptability curve (CEAC) was also derived to present the probability of the intervention being cost-effective at different WTP thresholds.

Sensitivity and Subgroup Analyses

We conducted several sensitivity and subgroup analyses to assess the uncertainty around the base-case results. Sensitivity analyses were reported for (1) people with MCI, (2) caregivers, and (3) dyads, where applicable (Textbox 1).

XSL•FO
RenderX

Textbox 1. Additional analyses.

1.Multiple imputation for missing quality-adjusted life-years

Missing information on the EQ-5D-3L index score was imputed using multiple imputation (20 datasets), based on baseline age, sex, education, living arrangements, EQ-5D-3L index score, Quality of Life in Alzheimer's Disease Scale score of people with mild cognitive impairment, Mini-Mental State Examination score, 12-item Zarit Burden Interview score, and intervention/control group [34]. After generating the multiple datasets, pooled estimates were computed [35].

2. Intervention cost

The intervention costs include the tablet purchasing cost, mobile data, and the time of the research nurse conducting training sessions on app usage. As these costs are not expected to be covered by the health care provider in the case of widespread implementation, they were included only in a sensitivity analysis.

3. Removing zero health care cost

During the trial, people with mild cognitive impairment were expected to have health care contacts due to their age and health condition. Thus, dyads with zero health care costs were removed in a sensitivity analysis, as these could be considered outliers.

4. Subgroup analysis—sex

Results were stratified by sex to explore whether they were influenced by differences in health-seeking behavior between men and women.

5. Subgroup analysis—age

Results were stratified by age (up to 70 vs ≥70 years) to explore whether they were influenced by differences in familiarity with and use of tablets, which is assumed to be correlated with age [36,37].

6. Subgroup analysis—Mini-Mental State Examination

Results were stratified based on baseline Mini-Mental State Examination score (≤26 vs >26) [38] to explore whether they were influenced by the level of cognitive decline at the time of introduction to the app. Furthermore, prior research indicates that this cutoff is advantageous due to its enhanced specificity and sensitivity [38,39]. Moreover, this threshold aligns with the median of our sample.

7. Subgroup analysis—Zarit burden

Results were stratified based on baseline Zarit burden score (no burden [12-item Zarit Burden Interview >31] vs some burden [12-item Zarit Burden Interview ≤31]) to explore whether they were influenced by the level of caregiving burden.

8. User behavior

Usage of the Support, Monitoring, and Reminder Technology for Mild Dementia (SMART4MD) app was assessed by the number of times it was launched during the first 12-month period (information was unavailable for the last 6 months of the trial). Results were stratified based on high versus low usage (median cutoff of 125 launches in our sample during the first year) to explore whether more frequent use of the app influenced the results.

Scenario Analyses

Two scenario analyses were performed. The first scenario analysis was conducted for one of the Spanish sites (CST), where cost data for people with MCI were available. A Spanish tariff was used to calculate QALYs [40]. Although Spain does not use an explicit threshold to establish the cost-effectiveness of health care interventions, a threshold of €30,000 per QALY is the most frequently cited in Spanish economic evaluation studies [41]. Therefore, we also used €30,000 per QALY as the threshold to establish the cost-effectiveness of the SMART4MD app for people with MCI participating at the Spanish site in this study. Health care utilization data were collected from Hospital de Terrassa, Terrassa Sanitary Consortium, Terrassa (Barcelona). All costs were estimated in euros (€) and reported in 2019 prices [42].

The second scenario analysis was conducted to evaluate the cost-effectiveness of people with MCI who participated from both BTH and CST sites, utilizing costs, QALYs, QoL-AD, and MMSE scores. The European EQ-5D VAS tariff was used to calculate QALYs in the second scenario [43], and a threshold value of €30,000 per QALY was applied [41].

Statistical Analysis

Intergroup (between intervention and control groups) statistical differences were assessed using an independent *t* test (unpaired and 2-tailed) for continuous variables and a chi-square test for categorical variables. Intragroup (within intervention and control groups) statistical differences were assessed using a paired *t* test. The scores of both people with MCI and their informal caregivers were combined to calculate dyad scores, and the results were presented as mean (SD) or mean differences. All analyses were conducted using Stata/SE 15.1 (StataCorp LP).

Results

Baseline Characteristics and Follow-Up Outcomes

Table 1 presents baseline and 18-month follow-up demographic characteristics of people with MCI and informal caregivers, where no considerable differences were observed between the intervention and control groups at baseline. At the 18-month follow-up, both people with MCI and dyads had significantly lower QALYs (P=.047 and .03, respectively) in the intervention group compared with the control group at the 12-month follow-up, whereas informal caregivers (P=.02) and dyads (P=.03) had significantly higher EQ-5D-3L index scores in the intervention group compared with the control group at the 18-month follow-up (Table S2 in Multimedia Appendix 2).

XSL•FO
RenderX

After 18 months, of the 345 dyads, 73 (21.2%) had left the trial, with the most prominent reason being "simply do not want to participate" (45/73, 62%), followed by physical (9/73, 12%) and cognitive reasons (6/73, 8%; see Figure S1 in Multimedia Appendix 2). Further, we excluded 5 informal caregivers who had not reported any health outcomes. Three people with MCI had changed their primary caregivers during the trial. As it is not reasonable to compare different caregivers in terms of health outcomes, these cases were excluded from the analyses (see Figure S1 in Multimedia Appendix 2).

The dropout versus nondropout analysis of baseline characteristics for people with MCI showed that those who dropped out had significantly worse EQ-5D-3L index score at baseline in both the intervention (*P*=.03) and control (*P*=.0097) groups. People with MCI who dropped out of the control group were more likely to live with a spouse or partner and had worse MMSE scores. The dropout analysis for informal caregivers in the control group showed that, at baseline, those who dropped out had higher Zarit burden scores and reported worse proxy QoL-AD scores on behalf of people with MCI (see Tables S3 and S4 in Multimedia Appendix 2).

Table 1. Demographic characteristics of people with MCI[a] and informal caregivers at baseline and 18-month follow-up.

[a]MCI: mild cognitive impairment.

[b]n=130 people with MCI in the intervention group at follow-up; n=125 carers in the intervention group at follow-up.

Cost Measures

The average per-person cost for people with MCI was €7032 in the intervention group and €7024 in the control group over the 18-month period (see Table S5 in Multimedia Appendix 2). Outpatient care accounted for the majority of health care costs in both groups, representing total costs of €5466 (77.73%) in the intervention group and €5639 (80.28%) in the control group. The average cost per informal caregiver in the intervention group was €5371, while in the control group it was €4903. In contrast to the intervention group, informal caregivers in the control group had higher outpatient and lower inpatient costs.

XSL•FO
RenderX

However, no statistically significant differences were observed between the 2 groups (*P*=.63).

Effect Measures

Over the 18-month period, people with MCI in both groups experienced a statistically significant decline (*P*<.001 in both groups) in their quality of life (composite QoL-AD score). However, there was a significant improvement in MMSE scores for people with MCI in both groups (*P*<.001 in the intervention group and *P*=.02 in the control group; see Table S6 in Multimedia Appendix 2). Informal caregivers in both groups also experienced a decline in their quality of life (EQ-5D-3L index score) over the study period; however, this decline was statistically significant only in the control group (*P*<.001). The inverse ZBI-12 score indicated an insignificant decrease (*P*=.52) in caregivers' burden in the intervention group after 18 months. It further illustrates that dyads in the control group experienced a statistically significant decline in quality of life (EQ-5D-3L index score; *P*=.001) over the 18-month period. Intergroup differences for all effect measures were insignificant (for people with MCI: EQ-5D-3L, *P*=.72; composite QoL-AD, *P*=.73; for informal caregiver: EQ-5D-3L, *P*=.07; ZBI-12, *P*=.25; and for dyad: EQ-5D-3L, *P*=.25), except for MMSE scores, where the intervention group showed a statistically significant improvement (*P*=.03) compared with the control group.

Cost-Effectiveness Analysis

The intervention was dominated by standard care for people with MCI (Table 2), as the intervention group had higher costs (€9) and lower QALYs (−0.015) compared with the control group. However, the differences were not statistically significant for either costs (*P*=.99) or QALYs (*P*=.46). Additionally, the negative NMB (–€742) suggests that the intervention was not cost-effective. Of the 5000 incremental CE pairs for QALYs, 1908 (38.16%) were in the northwest quadrant (more costly and less effective) of the CE plane (Figure 1). At a WTP of €48,876 per QALY, the CEAC indicated an approximately 30% likelihood of the intervention being cost-effective (Figure 1). The ICERs for the composite QoL-AD and MMSE scores were €56 and €15 per unit gain, respectively.

For informal caregivers, the intervention group demonstrated an improvement in QALYs (0.006) at higher costs (€468) compared with the control group. The resulting ICER of €78,000 per QALY and a negative NMB (−€175) indicate that the intervention is not cost-effective at the WTP threshold of €48,876 per QALY. On the CE plane, 2157 out of 5000 (43.14%) CE pairs were in the northeast quadrant, indicating higher costs and higher effectiveness. The CEAC indicated that the likelihood of the intervention being cost-effective for caregivers was approximately 48% at a WTP of €48,876 per QALY (Figure 1). Moreover, due to a reduction in caregiving burden in the intervention group compared with the control group, the ICER for ZBI-12 was €613 per unit reduction in caregiving burden.

Table 2 shows higher costs (€630) and lower QALYs (−0.014) for dyads in the intervention group compared with the control group. These results, along with the negative NMB (−€1314), indicate that the intervention is dominated by standard care. The probability of the intervention being cost-effective at a WTP of €48,876 was estimated to be around 25% (Figure 1).

Figure 1. Cost-effectiveness (CE) plane from the health care provider perspective and cost-effectiveness acceptability curve (CEAC), showing the probability that Support, Monitoring, and Reminder Technology for Mild Dementia (SMART4MD) is cost-effective across different willingness-to-pay (€) thresholds per quality-adjusted life-year (QALY) gained.

Sensitivity and Subgroup Analyses

Table 3 presents the results of the sensitivity and subgroup analyses. While numerical changes in costs and effects were observed across different analyses, the base-case findings remained generally consistent. Some exceptions were observed. Sensitivity analyses for people with MCI older than 70 years and with MMSE ≤26 showed that the intervention was less costly and less effective. For informal caregivers, the intervention was dominant among low app users. Further, the intervention was cost-effective for informal caregivers older than 70 years, female informal caregivers, those with health care costs greater than zero, and when QALYs were imputed.

Scenario Analyses

Results for the scenario analysis of people with MCI who participated in the CST site are presented in Table 4. The intervention was more costly and more effective in terms of QALYs, with an ICER of €3653/QALY and an NMB of €1897, indicating that the intervention is cost-effective at the threshold of €30,000/QALY. The results for the composite QoL-AD score showed that the intervention was more costly and more effective, with an ICER of €17,533 per unit gain. However, a negative effect of the intervention in terms of MMSE indicates that the intervention was dominated by standard care. All differences in costs and outcomes between the intervention and control groups were statistically insignificant (difference in cost, *P*=.66; QALY Spain, *P*=.29; QoL-AD, .98; and MMSE, .55). Further, intergroup differences in demographic characteristics and health outcomes for the Spanish site (CST) are presented in Table S7 in Multimedia Appendix 2. The MMSE score was statistically significant at baseline (*P*=.04), indicating that people with MCI in the intervention group had lower cognitive abilities than those in the control group.

The results of the scenario analyses for people with MCI from both the BTH and CST sites indicated that the intervention was less costly and more effective compared with the control group, as measured by QALYs, QoL-AD, and MMSE scores.

[a]ICER: incremental cost-effectiveness ratio.

[b]NMB: net monetary benefit.

[c]€1=US $1.16.

[d]No significant differences in incremental costs and effects were found (independent *t* test).

[e]Number of participants available for cost estimation first, followed by number of participants available for health effects.

[f]N/A: not applicable.

Discussion

Principal Findings

We performed an economic evaluation of the SMART4MD trial from a health care provider's perspective over the trial duration. Our findings indicate that, except for MMSE scores, there were no significant differences in effects and costs between the intervention and control groups. The estimated cost-effectiveness ratios show that the intervention is dominated by standard care for both people with MCI and dyads, and it was not found to be cost-effective for informal caregivers when QALYs were the outcome. However, for the Spanish site, the intervention was cost-effective, with an ICER of €3337/QALY.

In the base-case analysis, the intervention was not cost-effective in Sweden at the country-specific WTP threshold, whereas it was cost-effective in Spain. This divergence is likely driven primarily by structural and contextual differences between settings. First, country-specific cost inputs played an important

XSL•FO
RenderX

role: higher unit costs of health care utilization and intervention delivery in Sweden increased incremental costs relative to usual care, while lower unit costs in Spain resulted in smaller incremental costs. Second, baseline risk and disease severity differed between countries, with the Spanish population exhibiting a less favorable risk profile; consequently, the same relative treatment effect translated into larger absolute health gains and more favorable ICERs in Spain. Third, variation in usual care meant that more intensive standard care in Sweden reduced the marginal benefit of the intervention, whereas in Spain, a less intensive usual care comparator allowed greater incremental benefit. Taken together, these factors suggest that the observed cross-country differences in cost-effectiveness are driven more by contextual variation in costs, baseline risk, and usual care than by differences in the intrinsic effectiveness of the intervention itself, underscoring the need for caution when extrapolating our findings to health systems with substantially different cost structures and treatment pathways.

The findings of this study for people with MCI concur with our previously published short-term (6-month) economic evaluation of the SMART4MD trial [12]. Both studies indicate that the intervention is dominated by standard care for people with MCI and dyads in terms of QALYs and is not cost-effective for informal caregivers at a WTP threshold of €48,876 per QALY [12]. While the ICER for people with MCI, when aggregating data from the Swedish and Spanish sites, indicates a dominant point estimate, the differences in costs and QALYs were not statistically significant.

It is well established in the literature that using the EQ-5D-3L instrument might not be the most suitable approach for assessing the quality of life of people with dementia. This is because the EQ-5D-3L does not encompass attributes that adequately capture cognitive function [44], relationships with caregivers, and social support, which are recognized as important factors in measuring quality of life for people with dementia [45]. However, we also included other health outcome measures, such as MMSE scores, QoL-AD, and caregiving burden (ZBI-12 score), to cover these aspects to some extent and complement the results of the primary outcome measure.

For people with MCI, the ICERs for the remaining 2 outcome measures were €55 per unit gain in composite QoL-AD and €15 per unit gain in MMSE score, respectively. It is uncertain whether these values can be deemed cost-effective due to the absence of established cost-effectiveness thresholds for QoL-AD and MMSE. However, low ICER values may indicate that the societal value associated with a 1-unit change in these outcome measures is likely to be higher.

Similar to previous effectiveness and cost-effectiveness studies on the SMART4MD trial [12,46], this study also indicates an improvement in the quality of life of informal caregivers in the intervention group compared with the control group. This may suggest that informal caregivers gained the most from the intervention, even though it was intended to be used primarily by people with MCI themselves. It is possible that the app served as a reminder for informal caregivers regarding medication schedules and doctors' appointments for people with MCI. Furthermore, it is important to acknowledge that the involvement of multiple informal caregivers for an individual with dementia may enhance the benefits of SMART4MD, potentially leading to an underestimation of its impact.

The available research on the cost-effectiveness of mHealth interventions aimed at older adults with chronic conditions in a home-care setting is inconclusive [47]. For example, some studies have shown that mHealth interventions for patients with chronic obstructive pulmonary disease in the United Kingdom [48] and in Denmark [49] were not cost-effective. However, mHealth interventions were deemed cost-effective for older adults diagnosed with Parkinson disease [50] and for cardiac rehabilitation [42]. Therefore, comprehensive evidence regarding the cost-effectiveness of mHealth for older adults living with chronic conditions in general, and with MCI or dementia in particular, appears to be lacking. The generalizability of a specific mHealth intervention is also limited due to several factors, such as the learning curve of health care professionals and participants [48,49], the level of engagement of health care professionals [49], and participants' adherence rates [50].

In our previous study [12], we reasoned that the cost-effectiveness of the SMART4MD intervention might be underestimated due to the short (6-month) follow-up period. This study, conducted over a longer follow-up period of 18 months, still did not find significant differences between the intervention and control groups, especially with respect to QoL outcome measures. One reason could be that the 18-month period may still not be long enough to capture the full health effects. A model-based economic evaluation could be used to extrapolate the health effects of such an intervention over a lifetime horizon, which was beyond the scope of this study. By contrast, short follow-up periods are common in dementia research due to its rapid progression [51]. Thus, it is possible that the SMART4MD app is not a cost-effective intervention, as suggested by the results of our study. However, the results also show a statistically significant improvement in MMSE scores for people with MCI in the intervention group compared with the control group. The insignificant results for QoL outcome measures might be due to an underpowered trial with respect to cost-effectiveness analysis. The sample size of this trial was based on clinical effectiveness rather than cost-effectiveness. However, it is important to note that no significant differences were observed for QoL-AD, which was the primary outcome measure of the trial and was used to calculate the sample size [11].

A high dropout rate is a common issue when mHealth interventions are introduced [52], and the SMART4MD trial is no exception. At the 18-month follow-up, 42 of the 173 (24.2%) participants in the intervention group and 31 of the 172 (18.0%) in the control group had left the trial. As previously discussed [12,46], a potential explanation for leaving the trial could be the perceived burden of participation. However, a previously published qualitative study, using individual semistructured interviews, was conducted with 16 people with MCI who participated in the SMART4MD trial. The findings showed that these individuals did not perceive the app's reminder feature as beneficial [53], potentially affecting their level of engagement with the app. This is also evident from the data, which show that only 195 of 312 (62.5%) individuals with MCI accessed

XSL•FO
RenderX

the app between 6 and 12 months, compared with 299 out of 312 (95.8%) during the initial 6 months. Given that the difference in dropout rates between the groups was not statistically significant (P=.15), we assume that it does not have a meaningful impact on the cost-effectiveness results of this study. However, we conducted our primary analysis on an intention-to-treat basis, which preserves the benefits of randomization and reflects the effectiveness of offering the intervention under real-world patterns of uptake and adherence, including the observed decline in app use over time. In this context, a per-protocol analysis restricted to highly adherent users would likely yield more favorable ICERs but would be less representative of routine practice and more vulnerable to selection bias. We therefore did not perform such an analysis and interpret our results as estimates of cost-effectiveness under realistic, rather than optimal, adherence.

Missing cost data due to attrition were handled within the same multiple imputation framework used for missing outcomes, assuming data were missing at random, conditional on treatment group, baseline covariates, and observed intermediate costs and effects. All relevant cost components and utility measures at each time point were included in the imputation model, and imputed individual-level costs were then used to construct total costs over the trial horizon and estimate ICERs, with results pooled across imputations using rules proposed by Rubin [35]. While this approach is recommended over complete-case analysis, it still relies on untestable assumptions about the missingness mechanism; we therefore interpret the cost-effectiveness results with appropriate caution.

Study Strengths

The study has several strengths. Given the limited evidence available on the cost-effectiveness of mHealth interventions designed for people with MCI and their informal caregivers [12], this study extends the knowledge base for this type of intervention. Moreover, this economic evaluation is based on a pragmatic RCT [54], which improves the generalizability of the findings to older adults who visit primary care facilities seeking assistance with memory-related concerns. The absence of data on medication is one limitation of this study, as it is an important component of the health care provider's perspective. Furthermore, it is recommended in the literature to collect health care utilization data before randomization for a specific period, such as 1, 3, or 12 months. This prerandomization cost data could serve as a predictor of postrandomization costs and potentially capture variations in health care use before and after the trial [55]. Unfortunately, in our study, we did not have access to prerandomization cost data. Also, due to the absence of cost data from Spanish sites, the findings of this study relied exclusively on Swedish data; consequently, the results may not represent all participating sites. Finally, we were unable to analyze from a societal perspective due to the absence of crucial cost categories. These include the costs of social support, informal care, and participants' out-of-pocket expenses. Considering the positive outcomes for caregivers in this study, and that informal care constitutes around 50% of the total cost of dementia [56], an analysis from a societal perspective would have been informative.

Due to a lack of data regarding the app's actual utilization, our analysis is restricted to examining its presence, which offers people with MCI the opportunity to use it. Consequently, we also lack data on any behavioral changes associated with app usage. Therefore, the focus of this study was on enhancement in health-related quality of life, as such an improvement in QoL would suggest a behavioral change. Given the results, further investigations are necessary to determine whether the intervention failed to induce behavioral changes in participants or whether any behavioral changes observed had no impact on the primary outcome measure of health-related quality of life.

Neither the researchers nor the participants were blinded to the intervention and control groups, which could have introduced bias. However, blinding may be less critical in pragmatic trials that aim to closely replicate real-world practice [57]. Future studies could address this issue by providing an app with limited features to the control group. Another limitation was the lack of detailed characterization of informal caregivers. Key details, such as the primary caregiver's relationship with people with MCI, caregiving hours per day or week, and employment status, were not recorded. Additionally, the impact of the SMART4MD app was not analyzed based on caregiver type (spouse, adult child, or other), which could have offered valuable insights into which group benefited most from the intervention.

Conclusions

In conclusion, total costs and QALYs over the 18-month trial period were not significantly different between the intervention and control groups, indicating that the SMART4MD intervention was neither better nor worse than standard care. The results suggest that this type of tablet-based app for people with MCI and dyads is not cost-effective.

Acknowledgments

The authors are grateful to everyone who volunteered to participate in the SMART4MD trial, as well as to the staff for their collaboration in data collection and management. The authors also thank Region Blekinge for providing health care utilization data.

Funding

This study is part of SMART4MD (Support, Monitoring, and Reminder Technology for Mild Dementia), a European Commission Horizon 2020 project (grant 643399; SMART4MD Project Factsheet, H2020 CORDIS, European Commission). SS is an Atlantic Fellow for Equity in Brain Health at the Global Brain Health Institute (GBHI) and acknowledges support from GBHI, the Alzheimer's Association, and the Alzheimer's Society (grant GBHI ALZ UK-22-869016). Abstract

Background: Scaling youth mental health services in low-resource settings requires digital infrastructure that supports not just clinical delivery but the full operational, supervisory, and engagement demands of community-based, task-shifted models. Existing platforms—whether commercial health systems, open-source medical records, or consumer-facing wellness apps—address fragments of this need, but none provide the integrated, offline-capable, and affordable architecture required for lay-provider delivery at scale.

Objective: We introduce shamiriOS, an open-source, modular digital platform comprising 3 interlinked suites—the Shamiri Digital Hub (SDH) for operational management, Rafi for youth engagement, and the Shamiri Provider Platform (SPP) for clinical workflows—designed for scalable, stepped-care youth mental health delivery in Kenya. Our objectives were (1) to conduct an environmental scan of existing platforms and characterize their limitations, (2) to describe the user-centered design and development of shamiriOS, and (3) to report early deployment outcomes across centralized and decentralized settings between 2023 and 2024.

Methods: We conducted a structured environmental scan of 6 case management platforms and 28 youth-facing mental health apps, assessing cost, usability, open-source availability, customizability, offline capability, and suitability for task-shifted delivery. Based on identified gaps, SDH was built as a browser-based operation platform, and Rafi was developed as a native mobile app (Android or iOS) with an offline-first architecture. The SPP was adapted from an existing electronic medical record system. Development followed a user-centered design process with community consultation, including cocreation workshops with 77 university-aged youths. Deployment was evaluated using use analytics, usability ratings, and Net Promoter Scores.

Results: No reviewed platform met the combined requirements for stepped-care delivery. SDH was deployed across 11 sites serving 76,344 youths via 1195 lay providers and 111 clinical supervisors by Q1 2024. Staff reported high satisfaction (usability: mean 8.36/10, SD 1.49; Net Promoter Score: mean 8.63/10, SD 1.46). Rafi achieved 74.7% (n=3737) registration at Mount Kenya University, with 50.4% (508/1008) booking therapy sessions, but sustained engagement with self-guided features declined to near 0 by 9 months.

Conclusions: shamiriOS demonstrates the feasibility of building modular, open-source digital infrastructure for scalable, task-shifted youth mental health delivery. Its component-based architecture is designed for adaptation to other contexts, though extension would require participatory redesign. The most significant obstacles to impact lie not in platform design but in implementation readiness, incentive alignment, and institutional integration. Future priorities include SPP deployment, artificial intelligence–assisted supervision features (shamiriAI), and strengthening sustained engagement.

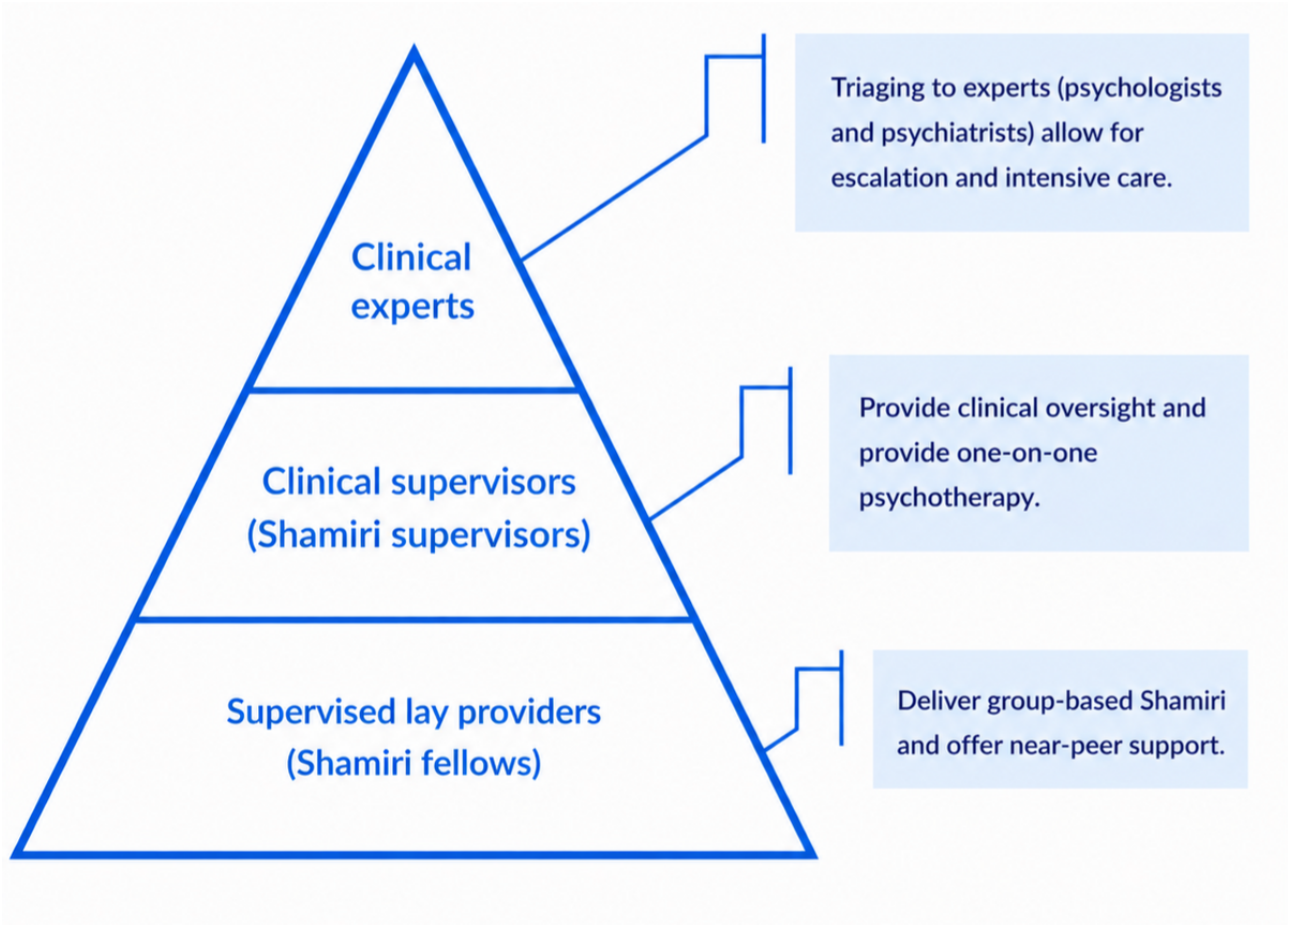
Introduction

Background



Youth mental health challenges are among the most pressing global health issues today [1,2]. Half of all lifetime mental disorders begin by age 14 [3,4]. Most go untreated—particularly in low- and middle-income countries (LMICs), where shortages of trained clinicians and fragile health systems produce a significant treatment gap [1,2,5,6]. Closing this gap requires care models that are cost-effective at scale, contextually grounded, and delivered beyond traditional clinical settings into community spaces [1,7,8].

Stepped Care Models Can Close the Treatment Gap

Task-shifting—training nonprofessionals to deliver structured, evidence-based treatments under supervision—has emerged as a promising strategy for closing the treatment gap [9,10]. When embedded within stepped-care systems, where the intensity of care is matched to individual need [9-12], this approach maximizes scarce resources, reduces costs, and leverages community infrastructure for delivery [12,13].

The Shamiri model is an example of task-shifting within a stepped-care system: a 3-tier school-based mental health program delivered by lay providers and clinical staff (Figure 1) [14,15]. In the first tier, lay providers aged 18-22 years are trained and supervised to deliver brief, group-based psychological interventions—typically weekly sessions of 4 weeks with groups of 6 to 15 students [16,17]. Clinical supervisors with backgrounds in psychology or clinical social work form the second tier, providing oversight of lay providers and direct one-on-one psychotherapy where needed [16,18,19]. Severe or complex cases are escalated to clinical psychologists and psychiatrists in the third tier [16,18,19]. Randomized controlled trials demonstrate that the Shamiri model significantly reduces depression and anxiety symptoms in secondary school students, with effects sustained at least 7 months after the intervention [14,15,20,21]. Cost-effectiveness analyses place delivery at approximately US $7.48 per student in 2024—among the most affordable youth mental health interventions globally [22,23].

Figure 1. The Shamiri model: a 3-tier stepped care model for youth mental health.

Despite these outcomes, scaling innovations like Shamiri while maintaining fidelity and efficacy across diverse contexts remains a challenge. Two main dissemination strategies have been used [24,25]. The centralized approach, where the originating

XSL•FO
RenderX

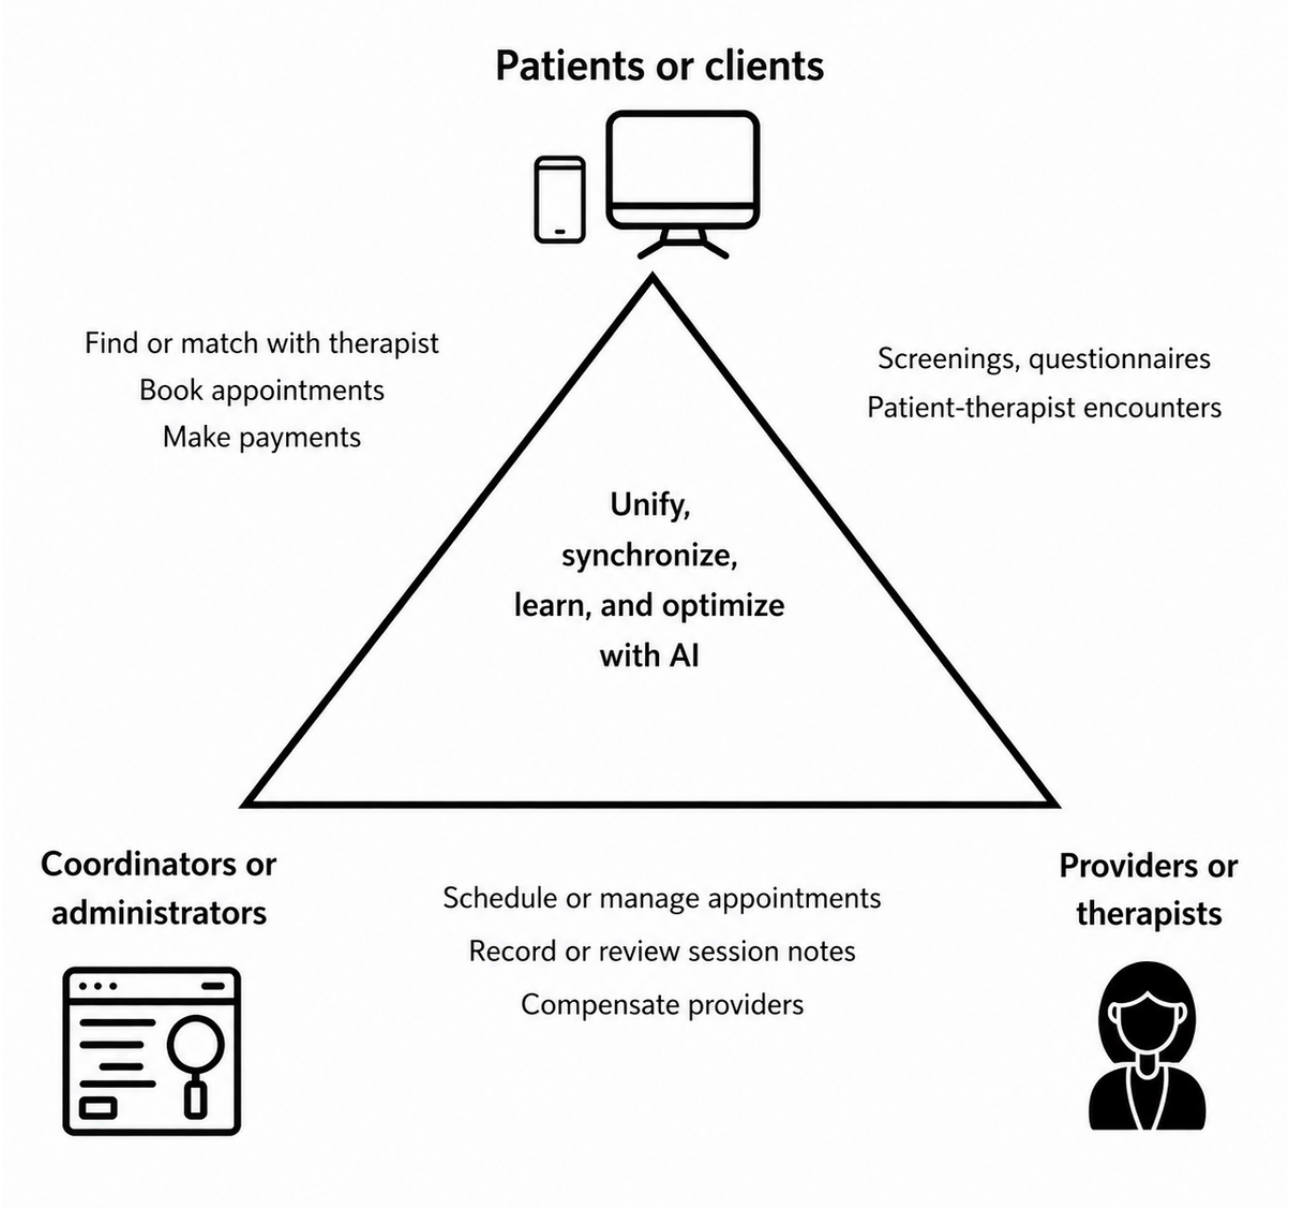
organization retains direct control, allows for tighter quality control but limits reach [23]. The decentralized—or "train-the-trainer"—approach, where other organizations implement independently, enables rapid scale-up but carries risks to fidelity and consistency [24,25]. Recent research comparing both approaches in Kenya found both effective at improving youth outcomes, though decentralized models require more robust support structures and greater funding to maintain effectiveness and fidelity [23].

As implementation moves across contexts and implementers, additional operational challenges arise—particularly for small or resource-constrained community-based organizations [23,26,27]. Coordinating multitiered teams, managing logistics and financial workflows, tracking real-time outcomes, and maintaining consistent training and supervision all pose barriers to broader uptake of otherwise effective interventions [23,26,27].

Technology as a Catalyst for Scale

Digital platforms can address these bottlenecks. Purpose-built technology can reduce administrative burden, standardize supervision workflows, enable real-time monitoring, and facilitate client transitions across care tiers [13,28,29]. For task-shifted stepped-care models specifically, digital tools can provide lay providers with structured session prompts, automate operational workflows, support triage, and coordinate across roles [13,28-31].

Most existing digital mental health tools fall short of what community-based delivery in Kenya—and similar contexts—requires [13,30-32]. Available platforms are typically designed for high-resource clinical environments, carry prohibitive licensing costs, lack customizability for task-shifted workflows, and offer little or no offline functionality [29,33,34]. Multiple recent reviews confirm this infrastructure gap: digital mental health interventions developed for LMICs remain limited in number, and those that exist rarely include the operational architecture needed for stepped-care delivery, provider supervision, or scalable implementation [29,35-37]. Platforms built to coordinate lay-provider delivery, integrate operational and clinical workflows, and function in bandwidth-constrained settings are largely absent from the literature [29,37]. This gap is not unique to Kenya: across sub-Saharan Africa, South Asia, and Southeast Asia—settings characterized by severe mental health workforce shortages and limited digital infrastructure—the distance between the promise of digital health tools and the availability of platforms suited for community-based delivery remains wide [1,38].



Development of shamiriOS: A 3-Product Platform for Delivery at Scale

To address this gap, we developed shamiriOS—an open-source digital platform built to support the scalable delivery of task-shifted youth mental health services in Kenya and similar settings. The name reflects its purpose: an integrated operating system for service delivery, not a conventional computer operating system. The platform comprises 3 interoperable product suites—the Shamiri Digital Hub (SDH), the Shamiri Provider Platform (SPP), and Rafi—each designed for a distinct user group within a task-shifted care approach like the Shamiri model (Figure 2):

- SDH is an operational command center for program management, coordination, supervision oversight, and financial workflows.
- SPP is a clinical workflow tool supporting fellows, supervisors, and therapists in delivering and documenting care.
- Rafi is a client-facing mobile app through which young people access care, navigate support pathways, and engage with mental health resources. Available on Android and iOS, Rafi is built with an offline-first architecture to remain functional in the low-bandwidth environments common across Kenyan schools and universities.

XSL•FO
RenderX

Figure 2. shamiriOS overview. AI: artificial intelligence.

These 3 products function as a unified delivery ecosystem: SDH runs the program, SPP supports the providers, and Rafi connects young people to care. Each component can be deployed independently or in combination, depending on an implementing organization's context and capacity. Additionally, each component is "modular" in design: its features can be configured and adapted to meet the specific needs of different implementing partners, contexts, and end users.

Although the broader vision for shamiriOS encompasses all 3 components, this paper focuses primarily on the development and deployment of SDH and Rafi—built from the ground up—and on the initial integration of SPP, adapted from an existing clinical platform. shamiriOS builds on the capabilities and limitations of existing platforms, including case management systems such as CommCare and OpenMRS (Open Medical Record System), and youth-facing tools reviewed in our environmental scan [29,35-37]. Its distinctive contribution is an integrated, 3-product architecture combining operational management, clinical workflows, and client-facing engagement within a single open-source, context-specific system—a combination not found in existing platforms in Kenya or comparable settings. Successful adaptation for other countries is feasible with appropriate participatory redesign; the findings reported here are specific to the Kenyan context in which the platform was developed and validated.

Study Aims

This paper has 3 aims. First, we present an environmental scan of existing digital platforms to characterize their limitations for stepped-care youth mental health delivery in Kenya. Second, we describe the iterative, user-centered design and development process of shamiriOS. Third, we evaluate early outcomes from its deployment across centralized and decentralized implementation settings in Kenya between 2023 and 2024, reporting on adoption, user satisfaction, and feature refinement.

Together, these 3 elements—environmental scan, platform development, and early deployment—establish a foundational evidence layer for the ongoing development, evaluation, and

XSL•FO
RenderX

contextual adaptation of integrated digital mental health platforms in settings where such infrastructure is critically needed.

Methods

Overview

This section describes the review, development, and deployment processes underlying shamiriOS. We first describe the environmental scan of existing platforms that informed our decision to build a custom solution. We then outline the iterative development of each component—the SDH and Rafi, built from the ground up, and the SPP, adapted from an existing clinical system. We describe technical access specifications, the engagement measurement framework used to evaluate deployment outcomes, and the phased deployment of the platform across centralized and decentralized settings in Kenya between 2023 and 2024.

Environmental Scan of Existing Platforms

Overview and Evaluation Criteria

Prior to development, we conducted an environmental scan to assess whether existing digital platforms could support the operational, clinical, and engagement requirements of the Shamiri stepped-care model in Kenya. The scan assessed market availability, feature coverage, and contextual fit for community-based, task-shifted delivery—it was not a systematic review of clinical efficacy. We evaluated potential tools across 3 envisioned system functions: a backend operations platform (SDH), a client-facing engagement tool (Rafi), and a clinical provider platform (SPP).

Platforms were evaluated against 6 criteria tailored to the Kenyan implementation context: cost (upfront and ongoing), ease of use for administrators and end users, customizability for task-shifted workflows, open-source availability, suitability for mental health interventions, and appropriateness for low-resource settings including offline capability. These criteria were determined through prior field experience and consultation with Shamiri's operations and clinical teams (Table 1).

Table 1. Platform evaluation criteria and justification.

Criterion	Rationale for LMIC[a] or Kenyan context
Cost (upfront and ongoing)	Must be affordable for grassroots and mid-sized organizations; includes licensing, hosting, and support costs.
Ease of use	Must be usable by lay providers, supervisors, and adolescent clients with varying levels of digital literacy.
Customizability	Must accommodate task-shifting workflows, school-based implementation, and stepped-care triage.
Open-source availability	Ensures accessibility, adaptability, and long-term sustainability without vendor lock-in.
Suitability for mental health	Requires support for psychosocial content, triage workflows, and group or individual care formats.
Low-resource appropriateness	Must support offline use, low bandwidth environments, and options for local hosting.

[a]LMIC: low- and middle-income country.

Backend Operations Platforms

Between May and July 2023, we conducted a desktop scan of global case management platforms through public documentation, product demonstrations, and technical repositories. Six platforms were reviewed: Salesforce, Dimagi CommCare, KoboToolbox, Ona, ODK Collect, and Google Workspace. Platforms were assessed for their ability to support real-time multisite coordination, stipend disbursement tracking, session attendance logging, triage escalation, and role-differentiated access across lay providers, supervisors, and coordinators. Search methods and assessment criteria are described in Multimedia Appendix 1.

Client-Facing Youth Mental Health Apps

Searches were conducted on the Google Play Store and Apple App Store using terms including mental health, therapy, depression, and youth wellbeing. Consistent with prior research methodology, we examined the top 10 results for each term [39]. Eligible apps had a minimum of 100,000 downloads (Android) or a 4.0+ star rating (iOS), were available in English and accessible in East Africa, and had been updated within the prior 12 months. Apps focused solely on physical wellness or designed exclusively for clinicians were excluded. A total of 28 apps met eligibility criteria and were assessed across cost structure, provider matching and support features, validated assessment tools, delivery model, self-help resources, and user engagement mechanisms including gamification. Reviewed apps were disaggregated by whether they claim an explicit evidence base (eg, cognitive behavioral therapy and interpersonal therapy) versus general wellness positioning to enable a more precise assessment of their suitability for stepped-care delivery. Full details are in Multimedia Appendix 1.

Clinical Provider Platforms

Existing electronic medical record (EMR) and clinical workflow systems were reviewed for suitability as a provider-facing platform, including District Health Information System 2 (DHIS2), OpenMRS, Bahmni, and EasyClinic. Systems were assessed for clinical documentation capability, teletherapy support, appointment scheduling, analytics dashboards, data security, and ease of customization for a task-shifted delivery context.

XSL•FO
RenderX

Development of the shamiriOS Platform

Overview and Design Approach

The environmental scan confirmed that no existing solution fully met the operational, clinical, and youth engagement needs of the Shamiri model in Kenya. We initiated development of shamiriOS in mid-2023, conceptualizing it as a 3-product digital ecosystem: the SDH, Rafi, and the SPP. Initial development focused on building SDH and Rafi from the ground up while adapting SPP from an existing solution, EasyClinic (Table 2).

Table 2. Development of shamiriOS components.

Component and version	Period	Features	Feedback
Shamiri Digital Hub			
Version 1	Late 2022 to early 2023	Session attendance tracking, fellow performance monitoring, supervisory reviews	Improved mobile responsiveness, integration of payment and stipend tracking tools, support for multisite coordination
Version 2	Early to late 2023	Supervisor and coordinator dashboards, stipend reconciliation workflows, referral tracking, automated task reminders	Iterative feedback via field interviews and monthly user experience reviews
Version 3	Late 2023 to present	Multirole platform, multisite implementation management, Metabase-powered analytics dashboards, offline functionality	Development continues, phased rollouts planned for 2025 and beyond
Rafi			
Version 1.0	May 2022	Daily motivational content, well-being check-ins, therapy and group session booking, monthly score tracking, gamified system	Need for more frequent interaction, personalization, engaging visuals
Version 2.0	Early 2023	Daily mood check-ins, interactive reward system, artificial intelligence–generated mood art, triage pathway, community feed	Strong acceptability and usability, need for more modular content, deeper personalization
Version 3.0	Early 2024	Expanded self-help toolkit, upgraded triage flows, redesigned interface, anonymous messaging, session scheduling, offline functionality	Feasibility of integrating technology-driven triage and engagement tools into institutional frameworks
Shamiri Provider Platform			
Version 1.0	2024 to present	Client management, teletherapy support, session documentation, analytics dashboards, syncing user records, real-time therapist availability, appointment scheduling	Emphasis on data security, user-centered design, interoperability

The development of shamiriOS was guided by a user-centered design process with community consultation, adapted to the operational demands of building integrated health technology infrastructure in Kenya [40,41]. There is no single template for co-design and user-centered design; rather, the methods must be tailored to the nature of what is being designed, the stakeholders involved, and the constraints of the implementation environment [42-45]. The shared philosophy—centering the needs, experiences, and contexts of end users—remained constant across components; the specific methods varied by component type.

For shamiriOS, we distinguish 2 types of design work. The operational infrastructure components—SDH and SPP—were designed primarily as administrative and clinical workflow tools, and their development was guided by consultations with Shamiri's operations, clinical, and research teams. Rafi, the youth-facing component, was developed through a more participatory co-design process: youth end users shaped interface design, content tone, and feature prioritization through structured feedback sessions, card-sorting exercises, and prototype walkthroughs. Cocreation sessions for the initial version involved 77 students across 3 Kenyan universities (Multimedia Appendix 2).

Across all components, end users—lay providers, clinical supervisors, hub coordinators, and youth participants—acted as consultants and testers, informing design through structured feedback, usability tests, and pain-point mapping. Strategic decisions regarding platform architecture, feature prioritization, and technical implementation remained with Shamiri's technical and clinical leadership. This approach sits at the consultation end of the community engagement spectrum rather than representing fully community-led development; its implications and our future commitments are discussed in the Discussion section.

Development of the SDH

Overview

The SDH was designed to replace fragmented operational tools—spreadsheets, WhatsApp messaging, and paper logs—that were prone to error and coordination breakdowns as the number of supervisors, fellows, and implementation sites grew. The goal was a centralized platform enabling real-time monitoring, stipend disbursement, and data-driven supervision across multisite teams.

SDH development occurred across 3 cycles between 2022 and 2024, each guided by user consultation with Shamiri's

XSL•FO
RenderX

operations, clinical, and research teams. Each development cycle followed a hybrid Agile-Waterfall methodology. Agile development is an iterative approach in which work is broken into short, time-boxed cycles called sprints—typically 2 to 4 weeks—with working software produced at the end of each cycle based on user feedback [46]. Waterfall is a sequential approach in which requirements are fully scoped before development begins [47]. The hybrid model we used scoped core feature requirements in advance (Waterfall) but delivered them through sprint-based cycles with regular stakeholder check-ins and usability testing (Agile), allowing responsiveness to evolving user needs while maintaining predictable development milestones [46,47]. This approach maintained predictable milestones while remaining responsive to evolving user needs.

Version 1: Prototype Development (Late 2022 to Early 2023)

Version 1 was built on Bubble, a no-code development platform, and served as a minimum viable product to address the most critical operational needs: session attendance tracking, fellow oversight, and performance review. It was deployed in a small usability pilot across 3 implementation hubs and 20 field staff to assess basic usability, workflow alignment, and feasibility of replacing paper-based tracking. User feedback identified 3 priorities for subsequent development: improved mobile responsiveness, integration of payment and stipend tracking, and support for multisite coordination.

Version 2: Supervisor-Centered Platform Expansion (Early to Late 2023)

Version 2 rebuilt SDH on a scalable web app architecture: a Node.js and Express backend, a Next.js frontend, and a PostgreSQL database, with components communicating via RESTful (Representational State Transfer) application programming interfaces (APIs), JSON Web Token–based authentication, and role-based access control (RBAC) at the API layer. Full technical specifications, including the data architecture and security model, are in Multimedia Appendix 3.

Version 2 introduced supervisor and coordinator dashboards, stipend reconciliation workflows, referral tracking, and automated task reminders. It was deployed across 5 hubs, with iterative feedback collected via field interviews and monthly user experience reviews.

Version 3: Multirole Platform and Offline Functionality (Late 2023 to Present)

Version 3 began development in late 2023 to accommodate scaling demands and a more diverse user base. The platform was expanded to include fellows, supervisors, coordinators, and clinical leads; introduced multisite implementation management; and integrated Metabase-powered analytics dashboards. Metabase is an open-source business intelligence tool that enables nontechnical users to query databases and generate visual reports without writing code [48,49]; its integration allows hub coordinators and supervisors to access real-time program data without developer support. Version 3 also introduced offline-first data capture with automatic synchronization upon network reconnection, supporting use in the low-connectivity environments common across Kenyan schools and community centers. Local server deployment options are under active development.

Development of Rafi

Overview

Rafi (derived from rafiki, Kiswahili for “friend”) is a client-facing native mobile app for young people—primarily university students aged 17 to 22 years—supporting mental health screenings, patient-therapist encounters, and community engagement within Shamiri’s stepped-care model. Rafi is available on Android (Google Play Store) and iOS (Apple App Store) and was designed with an offline-first architecture: core features—including self-guided content (affirmations, journaling, and goal tracking), mood check-ins, and well-being score tracking—remain functional without internet access. Features requiring connectivity—therapy booking, artificial intelligence (AI)–generated mood artwork, community feed posts, and data synchronization—queue locally and sync automatically on reconnection. This design decision was informed by the environmental scan finding that only 5 of 28 reviewed youth-facing apps offered any offline capability, despite the intermittent-connectivity environments common across Kenyan universities and schools.

Conception and Design

Rafi’s development followed the user-centered design process described earlier. Youth end users were engaged as testers and consultants across each version through structured feedback sessions, card-sorting exercises, prototype walkthroughs, and focus group discussions. Cocreation sessions for the initial version involved 77 students across 3 universities (Multimedia Appendix 2). Architectural and design decisions were made by the Shamiri technical team.

Rafi 1.0: Initial Prototype

Version 1.0 was developed as a mobile app available on Android, iOS, and a supplementary web portal to maximize accessibility across Kenya’s variable connectivity landscape. Core features included daily and weekly mental health check-ins, access to the Shamiri-Digital self-guided intervention, low-cost caregiver connections, clinical referral pathways, and gamification elements (points and rewards). Version 1.0 was piloted at 7 Kenyan universities through partnerships with peer counseling groups (Multimedia Appendix 2).

Rafi 2.0: Stable Platform

Following pilot feedback, version 2.0 introduced mood-based AI-generated artwork (the “wellness gallery”), enhanced triage tools, and expanded the gamification system. It was cocreated with 77 youth users through structured feedback sessions and deployed across select student clubs at additional universities using QR code–based registration and peer ambassador–led outreach.

Rafi 3.0: Integrated Platform

Version 3.0 was designed to address persistent retention challenges from earlier deployments. Key design priorities included gamified onboarding sequences, mood-responsive motivational content, and more direct pathways connecting

XSL•FO
RenderX

users to therapists. The interface was restructured to reduce feature overload, and the backend was refactored for tighter SPP integration, supporting seamless transitions from self-guided to provider-supported care. Version 3.0 was the platform used in the Mount Kenya University (MKU) institutional deployment described below.

Development of the SPP

The SPP was adapted from EasyClinic, an existing EMR solution selected for its modular design, customizable clinical workflows, and prior use in resource-constrained health care settings. Rather than building a clinical platform from the ground up, we adapted an existing, maintained solution to reduce development cost and time to deployment. Development followed an iterative sprint-based approach incorporating therapist feedback, usability testing, and emphasis on data security and interoperability within the shamiriOS architecture.

Adaptations include (1) migration of legacy patient records from Rafi and SDH to EasyClinic to establish unified clinical histories; (2) integration of real-time therapist availability and appointment scheduling into Rafi's booking interface, synchronized with the EasyClinic backend; and (3) subscription and plan management enabling users to initiate and manage therapy plans through Rafi with real-time synchronization to EasyClinic. Full technical specifications are in Multimedia Appendix 4.

Technical Access and Compatibility

All shamiriOS components are web-based or app-based and require no operating system modification, installation privileges, or proprietary software. This was a deliberate design choice to maximize accessibility for nontechnical users and reduce dependency on institutional IT infrastructure across diverse Kenyan implementation settings.

SDH and SPP are web apps accessible via any modern browser on desktop, laptop, or mobile devices. Both incorporate offline-first data capture with automatic synchronization on reconnection. Rafi is a native mobile app available on Android and iOS; core self-help content and check-in features are accessible offline, while therapy booking, triage escalation, and data synchronization require an active internet connection. A supplementary web portal provides browser-based access for users without smartphone access, synced with app data. Table 3 summarizes the minimum technical requirements and offline capabilities for each component.

Table 3. Technical access requirements for shamiriOS components[a].

Component	Access method	Supported browsers or platforms	Device or OS[b] compatibility	Offline capability
Shamiri Digital Hub	Web app	Chrome 90+, Firefox 88+, Safari 14+, Edge 90+	Desktop, laptop, or mobile—Windows, macOS, Linux, Android, iOS	Partial: offline data capture with automatic sync on reconnection
Rafi	Native mobile app+supplementary web portal	Google Play (Android), App Store (iOS), modern browser (web portal)	Android 8.0+, iOS 12+, web portal via modern browser	Limited: self-help content and check-ins accessible offline; therapy booking, triage, and sync require connectivity
Shamiri Provider Platform	Web app (adapted from EasyClinic)	Chrome 90+, Firefox 88+, Safari 14+, Edge 90+	Desktop, laptop, or mobile—Windows, macOS, Linux, Android, iOS	Not available in current version

[a]All data transmission is encrypted via HTTPS. Authentication uses Open Authorization 2.0 protocols across all components. Full technical specifications are in Multimedia Appendices 2-4.

[b]OS: operating system.

Engagement Measurement Framework

Engagement with digital health platforms is multifaceted and context-dependent. We adapted a framework defining engagement as the extent to which users interact with each shamiriOS component in ways intended by the design and required for operational or clinical benefit [50]. We distinguish four levels:

1. Initial engagement: account creation, onboarding completion, and first active use.
2. Ongoing engagement: frequency, duration, and consistency of continued use over time.
3. Deep engagement: use of advanced or therapeutically substantive features requiring sustained investment (eg, journaling, clinical triage documentation, and supervisor analytics review).
4. Clinical or operational engagement: actions directly tied to service delivery outcomes (eg, therapy session booking, weekly session attendance logging, and triage escalation).

Engagement is reported separately for each component, reflecting their distinct purposes and user populations:

- SDH (operational or staff-facing): Measured through platform login frequency, data entry compliance rates, feature adoption across user roles, and staff-reported usability and acceptability (single-item satisfaction rating and Net Promoter Score [NPS]). Weekly engagement aligned with supervision and reporting cycles constitutes the target pattern for SDH users.
- Rafi (youth-facing): Measured through registration and onboarding completion (initial engagement), daily and monthly active user (MAU) rates (ongoing engagement), self-guided feature use such as journaling and mood

XSL•FO
RenderX

check-ins (deep engagement), and therapy booking and triage escalation (clinical engagement). Episodic or needs-driven engagement may be more clinically appropriate than sustained daily use for this population; we report both frequency-based and action-based metrics.

What constitutes meaningful engagement differs by user type and platform purpose. For youths using Rafi, therapy booking and triage pathway use may be more clinically significant than daily login frequency. For supervisors using SDH, weekly engagement aligned with supervision cycles was operationally sufficient. For clinicians using SPP, session-by-session engagement was anticipated. Engagement data were drawn from backend use logs, session analytics via Metabase, and NPS surveys administered after deployment [51].

Implementation Evaluation

Our evaluation used pragmatic metrics derived from implementation science instruments [50-53]: measures used were (1) usability—a single-item satisfaction rating on a 1-10 scale ("How easy is the platform to use?"), administered to supervisors and hub coordinators after deployment; (2) acceptability—a NPS item on a 1-10 scale ("How likely are you to recommend this platform to a colleague?") [51]; (3) engagement—backend use analytics tracking login frequency, feature adoption rates, data entry completeness, and retention over time, reported separately by component; and (4) qualitative feedback—open-ended survey questions and semistructured interviews conducted during and after training sessions.

The choice of pragmatic over standardized measures reflected several constraints. Sprint-based development cycles required rapid, actionable feedback that standard implementation science instruments—which typically require extensive administration time and psychometric analysis—could not reliably provide. The simultaneous development and evaluation of the platform also blurred the boundary between formative user research and summative implementation evaluation, making it difficult to administer standardized instruments at appropriate intervals. Field teams requested brief feedback mechanisms to reduce survey fatigue during intensive deployment.

Deployment of the shamiriOS Platform

Overview

Deployment of SDH and Rafi occurred in phased waves between 2023 and 2024, expanding the user base, geographic coverage, and implementation complexity across waves. SPP deployment is ongoing and is not reported here; a follow-on publication will report SPP deployment and clinical workflow integration separately. Table 4 provides a deployment overview.

Table 4. Development of shamiriOS components (Rafi and Shamiri Digital Hub).

Deployment and wave	Details	Time frame	Sites	Size
Shamiri Digital Hub				
Wave 1	Initial deployment in centralized school-based hubs	Q4 2023	5 school-based hubs in Nairobi and Kiambu	358 fellows
Wave 2	Expansion to decentralized partner sites and diverse implementation contexts	Early 2024	6 additional sites	1312 implementation team members
Rafi				
Rafi 1.0	Limited university pilot with peer counseling groups	2022	7 universities in Kenya	N/A[a]
Rafi 2.0	Soft-launched across select student clubs	2023	Other universities and colleges	N/A
Rafi 3.0	Formal deployment at scale through partnership with Mount Kenya University	Early 2024	Mount Kenya University	5000 students

[a]N/A: not applicable.

Deployment of the SDH

Wave 1: Centralized School-Based Hubs (Q4 2023)

The first SDH deployment targeted 5 school-based hubs in Nairobi and Kiambu counties, selected for high program activity, digital readiness, and established supervisory infrastructure. The goal was to transition day-to-day operations—previously managed through spreadsheets, WhatsApp, and manual logs—to the SDH platform. Training was delivered to 40 supervisors, 6 hub coordinators, and approximately 358 fellows through remote onboarding modules, in-person workshops, and helpdesk support. Each user received a role-based account scoped to their operational responsibilities. Adoption was monitored through backend use metrics and periodic supervisor check-ins, with real-time feedback informing feature refinements.

Wave 2: Decentralized Partner Sites (Early 2024)

In early 2024, deployment expanded to 6 additional sites including periurban schools, community centers, and regional nongovernmental organizations operating as local implementation partners. The platform was configured to support site-level customization including localized workflows. Asynchronous training modules, role-specific onboarding videos, and quick-start guides were developed for the more dispersed user base. Site-level implementation champions facilitated peer-to-peer learning beyond formal training periods. Weekly virtual support check-ins were offered during each new site's first month of onboarding.

XSL•FO
RenderX

Deployment of Rafi

Rafi 1.0 (2022)

Rafi 1.0 was piloted through partnerships with peer counseling groups at 7 Kenyan universities: the University of Nairobi, Kenyatta University, Jomo Kenyatta University of Agriculture and Technology, Technical University of Kenya, Cooperative University, MKU, and Maasai Mara University. Students were recruited through peer counseling clubs and campus outreach events, then onboarded and asked to provide structured feedback on usability, content tone, and visual design.

Rafi 2.0 (2023)

Rafi 2.0 was soft-launched across select student clubs at additional universities and colleges using QR code–based registration and peer ambassador–driven outreach. Students received promotional content and brief onboarding messages introducing Rafi's core features: wellness check-ins, journaling, triage alerts, and therapy booking.

Rafi 3.0—MKU Deployment (Early 2024)

Rafi 3.0 was deployed at scale through a formal partnership with MKU, serving a student population of approximately 25,000, with a targeted deployment cohort of 5000 enrolled students. Deployment included structured digital training for therapists and clinical supervisors covering the provider-facing dashboard and triage flagging protocols; a launch campaign conducted with the university's student services office and student associations, including peer-led classroom outreach, mental health fairs, and "Rafi Club" engagement events; and a dedicated peer ambassador network tasked with driving registrations. In-app analytics tracked early use trends and informed weekly engagement strategies. Backend dashboards allowed provider teams real-time oversight of flagged users and support queue management.

Ethical Considerations

The activities described in this paper comprised platform development, an environmental scan of existing digital tools, operational evaluation of the SDH using routine program monitoring data and satisfaction surveys from adult implementation staff, participatory design consultations with university students during Rafi's development, and aggregated platform use analytics. Per the National Guidelines for Ethical Conduct of Biomedical Research Involving Human Participants in Kenya [54], mandatory ethics review applies to research involving human participants who are "exposed to manipulation, intervention, observation, or other interaction with investigators" or who "become individually identifiable through investigators' collection, preparation or use of biological material, or medical or other records." The activities reported here did not meet these criteria: data collection was operational or design-oriented, no sensitive personal or health data were collected, and the intent was product development rather than systematic generation of new knowledge about individuals. Formal ethics committee review was therefore not sought. All data handling complied with Kenya's Data Protection Act [55] and Shamiri's institutional data governance framework.

Results

Findings From the Environmental Scan

Backend Operations Platforms

None of the 6 platforms reviewed met the combined requirements for cost, offline capability, and customizability for task-shifted delivery in Kenya. Salesforce and comparable enterprise systems offered extensive functionality but at licensing costs prohibitive for grassroots organizations. Dimagi CommCare and KoboToolbox offered greater affordability and open-source availability but lacked role-differentiated access, stipend management workflows, and real-time multisite coordination. No platform met all 6 evaluation criteria simultaneously; the highest-scoring alternatives met a maximum of 4 of 6. Full results are in Table 5.

Table 5. Review of existing case management and health systems.

Platform	Cost	Ease of use	Customizability	Open source	Ideal use case
Salesforce Health Cloud	High	Moderate	High	No	Care coordination, shared records, team collaboration
Dimagi CommCare	Medium	High	Moderate	No	Mobile-first field data collection
OpenMRS[a]	Low	Moderate	High	Yes	Customizable EMRs[b] for low-resource clinical settings
Odoo	Medium	High	High	Yes	Operations and resource management
Ona OpenSRP	Low	Moderate	High	Yes	Last-mile community health, offline syncing
Microsoft Dynamics	High	Moderate	High	No	Enterprise health care and operations

[a]OpenMRS: Open Medical Record System.

[b]EMR: electronic medical record.

Youth-Facing Digital Mental Health Apps

Of the 28 apps reviewed, 12 were explicitly evidence-based (citing cognitive behavioral therapy, interpersonal therapy, or other clinical frameworks), and 16 were general wellness apps. No app met all evaluation criteria. Common limitations included subscription-based pricing inaccessible to Kenyan university students, the absence of validated clinical content in local languages, no triage or escalation pathway to human providers, and limited or no offline functionality. Only 3 of the 28 apps

XSL•FO
RenderX

offered provider-matching features, and none were designed as part of an integrated stepped-care model with backend operational management. Full results are in Table 6, disaggregated by evidence-base status. Further details are in Multimedia Appendix 1.

Table 6. Review of existing mental health apps.

Category or feature	Apps with feature (n=28), n (%)	Evidence-based apps only (n=12), n (%)	General wellness apps only (n=16), n (%)
Evidence-base classification	—[a]	12 (43)	16 (57)
Freemium cost model	23 (82.1)	9 (75)	14 (87.5)
Subscription only	5 (17.9)	3 (25)	2 (12.5)
Provider access			
Therapist access	8 (28.6)	7 (58.3)	1 (6.3)
Peer support forums	11 (39.3)	4 (33.3)	7 (43.8)

[c]CBT: cognitive behavioral therapy.

Clinical Provider Platforms

Open-source EMR systems including OpenMRS and DHIS2 offered strong clinical documentation features but required substantial technical capacity for implementation and maintenance beyond the reach of most Shamiri implementation partners. EasyClinic was identified as the strongest candidate: it offered client management, teletherapy support, session documentation, appointment scheduling, and analytics dashboards at an accessible cost, with a modular architecture amenable to customization. These findings supported the adaptation of EasyClinic rather than the de novo development of the SPP.

Current State of shamiriOS

Overview

As of early 2025, shamiriOS comprises three interlinked product suites: (1) the SDH, the operational backbone for program management and real-time monitoring; (2) Rafi, a native mobile app (Android and iOS) through which young people access care and mental health resources; and (3) the SPP, an EMR and clinical workflow tool adapted from EasyClinic. SDH and Rafi are fully deployed across multiple centralized and decentralized sites; the SPP is currently in integration testing. Each suite is modular: features can be configured to meet the specific needs of different implementing partners and contexts.

Current State of the SDH

Roles and Permissions

SDH operates through a role-based permission system aligned with Shamiri's delivery hierarchy. Five user roles are defined, each scoped to their operational function (Table 7):

- Program administrators hold platform-wide permissions covering multisite oversight, intervention fidelity reporting, stipend management, and global configuration.
- Hub coordinators manage specific hubs, with permissions to assign fellows and supervisors, validate session attendance records, approve stipend submissions, and escalate triage cases.
- Supervisors verify weekly fellow activities, document supervision sessions, and initiate triage referrals for at-risk youths.

XSL•FO
RenderX

- Fellows (lay providers) log session data, track student attendance, and report implementation activities within their assigned hubs. Permissions are currently limited to data entry and personal activity tracking; future enhancements will expand access to include performance dashboards.
- Clinical leads access escalated clinical cases and review triage documentation across all sites.

Table 7. Roles and permissions in Shamiri Digital Hub.

Users	Roles and permissions
Program administrators	Possess platform-wide permissions, enabling oversight of multisite activities, intervention fidelity reporting, stipend management, and global settings configuration.
Hub coordinators	Manage specific hubs, with permissions to assign fellows and supervisors, validate session attendance records, approve stipend submissions, and escalate triage cases.
Supervisors	Responsible for the verification of weekly fellow activities, documentation of supervision sessions, and initiation of triage referrals for at-risk youths.
Fellows (lay providers)	Access the platform directly to log session data, track student attendance, and report key implementation activities. Their permissions are limited to data entry and personal activity tracking within assigned hubs. Future system enhancements may expand their access to include feedback tools and performance dashboards to support self-monitoring and reporting efficiency.
Clinical leads	Access escalated clinical cases and review triage documentation across all implementation sites.

Each user interaction is timestamped and logged, supporting full auditability and quality assurance monitoring across the implementation pipeline.

Software Architecture

SDH is built on a scalable, microservice-inspired architecture. The frontend is developed in ReactJS and deployed via Vercel's content delivery network, optimized for performance across variable connectivity environments on desktop and mobile browsers. The backend uses a Node.js runtime interfacing with a PostgreSQL database hosted on Amazon Web Services Relational Database Service; system interactions are managed through a RESTful API framework using JSON Web Tokens for session authentication and encrypted communications. A Metabase analytics layer provides real-time dashboards on session attendance, intervention frequency, supervision compliance, and flagged clinical concerns. Offline-first functionality enables data capture in low-connectivity settings with automatic synchronization on reconnection.

Features

The SDH system provides the following features in support of the Shamiri operational model:

- Staff and school management: Dynamic assignment of fellows to school-based groups, tracking intervention session coverage, and historical site performance monitoring.
- Session attendance and tracking: Supervisors enter weekly attendance, attach school visit summaries, and receive automated reminders to ensure data completeness.
- Performance monitoring: Visual analytics dashboards display fellow engagement metrics, session quality ratings, and supervisor oversight reports.
- Financial management: Integrated workflows for stipend submission, validation, and approval through multitiered administrative review pathways.
- Triage and clinical escalation: Supervisors flag students requiring advanced support, triggering structured triage documentation and clinical review workflows.
- Audit trail and compliance monitoring: Comprehensive backend logs maintain records of user interactions, system edits, and data submissions for quality assurance and troubleshooting.

Current State of Rafi

Roles and Permissions

Rafi's role and permission system balances user privacy and personalization with clinical oversight. Three roles are defined: (1) users (youths) create and manage personal accounts, complete check-ins, access self-help content, and manage therapy bookings and sharing preferences—all personally identifiable data are encrypted and access-controlled; (2) therapists and clinical staff access a provider dashboard displaying triaged users and appointment requests and may view anonymized user content when the user grants permission; and (3) administrators manage content deployment, update activity flows, and monitor platform use metrics.

Software Architecture

Rafi is delivered as a native mobile app (Android and iOS) with a supplementary web portal for users without smartphone access. The frontend is built with the Remix framework, hosted on Vercel, with a responsive design for mobile browsers. The backend uses a hybrid Node.js and Python architecture supporting modular feature development—including AI-generated affirmations and journaling workflows. Structured data (user check-ins and activity logs) are stored in PostgreSQL; media files (eg, journal artwork) are stored in Digital Ocean object storage. Integrations include Google Calendar API for therapist scheduling, Firebase Cloud Messaging for push notifications, and AI services for mood-based artwork generation and personalized reflection prompts. All backend services use HTTPS encryption and Open Authorization 2.0 protocols.

Features

Rafi's feature set is designed to engage youths in a nonclinical but supportive way, supporting well-being monitoring, self-help access, and connection to care:

XSL•FO
RenderX

- Wellness check-ins: Daily and weekly self-ratings across 5 domains (social connection, motivation, academic stress, and others) generating a personalized wellness score and surfacing tailored content.
- AI mood art (Wellness Gallery): Weekly check-in responses are transformed into AI-generated artwork that users can share on the community feed.
- Therapy booking: Users directly schedule individual or group sessions through integrated booking modules connected to therapist availability in the SPP.
- Triage pathways: Algorithmic triggers escalate users to therapist connection workflows based on risk indicators detected during check-ins.
- Community feed: A moderated, anonymous social space where users can share mood art and connect with peers, monitored by peer counselors and the administrator team.
- Reward hub: Gamification elements including badges, streak tracking, and unlockable achievements to promote continued engagement.
- Web portal: A lightweight browser-accessible version providing basic check-in and booking functionality, synced with app data.

Core features—self-guided content (affirmations, journaling, and goal tracking), daily mood check-ins, and well-being score tracking—remain fully functional without internet connectivity. Features requiring server connectivity—therapy booking, AI-generated mood artwork, community feed posts, and data synchronization—queue locally and sync automatically on reconnection.

Current State of the SPP

The SPP was adapted from EasyClinic and is currently in integration testing. Formal deployment results are not reported here, as the SPP reached production readiness after the observation period of this study. Adaptations completed to date include migration of legacy patient records from Rafi and SDH to EasyClinic to establish unified clinical histories; integration of real-time therapist availability into Rafi's booking interface; and subscription plan management enabling users to manage therapy plans through Rafi with synchronization to EasyClinic. The SPP is actively used in Shamiri's clinic-based services. A dedicated follow-on publication will report SPP deployment, clinical workflow integration, and cross-component data flows.

Engagement With shamiriOS Components

Engagement With the SDH

Wave 1 Outcomes (Q4 2023)

By the end of 2023, SDH supported program management across all 5 target hubs, coordinating 358 fellows serving over 20,697 students. Platform acceptability was assessed via postdeployment NPS survey administered to supervisors and hub coordinators (n=22). Respondents reported a mean likelihood of recommending SDH of 8.63 (SD 1.46) and a mean user experience satisfaction score of 8.36 (SD 1.49) on 10-point scales. Qualitative feedback emphasized ease of navigation, the value of real-time data capture, and substantial reductions in administrative workload relative to prior spreadsheet and WhatsApp-based systems. Stipend workflow automation and centralized fellow attendance tracking were the most frequently cited valued features (Multimedia Appendix 3).

Wave 2 Outcomes (Q1 2024)

By the end of Q1 2024, SDH supported 1195 fellows, 111 supervisors, and over 76,344 students across all active hubs—representing a 3.3-fold increase in fellows, a 2.8-fold increase in supervisors, and a 3.7-fold increase in student reach relative to wave 1. Ongoing monitoring included automated alerts for low engagement, biweekly platform review meetings with operations staff, and structured feedback channels informing subsequent sprint planning cycles (Multimedia Appendix 3).

Engagement With Rafi

Overview

Rafi engagement is reported across 4 dimensions: initial engagement (registration and onboarding), ongoing engagement (MAU rates), deep engagement (self-guided feature use), and clinical or operational engagement (therapy booking and triage escalation). As noted in the Methods section, episodic or needs-driven engagement may be more clinically meaningful than sustained daily use for a youth mental health platform; we report both frequency-based and action-based metrics.

Rafi 1.0—Initial Pilot (2022)

Of the 1349 students who registered interest, 857 (63.5%) enrolled as active users by the end of 2022. Among enrolled users, 74% (634/857) engaged with the self-guided digital wellness courses—the platform's highest-engagement feature. In total, 37.1% (318/857) booked at least 1 therapy session, and 33% (105/318) of those who booked attended.

Rafi 2.0—Expanded Deployment (2023)

During the 2.0 deployment, 1008 students registered accounts. Therapy booking improved markedly: 50.4% (508/1008) of users booked at least 1 session (compared to 318/857, 37.1% in version 1.0), and 44.9% (228/508) of those attended (compared to 105/318, 33%). Self-guided wellness module engagement remained high at 77.3% (779/1008). Monthly active engagement declined significantly after the first 4 weeks, however—a persistent attrition pattern that directly informed the gamified re-engagement architecture of Rafi 3.0.

Rafi 3.0—Institutional Deployment, MKU (2024)

Initial Engagement

Between January and September 2024, a total of 3737 of the 5000 targeted MKU students registered on Rafi—a 74.7% initial registration rate and the largest single-cohort registration in the platform's deployment history.

Ongoing Engagement and Attrition

Despite strong initial registration, MAU rates declined significantly across the 9-month observation window—from 7.4% in January 2024 to 0% by September—indicating near-complete disengagement among the registered cohort by the end of the observation period. Daily active user rates showed a consistent downward trend from the weeks following launch.

XSL•FO
RenderX

Feature-Specific Engagement

Across the observation period, 3.8% (n=142) of registered users used the daily check-in tool, 1.5% (n=56) used journaling features, 0.5% (n=20) booked therapy sessions, and 0.4% (n=15) used the Ask a Therapist chat feature. Affirmations and other low-touch tools demonstrated limited traction (<0.2%). An NPS survey administered in June 2024 (n=275) found that 15% (n=41) of respondents had attended at least 1 therapy session; among users who engaged with self-guided tools, 99.4% (n=141) subsequently booked therapy appointments.

Implementation Barriers and Facilitators: Preliminary Observations

The following observations were documented through operational feedback channels—training session notes, helpdesk tickets, monthly check-in meetings, NPS survey comments, and sprint planning discussions (Multimedia Appendices 2 and 3).

Barriers

Internet Connectivity

Inconsistent connectivity in periurban schools and community centers caused data synchronization failures and incomplete session logging in SDH. Supervisors at some sites reported traveling to areas with stronger connectivity to submit weekly reports, reducing data timeliness. For Rafi, the connectivity requirement for therapy booking and triage constrained clinical pathway use among students at lower-resourced sites.

Device Constraints

Not all fellows had personal smartphones capable of running modern browser-based apps; device sharing at some hubs created bottlenecks for timely data entry. For Rafi, storage constraints on student smartphones contributed to postregistration uninstalls—limited phone storage was cited in helpdesk and peer ambassador feedback as a contributing factor.

Engagement Infrastructure Readiness

The MKU deployment of Rafi 3.0 launched before its engagement infrastructure was fully operational. Push notification workflows, in-app communication features, and the gamification reward system were not functioning as intended at launch. This prevented timely re-engagement of users experiencing early drop-off and left the team without the real-time use tracking needed to respond to emerging attrition patterns.

Ambassador Incentivization Misalignment

The peer ambassador model at MKU incentivized students financially based on registration counts, producing high initial sign-ups but not the values-based peer promotion needed to drive sustained engagement. Postlaunch operational review found that peer counselors—who combined mental health training with authentic relational credibility—were substantially more effective at converting registrations into active users than financially incentivized ambassadors.

Absence of Institutional Integration

At MKU, the absence of a formal Memorandum of Understanding with university leadership limited institutional buy-in and delayed clinical pathway activation. Caregivers and clinical staff were not fully onboarded at the time of the student launch, meaning therapy booking and triage escalation features were not immediately functional during the highest-engagement window following sign-up.

Facilitators

Alignment With Existing Workflows

SDH adoption was strongest at sites, where the platform mirrored and enhanced existing workflows rather than replacing them entirely. Users at these sites reported reduced learning curves and described the platform as intuitive to adopt.

Role-Based Access Design

The role-differentiated account structure in SDH was consistently cited as a facilitator. Users received dashboards and input fields scoped to their specific responsibilities, reducing cognitive overload and increasing the perceived relevance of the platform to day-to-day tasks.

Peer Counselor-Led Outreach

Peer counselors with mental health training and established peer relationships demonstrated significantly higher engagement conversion than incentivized ambassadors. This has directly informed the revised outreach strategy for subsequent Rafi deployments, shifting from large launch-event acquisition toward gradual rollout through trusted peer networks.

Free Access Model

The absence of licensing fees for both SDH and Rafi was consistently identified by implementation partners as a critical enabler, removing the cost barrier that had prevented uptake of commercially licensed platforms reviewed in the environmental scan.

Offline-First Functionality in SDH

The ability to capture session data without active internet connectivity was consistently highlighted by supervisors at periurban sites as a key facilitator, reducing dependency on stable connectivity for core operational data entry.

Discussion

Principal Findings

This study documents the development and early deployment of shamiriOS, an open-source, modular digital platform for scalable, task-shifted youth mental health service delivery in Kenya [15,20,23]. Three principal findings emerge.

First, an environmental scan confirmed that no existing platform adequately met the combined operational, clinical, and youth engagement requirements of the Shamiri stepped-care model. Reviewed platforms failed on at least 2 of 6 evaluation criteria—most commonly cost, offline capability, and customizability for task-shifted workflows. This reflects not a critique of those platforms, but confirmation that the infrastructure gap in community-based mental health delivery in Kenya was real and unaddressed by the global product landscape [34].

Second, the SDH demonstrated strong early feasibility and acceptability. Deployed across 5 hubs by the end of 2023 and

XSL•FO
RenderX

expanding to 11 sites supporting over 76,344 students by Q1 2024, SDH replaced fragmented operational systems with real-time, role-differentiated digital infrastructure. Implementation staff reported high satisfaction (usability: mean 8.36, SD 1.49; NPS: mean 8.63, SD 1.46), and qualitative feedback consistently identified reductions in administrative burden and improvements in data timeliness and completeness. These results are consistent with evidence that well-designed operational platforms improve efficiency and oversight capacity in task-shifted delivery systems in LMICs [29,31,35-37,56].

Third, Rafi demonstrated strong initial reach—74.7% (n=3737) registration among the targeted MKU cohort—but significant engagement attrition, with MAU rates declining from 7.4% in January 2024 to near 0 by September. This pattern is common in digital mental health globally [37,39,57-60], but operational analysis identified specific, modifiable causes beyond structural or population-level explanations [39,58-60]. Among users who engaged with self-guided features, 99.4% subsequently booked therapy appointments—a cross-sectional finding requiring cautious interpretation, but one suggesting that self-help engagement may function as a gateway to clinical help-seeking for those who remain on the platform.

shamiriOS in the Context of Existing Digital Mental Health Platforms

shamiriOS contributes to a growing landscape of digital mental health platforms in LMICs [29-31,35-37]. What distinguishes it is not any single feature, similar apps exist, but 3 architectural characteristics that together address gaps in the current platform landscape [61,62].

First, shamiriOS integrates operational management (SDH), youth engagement (Rafi), and clinical workflows (SPP) within a single interoperable ecosystem. Most existing platforms address one of these functions; few attempt integration across all 3. This reflects our view that sustainable digital mental health infrastructure must support not just the end-user experience, but the full organizational and clinical system within which that experience is embedded [63,64].

Second, the platform uses a modular, component-based design in which each suite operates as an independent service with its own codebase, database, and deployment pipeline, connected through defined API contracts. An implementing organization could adopt SDH without deploying Rafi or adapt Rafi for a different clinical context without requiring the full SDH infrastructure. RBAC is configurable per deployment—the same instance can serve a secondary school program with 3 user roles or a university-based stepped-care service with 10—without code changes. This modularity is deliberate: no 2 implementation contexts share identical operational requirements, and platform rigidity is a common reason digital health tools fail when transferred across settings [63,64].

Third, the open-source architecture—built on Node.js, PostgreSQL, and React, with RESTful APIs and a phased Fast Healthcare Interoperability Resources compliance roadmap—lowers the barrier to adaptation by other technical teams [63-65]. Offline-first data capture, customizable reporting, and flexible intervention workflows are configurable features rather than hardcoded assumptions [63-65].

To the best of our knowledge, no comparable integrated open-source platform has been developed and deployed for community-based stepped-care mental health delivery in Kenya or comparable East African settings. We make no claim to novelty for the global landscape, where numerous digital mental health platforms exist [30,31,35]. The contribution is contextual: a platform built from the ground up for the operational, cultural, and infrastructural realities of implementation in Kenya and similar low-resource settings.

Extending shamiriOS to nonmental-health domains is a plausible future direction, but currently hypothetical. The modular architecture could, in principle, support other task-shifted, community-based delivery programs, but such extensions would require domain-specific user research and evaluation rather than direct platform transfer.

We believe publishing shamiriOS as open source serves an important purpose: making the architecture and code available for other teams to adapt, critique, and build upon. The precedent set by OpenMRS and DHIS2—adapted across dozens of countries while maintaining core architectural integrity—suggests that platform-level adaptability is achievable when accompanied by community-led localization [65-68]. Implementation toolkits, training modules, and documentation are being developed to lower the barrier for organizations in Kenya and comparable settings, with the explicit expectation that substantial localization will be required.

shamiriOS Can Support Backend Operations Within Task-Shifted Youth Mental Health Systems

The SDH was feasible and acceptable across both centralized and decentralized implementation contexts. The transition from fragmented workflows—spreadsheets, manual stipend logs, and WhatsApp-based supervision coordination—to a unified real-time platform was achieved across 5 hubs in Q4 2023, expanding to 11 sites supporting 1195 fellows, 111 supervisors, and over 76,344 students by Q1 2024. A 3.7-fold increase in student reach within a single year, maintained alongside high satisfaction scores, suggests that the platform can scale without deterioration in usability or staff experience. An NPS of 8.63 and a usability rating of 8.36 are consistent with evidence that well-designed operational platforms improve efficiency and oversight capacity in task-shifted delivery systems [30,31,35,56]. Qualitative feedback highlighted 3 valued features: centralized real-time visibility of fellow attendance across sites; automated stipend workflows, which reduced manual verification errors; and Metabase analytics dashboards, which allowed nontechnical supervisors to interrogate program data without developer support. The last is particularly relevant for scale: building analytical self-sufficiency into the platform reduces long-term dependency on the central technical team [30,31,35,56].

Operational feedback from the wave 2 expansion revealed several implementation-relevant patterns. Adoption was strongest at sites where SDH mirrored and enhanced existing workflows rather than replacing them wholesale—consistent with implementation science evidence that technology adoption

XSL•FO
RenderX

is smoother when tools augment rather than disrupt established practice [31,64]. Device sharing at some hubs created bottlenecks in timely data entry, temporarily reducing completeness in the first weeks of deployment. Offline-first data capture—introduced in version 3—addressed connectivity constraints but not device access. Future deployments to settings with low device-to-user ratios may need to treat hardware access as a precondition for adoption or consider lighter-weight interfaces optimized for brief interactions on shared devices.

Engagement Is a Challenge for Youth-Facing Apps Like Rafi

The gap between registration and sustained engagement was striking. High initial registration confirms that broad uptake is achievable through institutional partnerships and peer-led outreach. The subsequent decline—with sustained active use falling well below the 4% at 6 months common in reviews of consumer mental health apps [39,58]—is consistent with the literature but requires careful disaggregation.

Qualitative feedback identified several contributing factors: low perceived ongoing need among students who registered out of curiosity during launch, feature overload from multiple simultaneous engagement pathways, device storage constraints, and notification fatigue. These represent different problems requiring different solutions—notification calibration addresses fatigue but does nothing for users with genuinely low perceived need or stigma concerns [69-71].

More structurally, Rafi was designed around continuous self-monitoring—daily check-ins, journaling, and affirmations—which requires users to perceive ongoing value in routine self-assessment. For a predominantly healthy student population, this model may not fit typical help-seeking patterns, which tend to be episodic and crisis-driven rather than habitual [69-71]. Future iterations should consider whether a shift toward episodic engagement—designed for crisis-prompted access to care rather than daily wellness tracking—would better match actual user needs [39].

The finding that 99.4% of Rafi users who engaged with self-guided tools subsequently booked a therapy appointment—though cross-sectional and not causal—suggests that for students who do engage, the platform functions effectively as a gateway to higher-intensity care [69,71]. This points to a segmented engagement strategy: prioritizing acquisition and early retention for students with active mental health needs, rather than sustained mass engagement across the full student population.

shamiriOS Features in Development

Overview

Ongoing development is guided by field feedback, platform analytics, and emerging implementation needs [18,20,23,72,73].

SDH is being upgraded for more robust multisite operations, with planned enhancements including automated triage escalation for flagged students, expanded school and hub-level reporting, credential management, and intervention quality dashboards [18,23]. Standardized onboarding and role-based interfaces are being embedded to support consistency, as the platform scales to new partner organizations [18,23].

The next version of Rafi is designed to address the engagement challenges described earlier. Design priorities include gamified onboarding sequences, mood-responsive motivational content, and more direct pathways connecting students to therapists. Personalized content journeys adapted to user behavior are intended to reduce early drop-off [32,74,75]. The interface is being restructured to reduce feature overload, beginning with a simpler onboarding pathway before exposing users to the full feature set. Rafi's architecture is also being refactored for tighter SPP integration, supporting seamless transitions from self-guided to provider-supported care [30,32].

SPP is not reported as a deployed component in this study by design: it reached production readiness after the observation period, and its deployment and clinical integration merit are ongoing. Still, SPP integration continues with development priorities including real-time therapist scheduling, digital session documentation, and bidirectional data flow between clinical and operational layers. Historical client data migration is in progress to ensure continuity of care across platforms [33,34].

Future Development: AI Integration

A key area of planned development is the integration of AI tools—referred to internally as shamiriAI—across 3 priority domains: AI-assisted provider training and supervision, including automated fidelity scoring of intervention sessions; precision-matching of users to content and care levels based on symptom severity and engagement behavior; and symptom network analysis to inform modular intervention design. The potential benefits—particularly for supervision at scale, where human oversight capacity is a binding constraint in task-shifted delivery—are significant [31,76].

AI integration in mental health carries well-documented risks that are amplified in the Kenyan context [77-80]. These include dangerous clinical advice from language models, inappropriate substitution of AI for human therapeutic relationships, exploitation of sensitive personal data, and perpetuation of biases embedded in training datasets [77,81,82]. Dominant large language models are trained overwhelmingly on English-language [83], Western psychological literature [84,85], creating fundamental misalignment with Kenyan contexts where the experience of mental health may differ from Western models [86-90]. Regulatory frameworks in most African countries have not kept pace with the speed of AI deployment [77,78,91].

For these reasons, shamiriOS approaches AI integration as a learning-first rather than deployment-first activity. Guiding principles include an "AI-in-the-loop" design retaining human agency over care; training data grounded in African languages and contexts; community oversight involving youths, fellows, and clinicians as reviewers rather than only end users; strict data governance; and prospective safety monitoring. shamiriAI is presented as a set of research questions to be answered through rigorous evaluation. Future phases will assess feasibility, acceptability, cultural appropriateness, and safety before any AI feature enters service delivery [77].

XSL•FO
RenderX

Data Protection and Engagement Considerations

shamiriOS was designed to improve access to youth mental health services, but digital data collection introduces risks requiring explicit acknowledgment. Kenya's Data Protection Act (2019) provides a legal framework [91], but enforcement capacity is limited, and the gap between legal protection and practical data security in community-based implementations remains significant [92-94].

Current data protection measures include end-to-end HTTPS encryption, data deidentification, RBACs, separation of operational data (SDH) from clinical and personal data (Rafi and SPP), secure cloud hosting with encrypted databases, and Open Authorization 2.0 authentication. Rafi does not collect passive sensor data. Anonymous community feed features allow engagement without linking posts to clinical data.

These measures reduce but do not eliminate risk [92-94]. Future work will strengthen protections through user-controlled data deletion and full data export; transparent disclosure about what data are collected, how they are stored, and scenarios under which they could be accessed by third parties; and, where technically feasible, local device storage options that reduce cloud dependency [92-94]. shamiriOS's data governance policies will be published openly as part of the open-source repository to enable external scrutiny.

shamiriOS was developed through a user-centered design process [40,41]—not community-led development. End users informed design decisions as consultants and testers; strategic and architectural decisions were made by Shamiri's technical and clinical leadership. This reflects pragmatic constraints of real-world development and believe that the level of inclusion on feature development, content priorities, and data governance is appropriate for platforms at this stage. Future governance structures should consider greater community ownership [42,45].

Limitations

Several limitations should inform the interpretation of these findings. The environmental scan was structured but not exhaustive. Proprietary, region-specific, or non-English–language platforms may not have been captured, and the scan assessed market availability and feature coverage rather than clinical efficacy; it should not be read as a systematic review.

We did not use validated implementation science measures for feasibility, acceptability, or usability. Pragmatic industry metrics—NPS, MAU rates, and feature adoption rates—provided actionable feedback for development sprints but lack the reliability and cross-study comparability of instruments such as the System Usability Scale [95], Acceptability of Intervention Measure [53], or Feasibility of Intervention Measure [53]. Future evaluations of the stable platform should use these standardized instruments.

Barriers and facilitators were documented through operational feedback channels—training sessions, helpdesk tickets, monthly check-ins, and NPS qualitative responses—rather than formal implementation research using validated frameworks such as Consolidated Framework for Implementation Research or Exploration, Preparation, Implementation, Sustainment [96,97]. Our understanding of why engagement varied across sites and user groups is therefore incomplete. Future studies must prioritize rigorous implementation science methods.

Deployment results—particularly Rafi's MKU engagement data—reflect a 9-month observation window. Longitudinal engagement patterns, clinical outcomes, and cost-effectiveness at scale have not been assessed. The 99.4% therapy-booking rate is a cross-sectional observation that cannot establish causality.

Finally, shamiriOS used user-centered design with consultation, not fully participatory or community-led design. Future studies should consider a full participatory approach and investigate the implications of different approaches on cultural grounding, local ownership, and long-term sustainability.

Conclusions

The development and early deployment of shamiriOS demonstrate the feasibility of modular, open-source digital infrastructure for scalable, task-shifted youth mental health service delivery in Kenya. SDH showed strong feasibility and acceptability at scale, with satisfaction scores comparing favorably with digital health benchmarks and a 3.7-fold expansion in reach over a single year. Rafi demonstrated broad initial reach but surfaced important, actionable lessons about the conditions required for sustained engagement—lessons specific enough to have directly informed deployment strategy for future cohorts.

shamiriOS is not a finished product. Its full value will only be realized once all 3 components are deployed, integrated, and rigorously evaluated. The evidence here establishes a foundation: the core infrastructure works, it is valued by its users, and the most significant obstacles to impact lie not in platform design but in implementation readiness, incentive structures, and institutional integration—all of which are addressable.

We envision shamiriOS as an open-source, contextually grounded infrastructure for decentralized mental health service delivery in Kenya, available for adaptation by teams in comparable settings—with adaptation requiring necessary contextual redesign. By publishing both the platform and an account of its early deployment, we aim to contribute not only a technical resource but a set of implementation lessons to the broader community working to close the youth mental health treatment gap in Kenya and beyond.

Acknowledgments

The authors would like to acknowledge the contributions of the Agency Fund team, including Linus Wong, Robert On, Paul Wang, and James Walsh, who provided critical support during the conceptualization, design, and early development phases of

XSL•FO
RenderX

the platform. The authors also thank Rosine Baseke, Veronica Ngatia, and other members of the Shamiri Institute staff whose input and collaboration were instrumental in shaping the design and functionality of shamiriOS.

Funding

The development of shamiriOS was supported by funding from the Agency Fund, the Fund for Innovation in Development, and the Inner Foundation.

Conflicts of Interest

SL, TLO, WM, JK, BO, IE, and CW are current or former employees of Shamiri Institute, the nonprofit organization that developed and maintains shamiriOS. Shamiri Institute received funding from the Agency Fund, the Fund for Innovation in Development, and the Inner Foundation to support platform development. JT and EK are affiliated with external organizations that provided technical or funding support. No author received personal financial benefit from shamiriOS, and the platform is released as open-source software. The authors report no other conflicts of interest.

Abstract

Background: The incidence of type 2 diabetes (T2D) continues to increase, and the lack of individualized therapy strategies hinders patient engagement with and commitment to a healthy lifestyle. The PROTEIN project aimed to facilitate users in choosing healthy living, thereby improving their metabolism and T2D management.

Objective: This study aims to assess the efficacy of a personalized mobile app to achieve a 5% time in range (TIR) improvement over a 12-week intervention in adults with prediabetes or T2D.

Methods: We conducted an exploratory pilot randomized controlled trial with 21 individuals with T2D or prediabetes who used a continuous glucose monitoring system and the PROTEIN mobile app for personalized meals and exercise recommendations based on their glucose levels and physical activity.

Results: The TIR of the participants increased (P<.05; from 71.8%, SD 27.3% to 76%, SD 28.1%) with individual use of the PROTEIN app but did not achieve a 5% improvement overall; however, given the exploratory design and small sample size, this finding should be interpreted with caution. Glycated hemoglobin, fasting blood glucose, and body weight did not fluctuate throughout the 12-week intervention. The dropout rate was high, and the average duration of use of the PROTEIN app was 42 (range 5-84) days.

Conclusions: Our results showed a modest increase in TIR with the use of the PROTEIN app; however, considering the exploratory design and small sample size, this finding should be interpreted as preliminary. Integrating wearables and automated personalization for well-being is an innovative approach that must keep pace with the accelerated development of ever-evolving technologies. The COVID-19 pandemic was a major obstacle to recruitment in our clinical trial.

KEYWORDS

type 2 diabetes; personalized nutrition; glucose management; time in range; CGM; continuous glucose monitoring

Introduction

Identifying optimal diets for individuals with type 2 diabetes (T2D) and prediabetes remains challenging [1]. The World Health Organization defines mobile health (mHealth) as medical and public health practices supported by mobile devices, which have become increasingly prevalent [2]. Together, these developments highlight the growing potential of digital tools to support personalized diabetes management.

Advances in artificial intelligence (AI) now enable the processing of large datasets to deliver personalized nutrition advice that aligns with individual values and preferences, potentially supporting sustained patient engagement in healthy dietary choices [3,4]. However, despite the constant and rapid evolution of diabetes-related mobile apps, few offer adaptive, evidence-based nutrition guidance for patients with T2D in Germany [5-7].

Given the significant interindividual variability in postprandial glucose responses, generic recommendations are insufficient. Integrating data from continuous glucose monitoring (CGM) and user preferences allows for more tailored interventions, using algorithms powered by machine learning and AI to enhance diabetes self-management [6,8-11].

Within the European H2020 "PROTEIN: PeRsOnalized nutriTion for hEalthy living" project (2019-2022), we aimed to develop and evaluate a personalized nutrition and exercise mobile app to support daily T2D management [12]. The PROTEIN project involved 20 partners from 11 European countries, focusing on health promotion through multidisciplinary collaboration. Our exploratory pilot study specifically assessed whether the PROTEIN app could improve dietary compliance and glucose management in T2D, using time in range (TIR) as the primary outcome - a metric not commonly used as a primary endpoint in similar randomized controlled trials (RCTs) [7]. TIR is the proportion of time that a person spends within a target range of glucose levels, usually between 70 and 180 mg/dL, as predetermined by a health practitioner or the person with diabetes [13].

Following Germany's 2019 digital health reform, only approved apps can be prescribed for diabetes management, ensuring patient safety and reliability [14]. Only 6 of 59 mHealth apps have been approved for people with diabetes [15]. The PROTEIN trial provides prospective, controlled, long-term evidence on AI-driven mobile apps that deliver personalized recommendations using CGM data, user interaction, and preferences. This adaptive AI approach addressing engagement and patient engagement challenges is novel in digital therapeutics.

To our knowledge, this adaptive approach has not been reported in previous studies [16-19]. Therefore, our exploratory pilot study aimed to automatically customize meal plans and physical activity (PA) according to user phenotype and food preferences by integrating CGM data of patients with T2D. The primary objective was to increase the TIR of the study participants by 5% while improving eating behaviors.

Expanding upon existing research findings, we aimed to address the following questions:

1. Does TIR increase when using the PROTEIN app?
2. Are there associated changes in weight?

Methods

Study Design

We conducted a 12-week RCT in Germany (June-December 2022) to evaluate the PROTEIN app's impact on glucose management in T2D.

The PROTEIN System

Developed and tested [20-24] by a European consortium, the PROTEIN system comprised:

1. Nutrium dashboard: used by nutritionists to manage participants and create meal plans using country-specific food composition datasets [25].
2. PROTEIN app: enabled participants to view, plan, and log meals and activities, and interact with personalized recommendations.
3. User dashboard: provided participants with an alternative visualization tool through a web browser.

The AI-driven advisor included a food and activity recommender system, a reasoning-based decision support system [8] built on the Nutrition & Activity Ontology for Healthy Living, which encoded the rules and relations used by the AI advisor [26], and generated individualized meal and activity plans every two weeks. These were based on the user profile, preferences, CGM data, and aligned with the "knowledge tracker," a framework for the meal and PA suggestions [27] that was integrated into the application. Nutrition requirements followed European guidelines [28].

Intervention

We conducted a 12-week intervention. The participants used the PROTEIN app and the CGM Freestyle Libre (Abbott Diabetes Care, Wiesbaden, Germany) to collect data to enable further personalization. We randomized and allocated the participants into two groups after successful screening:

1. Start-group: participants used the activity tracker, CGM, and PROTEIN app for 12 weeks, followed by a 6-week

XSL•FO
RenderX

period without the PROTEIN app, but where the wearables continued to be used.

2. Wait-group: participants only used the activity tracker and CGM for 6 weeks, followed by a 12-week period of using the PROTEIN app as well.

This study design, as shown in Figure 1, allowed us to clearly understand the influence of the PROTEIN app. The randomization sequence was computer-generated (Microsoft Excel 2019, Microsoft Corporation) and was performed on-site by the study team. Stratification considered sex, age (cut-off 60 years), and BMI (cut-off 30kg/m^2) at screening. Given the nature of the trial, blinding was not possible for either participants or study personnel. After generating the randomization sequence, participants were assigned on-site by the study team, without formal allocation concealment.

Figure 1. Study design illustrating the start-group (blue, top panel) and the wait-group (green, bottom panel).

The participants allocated to the start-group attended their first clinical visit, where baseline clinical and laboratory assessments, including blood count, lipid panel, liver profile, uric acid, C-reactive protein, fasting glucose, hemoglobin A_{1c} (HbA_{1c}), ankle-brachial index, and body composition, were collected after an overnight fast.

On a typical day, the participants would open the app to review the recommended meal and activity plans, confirm or delete items, rate meals on a 1- to 5-star scale, and add alternative foods or activities.

Participants and Recruitment

Participants were recruited via hospital and newspaper advertisements, outreach to physicians, and online postings. Eligibility criteria are given in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Prediabetes or T2D (HbA_{1c} ≥5.7%, fasting glucose ≥100 mg/dL, or 2-hour glucose ≥140 mg/dL) [29]
- Age >18 years
- BMI 20-45 kg/m^2

Exclusion criteria

- Type 1 diabetes
- Severe metabolic conditions
- Insulin, sulfonylureas, and glucagon-like peptide-1 (GLP-1) agonists
- No Android smartphone
- Use of continuous glucose monitoring (CGM) or activity tracking apps in the last 3 months

Some eligibility criteria were further specified during study implementation to ensure participant safety. In particular, individuals using sulfonylureas and glucagon-like peptide-1 receptor agonists were excluded, although these criteria were not explicitly detailed in the trial registry. The BMI inclusion range (20-45 kg/m^2) was applied consistently during recruitment. After telephone screening, 71 candidates were invited for on-site screening.

The PROTEIN trial conducted in Germany was retrospectively registered after completion of data collection at ClinicalTrials.gov: registration number NCT05951140 [30];

that said, the protocol and outcomes had been defined prior to data analysis.

Meal Plan Personalization

Meal plans were developed using the PROTEIN knowledge tracker, tailored for prediabetes or T2D as shown in Table 1, and based on participant profile (age, sex, diagnosis, weight, dietary history, goals, allergies, intolerances, and religious preferences). Plans were updated biweekly, with participant feedback and CGM data guiding further personalization.

Table 1. Dietary framework of the knowledge tracker developed for prediabetes and type 2 diabetes.

Nutrient recommendations	Male	Female
Energy intake (kcal)	2100 (300)	2100 (300)
Salt (g)	<5	<5
CHO[a] (%EI[b])	45 (10)	45 (10)
Sugar (%EI)	<10	<10
Protein (g/kg/BW[c])	0.8-1.4	0.8-1.4
Fat (%EI)	30 (10)	30 (10)
Fiber (g/day)	30-45	30-45
Fruit (portions)	2	2
Vegetables (portions)	≥3	≥3

[a]CHO: carbohydrates.

[b]EI: energy intake.

[c]BW: body weight.

Participants interacted with the app by confirming, deleting, or rating meals (1-5 stars) and activities. Customization increased as participants engaged with the app, especially during the initial 2 weeks, enabling the AI to learn user preferences. Engagement metrics were monitored to assess correlations with health behavior changes.

Glucose Data

Each participant used a Freestyle Libre CGM system, with data uploaded weekly to inform recommendations. A TIR ≥70% (equivalent to HbA_{1c} ≤6.7%) was set as the target, following the international consensus on CGM [31].

If TIR dropped below 70%, the app automatically reduced daily carbohydrate recommendations by 10% for the following week. This allowed a stepwise personalization within the ranges of evidence-based dietary recommendations for the dietary management of diabetes [32,33]. Foods, apart from vegetables and pulses, causing high glucose excursions (≥140 mg/dL for 2-4 hours postprandial, on ≥2 occasions), activated a push notification directly to the user and were excluded from the meal plans the following week.

The data extracted from the CGM was only used if at least 70% of the glucose data was available per day. We based this modified approach on the recommendations for interpretations of TIR [31]. We compared the average TIR of the user during the time they were actively using the app to the average TIR during their planned waiting time in the study protocol. This approach was used to account for the fact that most participants did not use the application for the planned 12 weeks.

Sample Size and Power Calculation

The study aimed for 300 participants to detect a 5% TIR difference with 80% power (β=0.20) and α=0.05, enabling detection of medium to small effects (Cohen d=0.348) [34]. Due to recruitment challenges, only 27 participants were enrolled, and 21 were included in the final analysis. The study is substantially underpowered for our primary aim, and the analysis that focused on periods of active app use should be interpreted as exploratory.

Statistical Analysis

Initially, an as-treated analysis was planned for all completers. Due to low adherence and high dropout, the originally planned RCT analysis was not feasible. Therefore, the analyses presented are exploratory and were limited to periods of active app use compared with nonuse days. This approach introduces selection bias and does not preserve the randomized design. No intention-to-treat analysis was possible due to the limited sample size and missing data. Subgroup analyses (start-group vs wait-group) and analyses restricted to periods of active app use were not prespecified and should be interpreted as exploratory. Active app use days were defined as days with at least one logged interaction with the PROTEIN app and valid CGM data. Noncompliance was defined as <30% app use (<25 days) [35]. Statistical analyses were performed using SPSS 26.0 and Prism 8. Data are presented as mean (SD) in tables or mean (SEM) in figures. Paired 2-tailed t tests or nonparametric equivalents were used as appropriate, with significance set at P<.05. Outliers (>3× IQR) were excluded.

Due to early termination of recruitment, high attrition, and deviation from the planned randomized analysis, this study should be considered an exploratory pilot study. All analyses

XSL•FO
RenderX

are hypothesis-generating and do not provide confirmatory evidence of effectiveness.

Registered Outcomes and Reporting

To ensure transparency between the prespecified trial registration and the analyses reported in the results section, all registered outcomes were systematically compared with the outcomes analyzed. A summary of registered primary and secondary outcomes, their reporting status in this manuscript, and reasons for nonreporting where applicable, is provided in Table 2.

Table 2. Comparison of registered outcomes and outcomes reported in this manuscript.

Outcome (as registered at ClinicalTrials.gov)	Type	Reported in this manuscript	Reason for nonreporting (if applicable)
Time in range (TIR)	Primary	Yes	—[a]
Improve eating behavior toward healthier choices	Primary	No	Insufficient and inconsistent dietary data and absence of a predefined validated combined measure
Adherence to the dietary recommendations of the app	Secondary	Exploratory and descriptive only	Exploratory indicators (eg, app engagement, meal ratings) reported
Glycemic metabolism (HbA_{1c}[b], fasting glucose)	Secondary	Yes	—
Sedentary time	Secondary	No	Data are incomplete and not consistently recorded across participants
Energy intake	Secondary	Partially	Reported descriptively (Table 7); not analyzed as a formal outcome due to limited sample size
Microbiome	Secondary	No	Insufficient samples available for robust analysis
Polygenic risk score	Secondary	No	Not available for the analyzed cohort

[a]Not applicable.

[b]HbA_{1c}: glycated hemoglobin A_{1c}

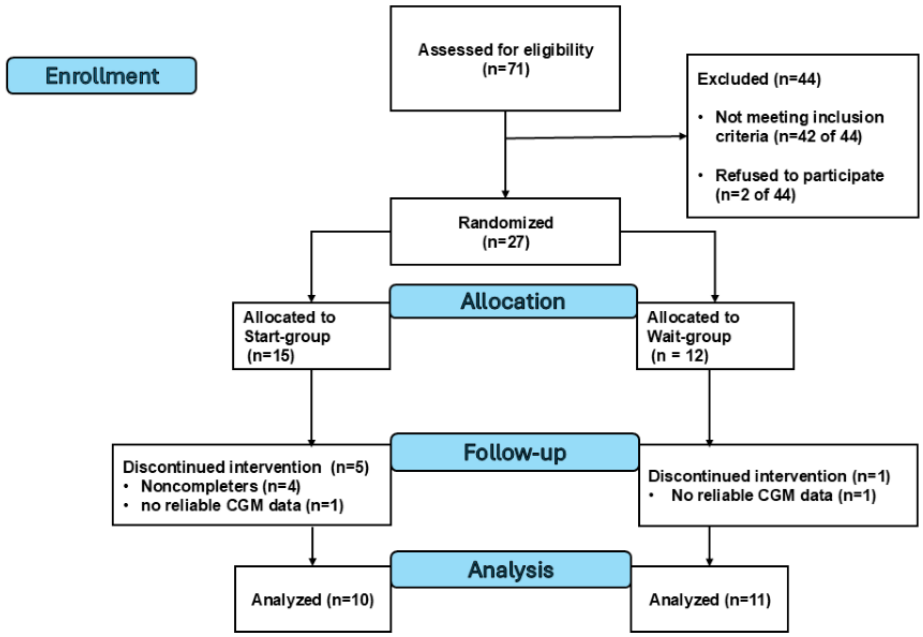
In particular, the primary outcome “healthier eating behavior” could not be formally analyzed due to insufficient and inconsistent dietary data.

Ethical Considerations

The pilot study PROTEIN was conducted at the University Hospital Charité. The ethics committee of the Charité University Hospital Berlin approved all trial procedures and amendments (approval number EA4/110/20 on September 11, 2020). We retrospectively registered the trial at ClinicalTrials.gov (registration number NCT05951140) after completion of data collection due to administrative delays; we defined the protocol and outcomes prior to data analysis. Written informed consent was obtained from all participants.

CONSORT Guidelines

This randomized controlled trial was conducted in accordance with the CONSORT (Consolidated Standards of Reporting Trials) 2025 guidelines for reporting RCTs (Multimedia Appendix 1) [36].



Results

Demographic Characteristics

Overall, 27 participants (n=13 male, n=14 female) were enrolled in the study. Twelve participants (44%) stopped using the PROTEIN app after 12 days, 11 of whom continued to use the wearables. In total, 21 participants had reliable CGM data and were included in the analysis (12 female and 9 male) (Figure 2). The baseline characteristics of the participants are shown in Table 3.

[e]LDL: low-density lipoprotein.

CGM Data

We compared the TIR of the participants during the waiting phase (without the use of the PROTEIN app) to the intervention (with the use of the PROTEIN app). TIR increased significantly (*P*=.04), rising from 71.8% (SD 27.3%) to 76% (SD 28.1%). This represented a 4.2% (9%). Improvement, not meeting the 5% target set.

We then examined potential differences between the wait- and the start-group. In the start-group (n=10), the TIR decreased (not statistically significant) from 68.9 (SD 32.7%) to 64.9 (SD 31.1%) (*P*=.14) once they stopped using the application, whereas the TIR of the wait-group (n=11) increased from 78.0 (SD 23%) to 82.4 (SD 22.9%) (*P*=.10) once they started using the application. Having considered the positive effect on the TIR, we investigated whether starting to use the PROTEIN app first (start: 4, SD 9.4 vs wait: 4.3, SD 8) yielded a stronger change in the TIR. No significant difference in the change of the TIR between the 2 groups was seen (*P*=.94).

Routine Glucose Parameters

HbA_{1c} and fasting blood glucose did not change significantly during the study, as shown in Tables 4 and 5. Values remained comparable across study visits within both groups. No statistically significant differences were observed between the intervention and waiting phases.

XSL•FO

Use of the PROTEIN App

The intended duration of the PROTEIN app usage was 84 days (12 weeks), but only 2 participants completed the full period. To account for this, we assessed the time period between first and last use of the PROTEIN app, irrespective of intermittent pauses. Participants' average app usage was 42 days (range 5-84 days). Contrary to expectations, there was no significant correlation between days of app usage and change in TIR (r= –0.224; *P*=.33). No adverse events or study-related harms were observed during the study period.

Personalization

The process of personalization is described in detail in the PROTEIN AI-Advisor [8].

To test the accuracy of the recommended meal plans, the data from the nutrition and activity plans were extracted and compared to the knowledge tracker, as seen in Table 7. We did not detect any high glucose excursions caused by pulses or vegetables, nor exclusions of specific foods.

Table 7. Nutrient recommendations via the PROTEIN app compared to the knowledge tracker.

Nutrient recommendations	Values, mean (SD; n=21)	Knowledge tracker (male/female)
Energy intake (kcal)	2048 (376)	2100 (300)/1750 (250)
Protein (g/kg/BW)	1.2 (0.2)	0.8-1.4
Carbohydrates (%EI)	49 (5)	45 (10)
Fat (%EI)	31 (4)	30 (10)
Fiber (g/d)	36 (6)	30-45
Fruit (portions/day)	3 (1)	2
Vegetables (portions/day)	5 (2)	≥3

Overall, the average star ratings ranged from 3 out of 5 stars for lunch and dinner to 3,5 out of 5 stars for breakfast, afternoon snack, and supper, and 4 out of 5 stars for morning snack.

In addition, we investigated the total variety of meal composition that was yielded for 17 participants; 159 unique options for breakfast were recommended, 114 for morning snacks, 145 for lunches, 112 for afternoon snacks, 123 for dinner, and 27 for

XSL•FO
RenderX

suppers. Furthermore, 6 (29%) participants reported trying new meals that they had not thought of before as a result of using the PROTEIN app.

Discussion

Our study addressed two research questions: whether the PROTEIN app increases TIR and whether it affects body weight. The results indicate a modest improvement in TIR (4.2%) during app use, with no change in weight. In summary, our data indicated that the TIR improved with the use of the PROTEIN app for only an average of 12 days, but this fell short of the expected 5% improvement and of the expected 12-week usage period. Unexpectedly, we did not find a significant correlation between the duration of app use and the improvement of the TIR, which could be due to the small sample size and narrow range of usage durations. Despite the high rates of noncompliance in the intervention phase, the TIR improved in parallel with the use of the mobile nutrition app, suggesting a potential signal that a tailored recommendation approach delivered with wearables through a mobile app may be associated with small increases in TIR and may encourage greater concordance with dietary recommendations. However, this observation is exploratory and cannot be distinguished from selection bias or confounding, and any effect on dietary concordance remains uncertain. Our study, therefore, also illustrates the need to balance technological capabilities with user experience since using an app with many features and wearables is time-consuming, contributing to participant fatigue and dropout.

Overall, participants who took part in the intervention with valid CGM data (n=21) had an improvement of 4.2% in their TIR while they were using the PROTEIN app, suggesting that even though they did not follow the recommendations every day, there seems to be a degree of agreement and engagement while using the PROTEIN system [35,37]. It is noteworthy that the outcome relies on the adequate resources of the participants and may be influenced by different factors, including family network, profession, and socio-economic status.

Although the 4.2% increase in TIR reached statistical significance, its clinical relevance remains uncertain, because of the high baseline TIR (mean >70%) and the lack of change in HbA_{1c}, fasting glucose, and weight. International consensus recommends achieving and maintaining TIR ≥70% and states that a 5% change in TIR is strongly associated with a 0.5% decrease in HbA_{1c}, which is a clinically significant reduction. We therefore interpret the observed TIR change as a modest signal of potential benefit that requires confirmation in larger, adequately powered studies.

We anticipated that participants would use the PROTEIN app for a full 12 weeks; however, this was not achieved by the majority. This was largely due to the app being perceived as not user-friendly and occasionally too time-consuming. Defining dropouts was a difficult task, since several studies defined this differently. We based our definition of adherence on the days the app was used, namely, at least 30% of the planned time. According to this definition, the dropout rate in the study (43%) is consistent with the work reported by Meyerowitz-Katz et al [38].

Accordingly, after analyzing the differences between the two groups, we observed that the participants' TIRs improved regardless of whether they started with the intervention or the waiting phase. This may suggest that wearables alone are not sufficient to improve glucose management, but that extra feedback, in this case in the shape of an app, led participants toward better glucose management, although this cannot be determined definitively from the current data. The TIR of the start-group did not decrease significantly after they stopped using the PROTEIN app, suggesting there is a legacy effect for the users. The participants kept using the sensors as planned (12 weeks during intervention and 6 weeks in the waiting phase), which allowed us to compare the two periods of time. From these data, we observed patterns consistent with improved glucose management during the PROTEIN app use; however, causality cannot be inferred due to the exploratory design and potential selection bias. A dietary protocol before intervention could be added in further research to provide a better understanding of dietary change.

Furthermore, prior studies have shown that CGM is an important tool for the management of T2D [13,39,40]. When we analyzed our participants according to the assigned group, we can see that using wearables without guidance on how to effectively use them did not cause a change in the glucose levels. Interestingly, the participants who used the PROTEIN app right away (start-group) had a decrease in the TIR once they stopped using it, but this decrease was not statistically significant. This suggests that 12 weeks may not be enough to maintain a health-supporting behavior for a longer period. As no significant changes in weight were seen over the study period, improvements in TIR appear to be driven by the consumption of more adequate meals, independent of the group they were randomized into. Therefore, we cannot determine whether the PROTEIN app influences their caloric intake, but the findings are consistent with changes in food selection.

Overall, the PROTEIN application generally provided suitable meals for individuals with T2D and prediabetes. However, on a few occasions, the recommended protein amounts fell short when compared to the knowledge tracker. The first 2 weeks during which the participants were expected to train the app proved to be excessively time-consuming, leading to a decline in the compliance of our participants. Additional factors, including managing multiple devices and integrating the protocol into daily routines, were also identified as reasons for disengagement. The mobile app was programmed to change the meal plan for the whole week once the subject skipped a meal and added a new one instead. Moreover, the PROTEIN app sometimes failed to "learn" or adapt after two weeks, despite participants having the same breakfast daily.

The PROTEIN AI-advisor adjusted carbohydrate targets in response to low TIR and was programmed to exclude foods associated with repeated high excursions. We could not detect the frequency and magnitude of these adaptations in practice. Moreover, participants reported cases in which the system did not sufficiently adapt to repeated meal patterns, indicating that

XSL•FO
RenderX

the current personalization was only partially realized and requires further optimization.

It is important to acknowledge that 21 participants had reliable CGM data, making the trial substantially underpowered and exploratory relative to the original sample size calculation with 300 participants. All suggestions of effect should be interpreted as exploratory signals rather than solid evidence.

Furthermore, limiting analyses to periods of active app use introduces substantial selection bias toward more engaged users, likely underestimates variability in real-world use, and may overestimate potential effects.

Several limitations apply to our exploratory pilot study. Recruitment and retention were challenging, exacerbated by the COVID-19 pandemic and technical barriers (eg, Android-only compatibility). These factors limited the sample size and statistical power, highlighting the need for larger, more inclusive studies. Several prespecified outcomes were registered in the clinical trial registry but are not reported in this manuscript because of the limited sample size and incomplete data collection. A detailed comparison of registered and reported outcomes is provided in Table 2. Even though we saw a moderate difference in the TIRs while using the PROTEIN app, we were unable to assess participants' TIR prior to using the wearables and/ or using the application, which could provide further robust evidence as to the health behavior changes.

Therefore, we cannot fully exclude the effects influencing intra-participant TIR patterns, as preintervention blind CGM data periods were not available.

Despite these limitations, the study provides preliminary indications of the feasibility and potential of combining mHealth, AI, and CGM data to support individualized diabetes care; nevertheless, it must be recognized that our own evidence indicates the intervention does not feasibly support increased TIR, except for a short period and for a small proportion of app users. This emphasizes important limitations regarding the broader clinical use and sustainability of the approach.

Our exploratory pilot study adds novel data on the feasibility, adherence patterns, and preliminary glycemic impact of such an AI-driven system under real-world conditions.

Future research should focus on improving user engagement, expanding compatibility, and evaluating long-term clinical outcomes in larger, more diverse populations.

Conclusions

The level of personalization offered by the PROTEIN app needs to be enhanced [9], which could help reduce the time required for the app to learn and adapt. For example, allowing users to select in advance their favorite ingredients or meals could streamline the learning process. Ideally, greater integration of image recognition features, allowing participants to take and upload pictures of their meals rather than manually entering ingredients, and the ability to automatically upload and correlate CGM data with food intake would significantly improve the user and researcher experience. These conclusions are based on this combination of published evidence and participant input.

Considering the strong limitation in sample size and engagement relative to the original protocol, our study results should be seen as an exploratory trial that primarily provides information regarding feasibility, engagement, and potential effects.

Finally, the PROTEIN app was associated with a modest increase in TIR in adults with prediabetes or T2D; however, this exploratory finding does not establish effectiveness and requires confirmation in adequately powered trials, suggesting a possible role for AI-driven, personalized mHealth solutions for diabetes management. While the primary endpoint was not fully achieved, the study supports further development and evaluation of adaptive digital interventions designed to enhance personalized engagement with dietary recommendations and improve glycemic control.

Zhang et al [1] found that participants rated an emotion-adaptive clinical decision support system as clearer, easier to use, more reliable, and more trustworthy than a basic system. Both systems used the same core prediction model and explainability outputs. The empathic system added emotion sensing and a dialogue model that changed how the explanation was delivered.

A clinician who is stressed or confused may understand a difficult explanation better when the system changes how it speaks. But empathy cuts both ways. It can make correct advice easier to accept. It may also make wrong advice harder to reject.

The study measured users' ratings of trust, reliability, and clarity. It did not test whether the empathic system helped them make more accurate decisions or spot errors. The prediction models were tested separately, but that does not show whether the extra trust was deserved. A system can feel more reliable without being more accurate. A systematic review of large language model empathy found that 11 of 12 studies assessed empathy subjectively [2]. That gap matters because the goal is not the highest possible trust. Trust should match what the system can actually do. Users should accept correct AI advice and reject wrong advice [3].

The authors already identify one part of the problem. Participants reported that emotion adaptation sometimes changed the focus or specificity of the answer. Some replies became overly supportive and did not address the clinical question directly. The authors therefore call for controls that protect clinical precision and decision clarity [1]. But even a direct and precise answer can be wrong. When that answer is also empathic, it may be harder to reject.

This is not only a theoretical concern. In a clinical study, inaccurate advice reduced physicians' diagnostic accuracy [4]. Another study of health chatbots found that empathic responses increased perceived warmth, trust, and intentions to use the system [5]. These findings do not prove that empathy increases acceptance of wrong clinical advice. They show why the question needs to be tested. One objection is that empathy may raise trust because it improves understanding, not because it persuades. That may be true. The test should separate these effects. Better understanding should help users accept correct advice and reject wrong advice. Persuasion alone may increase acceptance of both.

Future studies should compare correct and wrong AI advice in empathic and neutral language. The clinical content should stay the same. Users could make a judgment before seeing the advice and again afterward. The main outcomes should be final decision accuracy, acceptance of correct advice, rejection of wrong advice, and a direct test of what users understood. Trust ratings can remain, but they should not stand alone.

Emotion-adaptive clinical AI should not make every answer more trusted. It should help trust follow correctness.

artificial intelligence; AI; clinical decision support systems; large language models; empathy; explainable AI; trust; human factors; reliance; human-AI interaction

Sorin and Klang's Letter to the Editor [1] regarding our evaluation [2] of an empathic clinical decision support system raises an important distinction between perceived trust and objectively warranted reliance. Emotion-adaptive communication may make accurate advice easier to understand and accept, but it could also make inaccurate advice harder to question or reject [1]. We agree that such communication should not indiscriminately increase acceptance of AI output.

Our study compared explanation delivery; it did not evaluate clinical effectiveness or appropriate reliance. The study's empathy-enhanced and basic conditions used the same cannabis-intoxication prediction and explainable AI pipeline; the empathic condition added affect sensing and emotion-adaptive delivery. We measured perceived usability, clarity, trustworthiness, and reliability—not decision accuracy, error detection, reliance, or patient outcomes. Separately reported predictive-model performance therefore does not establish that the increase in perceived trust was warranted. Consistent with this measurement concern, Sorin et al's systematic review [3] found that all but 1 of 12 studies assessed large language model empathy subjectively, underscoring the need for objective behavioral outcomes.

The relationships among accuracy, trust, and appropriate reliance require nuance to understand [4]. Users may consult decision support because they cannot independently determine whether advice is correct. Their ability to evaluate recommendations varies with clinical expertise, AI literacy, case difficulty, prior beliefs, and confidence—important considerations in our heterogeneous sample [2]. Objective accuracy is necessary but not sufficient for trustworthy use. Accurate information may be underused when presented confusingly, too technically, or without sufficient context [2]. Conversely, empathic delivery must not conceal uncertainty, weaken explanation fidelity, or make unsupported advice appear authoritative. Our design cannot determine whether higher trust reflected improved comprehension, persuasive delivery, or both.

Our study addressed the first communication barrier. We did not manipulate advice correctness; therefore, our data neither demonstrate nor rule out empathy-induced overreliance on AI-generated output. Participants reported that adaptation sometimes changed response focus or specificity, and we acknowledged the need for guardrails preserving clinical precision and explanation fidelity [2]. The same concern applies when an underlying prediction or recommendation is inaccurate, because inaccurate AI advice can impair clinical judgment [5].

Future studies should examine trust mechanisms beyond ratings. A useful design might, for example, vary advice correctness and communication style, hold the clinical scenario and evidentiary content constant across communication-style conditions, and assess effects across levels of clinician expertise. Outcomes could include objective comprehension, pre- and postadvice decisions, confidence calibration, verification behavior, acceptance of correct advice, rejection of incorrect advice, and both overreliance and underreliance on AI-generated output. Uncertainty communication and explanation fidelity also could be assessed.

Accordingly, our findings provide preliminary evidence that emotion-adaptive delivery can improve perceived clarity, usability, and trust; they do not establish improved decision

XSL•FO
RenderX

accuracy or appropriate reliance. The goal should not be maximal perceived trust but warranted trust and appropriate reliance grounded in system performance, transparent uncertainty, faithful explanation, and users' ability to interpret the evidence.

Abstract

Background: Diabetic foot ulceration (DFU) is the leading cause of nontraumatic amputations in people with diabetes. Research shows that improving patient awareness can result in short-term improvements, but Cochrane reviews report insufficient high-quality evidence.

Objective: This study aims to investigate the effects of multimedia presentation and smartphone alerts to enhance long-term knowledge and foot care behaviors in individuals at moderate-to-high risk of DFU.

Methods: Participants were randomized to a control group, receiving usual diabetic foot care advice (n=40), or an intervention group, receiving a multimedia diabetic foot care presentation and regular "foot alerts" through the MyU smartphone app on top of usual care (n=37). Patient's knowledge and behaviors related to diabetic foot care were assessed at baseline and after 12 months. Repeated measures ANOVA was conducted in both intention-to-treat and per-protocol analyses to evaluate the intervention's effectiveness.

Results: The findings were consistent across intention-to-treat and per-protocol analyses. In the intervention group, the number of podiatry visits was positively correlated with improved foot care behavior (r=0.408; P=.02), while the control group showed a negative correlation (r=−0.402; P=.02). No significant correlations were observed with knowledge scores. Although no significant time×group interactions were seen, the main effects of time were found for both knowledge (η^2=0.12; P=.004) and behavior scores (η^2=0.31; P<.001). Post hoc analysis showed a decline in knowledge scores in the control group (Cohen d=−0.24; P=.007) and improvements in behavior scores in both groups (Cohen d: intervention=0.61, control=0.63; all P<.001).

Conclusions: The MyU app−based multimedia intervention was associated with improved foot care behaviors over 12 months, indicating potential benefits as an adjunct to usual diabetic foot care. However, no significant changes in diabetic foot care knowledge were observed. These findings suggest that while the applied digital multimedia tool may support behavior change, further research is needed to enhance knowledge retention and clinical impact. The study revealed that multimedia education alone may not be effective for long-term improvement in foot self-care knowledge and behavior among individuals at moderate-high DFU risk, but the reinforcement of educational material during follow-up podiatry visits could be effective.

Introduction

The escalating incidence of diabetes worldwide has turned it into a global pandemic impacting over 500 million individuals [1]. Health costs associated with diabetes are expected to reach US $1054 billion by 2045, up from US $966 billion in 2021 [2], with 80% of this spent on managing avoidable complications [3]. One of the most common long-term complications of diabetes is diabetic foot ulceration (DFU), with a lifetime risk of developing a DFU of between 12% and 25% [4-6]. DFU continues to be the leading cause of nontraumatic lower limb amputation [7], accounting for 84% of lower limb amputations [8]. Studies have shown that people with diabetes are 10 - 30 times more likely to have a lower limb amputation than someone without diabetes [9,10]. Furthermore, Armstrong et al [11] reported a 5-year mortality rate in people with DFU of as much as 43% at 1 year, worse than some of the most common cancers, and postamputation rates have shown that only 50% of patients survive the first year following amputation [12].

The early detection and treatment of minor foot injuries have been shown to reduce amputation rates by between 49% and 85% [13], yet amputation rates continue to rise [14]. Improved patient awareness and correct foot self-care practices can interrupt the amputation pathway [6]. Although systematic reviews have demonstrated the efficacy of foot care education in enhancing self-care behaviors and knowledge [15-17], there are insufficient data to support its clinical use in reducing ulceration and amputation incidence [18,19]. Furthermore, the delivery of education sessions is particularly difficult for those with limited literacy, and debates are ongoing about whether video-based or printed materials are most effective [20,21]. Comprehensive foot care education, which encompasses assessment, discussion, counseling, home visits, and telephone calls, has been proposed to enhance diabetic foot care and educational programs [18]. However, a systematic review of 6 randomized controlled trials (RCTs) revealed insufficient evidence to support its efficacy [22]. More recently, it has been suggested that mobile apps can effectively prevent DFU recurrence [23] and improve diabetic foot care outcomes by incorporating at least 1 information communication tool [24]. However, many of the RCTs focused on patients at low risk, limiting their utility to support improved clinical outcome in the measure of reducing the rate of ulceration [18,19,22].

Given these findings and the estimated financial savings in the prevention of DFU, there is a need to focus on its prevention [25]. This study, therefore, aims to (1) establish if the use of a multimedia presentation and weekly alerts from a smartphone app as an education tool improves long-term knowledge and foot care behaviors of patients with diabetes when compared to usual care, (2) assess the association between the change in participants' knowledge and behavior and the number of podiatry appointments over the study period, and (3) compare the number of new DFUs and hemoglobin A_{1c} (HbA_{1c}) levels between the 2 study groups.

Methods

Study Design

This randomized, investigator-blinded, 2-armed, pilot study was conducted on patients with diabetes who visited Dasman Diabetes Institute (Kuwait City, Kuwait) clinics from January 2019 to May 2024. Each participant was fully informed about the study prior to giving their written informed consent.

Eligibility Criteria

Participants had to meet the following inclusion criteria: (1) adult patients (≥18 years of age) with type 2 diabetes or adults with type 1 diabetes for ≥5 years, (2) be of medium or high DFU risk, defined as having at least 1 diabetic foot risk factor (loss of pain perception, peripheral vascular disease, foot deformity, history of DFU, or amputation), (3) able to understand study procedures and comply with them for the entire length of the study, and (4) must own a smartphone with internet access and agree to have the phone app uploaded for the duration of the study. People with chronic kidney disease, cognitive impairment, active psychiatric illness, inability to give written informed consent, hearing or visual impairment, or phone app inaccessibility for more than 4 weeks were excluded from the study.

Procedures

Overview

The study consisted of 2 main visits (at baseline and 12 mo) and up to 6 interim follow-up visits during the 1-year study period. A total of 98 participants were randomized by an independent researcher to either the control (“Usual Care” section) or intervention (“Multimedia Educational Intervention” section) arm in a 1:1 ratio. Participants were instructed not to disclose any information about their assigned group to the research team to maintain confidentiality. All written information for this study went through a process of back translation from English to Arabic, focusing on conceptual rather than literal translations and using natural language for a broad audience [26]. Prior to the intervention period, participants underwent diabetic foot assessment and were classified based on their diabetic foot risk as per NICE (National Institute for Health and Care Excellence) guidelines [27], with participants with moderate risk attending 2 additional follow-up visits at 6-month intervals and participants with high risk attending 6 additional follow-up visits at 2-month intervals. At the baseline visit, HbA_{1c} was measured, and participants received their assigned diabetic foot care education route. Then, they were asked to complete a diabetic foot care knowledge questionnaire and a foot care and diabetes self-care behaviors questionnaire. Interim follow-up visits included a visual inspection of feet, verbal advice in the usual manner (for both groups), and an educational audio-visual prerecorded presentation (for intervention group only). At the 12-month visit, all participants completed a foot care knowledge questionnaire, a foot care and diabetes self-care behaviors questionnaire, and underwent an HbA_{1c} test.

XSL•FO
RenderX

Usual Care

The control group received usual care and the usual route of education with educational leaflets to take home. Participants received verbal advice during their podiatry appointment about daily foot inspections, wearing well-fitting shoes, what to do in an emergency, and the use of emollient. More specific advice was given depending on the participant's risk classification. This usual route involved information by the podiatrist translated by a bilingual but not native Arabic-speaking nurse.

Multimedia Educational Intervention

The intervention group received an educational presentation and a smartphone app providing weekly foot alerts for the duration of the study, in addition to the usual care, education route, and leaflet. The details of the MyU app interface, including the layout and key features used to deliver educational content, are illustrated in Figure 1. The educational presentation was a 10-minute audio-visual prerecorded presentation based on the internationally recognized advice on preventing diabetic foot complications including good diabetes control, daily foot inspections, and footwear advice [27-29]. The research podiatry clinic allowed only 1 participant to attend at a time, ensuring privacy for viewing the educational video. In addition, a teaching- or education-based smartphone app called MyU was installed onto their smartphones, allowing educational information to be uploaded and delivered remotely. The app also remotely recorded the number of times the content was accessed by each participant. Adherence to the intervention was monitored based on these access logs, where each "access" was defined as opening the app and viewing the educational content. However, more detailed engagement metrics such as video completion or time spent on content were not captured. Adherence (%) was calculated as the percentage of scheduled videos viewed, based on the total video views recorded by the MyU app for each participant. Both the absolute number of videos viewed (count) and the corresponding percentage adherence were reported. This app also delivered a weekly "foot-alert" (notification) to remind the participant to view the uploaded educational video. There were 12 unique educational videos "alerts" repeated at 3-month cycles. Repeating the educational method has been shown to improve health literacy [30]. All foot alerts were uploaded in both Arabic and English.

XSL•FO
RenderX

Figure 1. MyU app interface showing the layout and key features used to deliver educational content. The home screen provides access to 12 educational videos, which were assigned to participants according to their recruitment date. Weekly push notifications (shown at the bottom of the screen) prompted users to engage with the app and view the assigned videos displayed on the Newsfeed page.

Foot Care Knowledge Questionnaire

The foot care knowledge questionnaire used in this study has been adapted from Pollock et al [31] and Rheeder et al [32]. The questionnaire covers 2 sections. The first section consisted of 7 questions with 3 options each: correct, incorrect, and don't know. A correct answer was awarded 1 point, while incorrect or "don't know" responses received 0 points. The second section consisted of 5 questions with multiple-choice options. A correct answer was awarded 1 point, while an incorrect answer received 0 points. The maximal total score is 12 points, with higher scores indicating a better understanding of foot care knowledge.

Foot Care and Diabetes Self-Care Behaviors Questionnaire

The foot care and diabetes self-care behaviors questionnaire has been adopted from the Summary of Diabetes Self-Care Activities (SDSCA). The SDSCA has been found to have both reliability and validity as a standard measure of diabetes self-management [33]. Furthermore, this test has been shown to be reliable and valid, giving consistent results when translated into Arabic in a sample size of 243 participants [34]. The SDSCA scale measures the frequency of each self-care activity in the last 7 days for 4 aspects related to diabetes routine: foot care (8 scaled questions), blood-glucose testing (2 scaled questions), medications adherence (2 scaled questions), and smoking habits (2 questions). For this analysis, the score of the scaled questions (from 0 to 7 d) was calculated as the average

XSL•FO
RenderX

of responses within each section [33]. A higher total score indicates better foot self-care behavior.

Sample Size

Although this is a pilot study, a sample size of 98 with a 1:1 ratio between intervention and control group (49:49) was calculated using G*power software (version 3.9.1.2; Heinrich-Heine-Universität Düsseldorf). An a priori difference between 2 independent means tests was performed to find a significance interaction with a power of 80% and probability of type 1 error of 0.05. The effect from a study by Baba et al [35] was a significant mean change of 1.8 (SD 2.6) reduction in foot score (based on the presence and severity of 15 podiatry disorders; n=78) compared to a 0.1 (SD 2.6) reduction in the foot score after receiving interactive education (n=76) over 3 months (effect size=0.58).

Statistical Analysis

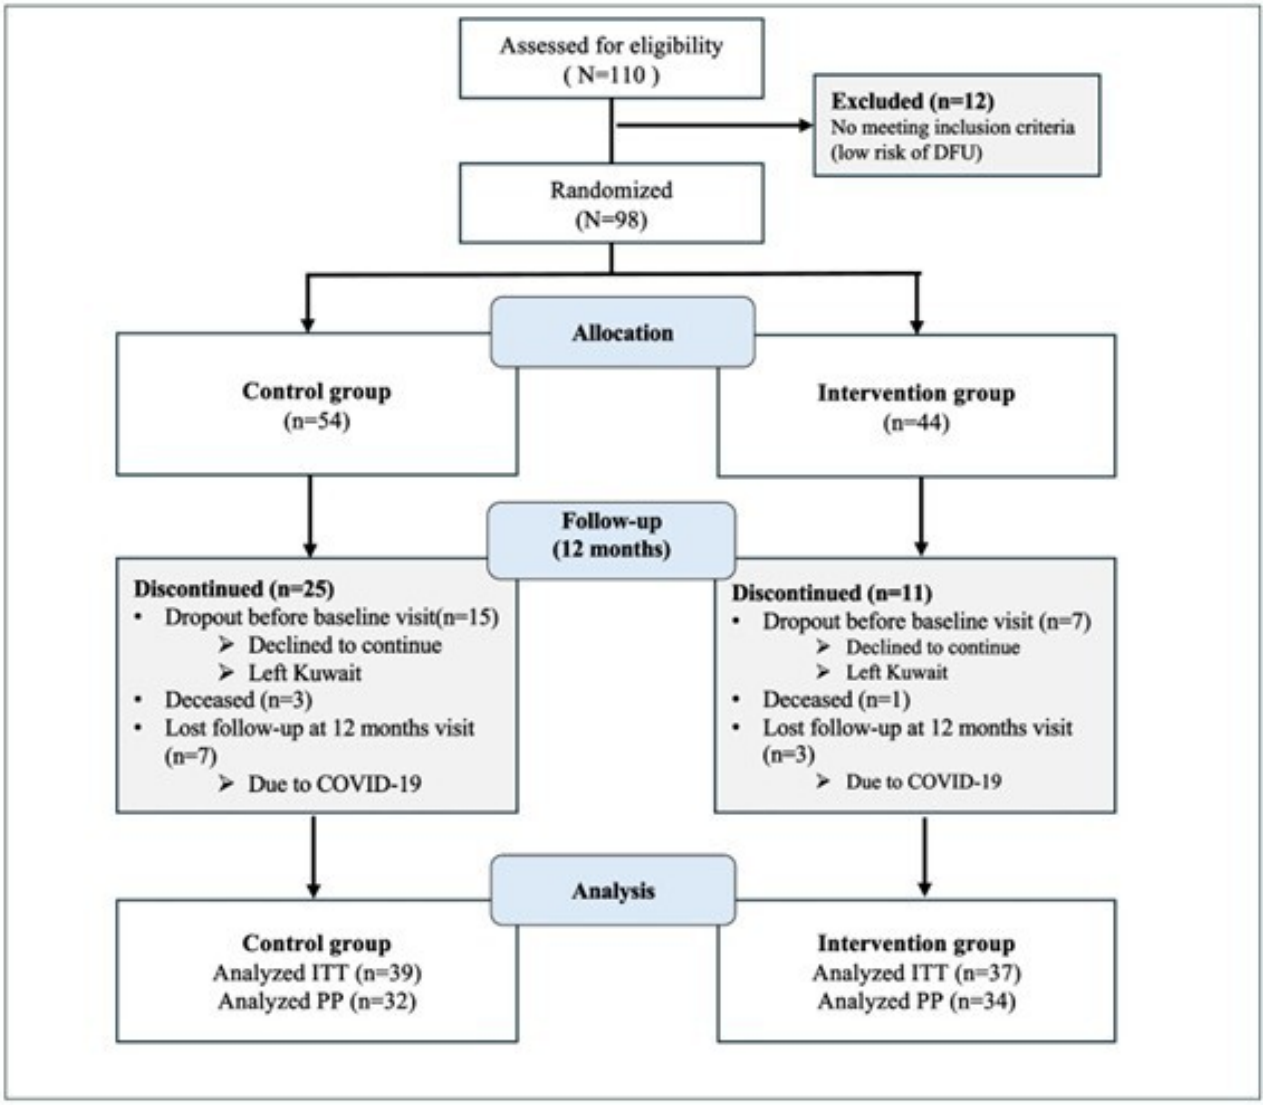
Data analysis was performed using SPSS Statistics (version 29.0; IBM Corp). Descriptive statistics were represented as mean (SD) for continuous variables and as frequencies for categorical variables. The Shapiro-Wilk test was used to assess normality for each continuous variable to determine the appropriate use of parametric or nonparametric tests. Chi-square tests and independent 2-tailed *t* tests were conducted to test to examine baseline differences between the groups and to compare the frequency of new DFU cases between the study groups. The Wilcoxon signed-rank test was used when the assumption of normality was violated.

Both intention-to-treat (ITT) and per-protocol (PP) analyses were conducted. The ITT analysis included all randomized participants with the available outcome data, regardless of adherence or dropout status. A linear mixed model was used to evaluate group, time, and group×time interaction effects on the outcome measures: foot care knowledge scores, foot care, blood-glucose testing, and medication adherence behaviors.

Post hoc pairwise comparisons were conducted using the matched pair 2-tailed Student *t* test or Wilcoxon signed-rank test, with Bonferroni adjustment applied for multiple comparisons. Bivariate Pearson or Spearman correlation analyses were performed to evaluate the strength and direction of relationships between the change in foot care knowledge scores and foot self-care behavior: scores and the number of follow-up visits. Changes in scores were calculated as 12 month values − baseline values. *P* values <.05 were considered statistically significant.

Ethical Considerations

Ethical approval was granted by the Dasman Diabetes Institute Ethical Review Committee (RA HM-2018-044). The study was conducted in accordance with the Declaration of Helsinki and Good Clinical Practice guidelines and was registered at ClinicalTrials.gov (NCT03934944). The trial was conducted and reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) 2011 guidelines (Checklist 1).



Written informed consent was obtained from all participants prior to enrollment. Participant privacy and confidentiality were strictly maintained throughout the study: all data were deidentified and stored on secure, password-protected servers accessible only to authorized research personnel, and no personally identifiable information was included in the analysis or reported in the manuscript. Participants did not receive financial compensation for their participation.

Results

A total of 66 participants completed the study visits and were included in the final PP analysis (Figure 2). Additionally, the ITT analysis included 77 participants who were randomized and had at least 1 outcome measure available. Table 1 shows the baseline characteristics of study participants in both ITT and PP populations. In the ITT population, the mean age of the participants was 60 (SD 7.85) years in the intervention group and 62 (SD 9.31) years in the control group. In both groups, the majority of the study participants were male participants, had attained an undergraduate degree, were nonsmokers, and had type 2 diabetes for over 20 years. In the intervention group, 75.7% (n=28) were classified as having a high DFU risk compared to a 62.5% (n=20) in the control group. All baseline characteristics were statistically comparable between the groups in both ITT and PP analyses, except for BMI, which showed a statistically significant difference between the groups in the ITT sample (*P*=.01) but not in the PP sample. Dropout analysis revealed that 8 participants from the control group (6 with high DFU risk and 2 with moderate risk) and 3 participants from the intervention group (all high risk) discontinued the study.

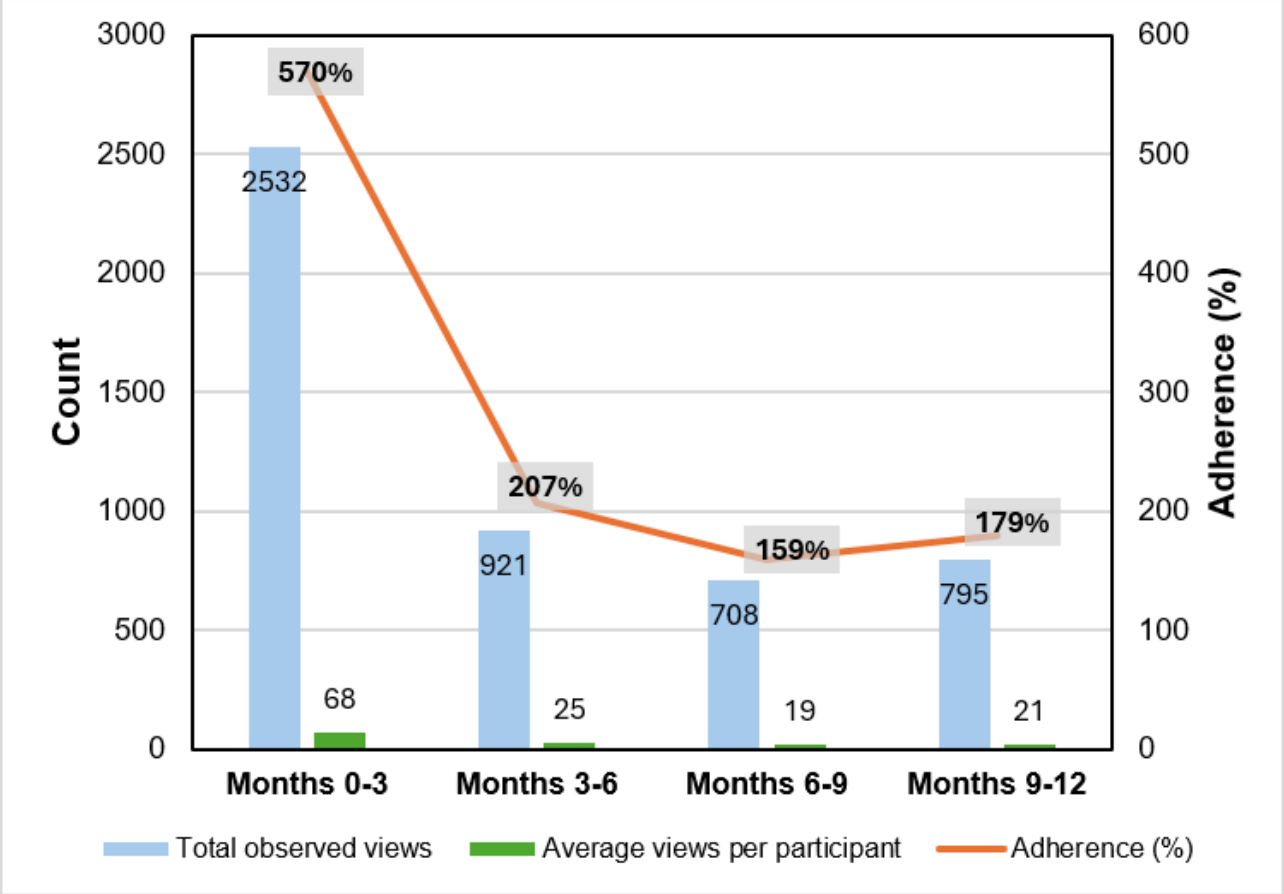
[b]PP: per protocol.

[c]*P value <.05

[d]HbA_{1c}: hemoglobin A_{1c}.

[e]ABPI: ankle-brachial pressure index.

[f]VPT: vibration perception threshold.



[g]PAD: peripheral artery disease.

[h]LOPS: diabetic peripheral neuropathy with loss of protective sensation.

[i]DFU: diabetic foot ulceration.

Adherence was estimated using the total video views recorded by the MyU app. The actual views exceeded the maximum expected views per interval (444 views), especially at baseline (mo 0 - 3: 2532 views, 570%), indicating repeated viewing. Engagement declined over time (mo 9 - 12: 795 views, 179%). These counts serve as a group-level proxy for adherence (Figure 3).

Figure 3. Total video views (blue bars), average views per participant (green bars), and adherence percentage (line) across study time points, based on MyU app data. Values represent group-level engagement with 12 videos per interval. Adherence (%) represents the percentage of the scheduled videos viewed, calculated from the total video views recorded by the MyU app. Both the absolute number of videos viewed (count) and the corresponding percentage are shown.

Both ITT and PP analyses revealed no significant time×group interactions for diabetic foot care knowledge and behavior scores. However, there were significant main effects of time for both outcomes (ITT: $F_{1,70}$=6.98, P=.01, partial η^2=0.09 for knowledge; $F_{1,70}$=28.36, P<.001, partial η^2=0.29 for behavior; PP: $F_{1,64}$=8.760; P=.004, partial η^2=0.12 for knowledge scores; $F_{1,64}$=28.139; P<.001, partial η^2=0.31 for behavior scores). Post hoc within-group comparisons showed a significant reduction in diabetic foot care knowledge scores (ITT: mean difference −0.878, SE 0.366 points, P value=.02, Cohen d=−0.21; PP: mean difference −1, SE 0.357 points, P value=.007, Cohen d=−0.22) in the control group, with no change in the intervention group (ITT: mean difference −0.45, SE 0.344

XSL•FO
RenderX

points, P=.2, Cohen d=−0.38; PP: mean difference −0.47, SE 0.346 points, $P_{t\,test}$=.18, Cohen d=−0.48). For diabetic foot care behavior, post hoc within-group comparisons showed a significant increase in both control (ITT: mean difference 1.129, SE 0.29 points, P<.001, Cohen d=0.62; PP: mean difference 1.109, SE 0.3 points, P<.001, Cohen d=0.61) and intervention (ITT: mean difference 1.139, SE 0.3 points, P<.001, Cohen d=0.60; PP: mean difference 1.121, SE 0.29 points, P<.001, Cohen d=0.63) groups. No interaction or main effects were seen in other self-care behaviors scores such as blood-glucose testing and medication adherence (Tables 2 and 3).

[a]*P*<.05.

[b]Em dashes indicate values that are identical for both groups because these results represent overall ANOVA model effects rather than group-specific estimates.

The mean of the number of podiatry follow-up visits over the 12 months was comparable between the ITT group (control: mean 3.27, SD 1.7 vs intervention: mean 3.24, SD 1.3 visits; *P*=.93) and PP group (control: mean 3.3, SD 1.6 vs intervention: mean 3.26, SD 1.3 visits; *P*=.83). Similarly, among participants at a high DFU risk, those in the intervention attended mean 3.52 (SD 1.2; ITT) and mean 3.64 (SD 1.1; PP) visits, while those in the control group attended mean 3.72 (SD 1.6; ITT) and mean 3.77 (SD 1.6; PP) visits. Among participants at a moderate DFU risk, the intervention group attended a mean of 2.25 (SD 1.48; ITT) visits, in both ITT and PP analyses, while the control group attended a mean of 2.53 (SD 1.6; ITT) visits and a mean of 2.76 (SD 1.58; PP) visits. The number of podiatry visits, however, was positively associated with the change in foot care behavior in the intervention group (ITT: *r*=0.390, *P*=.02; PP: *r*=0.408, *P*=.02), while the control group showed a negative correlation (ITT: *r*=−0.354, *P*=.03; PP: *r*=−0.402, *P*=.02; Figure 4). In ITT analysis, a significant negative association was observed in the control group between the number of podiatry visits and the change in the knowledge scores (*r*=−0.357; *P*=.02), but no such association was found in the intervention group. In the PP analysis, no significant associations were observed in either group. The frequency of new DFU during the course of the study was comparable between the 2 groups (ITT: control=17.5% vs intervention=21.6%, *P*=.64; PP: control=18.8% vs intervention=17.6%, *P*=.91). Both ITT and PP analyses revealed no statistically significant difference in the HbA_{1c} at 12 months between the intervention (ITT: mean 7.86%, SD 0.38%; PP: mean 7.93%, SD 1.08%) and the control (ITT: mean 8.28%, SD 0.36%; PP: mean 8.45%, SD 1.4%) groups, with a mean difference of 0.58% (95% CI −0.93 to 2.09; *P*=.44) in ITT, and 0.52% (95% CI −0.14 to 1.19; *P*=.12) in the PP analyses.

Discussion

Principal Findings

This pilot study investigated the effectiveness of a multimedia educational approach in improving foot care knowledge and behavior among individuals with diabetes over a 12-month period. Overall, this study found that there was no long-term benefit to using multimedia educational tools in addition to standard usual podiatry care to improve participants' knowledge and behavior. However, post hoc comparisons showed that while both usual care and multimedia educational approaches enhanced the foot care behaviors of participants, the usual care settings resulted in a decline in their foot care knowledge, whereas the multimedia educational settings maintained it. The effect on glycemic control, however, was marginal and not clinically relevant (nonsignificant reduction in HbA_{1c} of only 0.52%). The consistency of results between the ITT and PP analyses supports the robustness of our findings and indicates that participant dropout did not substantially bias the outcomes.

XSL•FO
RenderX

This consistency increases confidence that the observed effects are likely to be representative of real-world settings.

Delivering the appropriate foot self-care education is a crucial strategy for reducing the risk of DFUs in people with diabetes [36]. Though there is currently no consensus regarding the optimal education method on diabetic foot care among health care professionals [37]. In light of technological advancements, several interventional studies using smartphone apps and media aids were conducted to educate patients about foot self-care [38]. But their effectiveness remains unclear. To the best of our knowledge, this is the first study that examined the long-term (12 mo) effects of multimedia educational tools on diabetic foot care including both audio-visual presentation and smartphone app. In support of our findings, a short-term (3 mo) RCT on 120 individuals with diabetes found that an audio-visual educational presentation, supplementary to standard diabetic care and regular reinforcement of education in outpatient clinic, significantly enhanced knowledge scores by +1.17 (95% CI 0.7 - 1.64, *P* value<.001) compared to those receiving standard care alone (+0.1, 95% CI −0.3 to 0.5, *P*=.62), whereas the practice scores were significantly improved in both groups (intervention: +1.6, 95% CI 1.09 - 2.11, *P*<.001; control: +0.48, 95% CI 0.16 - 0.8, *P*=.004) [39]. A 3-week educational program involving presentation slides, booklets, and group discussions significantly improved knowledge (intervention: mean 8.08, SD 0.88 vs control: mean 7.17, SD 1.91; *P*=.02) and behavior scores (intervention: mean 19.32, SD 6.48 vs control: mean 18.96, SD 7.36; *P*=.0001) compared to usual care [40].

Contrary to our findings regarding the use of a smartphone app, a recent RCT study involving 88 participants found that m-DAKBAS, an educational mobile diabetic foot care app that involved information, prevention, and management interfaces, significantly improved knowledge scores over a 6-month period (intervention: mean 16.83, SD 1.56 vs control: mean 15.05, SD 2.17; *P*=.0001), with no significant differences in behavior scores (intervention: mean 62.59, SD 7.76 vs control: mean 59.45, SD 10.53*; P*=.23) [41]. Furthermore, a 2-month use of the MobileDiabetes self-care app, which allowed patients to improve their self-care practices with flexibility in timing, location, and choices, has been shown to increase both patients' self-care knowledge and behavior by 17% and 22%, respectively [42]. In a 1-month RCT, an animation-supported app (Mobile Diabetic Foot Care Education; M-DFCE) that delivered 2 push alerts per week and included a cartoon animation providing basic education on daily foot care to prevent foot wounds was evaluated [43]. The experimental group outperformed the control group in terms of foot care behavior (mean difference: 11.28, SD 10.47 for intervention vs 0.6, SD 24.85 for control; *P* =.01) and knowledge (mean difference: 0.87, SD 1.21 for intervention vs 0.01, SD 1.25 for control; *P*=.002) when compared to baseline [43]. According to a recent systematic review, for patients with diabetes, using a mobile health app enhanced their awareness of the disease and their capacity for self-care in studies of durations of less than 6 months [44]. A study involving 58 patients with uncontrolled diabetes found that integrating self-management, through peer-supporting video, a quiz game, and a feedback system, with the Diabetes Care App for 5 weeks, improved foot care behavior significantly (*P*<.01) when compared to usual care [45]. Similar improvements in foot care practices were observed on patients with type 2 diabetes after 1 month [46] and 3 months [47] of using self-management integration with smartphone apps. Furthermore, the use of smartphone apps and alerts interventions has been associated with improved glycemic control [48], which is contrary to our findings. We found a minor and comparable decrease in HbA_{1c} among the 2 groups, which might be reflected by their scores of the blood glucose-testing and medication adherence. While multimedia education on foot self-care is essential for improving the knowledge and behavior of individuals at a moderate-to-high risk of DFUs, it did not have a significant impact on glycemic control or long-term behavior changes.

In this study, there was no discernible difference in the overall incidence of DFU across the groups, although the overall incidence and thus the study power were low. This may suggest that the use of multimedia aids in foot self-care does not offer additional benefits above the usual care education. In agreement with our findings, a systematic review of 6 RCTs found insufficient evidence for the benefit of an integrated care approach, which involved combining multiple DFU prevention strategies at different levels of care (including the patient, health care provider, and health care structure), indicating the need for more high-quality studies [22]. Another systematic review of 11 RCTs, on the other hand, showed that educational technologies were protective against the incidence of lower limb amputations (relative risk=0.53, 95% CI 0.31 - 0.90; *P*=.02) and DFU (relative risk=0.40, 95% CI 0.18 - 0.90; *P*=.03), despite the lack of evidence of certainty assessment [49]. Other studies suggested that a more focused and intensive educational approach should be adopted to reduce the incidence of DFU. An RCT on people with type 2 diabetes found that 2-hour focused education sessions, including practical exercises on foot care behaviors, were effective in preventing the incidence of DFU during 6-month follow-ups compared to the control group (incidence of DFU=0% vs 10%; *P*=.01) [50]. Similarly, a quasi-experimental study found that combining educational sessions with foot assessment and care reduced the recurrence rate of DFU to 13.3% compared to 33.3% in the control group [51]. Intensive education approaches that included training and customized footwear have been shown to reduce the incidence rate of new DFU compared to usual care by 18% and 31%, respectively [52]. The results from a systematic review and meta-analysis of RCTs demonstrated that, in comparison to the control group, an intensive educational approach—a 45- to 1-hour education session reinforced by written instructions—significantly decreased the risk of DFU incidence (relative risk 0.37, 95% CI 0.14-1.01; *P*=.05) [53]. Nonetheless, the study showed that there was a substantial degree of variability in the studies, with 91% heterogeneity [53]. Thus, multimedia aids may not offer additional benefits beyond usual care in reducing the incidence of DFU among individuals at a moderate-high risk of DFUs, suggesting the need for more targeted educational approaches. Although our study did not find a significant effect on self-care behavior, this should not be interpreted as evidence against the long-term effectiveness of all media-based tools, which may require extended follow-ups, greater interactivity, or more tailored content to

XSL•FO
RenderX

achieve meaningful and sustained behavioral change. In addition, future studies should consider evaluating the effectiveness of media-based educational tools in lower-risk populations, where such interventions may have a greater impact on preventive behaviors and outcomes.

Strengths and Limitations

The strength of this pilot study is the long-term duration of the intervention at 12 months. However, a major limitation of this study is the unexpected COVID-19 global pandemic and associated government restrictions, which significantly impacted study conduct and led to lower enrollment and higher dropout rates than expected. This was potentially because, as a high-risk group for COVID-19, participants were reluctant to increase their contact with others unnecessarily. Although there was a higher dropout among participants with a high risk, particularly in the control group, our ITT analysis yielded results consistent with the PP analysis, suggesting that differential attrition did not substantially bias the study findings. The small sample size limits the generalizability of our findings, and thus, future studies with larger and more diverse populations are needed to validate these results and better evaluate the effectiveness of app-based interventions. Another limitation is that the MyU app lacked interactive features, which may have reduced its appeal—particularly among older participants [54,55]—although this was not formally assessed through usability testing or structured feedback during the study.

Conclusions and Future Directions

In conclusion, the study findings revealed that a multimedia education approach alone to improve foot self-care knowledge and behavior was unfeasible and not engaging for long-term use in people at a moderate-high DFU risk. However, the reinforcement of educational material in the follow-up podiatry visit might be effective in achieving persistent changes in foot care behavior of this patient group. Given the scope of this study, further confirmative RCT studies, with a larger sample size, are needed.

Acknowledgments

The authors would like to thank the participants for volunteering to take part in the study. The authors would also like to acknowledge the support of the nurses, clinical laboratory, and podiatry department at the Dasman Diabetes Institute.

Funding

The study has been funded by the Dasman Diabetes Institute, Kuwait.

Data Availability

The data supporting the results of this study are available from the corresponding author upon reasonable request, with a data transfer agreement if required.

Abstract

Background: Specialized mental health services are facing high demand, potentially leading to lower-quality care. One solution may be to prepare patients for attending treatment. Digital pretherapy psychoeducation may be particularly relevant. However, the effectiveness of such an intervention depends on user engagement and satisfaction, and usability is therefore one of the most important factors.

Objective: This article has 2 objectives. Study 1 describes the development of StartHelp, a co-created digital pretherapy psychoeducation program for patients on waiting lists before their first consultation in outpatient specialized mental health services. Study 2 explores the usability of StartHelp, aiming to identify potential issues and assess whether the intervention is suitable for further evaluation in a randomized controlled trial.

Methods: Guided by co-creation principles, we developed StartHelp in accordance with the Guidance for Reporting Involvement of Patients and the Public (GRIPP2) checklist. To assess the app's usability, we recruited 10 patients from specialized mental health care to complete tasks during individual think-aloud interviews. Afterward, they completed questionnaires, including open-ended questions, an item assessing perceived video quality, 2 versions of the System Usability Scale (SUS), the 4-item Client Satisfaction Questionnaire (CSQ-4), and a modified version of the CSQ-4 (CSQ-Video). The StartHelp project group discussed the results, and solutions to the identified issues were proposed and implemented.

Results: Study 1 involved the development of StartHelp over 24 months. The app comprises 27 tasks, including 24 videos and links to 14 websites containing in-depth information. Study 2 involved usability testing with 5 men and 5 women. SUS scores for StartHelp's videos indicated good usability, with a mean of 83.7. By contrast, SUS scores related to navigating StartHelp's overarching architecture were barely acceptable, with a mean of 63.6. For the CSQ-4, the sample mean was 12.3, indicating moderate satisfaction. Mean scores on the CSQ-Video (10.9) indicated satisfaction in the lower moderate range. However, patients perceived the videos as high quality and rated them as nonoffensive. The qualitative findings supported the quantitative results. The usability tests revealed 1 major issue and several minor issues. The primary issue concerned navigation of the overarching technological infrastructure on which StartHelp was developed, rather than StartHelp itself. To address these issues and impracticalities related to interacting with the overarching technological infrastructure, we made minor changes to the StartHelp app.

XSL•FO
RenderX

Conclusions: Through a collaborative co-creation process, we developed StartHelp, a digital pretherapy psychoeducation program. Usability testing indicated that the content itself was highly usable, with video-related SUS scores suggesting good usability, whereas navigation of the overarching technological infrastructure received lower scores. Although patients rated the clinical material as high quality and nonoffensive, satisfaction scores were lower than anticipated. Nevertheless, StartHelp was deemed ready for further testing in a clinical trial.

Introduction

Background

Globally, the high prevalence of mental disorders represents a growing public health concern [1,2]. This prevalence leads to heightened barriers to care in specialized mental health services [2] and results in a decline in service quality due to the measures implemented to address the high demand [3]. Such measures may include more restricted services or longer waiting times before the initial consultation, which could result in unmet needs [2], lower attendance [3], worsening of mental health symptoms during the waiting period [3], or changes in patient-reported variables that predict positive outcomes in future therapy [4]. To address this issue, a pluralistic approach is likely necessary, with a simultaneous focus on traditional psychotherapy, adjunctive interventions, and innovative technology-assisted approaches [2,3,5,6].

One type of intervention that may help meet this demand is the preparation of patients for specialized mental health services through psychoeducation [7-11]. Such pretherapy interventions have demonstrated promising results by increasing patients' knowledge of treatment options [9]. Furthermore, improvements in patient satisfaction [12] and patient-reported outcomes [7,12-14], reported in both the short term [8] and long term, suggest an association with more favorable treatment outcomes [7,8].

One dilemma faced by pretherapy interventions is the allocation of therapist resources: specifically, whether therapists should dedicate their time to preparing or treating patients. One way to address this issue is to involve user representatives as close collaborators, delivering pretherapy interventions in a group format [7-9], thereby reducing the number of health personnel required. Another solution is to provide pretherapy psychoeducation digitally [10], particularly given its potential for scalability [6,15,16] and lower barriers to entry [10]. However, researchers have highlighted the lack of rigorous testing of pretherapy digital interventions [10], both during their development and in clinical trials [15,16]. Some studies have also identified adverse effects of digital pretherapy [10], indicating that preparation is not without risk and that thorough evaluation is crucial. Moreover, the outcomes of digital interventions are highly dependent on user engagement and satisfaction, with usability being the primary barrier to engagement [17]. In other words, usefulness, ease of use, and satisfaction are core components of usability [18].

Recent developments have underscored the importance of patient and public involvement in research [19,20]. This involvement can begin during the development of health interventions [20-22], a practice commonly referred to as "co-creation" [22-24]. The process of co-creation goes beyond gathering user feedback; it involves active collaboration with all relevant nonacademic stakeholders throughout the research and development phases, grounded in a patient-centered perspective [25]. This approach results in more relevant content, increased engagement, and ultimately more effective implementation [20,22-24,26]. Despite these potential benefits, however, patients and user representatives are rarely engaged in the co-creation of mental health interventions [22], including both digital and nondigital pretherapy interventions [10,26].

StartHelp

To address these gaps in the literature, we developed StartHelp (Norwegian: "StartHjelp"), a co-created digital pretherapy psychoeducation program for patients awaiting their first consultation at outpatient specialized mental health services. StartHelp is designed to address the gap between referral and a patient's initial appointment with a therapist. The primary goal in developing StartHelp was to provide patients with essential information before starting treatment in a digital, automated way. This information includes legally mandated information, such as patient rights, as well as details regarding the psychological assessment process, practical considerations, and coping strategies during the waiting period. Moreover, different treatment approaches are presented, including video consultations, group therapy, therapist-guided internet-based interventions, medical treatment, and physical therapy. The aim of providing this information to patients before their first consultation is to enhance patient-centered care by preparing them for their upcoming therapy. Within this framework, StartHelp aims to improve patient satisfaction by making the waiting period more meaningful, clarifying the patient's role in therapy, establishing realistic expectations, and alleviating apprehension about the initial sessions.

Objectives and Hypotheses

This study aimed to evaluate whether StartHelp was ready for real-world testing in a clinical trial and had 2 objectives. The first was to describe the development process of StartHelp (study 1). The second objective was to investigate its usability by assessing program navigation, potential adverse effects, and suggestions for improving 4 of StartHelp's videos (study 2). We hypothesized that StartHelp would achieve a System

XSL•FO
RenderX

Usability Scale (SUS) score of >70, based on benchmark values for digital health apps [27] and Scandinavian patient portals [28]. Additionally, we hypothesized that StartHelp would achieve medium levels of satisfaction.

Methods

Study 1: Presentation of StartHelp and Its Development

Overview

We used the Guidance for Reporting Involvement of Patients and the Public (GRIPP2) checklist [19] as a reporting framework to ensure transparent reporting of user involvement (see Multimedia Appendix 1).

Ethics Approval

All necessary ethical approvals were obtained before the study began. The study protocol and consent form were evaluated and approved by the Regional Committee for Medical Research Ethics in Mid Norway (*Regional etisk komite* [regional ethics committee]: 2024/729793) and the Norwegian Agency for Shared Services in Education and Research (Norwegian: Kunnskapssektorens tjenesteleverandør [SIKT]: 2024/987092). When initially contacted, patients were told that participation was independent of their treatment process and that their decision whether to participate would not affect their treatment in any way. They were also informed that they could send an SMS text message at any time to cancel the appointment without having to explain why. Patients formally provided informed consent by signing a consent form on-site before starting the testing. The form consisted of information about the study, how the data were handled to secure anonymity, and patients' right to opt out of the study at any time without any consequences for treatment.

Description of StartHelp

StartHelp is a mobile app accessed through the official regional patient portal [29]. In StartHelp, patients are prompted with tasks at predetermined intervals, consisting of psychoeducation delivered through text and video. This stepwise approach serves 2 purposes. First, we believe that delivering information in this manner ensures that patients are not overwhelmed, allowing them to review the information carefully. Second, we reasoned that this approach may promote ongoing engagement and foster a sense of continuity during patients' time on the waiting list.

StartHelp's dashboard consists of a list of tasks that automatically updates. Clicking on a task reveals a brief text consisting of 1 or 2 paragraphs, and most tasks provide hyperlinks to websites containing more in-depth information [30]. The destinations of these links include websites of official Norwegian health authorities, patient organizations, official legal authorities, and "closed-off" websites hosted by the university hospital and created by the project group. These websites are accessible only through the app and not via search engines. On these websites, short videos accompanied by text provide more detailed information. The videos range in length from 1 to 3 minutes, with 1 video exceeding 4 minutes. In total, StartHelp consists of 27 tasks, 14 websites, and 24 videos. Figure 1 presents an overview of the task content and the timing of task administration. Figures 2 and 3 show screenshots of StartHelp and a website with a video and accompanying text. Figure 4 depicts the StartHelp dashboard in its right frame.

The intention was for every patient to read the initial information and watch most of the videos before selecting the in-depth information relevant to them. As patients must actively press a button to mark a task as complete, the app can track their activity, and checkmarks indicate which tasks have been completed.

Description of the Overarching Technological Infrastructure

StartHelp is not a standalone app; it is built upon an overarching technological infrastructure known as MyHealth (Norwegian: HelsaMi). MyHealth serves as a patient portal connected to the regional patient administration and journal system in the Central Norway health region. Patients need MyHealth to access StartHelp. StartHelp is free to use and does not require user registration.

MyHealth was designed to provide patients and, occasionally, their relatives with easy access to patient information and health care services. It offers a range of functions, including completing questionnaires relevant to the patient's care; providing secure video consultations; notifying the health care provider of the patient's arrival at the clinic; posing questions to the health care provider; receiving information; and providing an overview of planned consultations, personal information, medical prescriptions, and journal entries. Figure 4 presents screenshots of MyHealth and StartHelp, with the MyHealth front page displayed in the middle. MyHealth is comparable to other patient portals in other health regions across Norway and other Nordic countries due to collaborations with the same health system providers [28,31,32].

In addition to serving as a patient portal, one of MyHealth's goals is to provide a secure infrastructure integrated into the regional journal system, enabling the development of additional innovative programs tailored to specific patient groups without involving private third-party actors.

Development of StartHelp

User Involvement and Co-Creation

User involvement was deemed essential from the beginning of the development process, both in principle and to ensure the quality, relevance, and implementation of the final product [20,22]. As the objective was to digitize prior pretherapy educational interventions [7-9], user representatives who had collaborated in their design and delivery were contacted. We strove to ensure that these user representatives held a partner role, meaning they would have equal influence with other members of the project group in making important decisions throughout the process [33]. In addition to user representatives, the project group included experienced nonacademic clinicians, psychologists, psychiatrists, psychiatric nurses, and clinic middle management to ensure that all relevant perspectives were represented [34].

First, the group reviewed previous interventions and current service needs. User representatives highlighted frustrations regarding long wait times and limited communication. Consequently, the team identified a critical need for information regarding treatment options, self-help, patient rights, and user organizations, with a preference for video content over written text.

Development of Video Manuscripts and Informational Websites

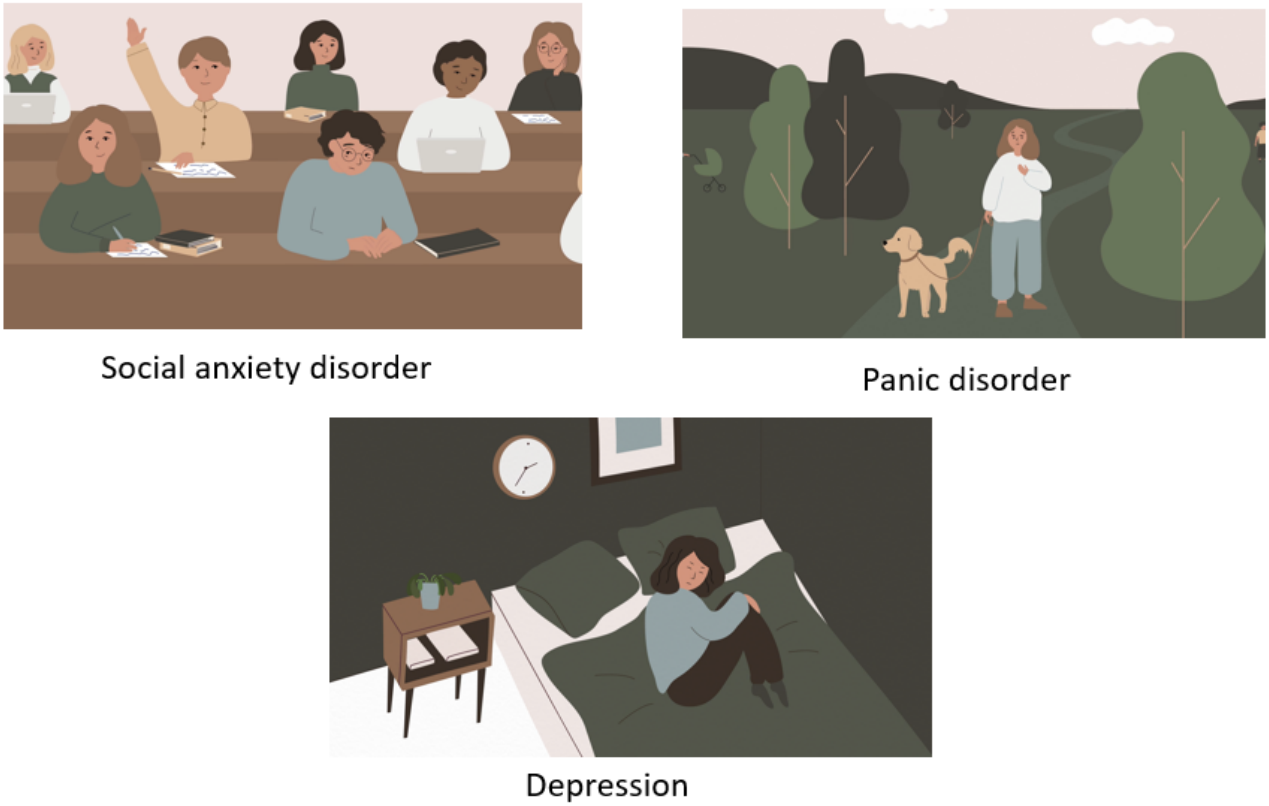
The project group decided to develop 2 general types of videos for StartHelp: one featuring a clinician speaking directly to the camera, accompanied by visual animations illustrating key points (experts talking), and animated videos with a voice-over.

Most of the work on the manuscripts for these videos was conducted collaboratively with the project group via videoconference. We collectively outlined the objectives for each video, aiming for concision. Thus, patients who find the content relevant may feel encouraged to explore the in-depth information provided through the links. The intention was that this proactive method of seeking relevant information would also engage patients at an early stage. We then allocated responsibility for the manuscripts among the project group

XSL•FO
RenderX

members and revised them together in subsequent meetings. In this process, the user representatives exerted significant influence on the phrasing.

After completing the video manuscripts, the project group contacted an advertising agency with an existing contractual relationship with the university hospital. The agency filmed all the videos, produced the animations, and recorded the voice-overs, which underwent iterative testing in 2 workshops with 6 participants each. Participants, recruited by user representatives, included individuals with attention-deficit/hyperactivity disorder, autism spectrum disorder, or both. This approach helped ensure that the content was accessible and comprehensible to a broad audience.



The feedback that emerged from the workshops prompted significant design changes. Participants rejected an initial "cartoon character" style as too similar to commercials and too distracting. We adopted a "1-line drawing" style that gradually appears on screen and decided to maintain this graphic style throughout StartHelp. Based on user requests, the project group also created an additional introductory video.

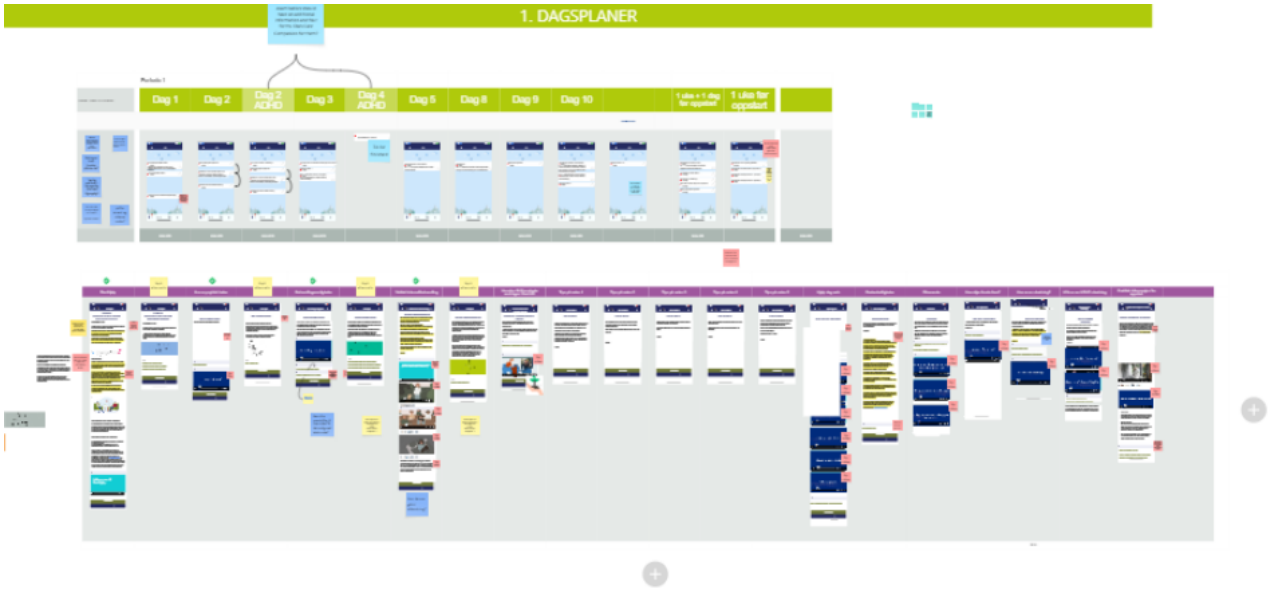
Website Design

After finalizing the video design, we created websites with comprehensive information. These websites use the hospital's web domain, which imposed template constraints, but we maintained the videos' style throughout. The content was designed for easy scanning, using headlines that function as drop-down menus.

During the development of the websites, the project group realized the need for 3 additional videos addressing panic disorder, social anxiety, and depression. The videos aimed to lower barriers to entry for specific treatment options, such as therapist-led internet treatment and group therapy. The videos used composite narratives derived from interviews with 3 patients per diagnosis to ensure anonymity and relatability. Unlike the earlier content, these videos were not tested in workshops and were therefore included in the usability testing. The graphic profile of these videos is illustrated in Figure 5.

Figure 5. The graphic profile of the videos depicting specific mental issues.

Initial Paper Testing



In January 2023, the project group conducted a "paper test" of a StartHelp prototype before integrating it into MyHealth. The group outlined the prototype in Miro Board, a cloud-based interactive whiteboard. The visual drafts were printed on paper and tested on 4 individuals aged 25-64 who were recruited from the associated outpatient mental health clinic.

In this test, patients navigated back and forth within the paper-based prototype app. They described which buttons they would press, and a flowchart guided them to different pages in the paper prototype. Two members of the project group participated in each user test: 1 conducted the test, and the other took notes based on the users' feedback. The test produced 10 key insights. These insights were then categorized according to recurring themes. Figure 6 depicts this process.

Finally, the project group conducted preliminary checks for major technical bugs before planning and conducting the usability testing outlined in study 2.

XSL•FO
RenderX

Figure 6. Visualization of paper prototype testing.

Study 2: Usability Testing

Methods and Procedures

Study 2 explored the usability of StartHelp, aiming to clarify usability issues that may hinder a clinical trial. Usability testing was conducted between May and July 2024 using a convenience sample of patients receiving treatment at a Norwegian outpatient mental health clinic. These patients were contacted because StartHelp's user base will primarily consist of individuals from the general clinical mental health population. Although StartHelp is intended for patients who have not yet started treatment, we recruited patients who had attended at least one consultation.

This approach ensured that participants had prior experience with the MyHealth patient portal, facilitating differentiation between StartHelp itself and the overarching portal infrastructure, MyHealth. We considered that this distinction would have been more difficult if both systems had been introduced simultaneously for the first time. During usability testing, the facilitator explicitly presented StartHelp as a distinct program accessed within MyHealth, and participants were instructed to evaluate StartHelp separately from the patient portal.

Research on usability testing has found that samples of 5 participants typically identify approximately 80% of usability issues [35]. To increase the likelihood of identifying not only common but also less frequent and potentially critical usability issues, we chose to include 10 participants. A sample of this size is considered sufficient to approach thematic saturation in qualitative usability data and to capture a broad range of user experiences relevant to refining the intervention before evaluation in a clinical trial. As recommended by Maramba et al [36], both qualitative and quantitative data were collected and interpreted together. This approach enables a comprehensive assessment of usability while highlighting specific issues that require attention.

To recruit patients for testing, the first author discussed the project with clinicians at a community mental health center in central Norway. There were no formal exclusion criteria other than requiring acute care due to suicide risk, current psychosis, or an inability to provide informed consent. Clinicians then asked patients whether they would be interested in learning more about a research project concerning a digital pretherapy intervention. If patients expressed interest and consented to be contacted, the first author (HP) called them, explained the project details (eg, the testing goals and expected duration), and scheduled a date and time for testing.

Data Collection and Analysis

The individual testing comprised 3 phases and lasted between 45 minutes and 1 hour in total. First, patients completed a series of questionnaires; afterward, they were assigned a set of tasks that included watching 4 selected videos before completing another set of questionnaires. At the end, they were asked the open-ended question, "Do you think all relevant issues regarding the app you tested today have been addressed in our conversation and the open questions in the questionnaires?" The think-aloud interviews were conducted by a facilitator (HP) who received training in the think-aloud methodology, including guidance on using neutral prompts and minimizing leading questions to reduce potential interactional bias. A member of the research team was present throughout all phases to observe and provide assistance. If participants had any questions, the facilitator responded with standard phrases such as "What do you think?" "What would you do?" "Are there any ambiguities we should become aware of?" or "If you find it difficult to circle an answer, please circle the response that you first thought of."

Tasks

After answering the first set of questions, participants were instructed to complete a series of tasks. The instructions provided to participants before starting are presented in Textbox 1. The tasks themselves are presented in Textbox 2. During task completion, the concurrent think-aloud method was used [37]. The facilitator observed all participants during the tasks but sat

XSL•FO
RenderX

at a desk elsewhere in the room while they completed the questionnaires.

Textbox 1. Instructions given orally to participants before starting on tasks.

- "Now, you will receive a series of tasks from me. These tasks will be quite straightforward and will involve navigating the program called StartHelp. The purpose of this exercise is to determine whether the program is easy to use."
- "The tasks may be easy for you to complete, but if they prove challenging, this information is valuable to us. Only by identifying what is difficult or illogical and trying to understand why can we determine what improvements are necessary. Therefore, we encourage you to think out loud while you solve the tasks. If, for example, I ask you to find a video titled 'social phobia', try your best while talking about your thought process."
- "If at any point you find yourself stuck or uncertain about what to do, let me know. I will take note of what was difficult and assist you before moving on to the next task."
- "I will be recording what you say so I can later write it down. This will help me to better remember everything that is said. None of what we do today will be stored with names, and the audio file will be deleted as soon as I have transcribed it. I will let you know when I have started the recording, and the first thing I would like you to do at that point is to confirm that you are aware I am recording, with a simple yes. After that, we will proceed with the tasks."
- "While we carry out the tasks, you will also see some of the videos we have created for the final program. We have selected these videos specifically because we want your feedback. After the tasks, you will be asked what you think about them."
- "Let me know after you have completed each of the tasks."

Textbox 2. Tasks given to participants during testing.

- "I have activated the StartHelp program for you. The first thing I would like you to check is whether you have received any form of SMS text message or email regarding this."
- "Then, view this notification and open StartHelp."
- "When you are inside the patient portal, the first thing I want you to visit is a page called 'StartHelp mental health'. When you are on this page, please read the information provided. After that, you may press 'Complete task'."
- "Next, I would like you to locate a page that provides information about various treatment options. Watch the video on this page."
- "After this, navigate around the same page and see if you can: (1) Find a video discussing various treatment options and watch it. (2) Find a video about social anxiety disorder and watch it. (3) Find a video about panic disorder and watch it. (4) Find a video about depression and watch it."
- "After this, you can return to the app and 'complete the task'."
- "Now you can completely exit the app, returning to your phone's home screen. After that, attempt to access StartHelp again."
- "Now, I would like you to locate a page that says something about patient rights and click on the link provided. Afterward, I want you to try to get back to the app."
- "Then, I would like you to navigate back to the social phobia video so that you can watch it again."
- "If this is difficult, please return to the 'Welcome to StartHelp' page, where you can find instructions on how to locate it."
- "Now, I would like you to return and locate a page that contains information about 'e-treatment', read the content provided there, and click the button to contact 'The centre for eTreatment'."

Videos Tested

Participants were shown 4 specific videos during task completion that the project group had determined required a more comprehensive evaluation. One video presented various treatment options available at the outpatient clinic, including face-to-face therapy (both individual and group therapy), video teletherapy, therapist-guided internet cognitive behavioral therapy, pharmacotherapy, and psychomotor physiotherapy. This video aimed to raise patients' awareness of different treatment options and to encourage discussions with their therapist regarding treatment preferences while assessing treatment needs. The graphic profile of this video is presented in Figure 3. The other 3 videos addressed challenges associated with specific common diagnoses, such as social phobia, panic disorder, and depression. The graphic profile of these videos is illustrated in Figure 5.

These 4 videos, in particular, were tested for 2 primary reasons. First, as mentioned previously, the 3 animated videos depicting specific diagnoses had not yet been evaluated by patients or user representatives. Second, the "treatment options" video was tested because user representatives emphasized its particular importance.

Questionnaires

Demographic Variables

In addition to the aforementioned questionnaires, participants were asked to provide demographic information, including age, gender, marital status, living situation, education level, and employment status.

XSL•FO
RenderX

Open-Ended Questions

To further explore potential usability issues, the questionnaire included the open-ended questions presented in Textbox 3. Patients provided free-text responses.

Textbox 3. Open-ended questions.

- Before completing tasks and watching videos.
  - Do you know about the various treatment options available at the community mental health center? If so, which ones?
- After completing tasks and watching videos.
  - Do you know about the various treatment options available at the community mental health center? If so, which ones?
  - Does the MyHealth app have any specific areas for improvement?
  - Do the videos you watched have any specific areas for improvement?
  - Do you believe there are aspects of these videos that some patients may find condescending, offensive, or uncomfortable, either in the short or long term?

The System Usability Scale

The SUS [38] is one of the most widely used questionnaires for measuring the usability of digital systems and technology. It consists of 10 items, half positively phrased (eg, "I thought the system was easy to use.") and half negatively phrased (eg, "I found the system unnecessarily complex."). Each question is scored on a 5-point scale, ranging from 0 (strongly disagree) to 4 (strongly agree). Scores are typically multiplied by 2.5 to create an intuitive score range of 0-100 [39]. Benchmarks exist for educational tools [40], digital health apps [27], and patient portals [28] based on Scandinavian norms.

Given StartHelp's integration with the MyHealth portal, the SUS was adapted into 2 different versions. Participants completed the SUS twice: once with MyHealth navigation and functionality in mind (SUS-MyHealth; eg, login, navigation between services; "I thought that MyHealth was easy to use") and once with StartHelp content in mind (SUS-Videos; eg, clarity, structure, and presentation of tasks and videos; "I found the videos unnecessarily complex"). This approach was used to reinforce the distinction between the overarching patient portal and the StartHelp program during evaluation.

Perceived Quality of the Videos and Adverse Effects

To assess perceived quality, we used a single-item scale ranging from 0 to 100, where 0 indicated *very low quality* and 100 represented the *highest possible quality.* Moreover, to assess how uncomfortable or offensive patients found the videos, we used a scale from 0 to 5, ranging from *not at all* to a *very large degree.*

Four-Item Client Satisfaction Questionnaire

In this study, we used 4-item Client Satisfaction Questionnaire (CSQ-4) scores to assess participants' baseline satisfaction, not to evaluate the effectiveness of treatment or the StartHelp intervention. The CSQ-4 [41,42], a shortened version of the 8-item Client Satisfaction Questionnaire [43,44], is a 4-item questionnaire that measures overall treatment satisfaction. Each item is answered on a 4-point scale, ranging from *no, definitely not/quite dissatisfied* to *yes, definitely/very satisfied*, yielding a possible total score range of 4-16. The Norwegian translation of the CSQ-4 [42,45] has shown psychometric properties comparable to those of the English version [41]. Cutoff values are based on Larsen et al [43], where a score of 4-10.5 indicates low satisfaction, 10.6-13.5 indicates medium satisfaction, and 13.6-16 indicates high satisfaction.

Client Satisfaction Questionnaire-Video

In addition to the standard CSQ-4, we used a modified version to assess satisfaction with the video content in StartHelp (hereafter referred to as CSQ-Video). Items were adapted to refer specifically to the videos (eg, "In an overall, general sense, how satisfied are you with the videos you have received?"). This adapted version has not been psychometrically validated and was therefore used for exploratory purposes only, to inform further refinement of the intervention rather than to evaluate acceptability or effectiveness.

Quantitative and Qualitative Data Analyses

Given the small number of patients in our sample, we analyzed all quantitative measures descriptively. We interpreted quantitative data alongside qualitative data to inform refinement and assess readiness for further evaluation in a clinical trial, rather than to establish effectiveness. Qualitative data consisted of think-aloud interview transcripts collected during task completion and participants' written responses to open-ended questions. These data were analyzed iteratively, with all comments and suggestions reviewed. Potential usability barriers were coded into categories, and comments were organized into themes [46]. Afterward, the working group responsible for the development of StartHelp discussed both the themes and categories.

Answers to questions (considering both before and after; see Textbox 3) "Do you know about the various treatment options available at the community mental health center? If so, which ones?" were first categorized and then counted. The project group organized the responses into meaningful categories: different treatment modalities and treatments that differed in ways that make a practical difference. For example, "psychoeducation" and "psychoeducation for family members" were counted as 2 separate suggestions, as the inclusion of family members was considered significant. Conversely, "talking to a psychologist" and "talking therapy" were not regarded as distinct treatment options. However, "individual

XSL•FO
RenderX

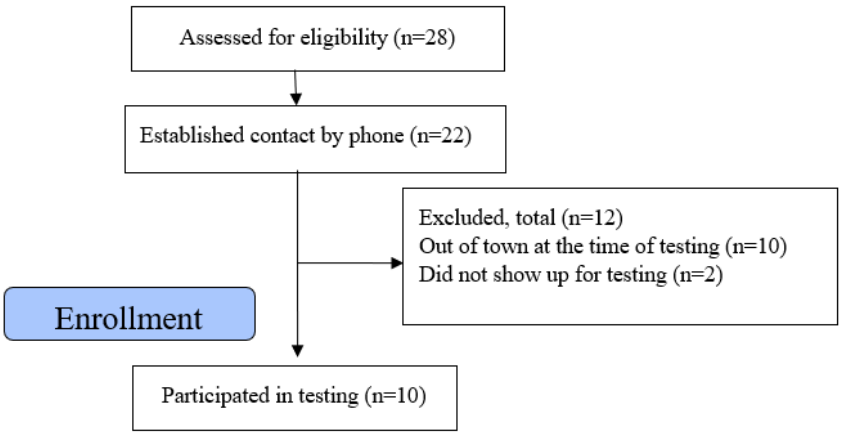
psychotherapy" and "psychotherapy over video" were classified as distinct, because awareness of video consultations may lead a patient to make meaningful choices during treatment. The listings of treatment options from all patients have been translated and are included in Multimedia Appendix 2.

Integration of Results Into the Development Process Through Discussion

After the first author (HP) synthesized the results, they were presented to the project group for discussion. The project group examined each patient's suggestion and issue in relation to StartHelp's overall goals. Potential solutions were then proposed. During this process, several key questions were considered: "Is a change in StartHelp warranted?" "What is the ideal change?" and "Is a change in StartHelp possible?"

Results

Development Process



The development process spanned approximately 2 years, from February 12, 2021, to January 26, 2023. During this period, we created StartHelp, consisting of a total of 27 tasks. These tasks included 24 videos and links to 14 websites containing in-depth information. A discussion of the usability testing results follows the presentation of these findings.

The insights from the initial prototype testing resulted in the following themes: the MyHealth app, the information letter regarding StartHelp, the questionnaire, general concerns, tasks within StartHelp, information in MyHealth, information on hospital websites, and videos. This feedback influenced the initial integration of StartHelp into MyHealth. As StartHelp was one of the first programs integrated into MyHealth, feedback from the user tests also led to change requests concerning MyHealth's core infrastructure, which may benefit future programs. A digital representation of the qualitative analysis process of the Post-it notes created during prototype testing and the abstracted themes is provided in Multimedia Appendix 3.

Usability Study Results: Participants

To assess usability, we invited 28 patients to participate. Of these, 6 did not answer their phones after 2 attempts, 10 were out of town at the time of testing because it took place during the summer months, and 2 withdrew after scheduling an appointment. Recruitment concluded when 10 participants had been included. Figure 7 presents a flowchart of this process.

Figure 7. Flowchart of the usability study recruitment process.

The mean age of the sample was 31.8 (range 21-44) years. Half of the participants (n=5) were women, and 6 of the 10 were married or cohabiting. Most (n=8) had completed 3 or more years of higher education, and 7 were on sick leave. Table 1 presents the collected demographic information for each patient.

XSL•FO
RenderX

Table 1. Demographic information about participants.

Patient ID	Gender; age (years)	Marital status	Living situation	Education[a]	Employment status	Work domain
Patient 1	Female; 44	Not married	Living with someone	Higher secondary education	Currently on sick leave	Management/administration

[a]Education refers to the highest completed education level.

Usability Issues Emerging From Task Completion

Overall, patients experienced few usability issues during task completion and made few suggestions for improvement, although one type of issue was mentioned by all participants. These issues primarily involved navigating the overarching app infrastructure, MyHealth, rather than StartHelp itself or the videos. Participants generally felt that too many features were presented that were not relevant to them at this time. This made the MyHealth home page difficult to navigate, especially when trying to find videos they had previously watched (n=10), which had to be accessed elsewhere than through the StartHelp dashboard after completing the related task. In the original design, tasks were automatically removed from the StartHelp dashboard shortly after completion. Other comments included that the text in MyHealth was too small (n=1) and that the "sheer number of options presented at once was overwhelming" (n=3). Finally, 3 patients had their language settings in MyHealth set to English instead of Norwegian, which made the StartHelp instructions for navigating the MyHealth menu redundant, as they referred only to the Norwegian menu.

Finally, the fourth video, which addressed depression, had not been properly uploaded. This issue was discovered during testing, and 4 patients were therefore unable to view or comment on the video. After that day of testing, the project team contacted the information technology personnel responsible, who reuploaded the video, checked all other videos, and reviewed the upload procedures to determine whether the problem was caused by a systematic error.

Quantitative Data

Treatment Options

Table 2 provides an overview of the treatment options reported by patients. Several general trends emerged from the questionnaires; 4 of the 10 patients reported a greater number of available treatment options after viewing the videos, with the total number of treatment options mentioned increasing from 19 to 31. Notably, 4 patients reported knowing no treatment options before task completion. All treatment options mentioned by patients are listed in Multimedia Appendix 2.

Pharmacotherapy	0	3
Total suggestions	19	30

[a]A complete overview of the treatment options mentioned by patients is provided in Multimedia Appendix 2.

System Usability Scale and the Perceived Quality of the Videos and Adverse Effects

All patients had either equal scores on the SUS-MyHealth (mean 63.6) and the SUS-Videos (mean 85) or higher scores on the SUS-Videos.

The depression video received the highest rating; however, this score may be artificially inflated, as only 6 participants viewed the video. Moreover, the 4 participants who did not view the depression video tended to rate the videos somewhat lower than the other 6. The video on treatment options received the second-highest rating.

Most patients rated the videos as not at all or only minimally offensive (mean 1.2; range 0-5). However, 1 patient rated the videos as uncomfortable or offensive "to a very large degree," while another rated them "to some degree." Table 3 presents an overview of all patient scores.

Table 3. Descriptive presentation of survey data.

Patient ID			Perceived quality of the videos tested				
	SUS[a] MyHealth	SUS[a] videos	Treatment options	Panic disorder	Social anxiety disorder	Depression	Feeling of discomfort when watching videos
Patient 1	47.5	87.5	100	100	100	__[b]	0
Patient 2	57.5	75	60	70	80	—	3
Patient 3	35	72	80	50	10	—	5
Patient 4	85	87.5	90	30	30	—	1
Patient 5	95	95	100	90	90	90	1
Patient 6	65	90	95	95	95	95	0
Patient 7	47.5	70	80	90	90	90	1
Patient 8	—	87.5	70	70	70	70	0
Patient 9	77.5	87.5	90	100	100	100	1
Patient 10	62.5	85	60	60	70	70	0
Sample mean	63.6[c]	83.7	82.5	75.5	73.5	85.8	1.2

[a]SUS: System Usability Scale.

[b]Not available (patients 1-4 are missing perceived quality scores on the "depression" video due to technical problems during testing. The mean for this video was therefore calculated only for patients 5-10; patient 8 did not answer the question).

[c]This number was divided by 9 due to 1 missing datapoint.

Satisfaction

Regarding the CSQ-4, the sample mean was 12.3, indicating medium satisfaction with treatment [43]. The score range was 9-15. The mean score on the CSQ-Video was somewhat lower (10.9), indicating satisfaction in the lower medium range [43]. The score range for the CSQ-Video was 8-14. Table 4 presents

XSL•FO

an overview of the means and SDs for all items, in addition to the total scores.

Table 4. Satisfaction scores.

Item	CSQ-4[a], mean (SD)	CSQ-Video[b], mean (SD)
Met needs	3.2 (0.63)	2.8 (0.42)
Improvement in self-efficacy	2.9 (0.88)	2.3 (0.48)
Overall satisfaction	3.3 (0.82)	3.1 (0.74)
Come back	3.3 (0.48)	2.7 (0.67)
Total score[c]	12.3 (2.26)	10.9 (1.91)

[a]CSQ-4: 4-item Client Satisfaction Questionnaire; score range 4-16.

[b]CSQ-Video: a modified version of the CSQ-4 for evaluating informational videos; score range 4-16.

[c]A score of 4-10.5 is regarded as low satisfaction, 10.6-13.5 medium satisfaction, and 13.6-16 high satisfaction.

Qualitative Data: Usability Issues

In response to the open-ended questions regarding potential improvements, 4 patients suggested improving the MyHealth app by tidying up the menu and reducing the number of options displayed at once. Another suggestion was to keep tasks visible on the StartHelp dashboard after completion. This would eliminate the need to exit the StartHelp dashboard and navigate through the MyHealth app to locate previously completed tasks elsewhere in the menu. In the current design, tasks were automatically removed from the StartHelp dashboard upon completion and stored under “Completed tasks.”

Patients made almost no suggestions for improvements regarding the videos. However, they raised 3 main concerns. First, 6 patients noted that not all individuals would identify with the content, stating, for example, “Social anxiety is so different for each person” or “If I do not experience my anxiety the way the video presents it, will I begin to think I do not have the disorder?” By contrast, 1 patient reflected on the risk of “self-diagnosis” that viewers might engage in while watching the videos. Second, 3 participants expressed frustration that the videos “only presented problems” and did not offer ways to cope with the symptoms. These 3 patients emphasized the need for further clarification of the types of treatment “we could offer them” to manage the issues presented in the videos.

Third, 5 patients expressed concerns that the videos might be distressing for some viewers, especially those dealing with the issues presented. For example, 1 patient reported becoming aware of their heartbeat while watching. As the videos were intended to help individuals on the waiting list identify with the scenarios presented, we considered this feedback potentially concerning and followed up with additional questions. We asked how distressed they found the videos and whether they had personal experience with the mental disorders portrayed. Interestingly, none of the patients reported significant distress in the form of anxiety, although they speculated that someone else might find the videos more distressing. The quantitative data corroborate these findings. Moreover, patients who spontaneously reported previous experiences with social anxiety or panic attacks rated these videos more highly than the other videos.

One patient reported difficulty concentrating during the 2 videos that presented clinical vignettes (only 2 were viewed due to a malfunction with the depression video) and described the sound design as chaotic. The same patient rated the videos as uncomfortable or offensive “to a very large degree.” In a follow-up question—“This is very important to us. We want to know what about the videos we made caused you to feel uncomfortable, and in what way.”—the patient explained that their discomfort stemmed from frustration at being unable to concentrate during the videos, rather than from anxiety or indignation. When asked further, the patient stated that they had no issues with the video on treatment options.

Addressing the Usability Test Results in the Project Group

Issues Identified As Important

The project group discussed all major themes and the usability issues identified. The most pressing concern was the navigation issue, which made it difficult for patients to locate completed tasks in MyHealth outside the StartHelp dashboard. Most of the discussion focused on how to resolve these issues without modifying the MyHealth infrastructure, which would require changes deeper in the technological architecture. After reviewing the information presented to patients, the project group concluded that the guidance on how to schedule the first session as a video consultation required improvement. Other issues discussed included potential discomfort when watching the videos and whether they effectively served their intended purpose. Regarding the MyHealth app, an issue raised by user representatives during preliminary testing of the software following the paper prototype tests was that they experienced the login procedures as unnecessarily cumbersome.

We communicated all findings to the owners of MyHealth, which is part of the regional hospital administration, through 2 complementary approaches. First, we held verbal discussions to explore potential solutions that could be implemented without significantly altering MyHealth’s core features. Second, any new programs or modifications to existing programs require final approval from the owners—a safety mechanism that ensures appropriate regulation of MyHealth as a platform for innovation. Therefore, all requested changes were formally registered and archived.

XSL•FO
RenderX

Changes Made to MyHealth and StartHelp

Few changes were made to MyHealth during the development and usability testing of StartHelp. However, new login alternatives were added, which now include login via fingerprint or facial recognition, as well as faster login using a personalized numeric PIN (personal identification number). Following the usability testing of StartHelp, 1 improvement implemented was the provision of clearer information on how patients can request a video consultation for their first appointment. This information is now prominently displayed on the web page containing more in-depth details about the first session. We did not modify the videos themselves, as the treatment options video already presents video consultations as an option and encourages viewers to consult the additional information on the website. Notably, it was this video that prompted 1 patient to request more concrete information on the topic. Additionally, information on how to locate previously completed tasks is now clearly presented in bold at the bottom of every task: "Remember that all completed tasks can be found in the MyHealth menu under 'Education' and then 'StartHelp.' Go there if you wish to view your previous tasks." Moreover, we updated the app to allow tasks to remain on the dashboard for a full week after completion.

Regarding the videos, we concluded that they were unlikely to cause unnecessary discomfort. One patient rated the 3 videos containing patient stories as uncomfortable or offensive "to a very large degree," primarily due to chaotic sound and graphic design that made it difficult to concentrate. This patient did not report any issues with the treatment options video, which had been revised based on workshop feedback.

The project group reasoned that individuals who have difficulty tolerating the current video design are unlikely to be part of the target population for the associated treatments, which focus specifically on social anxiety disorder, panic disorder, or depression without concurrent disorders. Additionally, the videos are optional, presented alongside written information, and accessed primarily by users seeking in-depth information about these treatment modalities. Although some degree of emotional discomfort may be unavoidable when videos encourage patients to identify with patient stories, the overall reported discomfort during testing was relatively low.

Keeping StartHelp's goal in mind—namely, to inform patients and encourage active involvement in treatment decisions so that they can better tailor their treatment—we chose not to modify the videos themselves. Instead, we revised the surrounding text to strengthen the connection between the videos and the clinic's specific treatment options. For instance, using therapist-guided internet therapy as an example:

> *Panic disorder, social anxiety, and depression are three disorders currently being treated through therapist-guided internet therapy at the Centre for eTherapy. If you believe that one of these disorders may be your primary concern and are interested in trying out therapist-guided internet therapy, here is how to contact us for an assessment to determine whether this approach may be beneficial for you. Therapist-guided internet therapy typically has much shorter waiting lists, and participating in this assessment will not remove you from the current waiting list for other treatments.*

We concluded that the aforementioned changes were sufficient. As the project group did not anticipate any new critical usability issues arising from the proposed changes, no additional isolated usability testing was deemed necessary. The remaining potential issues were considered best evaluated within the context of a clinical trial.

Discussion

Principal Findings

This study had 2 objectives: to describe the development of StartHelp and to explore its usability and perceived user satisfaction. The purpose was to evaluate whether StartHelp was ready for further evaluation in a clinical trial. The study, therefore, represents an exploratory, early-stage evaluation rather than definitive evidence of StartHelp's usability or user satisfaction, as such evidence would require further testing in its intended real-world context. In the following sections, we discuss the development process in accordance with the GRIPP2 guidelines [19], the usability findings, user satisfaction with the video content, and implications for future research.

Development Process

When developing StartHelp, we aimed to ensure that user representatives were involved as "partners" [33]. To achieve this, we engaged user representatives who had prior experience working with members of the project team and were familiar with the interventions on which StartHelp is based [7-9]. The project was designed with a long-term collaborative relationship in mind, reinforcing the academic team's commitment to the perspectives and goals of user representatives. Our approach was informed by previous research on user involvement, which indicates that even in nonhierarchical collaborations, an indirect hierarchy can develop, especially when partnerships are short term [20]. However, partnering with the same user representatives over an extended period may also have drawbacks, as it could limit the diversity of viewpoints represented.

To mitigate this, we included patients with no prior experience working with the project group in the initial focus groups and subsequent usability testing. Another way to mitigate this issue could have been to involve at least one patient with no prior experience working with the project group. During the development phase, before usability testing, we primarily involved patients with attention-deficit/hyperactivity disorder or autism spectrum disorder, which may have introduced bias. As previously stated, however, we reasoned that if StartHelp is accessible to these populations, it should also be accessible to most other populations.

Usability

In line with the recommendations of Maramba et al [36], the usability evaluation included both quantitative and qualitative data. The quantitative data revealed some discrepancies. The average SUS scores for the sample were 63.6 for the MyHealth

XSL•FO
RenderX

app and 83.7 for the videos. Notably, none of the patients rated the MyHealth app higher than the videos, indicating that navigating the overarching MyHealth app was more complicated than engaging with the informational video content and using the StartHelp dashboard. According to Bangor et al [47], a score of 83.7 is considered good to excellent, whereas a score of 63.7 is deemed acceptable. Moreover, a mean score of 63.6 is below the benchmark for digital health apps (68) [39] and for other Norwegian patient portals (72.1) [28]. This suggests that MyHealth's usability may be lower than that of the average health app or patient portal. Intuitively, there should not be such a large difference in SUS scores between the Norwegian benchmark values and those observed for MyHealth. This discrepancy may be explained either by the small sample size or by interactions between StartHelp's features and MyHealth, which may result in usability challenges not present when using MyHealth alone. This finding is explored further below in the discussion of the qualitative data. However, the marked difference between usability ratings for StartHelp and the MyHealth portal further suggests that participants were able to distinguish between the 2 systems during testing.

Satisfaction and Video Quality

Mean scores and SDs on the CSQ-4 are comparable to those observed in Norwegian specialist mental health care [42,48,49], suggesting that the current sample was representative in this regard. Moreover, none of the patients who participated in the usability testing reported extreme CSQ-4 scores before testing, making it less likely that overall treatment satisfaction biased the results. By contrast, scores on the CSQ-Video indicated satisfaction in the lower medium range [43]. Few studies have used the CSQ in the context of pretherapy interventions [8,50], and only 1 used the CSQ to evaluate patients' satisfaction with the intervention itself [8]. By contrast, Zwick and Attkisson [50] used it to assess how their intervention affected patients' perceptions of services provided after treatment ended. Lara-Cabrera et al [8] reported an item-level mean of 3.28 on the CSQ-8 [8], which is higher than the item-level mean in this study (2.73). This discrepancy may be attributed to the use of different CSQ versions; however, this explanation seems unlikely because the CSQ-8 and CSQ-4 have demonstrated similar psychometric properties and mean values in outpatients receiving specialized mental health care [42,51]. The discrepancy is more likely related to CSQ's association with respondents' personal needs at the time of assessment [44,52] or to the expected clinical utility within the study context. We would not expect the brief, nonclinical context of this study's usability testing to be sufficient to address participants' current problems in a general sense (ie, to alleviate mental health symptoms). This interpretation is further supported by the reported perceived quality of the videos, which was considerably higher than the CSQ-Video scores. For example, patient 5 reported low satisfaction (10; cutoff 10.5 [49]) yet rated the video quality as high (mean score 92.5 out of 100). Nevertheless, further research on the full StartHelp intervention—tested in its intended context, in which patients awaiting treatment receive the complete program—is needed to more comprehensively evaluate user satisfaction with the program.

Qualitative Findings

In general, the qualitative data derived from patients' task completion and responses to open-ended questions corroborated the quantitative findings. Most reported usability problems stemmed from attributes of the MyHealth app (eg, default language settings and text size) and from its navigation. Patients reported no usability issues with the StartHelp dashboard. Other researchers have noted that a major barrier to the widespread integration and implementation of digital interventions is poor or outdated information technology infrastructure [16,53,54]. Our results may reflect a similar tension between the infrastructure and the specific interventions designed within it. Building apps within an overarching app and patient portal, such as MyHealth, offers several advantages, including secure handling of patient data and integration with the patient administration system to provide easy access to other health information collected through routine clinical practice. One downside, however, is that app development within such infrastructures may be constrained in terms of design and available features. Moreover, adding new features to an app or intervention may prove difficult if doing so requires fundamental changes to the overarching technological infrastructure. It is also challenging to predict whether such modifications will result in unintended interactions with other functions or integrated apps. We attempted to mitigate these challenges by conducting initial prototype testing and limiting changes to MyHealth, instead modifying only aspects of StartHelp, as discussed above in the "Changes Made to MyHealth and StartHelp" section. These changes were intended to minimize the need for patients to switch between the MyHealth menu and the StartHelp dashboard.

Patients also offered reflections on the videos, which primarily fell into 2 categories: their function and their potential to cause discomfort. Ultimately, we modified the accompanying information rather than the videos themselves. Interestingly, although several patients expressed concern that the videos might disturb others and provoke anxiety symptoms, they reported experiencing few symptoms themselves. Although we did not alter the videos, we ensured that none were mandatory and that all content was also readily available in text format.

Strengths and Limitations

Five users are often sufficient to identify approximately 80% of usability problems [35]. However, this depends largely on the nature and number of issues present in the program; common and critical problems are generally easier to detect. Although we cannot be certain that all usability issues were identified, most of the tasks assigned to patients were completed without difficulty. Therefore, we consider our sample size of 10 adequate for identifying critical usability issues before further testing in a clinical trial. A strength of the study is that actual patients were involved in the testing and that both quantitative and qualitative data were collected [36]. However, a sample of 10 is small for quantitative estimates of usability and satisfaction, and further evaluation with larger samples is required. The qualitative data consisted primarily of written responses to open-ended questions; in-depth interviews could provide additional insights.

XSL•FO
RenderX

Another strength is the involvement of user representatives, as well as the study's novelty. To our knowledge, no other digital pretherapy interventions have been developed for a general outpatient population in specialized mental health care in close collaboration with user representatives.

Although sex was evenly distributed in our sample, most participants were highly educated and relatively young. We consider the sample representative of the clinical population treated at the outpatient clinic and at other similar Norwegian outpatient specialized mental health services [55]. Nevertheless, the absence of older adults or individuals with little formal education is a limitation. Although these groups represent minorities in similar outpatient settings [53], further real-world testing should examine whether they encounter difficulties using StartHelp—for example, by assessing lower app usage or higher dropout rates. As we developed StartHelp for a Norwegian context, the results may not be generalizable to international settings. However, some issues that emerged during testing may be transferable, as developing programs within existing infrastructures may be necessary for full implementation within current health care information technology systems. Moreover, MyHealth is comparable to other patient portals across Norway and other Nordic countries due to collaborations with the same health system providers [35,37,38].

Another limitation is the staged setting in which the testing took place. We assessed the usability of the program itself; however, we do not know whether issues specific to more naturalistic use may arise during a potential feasibility trial involving a waiting list population, in which most users are unlikely to explore all aspects of the app simultaneously. The current study design is well-suited to identifying concrete usability and technical issues related to navigating and using StartHelp. However, further research is needed to evaluate how patients use StartHelp before their first consultation and how this influences patient satisfaction.

Additionally, further research is needed to establish StartHelp's usability and to evaluate its preliminary effects on patient satisfaction with treatment. Conducting a randomized controlled feasibility trial that recruits patients awaiting their first consultation in specialized mental health care would be particularly valuable. Moreover, StartHelp's intended downstream effects on treatment outcomes—by enhancing treatment satisfaction and patient-reported outcomes associated with improved clinical outcomes—should be investigated further.

Conclusions

Through a collaborative co-creation process, we developed StartHelp, a pretherapy psychoeducation program for outpatients awaiting specialized mental health treatment. During usability testing, a few issues related to StartHelp itself emerged; however, participants reported difficulties navigating the overarching MyHealth portal, which received usability scores lower than hypothesized. The project group discussed and addressed the problems identified during usability testing, thereby minimizing the need to navigate the overarching patient portal. Although the perceived quality and usability of the clinical material were high, patients reported lower satisfaction than anticipated. Taken together, these findings suggest that StartHelp is suitable for further evaluation in a feasibility trial conducted within its intended context, involving outpatients awaiting specialized mental health treatment.

Abstract

Background: The emergence of artificial intelligence (AI) is driving digital transformation and reshaping medical education in China. Numerous medical schools and institutions are actively implementing AI tools for case-based learning, literature analysis, and lecture support. This expanding application is accelerating the adoption of localized AI platforms, which are poised to become integral components in the coming years.

Objective: The primary aim of this study was to investigate the current use of AI tools among medical students, including usage frequency, commonly used platforms, and purposes of use. The second aim was to explore students' needs and expectations toward AI-powered medical education platforms by collecting and assessing student feedback, and to identify practical requirements across disciplines and academic stages to inform more effective platform design.

Methods: Based on the task-technology fit model and 5 hypotheses, an anonymous online questionnaire was conducted to assess AI usage in learning, gather student feedback on AI-powered medical education platforms, and evaluate expected functionalities. The survey was conducted from March 1 to May 31, 2025, using a convenience sampling method to recruit medical students from various disciplines across Shanghai, China. The sample size was determined at 422, accounting for a 10% rate of invalid responses. The questionnaire was developed and distributed online via Wenjuanxing and promoted through WeChat groups and in-person interviews. Data analysis was conducted employing IBM SPSS Statistics (v 27.0).

Results: A total of 428 valid questionnaires were collected. The average frequency of AI-assisted learning among medical students was 5.06 (SD 2.05) times per week. Over 90% (388/428) of the students used more than 2 AI tools in their daily tasks. Students from different disciplines, educational stages, and academic systems demonstrated different usage patterns and expectations for AI-powered medical education platforms.

Conclusions: AI technology is widely accepted by medical students and is extensively applied across various aspects of medical education. Significant differences are observed in usage patterns across disciplines, educational stages, and academic systems. Understanding the actual needs of students is crucial for the construction of AI-powered medical education platforms.

KEYWORDS

AI chatbots; artificial intelligence; cross-sectional study; medical education; medical schools; medical students; technology acceptance

Introduction

The rapid development of artificial intelligence (AI) has profoundly accelerated the digital transformation of medical education worldwide. AI demonstrates significant potential across multiple domains of medical education, including case-based teaching, literature analysis, and lecture support [1,2].

Globally, previous studies have documented the successful integration of large language models (LLMs) and conversational agents in medical education, significantly enhancing teaching effectiveness [3,4]. Gilson et al [5] reported that ChatGPT and other LLMs have been deployed to simulate clinical reasoning sessions, automate feedback on student essays, and generate customized practice questions, demonstrating measurable gains in diagnostic accuracy and pedagogical efficiency. Simultaneously, students' mastery of both theoretical knowledge and practical skills has markedly improved, resulting in better

XSL•FO
RenderX

learning outcomes and clinical performance. These advances address existing challenges in medical education and open up promising pathways for its future development [6,7].

In China, supportive national policies and rapid technological advances have jointly facilitated the localized application of AI in medical education [8]. The national "AI Plus" Implementation Guidelines outline the strategic direction for the deep integration of AI technologies with public welfare services [9]. Meanwhile, Shanghai's pioneering Medical Artificial Intelligence Work Plan specifically proposes establishing an "intelligent medical education and training" platform, emphasizing the development of smart training environments using generative AI technologies [10]. This provides clear policy support and practical guidance for higher education institutions to develop localized AI−powered medical education platforms [11,12].

With the widespread adoption of AI, students' learning methods, habits, and institutional teaching models have been rapidly reshaped. However, systematic data on medical students' current AI usage patterns and their practical needs across different educational stages and disciplines remain limited. A deeper understanding of these aspects is crucial for effectively guiding the development and optimization of future AI−powered medical education platforms. Therefore, this study aimed to collect medical students' current use of AI and their practical needs across different educational stages and academic disciplines. We also explored effective strategies for developing AI-powered medical education platforms, with the goal of providing recommendations to guide the development and optimization of future AI−powered medical education platforms.

Methods

Participants and Procedures

This study employed a convenience sampling method to conduct a cross-sectional survey among medical students from various medical universities in Shanghai, China, with data collected from March 1 to May 31, 2025.

The inclusion criteria were (1) current enrollment in a medical program and (2) provision of informed consent to participate. The exclusion criteria were (1) nonmedical students, (2) students not currently enrolled in any program, (3) students attending medical schools outside Shanghai, and (4) students who declined participation.

Theoretical Framework and Hypotheses

This study is based on the task-technology fit (TTF) model. Its core proposition is that technology's effectiveness is determined not by its attributes or user attitudes alone but by the fit between technological functionalities and user task requirements.

Based on the TTF framework and a review of relevant literature [13,14], this study proposes 5 hypotheses. These hypotheses aim to examine differences in usage status, functional needs, and expectations regarding AI-powered medical education platforms among medical students across different disciplines, educational stages, and program types while identifying factors with a significant influence.

- H1: Perceived task-technology fit has a significant positive impact on platform satisfaction.
- H2: Disciplinary background moderates the relationship between TTF and platform satisfaction.
- H3: Program type (full-time vs part-time) moderates the relationship between TTF and platform satisfaction.
- H4: Educational stage moderates the relationship between TTF and platform satisfaction.
- H5: The frequency of AI usage has a significant positive impact on platform satisfaction.

Instrument Pretesting and Validation

Guided by these 5 hypotheses, we designed a concise online questionnaire. Prior to the formal survey, a pilot test was conducted through in-person interviews with 23 postgraduate clinical medicine students from the same institution to evaluate content validity, item clarity, and internal consistency reliability. The expected platform functions scale (Cronbach α=0.825, items with zero variance were excluded) and the most frequently used AI platforms scale (Cronbach α=0.858, items with zero variance were excluded) showed high internal consistency.

Questionnaire Design

Based on the feedback from the pilot study, we made appropriate revisions to certain items and their phrasing in the questionnaire. Our questionnaire covered 3 sections with 13 items (see the questionnaire in Multimedia Appendix 1): the first section is general information, including age, gender, major, school, educational stage, and academic program type; the second section is the current use of AI tools, including the frequency of use (average per week), preferred platforms, and usage purposes (eg, theoretical learning, literature assistance, among others); and the third section is current status and expectations for AI-powered medical education platforms (whether the institution has developed an AI-powered medical education platform, satisfaction with the platform, and expected functions of the future platform) [13].

To ensure data completeness, all questionnaire items were set as mandatory, and participants were required to complete all the questions before submission. The survey platform would automatically record device type and completion time.

Ethical Considerations

This study received an ethics exemption (EX-2025 - 017) from the Medical Ethics Committee of Renji Hospital, Shanghai Jiao Tong University School of Medicine, as it utilizes anonymized data, operates under standard informed consent protocols, and involves no sensitive biological materials or procedures.

We obtained informed consent from all student participants before the survey, providing full details about the study's purpose, procedures, and privacy protections. No compensation was provided, as the study involved minimal burden and no anticipated harm. All the data were strictly protected to ensure confidentiality and prevent any risk of information leakage. To this end, access was restricted to authorized research team members, and the data were used solely for analysis and reporting within this study.

XSL•FO
RenderX

Sample Size

To ensure adequate statistical power and precision for the intended analyses, we used a standard sample size calculation formula [15]. Assuming a 95% CI, a margin of error of 0.05, and an expected population proportion of 0.5, the minimum required sample size was calculated to be 384. Drawing on previous studies [16,17] and to improve the generalizability of the results, we further accounted for a 10% invalid questionnaire rate, resulting in a final target sample size of 422.

$n=Z^2 \cdot P \cdot (1-P) E^2$ (95% CI, Z=1.96, E=0.05, P=.50)

Finite population correction was not applied due to the use of convenience sampling and structural heterogeneity across institutions, which precluded the definition of a single unified sampling frame.

Statistical Analysis

Statistical analyses were performed using IBM SPSS Statistics (version 27.0). Descriptive statistics were computed using appropriate measures for each variable type: continuous variables were summarized with means and SDs, while categorical variables were presented as frequencies and percentages.

For group comparisons involving categorical variables, chi-square tests were employed. Multiple response analyses were conducted using multiple response sets combined with chi-square tests, with Bonferroni correction applied to account for multiple comparisons. For ordinal data or continuous variables violating normality assumptions, non-parametric tests (Mann-Whitney *U* for 2-group comparisons and Kruskal-Wallis *H* for multigroup comparisons) were utilized, with post hoc analyses performed where appropriate.

ANOVA was used for comparing continuous variables across multiple groups, while MANOVA was employed for analyses involving multiple continuous dependent variables. Multivariable analyses included linear regression for continuous outcomes and logistic regression for binary outcomes.

All statistical tests used a 2-tailed significance threshold of $P<.05$, with appropriate corrections for multiple testing implemented where necessary [18].

Results

Participants' Characteristics

A total of 440 questionnaires were collected. After excluding 12 responses from nonmedical students, students at institutions outside Shanghai, and nonenrolled individuals, 428 valid questionnaires were retained, yielding an effective response rate of 97.3%. The questionnaires were returned with complete and valid responses, thus containing no missing data.

Participants were drawn from 7 medical schools in Shanghai, with 188 (43.92%) male participants and 240 (56.07%) female participants, and a median age of 22 (IQR 20.07-24.62) years. Among them, 223 (52.10%) were undergraduate students, 174 (40.65%) were master's students, and 31 (7.24%) were doctoral students. The sample covered 8 major disciplines: clinical medicine, basic medicine, rehabilitation therapy, nursing, public health and epidemiology, pharmacy, traditional Chinese medicine, and medical engineering.

Frequency of AI Use Among Medical Students

Most respondents reported regular use of AI tools in academic work and daily tasks, with a mean usage frequency of 5.06 (SD 2.05) times per week. The mean (SD) frequency among undergraduates, master's students, and doctoral students was 5.09 (1.97), 4.99 (2.11), and 5.19 (2.27) times per week, respectively, with no significant differences based on educational stage or gender (Table 1).

[a]Chi-square test and Bonferroni correction were applied for multiple comparisons (α=.00625).

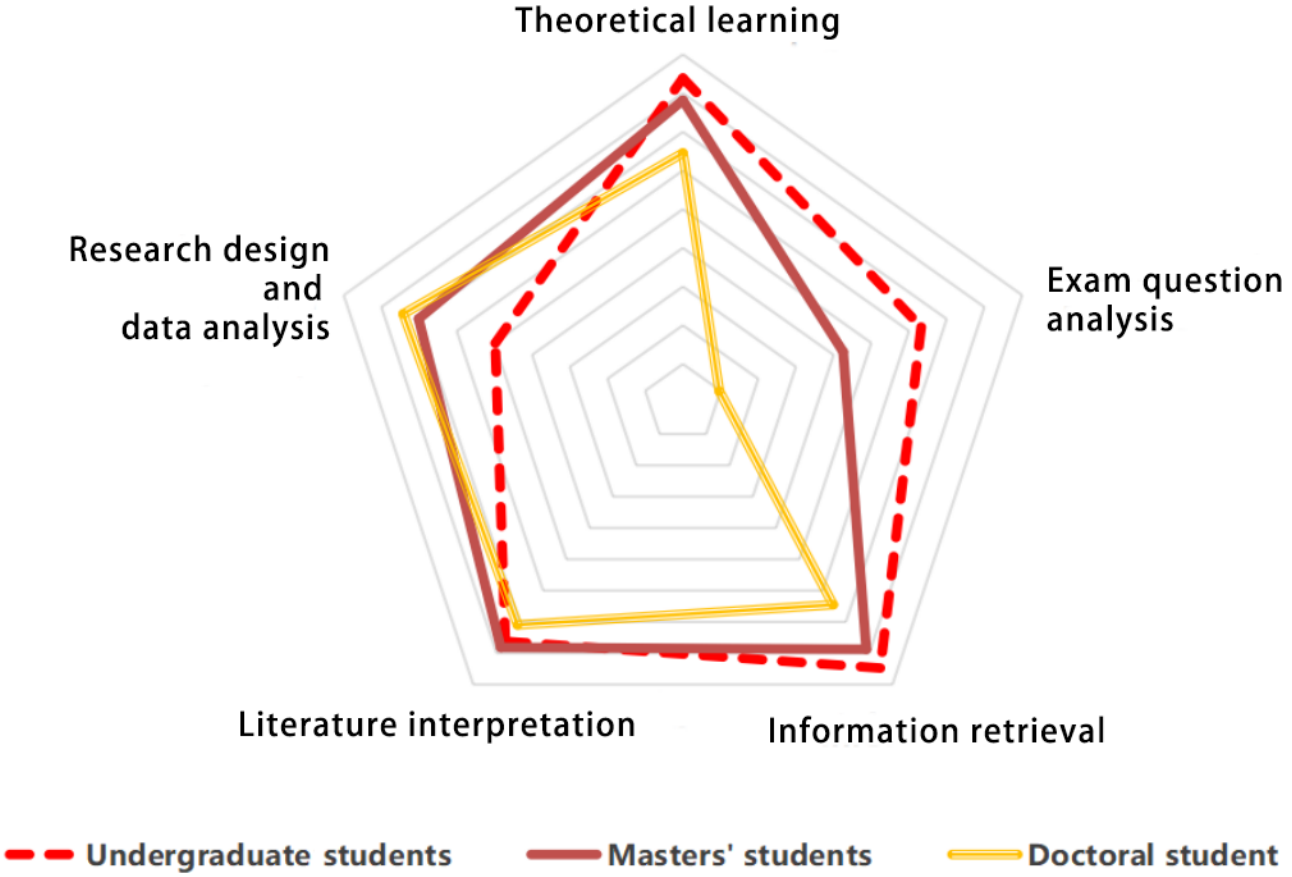
[b]AI platforms, including Qwen Chat, ERNIE Bot, Tencent Yuanbao, Poe, and Grok, were grouped together for analysis due to their relatively small sample sizes.

AI Platforms Used by Medical Students

In terms of AI platform selection, most medical students favor mainstream tools such as DeepSeek (n=404, 94.39%), Doubao (n=250, 58.41%), and ChatGPT (n=280, 65.42%) for their daily study and work. Survey results further indicated that the current use of multiple AI platforms has become a common practice among medical students, with over 90% (388/428) of the students reporting the use of 2 or more platforms, and over 60% (282/428) of the students reported using 3 or more platforms (Table 1).

Gender-based differences were observed in the adoption of specific AI platforms, with selected variations reaching statistical significance (χ^2_1=7.84; *P*=.005). Nonetheless, the overall variety of the platforms utilized remained consistent

XSL•FO
RenderX



across genders, as evidenced by a comparable number of the tools used (χ^2_7=3.86; *P*=.80).

AI Usage Patterns by Academic Program Type and Educational Stage

The application of AI in medical education spans multiple areas, including theoretical learning, question analysis, literature translation, and scientific research. Based on the literature review and preliminary survey feedback, our questionnaire categorized the application areas into 5 domains: “theoretical learning,” “exam question analysis,” “information retrieval,” “literature interpretation,” and “research design and data analysis.”

Regarding educational stage, undergraduate students primarily used AI for exam preparation, while graduate students focused more on research tasks such as study design and data analysis (Figure 1).

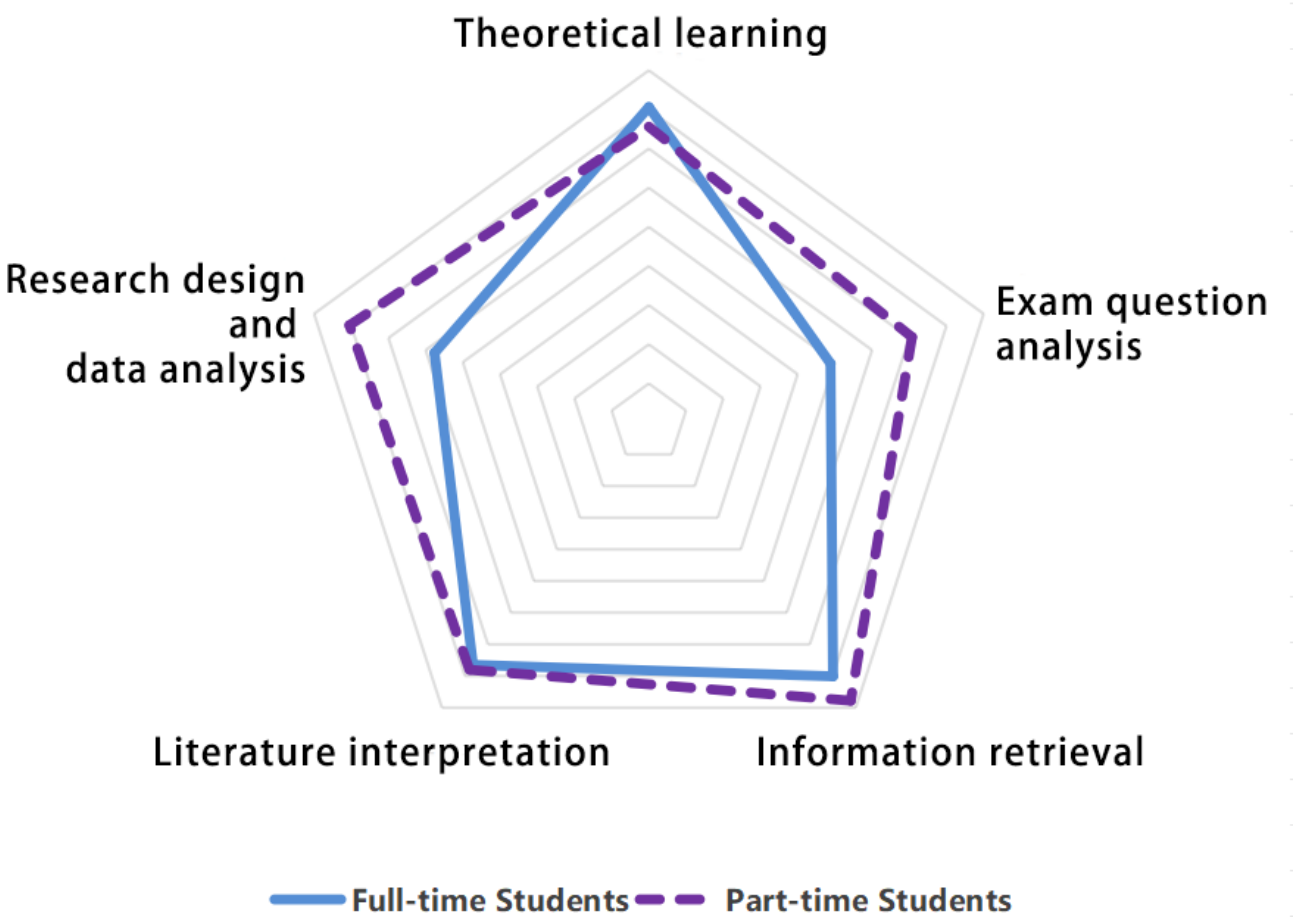


Figure 1. Usage of artificial intelligence (AI) tools in learning among medical students from different educational stages.

When grouped by academic program type, part-time students demonstrated stronger needs for AI support in practical research and exam question analysis. This preference pattern appears related to their need to balance studies with work commitments, requiring efficient learning solutions that yield immediate academic and professional applicability (Figure 2).

XSL•FO
RenderX

Figure 2. Usage of artificial intelligence (AI) tools in learning among medical students from different academic program types (full-time vs part-time).

AI Usage Patterns by Disciplines

Medical students from different academic disciplines exhibited distinct priorities in their application of AI-powered learning (Table 2). Initial analysis using a multiple response test revealed a significant overall difference in AI usage patterns across disciplines (χ^2_{30}=53.62; *P*=.005), prompting subsequent pairwise comparisons between disciplines with a Bonferroni-adjusted alpha of 0.01.

XSL•FO
RenderX

Table . Comparative analysis of artificial intelligence (AI) function usage across different medical disciplines.

Domain	Clinical medicine (n=245), n (%)	Nursing (n=65), n (%)	Rehabilitation therapy (n=31), n (%)	Basic medicine (n=31), n (%)	Public health and epidemiology and pharmacy[a] (n=11), n (%)	Traditional Chinese medicine (n=22), n (%)	Medical engineering (n=23), n (%)	Chi-square (*df*)	Cramer *V*	*P* value[b]
Theoretical learning	201 (82.04)	50 (76.92)	24 (77.42)	26 (83.87)	8 (72.73)	16 (72.73)	18 (78.26)	2.58 (6)	0.08	.86
Exam question analysis	139 (56.73)	37 (56.92)	12 (38.71)	14 (45.16)	4 (36.36)	7 (31.82)	5 (21.74)	18.49 (6)	0.21	.005
Information retrieval	202 (82.45)	56 (86.15)	19 (61.29)	28 (90.32)	8 (72.73)	15 (68.18)	18 (78.26)	13.89 (6)	0.18	.03
Literature interpretation	184 (75.10)	55 (84.62)	22 (70.97)	26 (83.87)	10 (90.91)	12 (54.55)	19 (82.61)	11.80 (6)	0.17	.07
Research design and data analysis	144 (58.78)	35 (53.85)	17 (54.84)	23 (74.19)	9 (81.82)	15 (68.18)	13 (56.52)	7.02 (6)	0.13	.32

[a]Disciplines including public health and epidemiology and pharmacy were grouped together for analysis due to their relatively small sample sizes.

[b]Chi-squared test and Bonferroni correction were applied for multiple comparisons (α=.01).

Across all disciplines, the usage demand for theoretical learning was similarly high, with no statistically significant differences identified.

Regarding exam question analysis, students in clinical medicine demonstrated significantly higher usage demand than those in medical engineering (χ^2_1=10.36; *P*=.001).

In terms of information retrieval, students from rehabilitation therapy demonstrated significantly lower usage demand compared to students in clinical medicine (χ^2_1=7.72; *P*=.005), nursing (χ^2_1=7.59; *P*=.006), and basic medicine (χ^2_1=7.12; *P*=.008).

For literature interpretation, traditional Chinese medicine students demonstrated a significantly lower level of usage demand relative to students in nursing (χ^2_1=8.40; *P*=.004).

Across disciplines, usage demand for research design and data analysis was moderate, peaking non-significantly among public health and epidemiology and pharmacy students.

Correlates of Satisfaction With the Institutional AI Platform

With the rapid development of AI, many universities have launched localized AI platforms. Our survey investigated the availability of institution-specific AI−powered medical education platforms among medical students. Furthermore, we assessed student satisfaction with these platforms.

Approximately one-fifth (86/428) of the respondents reported that their institutions had developed such platforms. Satisfaction scores among these users exhibited significant variation. The average satisfaction score among the 86 users was 72.23 (SD 21.84), distributed as 40 (46.51%) satisfied, 28 (32.56%) neutral, and 18 (20.93%) dissatisfied.

Nonparametric tests revealed a significant difference in satisfaction levels by gender (*U*=686.50; *z*=−2.06; *P*=.04). No significant associations were found with academic program type, educational stage, or discipline. A subsequent multivariable regression that included these variables and usage frequency identified no significant predictors. To assess the model's reliability, collinearity diagnostics were performed, and they revealed no substantial multicollinearity (Table 3).

XSL•FO
RenderX

Table . Medical students' satisfaction with the artificial intelligence (AI)−powered medical education platforms at their institutions.

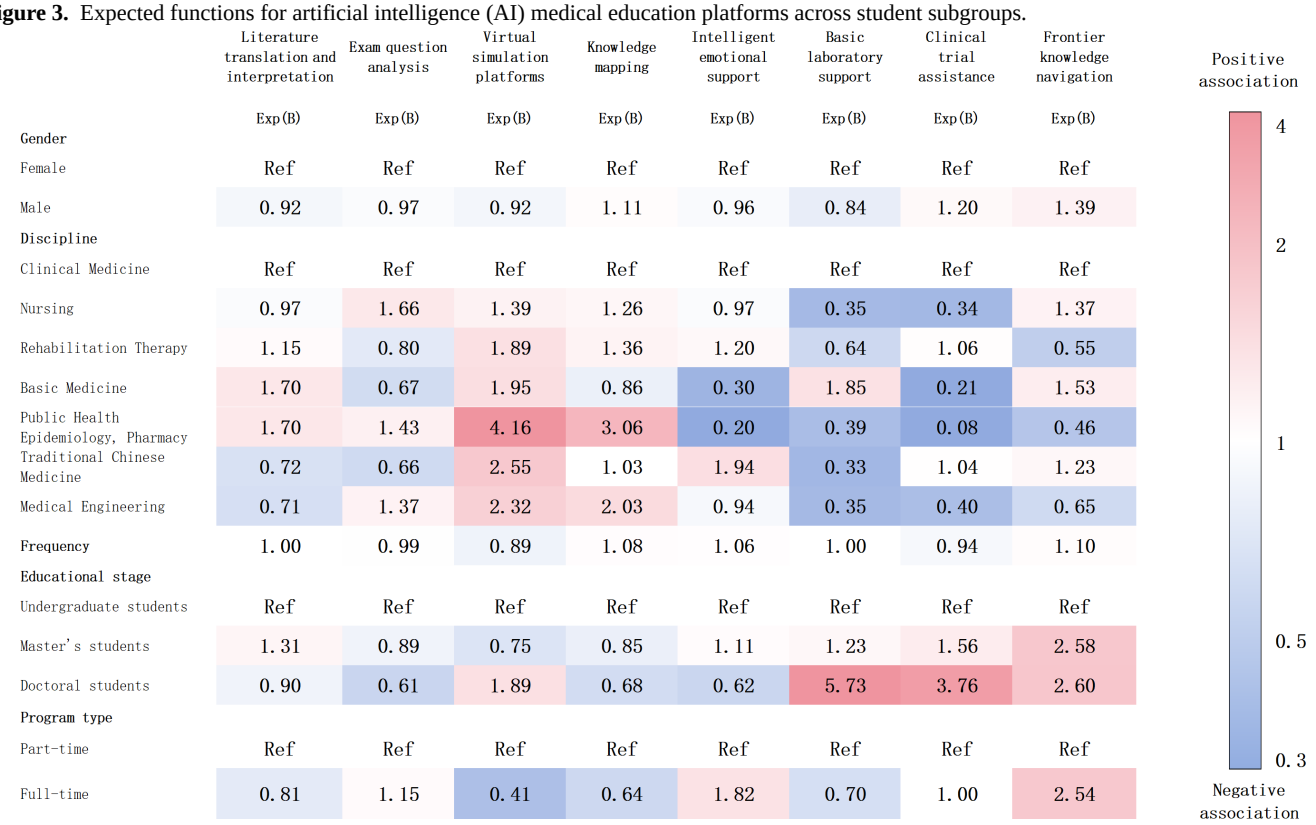
Predictor	Unstandardized coefficient		Standardized coefficient	*P* value	VIF[a]	95% CI for unstandardized coefficients (*B*)
	B	SE	β			
Constant	71.97	13.93	—[b]	<.001	—	44.22 to 99.72
Academic program type (reference: part-time)						
Full-time	−3.18	9.72	−0.04	.74	1.20	−22.55 to 16.19
Gender (reference: female)						
Male	8.52	5.12	0.20	.10	1.11	−1.68 to 18.72
Frequency	−0.39	1.34	−0.03	.77	1.08	−3.06 to 2.28
Discipline (reference: clinical medicine)						
Nursing	5.59	6.85	0.10	.42	1.14	−8.05 to 19.24
Rehabilitation therapy	−4.14	13.76	−0.04	.76	1.08	−31.55 to 23.26
Basic medicine	−0.36	7.38	−0.01	.96	1.11	−15.07 to 14.35
Public health and epidemiology and pharmacy	10.54	12.64	0.10	.41	1.20	−14.64 to 35.71
Medical engineering	−6.18	24.99	−0.03	.81	1.22	−55.96 to 43.61
Educational stage (reference: undergraduate student)						
Master's student	−2.43	5.97	−0.05	.69	1.33	−14.32 to 9.46
Doctoral student	8.59	10.83	0.10	.43	1.29	−12.99 to 30.18

[a]VIF: variance inflation factor.

[b]Not applicable.

The lack of significant predictors for satisfaction should be interpreted with caution. This result may reflect the inherently subjective and multifaceted nature of satisfaction, which can be influenced by factors beyond the scope of this study. Future research employing longitudinal or mixed methods designs is needed to unravel the complex drivers of user satisfaction.

Correlates of Expected Functions for the Institutional AI Platform



The majority (342/428) of the students reported that their institutions had not yet launched an AI platform specifically centered on medical education. To investigate the needs of this group, this survey further explored their practical needs and expectations for upcoming platforms.

Drawing on the current practical applications of AI technology and feedback from medical students, along with a review of relevant literature, our questionnaire categorized the expected functions of AI-powered medical education platforms into 8 aspects: literature translation and interpretation, exam question analysis, clinical trial assistance, basic laboratory support, knowledge mapping, virtual simulation platforms, frontier knowledge navigation, and intelligent emotional support.

Nonparametric testing revealed significant subgroup differences in the demand for specific platform functions. Guided by these initial findings, we advanced the analysis using binary logistic regression within a more rigorous multivariable framework. For comparing the relative effects of multiple predictors, the results are presented as odds ratios (Exp(B)) and visualized in the accompanying heatmap (Figure 3).

XSL•FO
RenderX

Figure 3. Expected functions for artificial intelligence (AI) medical education platforms across student subgroups.

Regarding gender, the regression analysis revealed a consistent pattern: no statistically significant associations were found between gender and any of the anticipated platform functions.

Analysis of academic program type (full-time vs part-time) revealed no significant differences in functional expectations. However, full-time students demonstrated a numerically stronger preference for frontier knowledge navigation (*B*=0.93; Exp(B)=2.54; *P*=.14), while they were less inclined toward Virtual Simulation Platforms (*B*=−0.90; Exp(B)=0.41; *P*=.08).

Regarding the educational stage, doctoral students demonstrated a significantly stronger preference for AI-assisted clinical trial support (*B*=1.32; Exp(B)=3.76; *P*=.01) and basic laboratory assistance (*B*=1.75; Exp(B)=5.73; *P*=.001) compared to undergraduates, while master's students showed significantly higher demand for frontier knowledge navigation (*B*=0.95; Exp(B)=2.58; *P*=.02).

Across different academic disciplines, medical students showed varying expectations for the functions of upcoming AI-powered medical education platforms. Students in clinical medicine demonstrated a significantly stronger demand for clinical trial assistance (*B*=−1.09; Exp(B)=0.34; *P*=.008) and Basic Laboratory Support (*B*=−1.05; Exp(B)=0.35; *P*=.005) compared to those in nursing. Conversely, nursing students were inclined toward personalized guidance on theoretical exam preparation, though this tendency did not reach statistical significance (*B*=0.51; Exp(B)=1.66; *P*=.08). Notably, students in clinical medicine demonstrated a significantly higher demand for clinical trial assistance compared to students in other disciplines. This difference reached statistical significance when compared specifically with students in basic medicine (*B*=−1.58; Exp(B)=0.21; *P*=.01) and those in public health and epidemiology and pharmacy (*B*=−2.54; Exp(B)=0.08; *P*=.02).

Test of the TTF Hypotheses

Based on the results of our prior data analysis and guided by the 5 research hypotheses derived from the TTF theory, we employed appropriate statistical methods to test these hypotheses (Table 4).

XSL•FO
RenderX

Table . Hypothesis testing results of the task-technology fit (TTF) model.

Hypothesis	Path relationship	Statistic[a]	Effect size[b]	*P* value	Supported
H1	TTF (current use) → satisfaction	$F(5, 80)=1.11$	Adjusted $R^2=0.006$	.36	No
H2	Discipline → TTF (current use)	$F(36, 2526)=1.60$	Partial $\eta^2=0.02$	.01	Yes
	Discipline → TTF (expected function)	$F(42, 840)=1.25$	Partial $\eta^2=0.06$	.13	No
H3	Academic program type → TTF (current use)	$F(6, 421)=3.32$	Partial $\eta^2=0.05$	.003	Yes
	Academic program type → TTF (expected function)	$F(7, 140)=1.22$	Partial $\eta^2=0.06$	.29	No
H4	Educational stage → TTF (current use)	$F(12, 842)=6.51$	Partial $\eta^2=0.09$	<.001	Yes
	Educational stage → TTF (expected function)	$F(14, 280)=1.53$	Partial $\eta^2=0.07$	.10	No
H5	Frequency → satisfaction	$B=-0.39$	95% CI for $B=-3.06$ to 2.28	.77	No

[a]Analytical methods were hypothesis-specific: ANOVA for a single outcome variable (H1); multivariate ANOVA for multiple outcome variables (H2-H4); linear regression with unstandardized coefficients for predictive modeling (H5).

[b]Effect size measures were selected and reported in accordance with the conventions for the specific statistical procedures applied.

The analytical approach was tailored to the characteristics of the variables under examination. For H1, ANOVA was used, which indicated no significant association between current AI usage patterns and satisfaction. For H2, H3, and H4, MANOVA was applied: the results showed that discipline, academic program type, and educational stage each had a significant influence on TTF (current use); however, none of these factors demonstrated a significant effect on TTF (expected function). For H5, linear regression analysis found no significant relationship between frequency and satisfaction.

Discussion

While previous studies have described broad trends in AI adoption among medical students, this study identifies the specific drivers of heterogeneity within a defined cohort from Shanghai. Through a granular subgroup analysis, we demonstrate how disciplinary background, educational stage, and program type significantly shape distinct patterns in usage frequency, functional preferences, and perceived value.

Popularity of AI Technology Among Medical Students

The rapid advancement of AI technology is demonstrating the potential to reshape traditional paradigms in medical education. For medical students, the integration of digital and intelligent technologies has significantly enhanced instructional quality and learning outcomes. With ongoing technological advancement, AI is now widely adopted and has become an essential part of students' academic work [19].

The survey revealed that medical students now engage with AI tools on a frequent basis, reflecting a notable shift in usage patterns compared to earlier adoption phases [20,21]. This suggests that, with ongoing technological advancement and the growing accessibility of AI, students are increasingly adopting this new technology and using it more in their learning.

In terms of LLM selection, most students preferred mainstream models, encompassing both domestic platforms such as DeepSeek and Doubao and international ones like ChatGPT. The choice appears to have been influenced by factors such as accessibility and performance. While mainstream LLMs meet most students' academic requirements, many still select specific models based on personal preferences and practical needs. This reflects a growing trend toward individualized AI tool usage.

Regarding mainstream LLM selection, international findings show that ChatGPT is widely popular globally [22,23]; however, its adoption among the surveyed medical students in Shanghai remains lower compared to DeepSeek. This observed usage pattern aligns with DeepSeek's established localization strategy and regulatory compliance within the Chinese environment. China's regulatory policies require GenAI services to complete local filing and security assessments [24]. ChatGPT, lacking such compliance, is inaccessible through conventional channels. Furthermore, China's exclusion from OpenAI's supported countries creates additional access barriers [25]. In contrast, DeepSeek operates in full compliance with these requirements, ensuring seamless accessibility for Chinese users and thus gaining a competitive edge in the local AI market.

The analysis of AI tool preferences revealed distinct gender−based patterns. Despite using a similar number of AI platforms, with mainstream tools being central for both groups, male students demonstrated greater enthusiasm for emerging options, whereas female students adopted a more cautious approach. These observed differences align with previous

XSL•FO
RenderX

findings on gendered perceptions of AI technology [26-28]. Notably, this variation further underscores the importance of developing flexible, multiplatform strategies to accommodate diverse user preferences in medical education.

The integration of AI technology has become a defining feature of contemporary medical education. Our findings reveal a clear consensus among students across all academic backgrounds on adopting a multiplatform approach. Regardless of educational stage or discipline, medical students are actively leveraging diverse AI tools, flexibly selecting platforms according to specific learning scenarios and practical needs [29].

Group Differences in AI Tool Usage for Academic Purposes

Medical knowledge covers a broad spectrum and involves extensive interdisciplinary integration. Although various medical specialties are inherently connected, they differ significantly in teaching method, clinical practice, and scientific research. These distinctions are also reflected in the application of AI.

From an educational stage perspective, undergraduate students tended to emphasize AI-assisted analysis of theoretical exam questions more than master's and doctoral students, who placed greater focus on AI's role in supporting practical research. This difference reflects the distinct teaching priorities at each educational stage: undergraduate students face a heavy burden of theoretical courses and professional qualification exams, so their learning focus tends to be on theoretical exam question analysis and knowledge mapping. In contrast, graduate students, facing less exam pressure, focus more on research-related tasks and thus place greater emphasis on AI as a tool for practical research support [30-32].

From the perspective of academic program type (full-time vs part-time), part-time students had broader and more comprehensive needs for AI-assisted learning compared to full-time students. Their demand for AI in scientific research and test analysis was more pronounced. This stems directly from the dual pressures faced by part-time medical students, who balance both academic studies and daily work. In dealing with research and exams, they tend to be more reliant on AI for assistance and guidance to alleviate the burden of learning [33].

From a disciplinary perspective, different majors have a significant impact on the direction of AI-assisted learning [34]. The data showed that students majoring in clinical medicine and nursing were more focused on AI-assisted exam question analysis [35], while traditional Chinese medicine students had a notably lower demand for literature translation and interpretation. Students in basic medicine, public health and epidemiology, and pharmacy were more concerned with AI's role in supporting research work. These differences directly reflect the distinct curricular focus, professional requirements, and learning objectives characterizing each discipline [7,20,36].

Student-Centered Design of Platform Functions

At present, the application of AI in medical education is still in an exploratory stage. Major computer and internet companies, both domestically and internationally, have launched AI models with diverse functionalities. In parallel, universities and research institutions have adopted various strategies to expand the potential of this emerging field. For example, the AI application platform at Tongji University integrates multiple large models such as DeepSeek, OpenAI, and Tongyi Qianwen, offering a wide range of AI tools. Faculty and students can select these tools based on their professional and academic requirements [37]. Similarly, Shanghai Jiao Tong University has launched the "Jiao Xiao Zhi" agent management platform, integrating LLMs including DeepSeek for localized AI deployment. The platform enables faculty and students to create customized AI assistants, streamlining teaching and research tasks through its secure campus−based infrastructure [38].

This survey focused on medical students' satisfaction with and expectations for AI-powered medical education platforms. While overall satisfaction was relatively high, a significant minority (approximately one-quarter) expressed dissatisfaction, with notable variations across academic stages and disciplines.

To address these divergent needs, we propose a tiered design framework for future platforms:

For undergraduate students: Platforms should prioritize structured learning support. This includes AI-powered tools for adaptive test preparation aligned with standardized exams, interactive virtual patient cases for foundational clinical exposure, and personalized review systems that target individual knowledge gaps.

For postgraduate students (master's or PhD): The focus should shift to research and specialized skill development. Key features should encompass advanced literature interpretation aids, data analysis modules for processing experimental or clinical data, and AI assistants for research design and grant writing, catering to their deep engagement in academic research.

Discipline-specific customization: Further refinement should distinguish between clinical and basic medicine disciplines. Clinically oriented tracks would benefit from advanced diagnostic simulators and patient management tools, while basic medicine tracks require robust support for experimental design, genomic data analysis, and scientific visualization.

By moving beyond a one-size-fits-all model to adopt such a stratified and discipline-aware approach, AI platforms can achieve deeper integration into medical education, ultimately enhancing both student satisfaction and educational outcomes [9,39].

Limitations

Due to constraints in personnel and resources, this study employed a convenience sampling method among medical students in Shanghai. This nonprobability sampling approach may have introduced selection bias, such as an overrepresentation of students already enthusiastic about AI, and limits the generalizability of the findings beyond similar urban, well-resourced contexts.

Moreover, this study relied on self-reported measures for key metrics—including AI usage frequency and satisfaction—for which formal psychometric validation was not conducted. This approach increased susceptibility to recall and social desirability biases across all these measures. Furthermore, as subjective

XSL•FO
RenderX

constructs, they were vulnerable to varying personal interpretations and benchmarks. This was particularly relevant for abstract constructs like satisfaction. Consequently, these subjective data may not fully capture the nuanced realities of actual user behavior.

Future research could therefore prioritize multicenter, large-sample designs that utilize standardized instruments. Such approaches would provide more robust and generalizable evidence to effectively guide the development of AI-powered medical education platforms.

Conclusions

This study conducted a cross-sectional survey across major medical institutions in Shanghai, China, collecting and analyzing the current use and practical needs of AI among medical students from different educational stages, academic program types, and disciplines. Our findings clearly indicate that AI is widely applied in medical education and has become a common tool for student learning. Students from different disciplines, educational stages, genders, and academic program types show significant differences in their functional demands for AI-assisted learning.

Furthermore, our study investigated the current status of AI-powered medical education platforms and explored students' expectations for such platforms. It is evident that the rapid integration of AI in medical education holds great promise, and our findings provide evidence-based support to guide the future development of AI-powered medical education platforms.

Acknowledgments

We thank all the medical students who participated in this survey for taking time to complete the questionnaires and providing valuable data for this study. We also appreciate those who assisted in questionnaire distribution and collection, which helped improve the response rate and data quality of the research.

We would like to extend special thanks to the Clinical Research Center of Renji Hospital for their guidance in study design, methodology, and ethics, as well as their ongoing technical and logistical support throughout the study.

GenAI was used for language polishing and reference formatting during manuscript preparation. The authors reviewed and edited all content and take the full responsibility for the work.

Funding

Abstract

Background: Formative assessment plays a central role in medical education by offering low-risk practice and timely feedback, particularly in visually and practically demanding courses, such as morphology. Gamified digital tools can foster active learning; however, their educational value relies on pedagogical integration rather than technology alone. The Technological Pedagogical Content Knowledge (TPACK) model provides a framework for understanding this relationship.

Objective: This study explored students' and a teacher's perceptions of Kahoot! as a gamified formative assessment tool in a first-year medical morphology course, identifying facilitators, tensions, and perceived educational value through the TPACK framework.

Methods: This qualitative, exploratory study adopted an interpretive phenomenological orientation. It was conducted within the framework of the RAÍCES 2 (Red de ayudantes de investigación comprometidos con la educación en salud; Network of Student Researchers Committed to Health Professions Education) educational research project at Universidad San Sebastián (Valdivia, Chile). Kahoot! was implemented at the end of class sessions to simulate the visual and time demands of authentic practical examinations. Data collection included 2 online focus groups with first-year medical students (n=14) and 1 semistructured interview with the course teacher (n=1). Transcripts were analyzed using deductive coding informed by the TPACK framework and the project's analytical axes, combined with reflexive thematic analysis following Braun and Clarke. ATLAS.ti was used to support the analysis.

Results: Six interrelated themes emerged: (1) techno-disciplinary alignment, reflecting the value of authentic, high-resolution anatomical images and time constraints mirroring practical examinations; (2) Kahoot! as a formative closure, serving as an exit check that guided self-assessment and the identification of learning gaps; (3) from score to learning, highlighting the importance of immediate postquestion instructor feedback explaining both correct and incorrect answers; (4) motivation and socioemotional climate, whereby gamification enhanced engagement but triggered evaluative anxiety and leaderboard frustration, which were buffered by participant anonymity; (5) implementation conditions, mediated by connectivity, device availability, and time allocation; and (6) projection and improvement, highlighting the need for institutional question repositories and systematic curriculum integration.

Conclusions: Kahoot! effectively functions as a formative assessment strategy when intentionally aligned with disciplinary and practical evaluative demands. Its educational value is not inherent to the software but is determined by explicit pedagogical mediation and careful attention to students' socioemotional dynamics.

Introduction

Formative Assessment and Gamification in Medical Education

In medical education, formative assessment plays a key role by allowing students to practice in academically low-risk environments and to receive timely feedback. These opportunities are particularly relevant for preparing students for high-stakes assessments, such as anatomical structure recognition exercises, which are common in courses with a strong practical and visual component.

In this context, the use of digital strategies for formative purposes has steadily increased in medical education. A recent review published in JMIR Medical Education highlights the expansion of digital teaching [1], noting that gamification tools, such as web-based quizzes, can help synthesize essential content [2] and support engaging synchronous learning activities for students [3]. Available evidence suggests that, when appropriately implemented, these tools are associated with higher levels of participation and satisfaction, thereby supporting learning processes.

Anatomical Training Demands and the Technological Pedagogical Content Knowledge Framework

In September 2025, an educational activity was implemented at Universidad San Sebastián (Valdivia, Chile) for first-year medical students enrolled in the morphology I course. The intervention consisted of an end-of-class formative assessment activity using the gamification tool Kahoot! It was intentionally designed to simulate the specific conditions, time constraints, and pressure encountered during authentic practical assessments in the course, such as gymkhanas (station-based examinations focused on timed anatomical structure identification).

Although Kahoot! is widely used for reviewing cross-cutting content [2], its effectiveness largely depends on context and pedagogical design. Previous studies have described this platform as a motivating tool in health professions education [3,4]; however, its impact does not reside solely in the technology itself, but rather in how it is pedagogically integrated. From the theoretical perspective of Technological Pedagogical Content Knowledge (TPACK), the effective use of educational technologies requires a balanced articulation among technology, pedagogy, and disciplinary content [5,6].

Despite its widespread use, evidence about how this type of tool is experienced in highly visual disciplines, such as morphology, remains limited. In particular, there is limited understanding of students' and teachers' perceptions regarding its contribution to learning, as well as the facilitators and barriers to its implementation. This study explored students' and a teacher's experiences with Kahoot! as a formative assessment tool in morphology I. Using qualitative methods and the TPACK framework, we identified implementation barriers, facilitators, and perceived learning outcomes.

In addition, this study extends beyond describing participants' perceptions by identifying pedagogical conditions and transferable design principles for gamified formative assessment in visually intensive medical courses. Interpreting these findings through the TPACK framework provides guidance for designing technology-enhanced formative assessment activities that align disciplinary content, pedagogy, and digital tools.

The aim of this study was to explore students' and the teacher's perceptions regarding the use of Kahoot! as a gamified formative assessment tool in a first-year medical morphology course. Specifically, this study sought to identify the facilitators, tensions, and perceived educational value of this tool when interpreted through the TPACK framework. Ultimately, we intend to provide transferable pedagogical conditions and design principles to guide educators in integrating technology-enhanced assessments within visually intensive medical disciplines.

Methods

Study Design and Context

This study followed a qualitative, exploratory design informed by an interpretive phenomenological orientation, which guided the study's focus on understanding participants' lived experiences and the meanings they attributed to the use of Kahoot! within the morphology course. Rather than adopting a specific phenomenological method, this orientation served as an epistemological framework to support an interpretive analysis of participants' accounts. The study was conducted within the framework of the RAÍCES 2 (Red de ayudantes de investigación comprometidos con la educación en salud; Network of Student Researchers Committed to Health Professions Education) project (2025) and reports findings derived from an educational intervention implemented in the morphology I course in the Medicine program at Universidad San Sebastián, Valdivia campus, Chile. Data collection took place in September 2025.

Participants and Recruitment

Participants were first-year medical students enrolled in the morphology I course, which had a total enrollment of 76 students during the intervention period. A voluntary sampling strategy was used. Inclusion criteria were as follows: (1) enrollment in the Medicine program at Universidad San Sebastián, Valdivia campus; (2) registration in the morphology I course in September 2025; and (3) participation in the Kahoot!-based educational activity. No exclusion criteria were applied.

After the intervention, students who met the inclusion criteria were invited in person during class sessions to participate in the study. In addition, the invitation was disseminated through social media, along with a link to a participation form. In total, 14 students agreed to participate, representing approximately 11% of the eligible student cohort. As participation was voluntary, this proportion reflects a self-selected sample of students willing to share their experiences.

Given the qualitative and exploratory nature of the study, the sample was considered adequate for the study's aims, providing sufficient depth and diversity of experiences to support an interpretive understanding of participants' perspectives. Consistent with qualitative research, emphasis was placed on the richness and relevance of the data rather than on statistical representativeness.

XSL•FO
RenderX

Prior to data collection, participants were invited to attend an in-person meeting at Universidad San Sebastián, Valdivia campus, during which the objectives of the study were explained and written informed consent was obtained. The volunteers were then assigned to 2 focus groups, each composed of 7 students. In addition, an individual semistructured interview was conducted with the course teacher, who was responsible for implementing the intervention, to complement the students' perspectives.

Data Collection

Data collection was conducted remotely in September 2025 through synchronous sessions held via Microsoft Teams. Two focus groups with students and 1 individual interview with the course teacher were held.

All sessions were semistructured and guided by interview protocols developed in advance by the research team. Separate guides were designed for students and for the teacher in order to capture their distinct perspectives.

The student focus group guide explored topics such as perceptions of Kahoot! as a formative assessment tool, its influence on learning and motivation, facilitators and barriers to its use, and its alignment with the visual and evaluative demands of the course.

The teacher interview guide focused on pedagogical intentions, implementation decisions, perceived educational value, challenges encountered, and reflections on the integration of technology, pedagogy, and content. The development of both guides was informed by the TPACK framework, ensuring alignment with the study's theoretical perspective. The full interview and focus group guides are provided in Multimedia Appendix 1.

Each focus group was moderated by a member of the research team. The first focus group was facilitated by EVZ, the second by VFRV, and the teacher interview was conducted by SPAF. None of the moderators had a direct teaching relationship with the participants in order to minimize potential biases related to academic hierarchies. The sessions lasted approximately 60 minutes. No field notes were taken. With participants' informed consent, all sessions were audio recorded for subsequent analysis. The recordings were transcribed verbatim; only the transcription of the first focus group was supported by AI-assisted tools. Subsequently, all transcripts were manually reviewed and corrected by members of the research team to ensure accuracy and fidelity to the original recordings.

Data Analysis

The analysis was conducted within an interpretive qualitative framework consistent with the study's phenomenological orientation, acknowledging that meaning is coconstructed through participants' accounts and researchers' interpretive engagement.

Data from the focus groups and the teacher interview were analyzed using a hybrid abductive analytic approach that combined sensitizing concepts derived from the TPACK framework (technology, pedagogy, and content) and the analytical axes of the RAÍCES project (motivation, facilitators, barriers, perceived learning, and transfer), together with an inductive, reflexive thematic analysis following Braun and Clarke [7]. Rather than functioning as a closed coding template, these theoretical dimensions served as an initial analytical scaffold to support familiarization with the data and the preliminary organization of participants' accounts. This method was selected for its theoretical flexibility and its compatibility with interpretive qualitative approaches, allowing for the identification of patterns of shared meaning while preserving sensitivity to participants' lived experiences. This process enabled deeper analysis and the integration of both theoretical categories and meanings constructed from participants' lived experiences.

Throughout the analytic process, the analysis followed a hybrid abductive approach in which theoretical concepts and data-driven insights informed one another iteratively. The TPACK dimensions and the RAÍCES analytical axes were used as an initial organizing structure, a sensitizing framework that provided a preliminary scaffold for indexing participants' accounts, rather than as a closed coding scheme. Building on this structure, inductive open coding was conducted to capture meanings not anticipated by the framework, such as the salience of the visual component and the emotional ambivalence of competition. Theme construction was therefore reflexive and primarily inductive: deductively derived categories were retained only when supported by the data, and emergent codes that exceeded the framework were preserved and developed into themes in their own right. Throughout this process, the research team moved iteratively between the empirical material and the theoretical framework, so that the final themes reflect participants' lived experiences while remaining interpretable through the TPACK lens. The full analytical workflow is summarized in Multimedia Appendix 2, which illustrates the iterative integration of deductive template coding and inductive reflexive thematic analysis, showing how theoretical categories served as an initial analytic scaffold while allowing themes to emerge from the data.

This hybrid analytic process generated the 6 thematic outcomes described in the *Results* section: "Techno-Disciplinary Alignment and Visuality," "Kahoot! as a Formative Closure: Rapid Check, Review, and Gap Diagnosis," "From Score to Learning: Feedback as a Condition for Being Truly Formative," "Motivation and socioemotional climate: between play, competition, and psychological safety," "Conditions of implementation: facilitators and barriers situated in the course context," and "Projection and improvement: from a single activity to a sustainable and transferable strategy."

The analysis was conducted collaboratively by members of the research team. The ATLAS.ti (Lumivero, LLC) software was used as a support tool for the management, organization, and coding of qualitative data.

Ethical Considerations

The study was approved by the institutional scientific ethics committee (CEC; protocol number 40 - 25, approved on June 25, 2025). Participation was voluntary, and all participants signed an informed consent form prior to data collection. Participants were also informed that they could withdraw from

XSL•FO
RenderX

the study at any time, without any academic or other consequences.

The collected data were accessible exclusively to the research team and were stored in private folders within the institution's secure cloud storage system (OneDrive). To ensure confidentiality, participants' names were replaced with pseudonyms in transcripts and in the presentation of results, with identifying information kept under restricted access.

Researcher Positionality and Reflexivity

To ensure qualitative rigor, the research team engaged in continuous reflexivity throughout the study design, data collection, and analysis. The primary analysis was conducted by 4 fourth-year medical students (SPAF, EVZ, VFRV, and RVCA) and supervised by 2 faculty physicians (AHA and CRB), all of whom were actively involved in the RAÍCES 2 educational project. The student researchers shared a common institutional and academic background with the participants, having previously completed the same morphology I course at Universidad San Sebastián. This insider positionality facilitated a deep, empathetic understanding of the students' lived experiences and the specific pressures of practical assessments. However, it also introduced potential biases about preconceived notions of student anxiety and course difficulty.

To manage these subjectivities and maintain an interpretive balance, reflexivity was operationalized through a collaborative, iterative coding process. The student researchers held weekly peer-debriefing meetings to compare preliminary codes generated in ATLAS.ti and discuss their interpretive lenses.

When disagreements emerged regarding the boundary or meaning of specific codes or subthemes, they were not resolved by a majority vote; instead, they were critically debated and cross-examined alongside the raw transcripts and under the guidance of the faculty members until an analytical consensus was reached. Alternative interpretations of participants' accounts were deliberately explored during these discussions, and emerging themes were repeatedly challenged against the full dataset to ensure that interpretations remained grounded in the data rather than reflecting researchers' initial assumptions or preferred explanations. Themes were iteratively refined through multiple rounds of dialogue, moving back and forth between the empirical data and the TPACK theoretical framework to ensure that the final interpretations truly reflected the participants' accounts rather than the researchers' preexisting assumptions.

Results

Theme 1: Techno-Disciplinary Visual Alignment

Kahoot!'s use was sustained by its intuitive interface and its direct alignment with the visual demands of the course. Participants valued the tool when it effectively simulated the formal objective structured practical examinations, such as gymkhanas (a local term for timed, station-based practical assessments analogous to objective structured practical examinations) by prioritizing the visual recognition of anatomical structures under time pressure. Quick entry via QR codes facilitated a seamless start without disrupting the laboratory flow.

Furthermore, although the image-based pin function required a brief initial learning curve regarding pointer manipulation, it demonstrated high formative potential for anatomical tasks. Ultimately, both students and the teacher emphasized that the success of the activity depended critically on using authentic, high-resolution images identical to physical laboratory resources (eg, physical models and anatomical tables) to effectively train the clinical eye.

Theme 2: Kahoot! as a Formative Closing Tool

Implemented as an end-of-class activity, Kahoot! effectively structured the laboratory session's closure. Acting as an integrative "exit ticket," the platform provided a crucial opportunity for immediate self-assessment. It allowed students to immediately apply the reviewed concepts and contrast their subjective perceived understanding with their objective performance.

Rather than introducing new material, both students and the teacher valued the tool primarily as a diagnostic resource to identify learning gaps and estimate the achievement of expected outcomes. Consequently, this rapid formative check helped guide subsequent independent study. However, its impact on long-term study habits varied; while some students integrated the platform into their personal study routines to simplify content, others viewed it strictly as a classroom complement that did not alter their established study methods.

Theme 3: The Role of Immediate Explanatory Feedback

While Kahoot!'s playful elements such as speed and ranking initially engaged students, these gamified features alone were insufficient for meaningful learning. The tool's true formative value depended entirely on the teacher's pedagogical mediation. Participants stressed that merely identifying correct or incorrect answers was inadequate; explicit explanatory feedback was required to understand the rationale behind the errors. Crucially, both students and the teacher noted that this feedback needed to be immediate, leveraging the brief interval between questions while the visual stimulus remained active in students' working memory.

However, this created a persistent pedagogical tension: teachers had to constantly balance the game's dynamic rhythm with the necessity of pausing for deeper conceptual discussions, a task that proved particularly challenging with complex or extensive content.

Furthermore, the effectiveness of this feedback loop was heavily reliant on precise question design. Learning was notably hindered when images lacked clarity or when items used terminology that deviated from the course's standard anatomical vocabulary.

Theme 4: Socioemotional Dynamics of Gamification

Gamification effectively disrupted the standard classroom routine, adding dynamism and recapturing sustained students' attention. While competition served as a powerful motivational

XSL•FO
RenderX

driver for personal improvement, it also generated emotional ambivalence. Students experienced initial evaluative nervousness, and participants recognized a risk of demotivation or frustration for those consistently achieving lower rankings. In this context, the platform's anonymity was identified as a crucial safeguard. It fostered psychological safety by allowing students to participate and take academic risks without the fear of public failure.

Theme 5: Contextual and Logistical Implementation Factors

The successful implementation of Kahoot! was heavily mediated by contextual and logistical variables. Functioning effectively as an end-of-class closure activity (10 - 15 min), it helped recapture waning attention without disrupting laboratory dynamics. However, students faced minor technological barriers, such as device-battery anxiety and reliance on institutional Wi-Fi, raising concerns about digital equity and exclusion. While the teacher found the platform intuitive to facilitate, students recognized the substantial workload required to design high-quality visual quizzes. Isolated technical and terminological incidents occurred but were quickly resolved without detracting from the overall positive evaluation.

Theme 6: Projections for Sustainable Pedagogical Use

Looking forward, participants projected that systematizing the use of Kahoot!, rather than using it as an isolated intervention, would yield a deeper impact on consistent study habits. To ensure sustainability and alleviate individual faculty workloads, students recommended developing a standardized, institutionally supported question bank. This repository should ensure disciplinary balance, specifically by integrating more histology items alongside macroscopic anatomy. Ultimately, participants affirmed that the core competencies practiced through this gamified tool, such as rapid image recognition and decision-making under time constraints, were directly transferable to formal practical assessments.

Reflexive thematic analysis identified 6 main themes that synthesize students' and the teacher's perceptions of the use of Kahoot! as a formative assessment strategy in morphology I. These themes reflect how the educational value of the tool emerged from the interaction between the visual and temporal design of the activities, the teacher's pedagogical mediation, the socioemotional climate generated by gamification, and contextual implementation conditions. Table 1 presents an interpretive synthesis of the identified themes. To preserve the inductive depth of the participants' accounts, these findings are presented chronologically based on their lived experiences, using the TPACK framework strictly as a subsequent interpretive lens in the discussion section.

Table . Main themes identified from the reflexive thematic analysis of the use of Kahoot! in morphology I.

Theme	Core meaning
Alignment with disciplinary and visual demands	Kahoot! was perceived as valuable when its visual design, task structure, and available time reproduced conditions similar to practical assessments and laboratory work.
Kahoot! as a formative closing activity	The activity functioned as a rapid formative check at the end of class, supporting self-assessment, identification of learning gaps, and guidance for subsequent study.
From score to learning: feedback as a critical condition	The formative value of the tool depended on immediate explanatory feedback from the teacher, which transformed game results into opportunities for meaningful learning.
Motivation and socioemotional climate	Gamification increased engagement and attention but also generated ambivalent emotional responses related to competition, time pressure, and performance visibility.
Contextual conditions of implementation	Factors such as connectivity, device availability, class time management, and teacher preparation conditioned the quality of the experience.
Projection toward sustainable use	Participants envisioned greater educational impact through more systematic use, improved item design, disciplinary balance, and institutional support.

Discussion

Principal Findings and Interpretation

In summary, the main findings of this study indicate that Kahoot! can effectively function as a formative assessment tool when its visual and temporal design aligns with authentic practical examinations. Furthermore, as experienced by the participants, its educational value is not inherent in the technology itself but relies crucially on the participating instructor's immediate explanatory feedback to mitigate competitive anxiety and transform gamified scores into meaningful learning.

The primary perception of Kahoot! as a low-stakes formative environment, rather than a summative measurement, highlights a successful pedagogical integration of technology to alleviate evaluative anxiety. From the perspective of the TPACK framework, this shift illustrates the pedagogical use of technology to support formative assessment, demonstrating how a digital tool technological knowledge (TK) can be intentionally steered away from evaluative pressure to serve a purely

XSL•FO
RenderX

diagnostic purpose pedagogical knowledge (PK) within a demanding discipline content knowledge (CK). By leveraging technological affordances specifically for formative closure, the classroom dynamic transitions from performance-oriented competition to a psychologically safe learning space where errors are embraced as pedagogical milestones for gap diagnosis.

Crucially, Kahoot!'s pedagogical value depended entirely on immediate explanatory feedback. Students found scores and rankings insufficient without clear justifications for correct and incorrect answers. In this sense, learning did not occur during the act of responding to the question but rather during the guided reflection that followed it, positioning the teacher's mediation as a central component perceived to support the transformation of errors into meaningful learning opportunities.

This friction between engagement and cognitive processing illuminates the critical pedagogical and socioemotional dimensions of technology use in high-stakes environments. Viewed through the lens of the TPACK framework, this finding reveals that when the inherent characteristics of a technology (TK), such as Kahoot!'s speed and countdown timer, override the needs of the content (CK), a direct tension arises with the pedagogical objectives (PK). In disciplines with a high cognitive and visual load, like morphology, technological fluency can conflict with the time required for conceptual consolidation.

This correlation between item design flaws and student errors underscores the critical need for a tight integration of disciplinary content, pedagogical decisions, and technological affordances. Viewed through the lens of the TPACK framework, this issue illustrates what happens when the technological execution (TK) fails to precisely mirror the unique visual demands of the content (CK). In a highly visual discipline like morphology, where anatomical pattern recognition is a core competency, the graphical fidelity of a digital tool is not a mere esthetic preference; it is a pedagogical prerequisite. When images lack clarity or distractors introduce terminological variance, the technological tool (TK) creates a barrier that interferes with the pedagogical goal (PK) of accurate self-assessment.

The coexistence of enthusiasm and evaluative anxiety further illuminates the pedagogical and socioemotional dimensions of technology use, revealing that gamified environments activate learners at both cognitive and affective levels. Viewed through the TPACK framework, the emotional impact of a digital tool (TK) is not neutral; rather, it is heavily modulated by how game mechanics (such as leaderboards and speed points) intersect with the pedagogical climate (PK) designed by the instructor. While competition serves as a powerful driver for engagement, persistent low rankings introduce socioemotional friction in which continuous peer comparison risks shifting student anxiety from a state of productive alertness to frustration and demotivation. In the face of these adverse situations, strategies that foster student security become paramount (such as real-time reassurance provided by the instructor and student anonymity), thereby ensuring that the competitive drive does not compromise psychological safety. Specifically, anonymity acts as a structural prerequisite embedded within the technological interface (TK) that mitigates the fear of public exposure, promoting broader participation by allowing students to take cognitive risks even when unsure of their answers. Without these supportive, feedback-oriented instances (PK) to buffer the pressures of the game, the technological tool (TK) loses its formative value and defaults to an evaluative stressor. Indeed, this anonymity facilitates active participation without fear of public exposure, reducing the dread of making mistakes, whereas competition remains an ambivalent strategy that requires careful pedagogical scaffolding to prevent demotivation when peer comparison becomes persistent.

The tight interdependence among these emergent findings demonstrates that a digital gamified environment alone remains pedagogically inert without deliberate technological, pedagogical, and content alignment. This systemic interaction offers a clear projection toward sustainable use and provides transferable design principles for educators in other visually intensive medical disciplines, such as histology, pathology, or radiology. To successfully transfer these insights, instructors must move away from using gamified tools as isolated recreational games. Instead, sustainable implementation requires a balanced articulation within the TPACK framework: first, ensuring that the technological execution (TK) achieves authentic visual alignment with disciplinary content demands (CK); second, positioning immediate, explicit teacher feedback (PK) as a strict prerequisite to automated scoring; and third, actively managing the socioemotional climate to preserve psychological safety. Rather than a mere classroom intervention, these conditions establish a reproducible pedagogical model that transforms gamified formative assessment into a sustainable tool for diagnostic gap recognition across medical curricula.

Comparison With Prior Work

The findings of this study are consistent with the literature indicating that the educational value of digital technologies in medical education depends less on the tool itself and more on its integration with the pedagogical and disciplinary demands of the learning context. In their review of the digital teaching landscape in medicine, Yeung et al [1] describe that technological interventions tend to be better valued when they are coherently aligned with learning objectives and with the practices inherent to each course. In line with this, our findings show that Kahoot! was perceived as useful mainly when it aligned with the practical performance required in morphology I, particularly the recognition of anatomical structures through authentic images under time constraints comparable to the course's practical assessments.

Previous studies have documented that the use of quiz-based and game-based platforms can foster engagement and content review among medical students. Both Yuenyongviwat and Bvonpanttarananon [2] and Cordero-Cordero et al [4] report positive perceptions of Kahoot! as a learning support strategy. However, the results of the present study add an important nuance by showing that a playful and competitive component alone does not guarantee learning perceived as meaningful. In this case, explanatory feedback provided by the teacher emerged as the central condition that transformed the game dynamics into a genuinely formative experience, in line with what Rodríguez Salvador and Arboniés Ortiz [8] propose regarding

XSL•FO
RenderX

the role of feedback in formative assessment in medical education.

From a motivational standpoint, the results partially align with studies describing gamification as a strategy capable of increasing student participation and interest. Rivera et al [3] note that technology-mediated interactive activities can foster engagement in medical teaching contexts. However, the present study offers a more complex view by evidencing that motivation associated with Kahoot! is highly ambivalent. While competition was described as stimulating for many students, accounts of evaluative anxiety and potential demotivation also emerged when peer comparison became persistent. This observation is consistent with findings by Kirsch and Spreckelsen [9], who warn that competitive gamification may generate initial enjoyment but not necessarily sustained benefits for intrinsic motivation or learning.

Crucially, this socioemotional vulnerability underscores broader digital health risks documented in recent literature. As demonstrated by Song et al [10] in their evaluation of classroom technology, inappropriate or excessive use of unintegrated digital tools can be positively correlated with academic burnout among university students. To mitigate these psychological risks, Song et al [10] emphasize the importance of enhancing teacher leadership in the digital classroom and strengthening student resilience. This directly supports our findings, suggesting that when a tool like Kahoot! is used under high time and visual constraints, the emotional toll can easily tip toward burnout or frustration if the tool functions in isolation. Therefore, robust pedagogical design and active instructor mediation are required to safeguard the socioemotional climate.

Taken together, these integrated findings strongly reinforce the propositions of the TPACK framework by Mishra and Koehler [5,6], showing that the effectiveness of educational technologies in medical training does not lie, in the technological component in isolation but in the deliberate interaction between disciplinary knowledge (content), pedagogical decisions, and the intentional use of technology. From this perspective, the present study contributes situated qualitative evidence that deepens the understanding of how gamified tools such as Kahoot! are experienced by students and teachers when integrated into practical medical contexts characterized by high cognitive, evaluative, and socioemotional demands.

Conceptual Contribution of the Study

Rather than demonstrating the effectiveness of a specific digital platform, this study identifies a set of pedagogical conditions that appear to be essential for designing effective gamified formative assessment in visually intensive medical courses. These principles were inductively derived from 6 themes identified in the reflexive thematic analysis and subsequently interpreted using the TPACK framework.

First, gamified activities should reproduce the authentic visual and temporal demands of disciplinary assessments to ensure alignment with learning objectives. Second, game mechanics should be embedded within intentional pedagogical design rather than functioning as isolated motivational elements. Third, immediate explanatory feedback should accompany each response to transform game performance into meaningful learning. Finally, implementation should explicitly consider students' socioemotional experiences by balancing engagement, competition, and psychological safety.

Together, these findings extend the application of the TPACK framework by proposing transferable design principles that can inform the development of gamified formative assessment beyond the specific context of morphology I and the use of Kahoot!

Strengths and Limitations

This study is distinguished by a comprehensive qualitative approach that enabled a rich and detailed understanding of students' and the teacher's experiences regarding the use of Kahoot! in morphology I. Methodological triangulation, integrating 2 student focus groups and 1 semistructured interview with the teacher, strengthened the credibility of the findings by contrasting pedagogical intentions with students' perceptions and needs.

The combination of a deductive theoretical framework based on the TPACK model and the RAÍCES project axes with an inductive reflexive thematic analysis (Braun and Clarke [7]) allowed for a systematic and nuanced interpretation of the data, identifying both expected patterns and relevant emergent elements, such as the importance of the visual component and the ambivalence of competition.

Among the limitations, the study was conducted in a single institutional context, the Universidad San Sebastián Valdivia campus, and with a specific cohort of medical students, which limits the transferability of the findings to other settings. Additionally, it is necessary to acknowledge that the faculty perspective is derived from a single instructor, meaning these specific pedagogical reflections may not represent the broader teaching body of the institution. Crucially, because this research was based on a single Kahoot! intervention, a potential "novelty effect" must be critically considered. The high levels of student motivation, focus, and even the acute evaluative anxiety reported may have been heavily influenced by the unique, disruptive nature of the activity within the standard laboratory routine. If the tool were integrated into a repeated or mandatory framework, these dynamics would likely shift; repeated exposure might normalize the format, thereby mitigating acute time-related anxiety, yet it concurrently risks inducing technological fatigue and diminishing the situational interest observed in this isolated trial.

Furthermore, our recruitment relied on a voluntary sampling strategy, which introduces a distinct self-selection bias. It is highly probable that the 14 students who chose to participate represented more academically engaged or more positive voices within the cohort, potentially overrepresenting favorable perceptions of Kahoot! Consequently, the perspectives of students who experienced severe demotivation, lower academic performance, or technological alienation may have been underrepresented, meaning the full spectrum of socioemotional friction was not entirely captured. Finally, the qualitative approach did not incorporate objective measures of academic performance, and the implementation under a bring your own

XSL•FO
RenderX

device model introduced variability in devices and connectivity, which heavily conditioned the individual user experience.

Future Directions

Future studies could evaluate the impact of a systematic and longitudinal implementation of Kahoot! as a formative assessment strategy in morphology I on objective academic performance indicators, using quasi-experimental designs or comparisons between course sections. It would also be valuable to explore, in a controlled manner, the effects of design variables identified as critical in this study—such as the quality of visual materials, the use of timed responses, and the presence of explanatory feedback—while incorporating complementary measures such as motivation, self-efficacy, cognitive load, and assessment-related anxiety.

Conclusions

Principal Insights and Disciplinary Transferability

This study explored the experiences of students and a teacher regarding the use of Kahoot! as a formative assessment strategy in the morphology I laboratory, showing that its pedagogical value does not lie in the technological tool itself, but rather in its alignment with the disciplinary, evaluative, and pedagogical demands of the course. Kahoot! was perceived as useful when it allowed students to practice the recognition of structures using authentic images under time constraints and in formats comparable to real practical assessments.

In this context, Kahoot! can constitute a relevant and transferable strategy in health sciences education, provided that it is implemented intentionally, with well-designed items, explicit pedagogical feedback, and a conscious consideration of its cognitive and emotional implications. Conceptually, our findings regarding the interplay between rapid image recognition and real-time faculty mediation possess significant transferability to other visually intensive medical disciplines, such as histology, pathology, and radiology. In these fields, undergraduate students face a steep learning curve characterized by a high visual cognitive load, in which they must transition from merely viewing complex structures to instantly recognizing clinical patterns under diagnostic time constraints. By demonstrating that gamified environments can effectively simulate these authentic evaluative pressures, our study offers a broader pedagogical model: digital tools serve as a valuable sandbox to test the "clinical eye," but their educational efficacy remains largely dependent on immediate instructor deconstruction of visual errors to prevent cognitive overload and safely foster diagnostic competence.

The findings indicate that within the scope of the analyzed experiences, the tool functioned primarily as a formative closing activity, supporting self-assessment, diagnosis of learning gaps, and consolidation of learning, rather than as a summative measurement mechanism. However, its formative impact was critically conditioned by the participating instructor's mediation, particularly through the provision of explanatory feedback following each question.

From a socioemotional perspective, gamification fostered motivation, participation, and attention but also activated ambivalent emotional responses associated with competition and time management. These results underscore the need for careful pedagogical design that considers not only students' engagement but also learners' psychological safety.

TPACK-Informed Design Principles and Practical Recommendations

Taken together, the results support the TPACK framework by suggesting that the perceived use and educational value of gamified tools in medical education emerge from the interaction between technology, pedagogy, and disciplinary content. More broadly, these findings suggest that the effectiveness of gamified formative assessment depends less on the digital platform itself than on the pedagogical conditions under which it is implemented. Authentic alignment with disciplinary tasks, immediate explanatory feedback, intentional instructor mediation, and attention to students' socioemotional experiences emerged as potentially transferable design principles that may guide the implementation of gamified formative assessment across visually intensive health professions education.

These findings suggest that educators implementing gamified formative assessment should approach these tools not as stand-alone games but as highly intentional pedagogical interventions. Instructors in visually demanding disciplines should specifically design digital quizzes to mirror the authentic time constraints and visual fidelity of real-world practical assessments. Furthermore, rather than relying on the platform's automated scoring, educators must actively deliver immediate, explanatory feedback between questions. This real-time mediation is essential to transforming the inherent competitive anxiety of gamification into a psychologically safe and meaningful learning opportunity.

Acknowledgments

The authors thank the medical students and the course teacher who participated in this study and shared their perspectives, as well as Universidad San Sebastián for the institutional support provided for the development of the RAÍCES 2 (Red de ayudantes de investigación comprometidos con la educación en salud; Network of Student Researchers Committed to Health Professions Education) project.

Generative AI Use

Generative AI tools (ChatGPT; OpenAI) were used exclusively to support the improvement of the manuscript's academic writing (language, clarity, and readability of the text) and to assist in the translation of the manuscript from Spanish into English, with the aim of enhancing clarity, coherence, and linguistic style. In addition, AI-assisted transcription was used only for the first

Abstract

Background: Competency-based medical education (CBME) in India emphasizes early competency formation, higher-order cognitive processing, and self-directed learning. Although e-learning is widely adopted, there is limited evidence on structured e-modules explicitly designed using Bloom taxonomy and the Miller pyramid for Indian MBBS students.

Objective: This study aims to design, validate, implement, and evaluate CBME-aligned e-modules for first-year MBBS foundational subjects (anatomy, physiology, and biochemistry) and to compare their effectiveness with traditional teaching on cognitive, psychomotor, and affective learning outcomes using Kirkpatrick levels 1 and 2.

Methods: A randomized controlled study was conducted among 690 first-year medical undergraduates (control: n=370; intervention: n=320). The intervention group received Sharable Content Object Reference Model–based interactive e-modules through Moodle (Modular Object-Oriented Dynamic Learning Environment) in addition to standard lectures, while the control group received lectures only. e-Modules were designed using Bloom taxonomy and the Miller pyramid, validated by internal and external experts, and implemented following Kern 6-step approach. Learning outcomes were assessed using structured feedback (Kirkpatrick level 1) and end-of-block internal assessments comprising multiple choice questions, short notes, and objective structured clinical examinations (Kirkpatrick level 2).

Results: Students in the intervention group performed significantly better across all cognitive levels compared with the control group: remember (mean 6.52, SD 2.24 vs mean 5.26, SD 2.89; $P<.001$), understand (mean 2.92, SD 1.45 vs mean 2.55, SD 1.13; $P<.001$), apply (mean 3.43, SD 1.06 vs mean 2.56, SD 1.08; $P<.001$), and analyze (mean 3.01, SD 0.83 vs mean 2.53, SD 1.11; $P<.001$). Psychomotor scores (objective structured clinical examination manipulation: mean 4.55, SD 1.12 vs mean 4.10, SD 1.42; $P<.001$) and affective domain scores (mean 3.02, SD 0.81 vs mean 2.03, SD 0.81; $P<.001$) were also significantly higher in the intervention group. Subgroup analysis showed the largest gains among medium achievers across domains.

Conclusions: CBME-aligned e-modules significantly enhanced student performance in cognitive, psychomotor, and affective domains compared with traditional teaching alone, with particularly pronounced benefits for medium achievers. Well-designed e-modules represent a scalable, adaptable strategy to support CBME implementation across diverse medical education settings in India.

Introduction

Background

The National Medical Commission in India introduced a new approach, known as competency-based medical education (CBME), in 2015 and officially implemented it in 2019 [1]. This updated curriculum encourages new ways of learning, including self-directed learning; elective modules; and training in attitude, ethics, and communication [2,3]. It is aimed at directing medical education to focus more on helping students build essential skills, such as critical thinking and decision-making.

While traditional lectures often struggle to maintain student interest and foster deeper understanding and critical reasoning skills [4,5], e-learning (computer-assisted learning), which uses electronic devices to support teaching and learning, is becoming increasingly popular [6]. A common way e-learning helps is through blended learning, which mixes classroom teaching with online materials, such as tutorials [7]. One such tool is e-modules. An e-module is defined as an e-learning strategy, which focuses on 1 or 2 learning concepts, usually incorporating a blend of teaching and assessment tools that may include multimedia, video clips, direct lecture instruction, game-based activities, and even links to social media [8,9] to help students stay engaged and learn better [7]. Such tools have been shown to improve short-term memory and keep learners engaged [10]. They are found useful in early medical training, where complex theory can be better understood through interactive content [11]. However, for e-learning to be successful, it must consider cognitive limitations and learning preferences [12].

Rationale

The COVID-19 pandemic led to a rapid increase in digital learning tools [13], and research over time has shown that these tools can help students gain both knowledge and skills [14,15]. CBME is based on well-known learning frameworks, such as Bloom taxonomy [16] and the Miller pyramid [17], which help structure learning in a step-by-step way. Yet, the use of digital modules built on these frameworks is limited [18]. There is a clear gap, and few studies have developed or tested e-modules created specifically for Indian medical students, especially those based on Bloom and Miller models [19].

Moreover, to evaluate training programs, studies in the past have not applied comprehensive evaluations of the Kirkpatrick model to assess e-learning interventions in medical education [20]. A study evaluating a teaching workshop for health care staff has used the first 3 levels, demonstrating improvements in satisfaction, knowledge, and behavior [8]. Such evaluations specifically targeting e-learning modules for Indian medical undergraduates are limited.

Study Objectives

Thus, this study aimed to develop, validate, implement, and evaluate e-modules tailored for Indian medical undergraduates. The objectives of the study are as follows:

1. To design e-modules for first-year MBBS foundational disciplines (anatomy, physiology, and biochemistry), using Bloom taxonomy and the Miller pyramid to target cognitive, affective, and psychomotor competencies outlined in the Indian CBME curriculum.
2. To evaluate the effectiveness of these e-modules, implemented through Moodle-SCORM (Modular Object-Oriented Dynamic Learning Environment–Sharable Content Object Reference Model), in comparison with traditional classroom teaching by examining learning outcomes across cognitive, psychomotor, and affective domains using Kirkpatrick levels 1 and 2.

This study provides one of the first large-scale evaluations of theory-driven e-modules designed specifically for Indian medical undergraduates, addressing a critical gap in CBME-aligned digital learning research. By addressing these objectives, this study seeks to bridge the gap between pedagogical strategies and technological advancements in medical education, ultimately enhancing the competency and preparedness of future health care professionals.

Methods

Study Design and Setting

This randomized controlled study was conducted between 2015 and 2018 at a tertiary medical university in south India. The study followed the Kern 6-step approach [7,21] for curriculum development and aimed to evaluate the effectiveness of e-learning modules, designed using Bloom taxonomy and the Miller pyramid, in enhancing learning outcomes among first-year MBBS students.

Ethical Considerations

This study received ethical approval from the Institutional Ethics Committee of Sri Ramachandra University, Chennai, India (Approval No: IEC-NI/12/OCT/30/53, approved on March 24, 2014). All procedures were conducted in accordance with the ethical standards of the institutional review board and the principles of the Declaration of Helsinki.

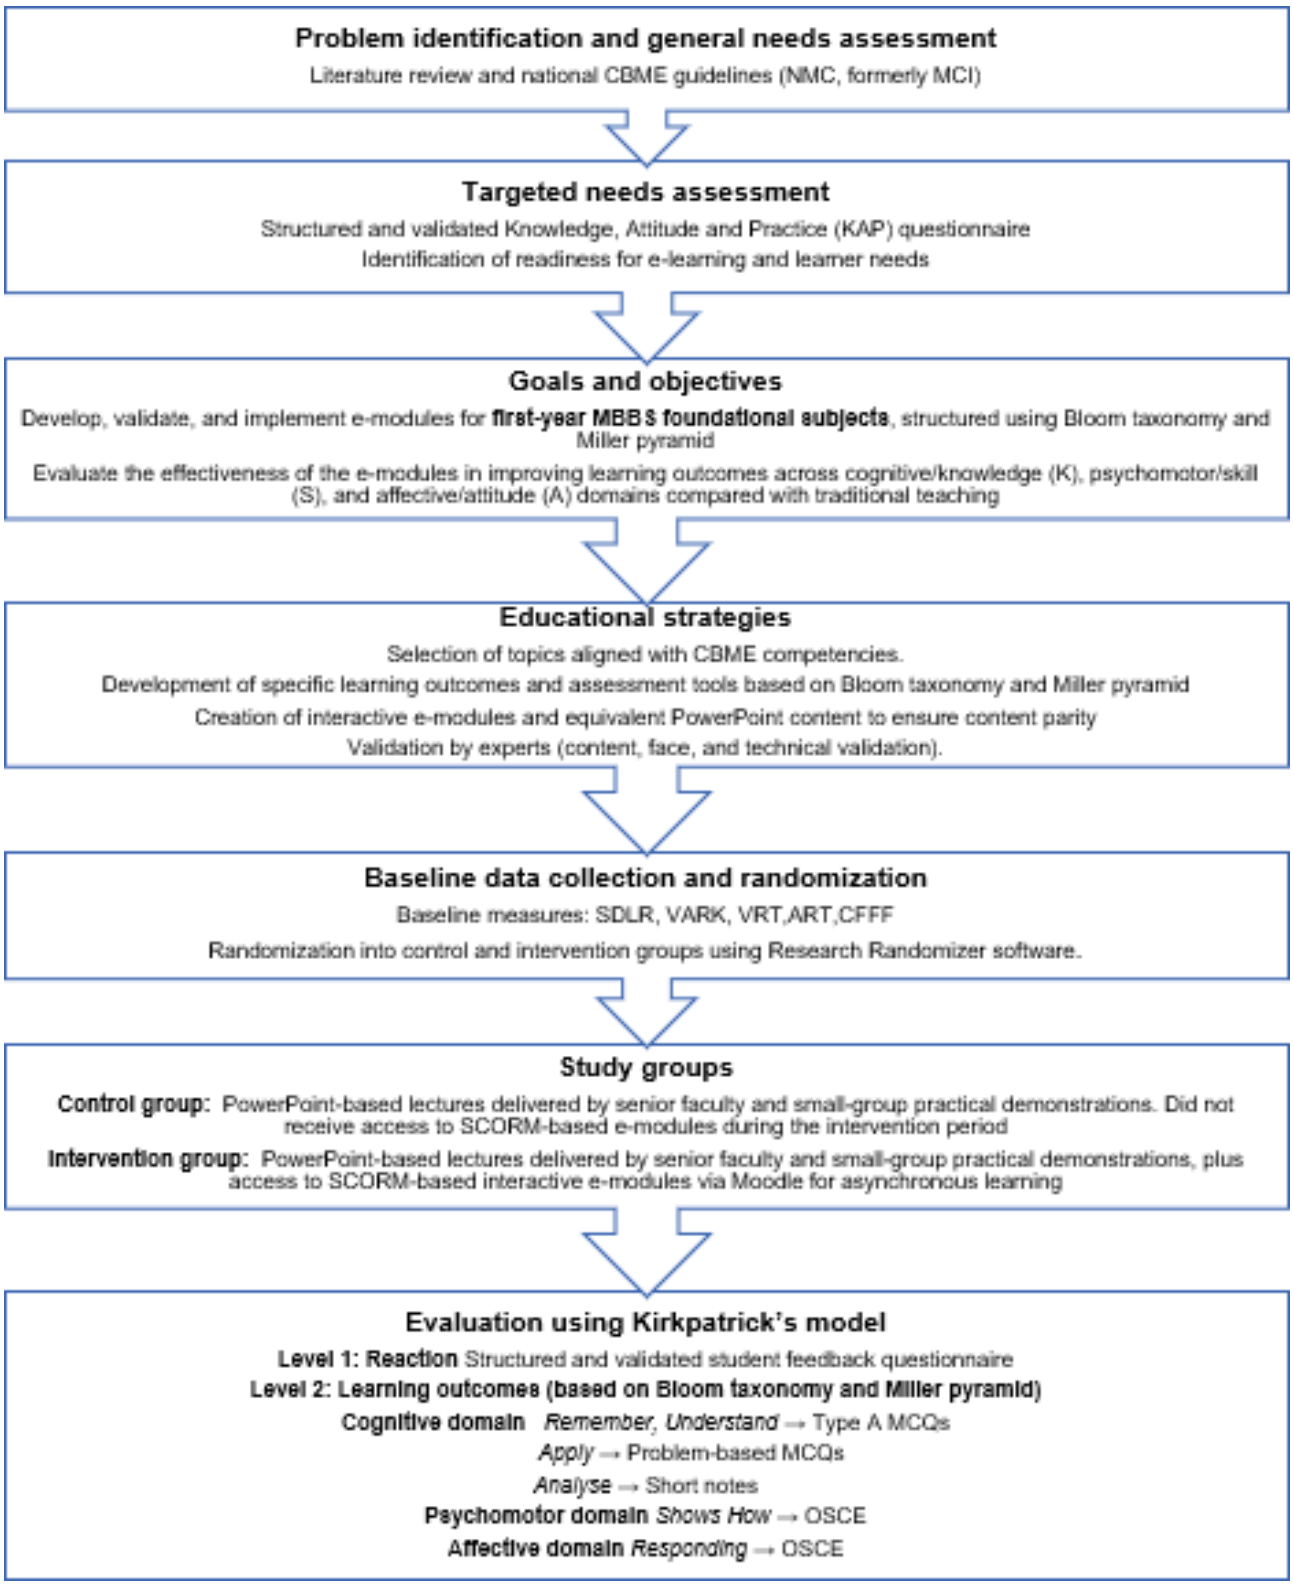
Participation in the study was voluntary, and all participants were informed about the purpose and procedures of the study prior to participation. Written informed consent was obtained from all participants. Participant privacy and confidentiality were strictly maintained. Data were anonymized prior to analysis, and no personally identifiable information was included in the dataset used for analysis or in the reporting of results. Participants did not receive any financial compensation or incentives for their participation in this study.

Participants and Randomization

A total of 690 first-year MBBS students enrolled during the study period were invited to participate. Students who completed all baseline assessments and attended the scheduled end-of-block internal assessments (EBIAs) were included in the final analysis.

Students were randomized into control and intervention groups using the Research Randomizer software (version 4.0; Geoffrey C. Urbaniak and Scott Plous; Multimedia Appendix 1).

- Control group: This group received standard PowerPoint (Microsoft Corp) lectures



XSL•FO
RenderX

- Intervention group: This group received both PowerPoint lectures and e-modules via Moodle with unique login credentials (Multimedia Appendix 2)

All students in the control group gained access to e-modules after the end-of-block assessment to ensure equitable learning opportunities.

The steps followed for data collection are shown in Figure 1.

Figure 1. Flowchart of curriculum development, implementation, and evaluation steps based on Kern 6-step approach and the Kirkpatrick model. ART: auditory reaction time; CBME: competency-based medical education; CFFF: critical flicker fusion frequency; MCI: Medical Council of India; NMC: National Medical Commission; OSCE: objective structured clinical examination; SDLR: self-directed learning readiness; SLO: specific learning outcomes; VARK: visual auditory reading kinesthetic; VRT: visual reaction time.

XSL•FO
RenderX

Targeted Needs Assessment

The data were collected using a structured and validated knowledge, attitude, and practice questionnaire (Multimedia Appendix 3) [6,10]. Knowledge, attitude, and practice analysis revealed high digital readiness, with all students owning internet-enabled devices, most confident in basic software use and strongly favoring interactive e-modules in education.

The results emphasized the need to develop self-directed e-learning tools tailored to the diverse learning styles of Indian medical undergraduates. E-learning strategies were identified as essential for the rapid and effective implementation of new curricula.

Educational Intervention

Selection of Topics

Four topics were selected based on global or national significance, core learning relevance, feasibility, faculty expertise, and alignment with the curriculum. A list of e-modules addressing the specific CBME competencies and learning objectives aligned with respective assessment tools was categorized under Bloom taxonomy and the Miller pyramid (Multimedia Appendix 4). The selected e-modules covered core foundational topics from anatomy, physiology, and biochemistry that map directly to first-year CBME competencies.

Development of e-Modules

e-Modules were developed as structured, interactive learning tools aligned with CBME competencies. Content (text, images, and animations) was created collaboratively by subject experts and educational technologists using standard multimedia authoring software. Visual elements were sourced from textbooks and open-access repositories in accordance with fair-use guidelines, and additional illustrations were created where needed (Multimedia Appendix 5).

Platform (Moodle-SCORM) and Delivery Approach

Multimedia components, including narration, animations, and interactive elements, were combined to produce SCORM-compliant packages suitable for delivery via Moodle. Each module included embedded self-assessment exercises (multiple choice questions [MCQs], case scenarios, and concept-based questions) with automated scoring and immediate feedback (Multimedia Appendices 6 and 7).

To ensure content equivalence, identical learning material (text and images) was used to create accompanying PowerPoint presentations for the control group, thereby avoiding content bias between instructional formats.

Validation of Learning Materials

The e-modules and PowerPoint were proofread and face-validated by students (second-year undergraduate students who were not part of this study). Content validation and technical validation were done by 2 internal and 2 external experts, following a structured checklist (Multimedia Appendix 8). Suggestions by the students and experts were incorporated wherever possible and feasible. There were certain similarities and differences between PowerPoint (2016) and the e-modules used in this study. Both platforms made use of text, images, audio, video, and animations. However, e-modules offered several interactive features over PowerPoint, such as interactive images, easy navigation with a toolbar or index, self-assessment with specific feedback, competitive scoring, and access restrictions based on performance. Additionally, e-modules enabled the tracking of student performance and the generation of reports, making them a more dynamic and data-driven learning tool compared to PowerPoint. Modules were converted into Sharable Content Object Reference Model (SCORM, 2016) format for integration into a Moodle (2016) [22].

Copyright and Intellectual Property

The developed e-modules were submitted for copyright registration and granted under L-83129/2019.

Baseline Measures

Before implementation, the data on self-directed learning readiness [23] and learning styles (Visual, Aural, Read/Write, and Kinesthetic questionnaire version 7.8) [24], visual reaction time, auditory reaction time, and critical flicker fusion frequency were collected. These measures were used to describe the learner profile and explore potential associations with learning outcomes, without influencing group allocation or intervention intensity. Prior authorization was obtained for administering these questionnaires (Multimedia Appendix 9). Although the self-directed learning readiness scale was administered during the study period (2015 - 2018), we have cited the 2021 validation study as the most current reference establishing construct validity in Indian MBBS learners. The scale itself predates this reference, and no post-2018 findings were incorporated into data collection or analysis.

Assessment Framework

The effectiveness of e-modules was based on the Kirkpatrick learning evaluation model [25]. Table 1 shows the different levels of the Kirkpatrick learning evaluation model, learning domains, and corresponding tools of evaluation used in this study.

XSL•FO
RenderX

Table . Evaluation of the effectiveness of e-modules based on the Kirkpatrick learning evaluation model.

[e]Classification by Dave, 1970 [26].

Level 1: Evaluation of Reaction

The students' reactions were evaluated using a structured and validated feedback questionnaire containing open- and closed-ended questions (Multimedia Appendix 10). The quantitative results of the evaluation of reaction and qualitative data were transcribed word by word verbatim in a Word document and analyzed thematically using a deductive coding approach (Multimedia Appendix 11).

Level 2: Evaluation of Learning

Evaluation of learning was assessed through MCQs (designed appropriately to assess "Remember," "Understand," and "Apply" levels of Bloom taxonomy) and short notes (designed to assess "Analysis" level) in the EBIA.

Standardization of EBIA

Fifteen MCQs (combination of levels of remember, understand, and application), 4 short notes (analysis level), and 1 structured essay totaled 50 marks. Question papers followed standardized blueprints and were administered within 90 minutes under invigilated conditions. The difficulty index was comparable with other EBIAs held during the academic year.

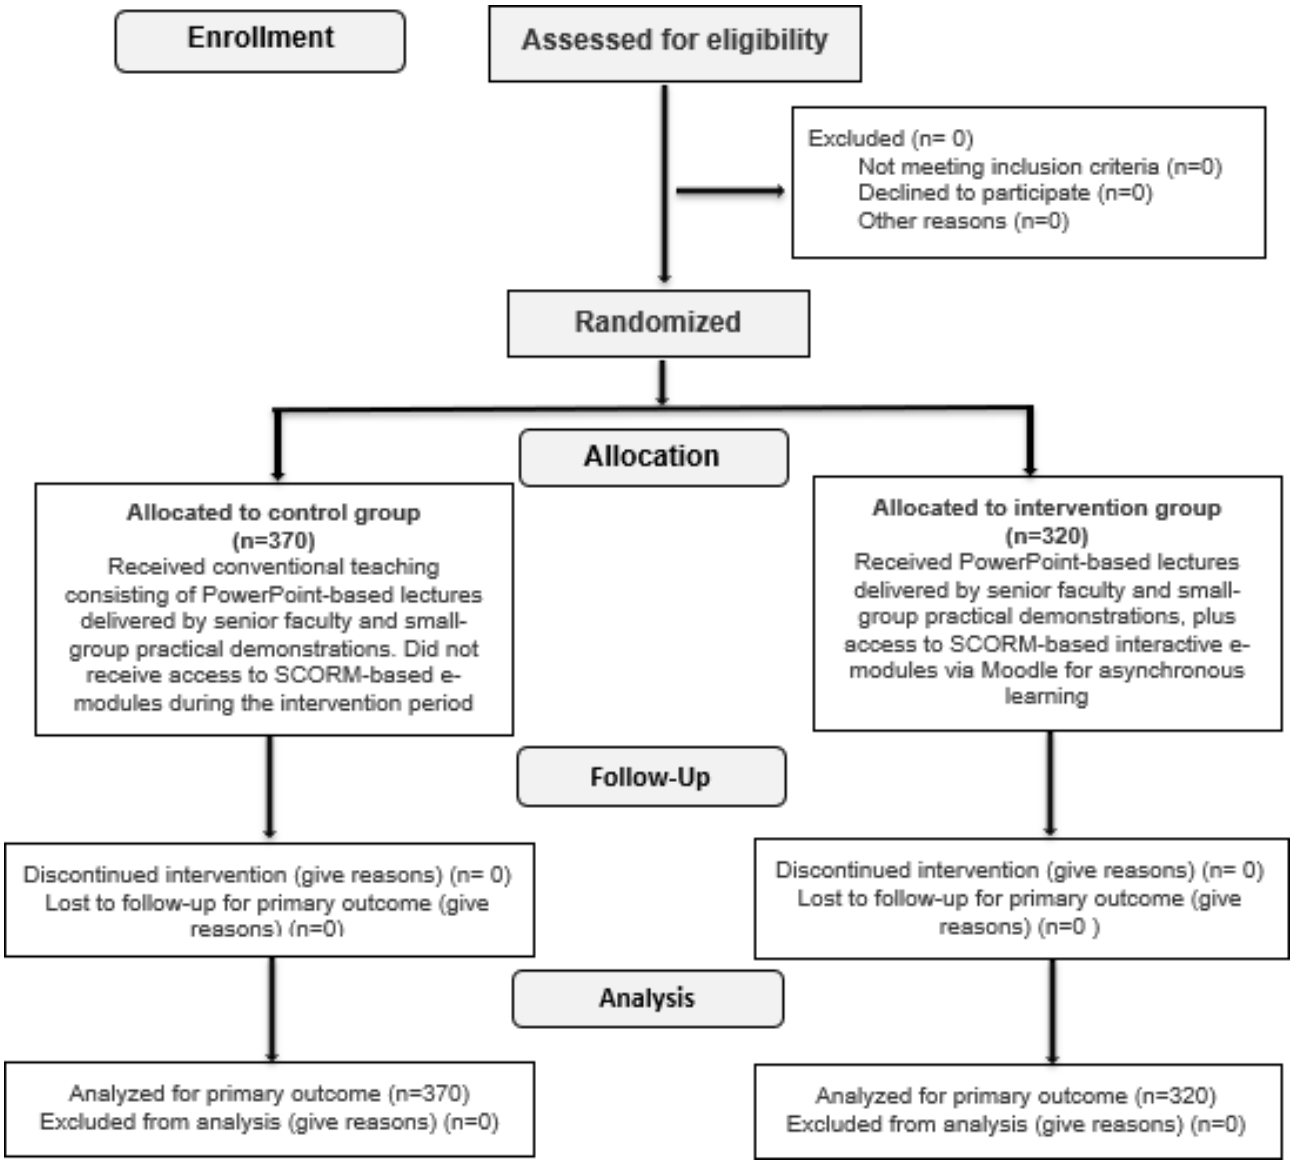
Outcome Measures and Scoring Procedures

Each internal assessment was graded by a single designated faculty member, as per the examination policy of the host university. All faculty involved in this research were exempted from any duty related to assessment and evaluation as per the examination or research ethics policy of the host university. This practice was intentionally adopted to maintain scoring consistency and minimize variability or rater-related bias (eg, halo effect). To further ensure fairness and uniformity, all answer sheets were anonymized using dummy roll numbers prior to evaluation. Additionally, the evaluating faculty member was provided with a standardized marking guide (answer key or scoring rubric) that detailed the expected key points and the corresponding marks to be awarded. This ensured transparent and objective grading across all responses.

Statistical Analysis

The data were analyzed using standard descriptive and inferential statistics. Continuous variables were summarized as means and SDs. Group comparisons were performed using independent 2-tailed *t* tests.

Effect sizes (Cohen *d*) were calculated to quantify the magnitude of differences between the groups across cognitive, psychomotor, and affective domains. Subgroup analyses were conducted to examine differential effects among high, medium, and low academic achievers. Students were categorized into low achievers (<40% in previous assessments) and high achievers (>70% in previous assessments) to analyze differential learning impacts within the control and intervention groups. A significance level of $P<.05$ was adopted for all analyses.



Results

Participant Characteristics

A total of 690 first-year undergraduate students participated in this study. The steps followed in participant enrollment, allocation, follow-up, and analysis are shown in Figure 2. The participants randomly assigned to the control groups were comparable in terms of baseline characteristics (Table 2). All students completed baseline assessments and the EBIAs.

Kirkpatrick Level 1: Student Reactions

During level 2, the intervention group received e-modules in addition to traditional lectures and outperformed the control group across all cognitive domains. The intervention group showed superior performance in motor and affective domains, indicating that e-modules significantly improved student performance not only in knowledge acquisition but also in practical skills and attitudinal engagement. Table 3 shows that students in the intervention group consistently outperformed the control group across all cognitive levels. The largest differences were observed in the apply and analyze domains, indicating that the e-modules were particularly effective in promoting higher-order thinking. All comparisons were statistically significant ($P<.001$), demonstrating a meaningful advantage of the blended e-learning approach.

[b]MCQ: multiple choice question.

[c]SAQ: short answer question.

[d]OSCE: objective structured clinical examination.

Kirkpatrick Level 2: Learning Outcomes

Cognitive Outcomes

Students who received the e-modules demonstrated significantly higher performance across all cognitive levels assessed (Table 3). Effect sizes ranged from small to large: remember (*d*=0.48; 6.52 vs 5.26; *P*<.001), understand (*d*=0.29; 2.92 vs 2.55; *P*<.001), application (*d*=0.81; 3.43 vs 2.56; *P*<.001), and analysis (*d*=0.48; 3.01 vs 2.53; *P*<.001). The large effect size for application skills indicates that e-modules were particularly effective in enhancing students' problem-solving abilities.

Psychomotor Outcomes

The intervention group demonstrated superior psychomotor performance (*d*=0.35; 4.55 vs 4.10; *P*<.001), suggesting that visual demonstrations and procedural guidance in e-modules effectively enhanced motor skill acquisition.

Affective Outcomes

Affective skills showed the most substantial improvement (*d*=1.21; 3.02 vs 2.03; *P*<.001), with the largest effect size across all domains. This highlights the exceptional value of structured e-modules with visual explanations, role-modeling, and repeated exposure to professional behaviors for developing interpersonal competencies and professional attitudes—outcomes traditionally challenging to achieve through conventional teaching.

Subgroup Analysis

The impact of e-modules was found to vary across different achievement groups (Table 4). Subgroup analysis revealed that the intervention was particularly effective among medium achievers, showing significant improvements across all domains (*P*<.001 for all comparisons). High achievers in the intervention group showed significant improvements in application (*P*<.001) and affective domains (*P*<.001). Low achievers demonstrated significant improvements in understanding (*P*<.001), application (*P*<.001), analysis (*P*=.01), and affective domains (*P*<.001).

Discussion

Summary of Principal Findings

In this randomized controlled study of 690 first-year MBBS students, we found that e-modules, when added to traditional teaching, significantly improved cognitive, psychomotor, and affective domain scores compared with lectures alone, with the greatest gains seen among medium achievers. The study contributes to medical education literature by demonstrating how structured, theory-driven e-modules, explicitly designed for the Indian CBME environment, can support competency development at scale. While prior studies have examined e-learning in general, few have contextualized module design within India's national curriculum reforms, digital readiness variations, and large cohort teaching realities. By aligning the e-modules with Bloom and Miller frameworks and evaluating them using the Kirkpatrick model, this study provides a comprehensive pedagogical and contextual analysis that is highly relevant for Indian medical colleges transitioning to CBME.

Interpretation of Findings Using Educational Frameworks: Integrating Bloom Taxonomy and the Miller Pyramid in e-Module Design

The decision to implement the e-modules within first-year MBBS foundational subjects (anatomy, physiology, and biochemistry) was intentional, as these disciplines carry a high cognitive load and require extensive visualization and conceptual integration. Early exposure to structured, interactive digital learning in these subjects can strengthen foundational understanding, support the development of higher-order competencies, and better prepare students for subsequent clinical learning, where the CBME framework expects early competency formation.

The development and implementation of the e-module were carefully structured around Bloom taxonomy and the Miller pyramid to ensure a progressive, competency-based learning experience. These frameworks provided a solid foundation for designing digital learning tools that promote cognitive development and practical skill acquisition, aligning well with CBME.

To ensure a structured learning progression, Bloom taxonomy guided the organization of learning objectives within the module. This structured approach ensured that students moved beyond rote memorization [28] and developed deeper conceptual understanding and analytical skills. In addition to cognitive development, the Miller pyramid was integrated to ensure that learning translated into practical competence. By blending theoretical content with multimedia demonstrations and self-assessments, the module ensured that students were not only gaining theoretical knowledge but also demonstrating their ability to apply concepts in practical scenarios.

XSL•FO
RenderX

This study further evaluated the effectiveness of e-modules in medical education using the Kirkpatrick learning evaluation model, which assesses learning outcomes across 4 levels. The study specifically examined level 1 (reaction) and level 2 (learning), focusing on cognitive, affective (attitude), and psychomotor (skill) domains. e-Modules were found to significantly enhance student engagement, knowledge acquisition, skill performance, and professional attitudes in students, reinforcing their role as an effective supplement to traditional teaching methods.

Level 1: Reaction—Student Perception of e-Modules

e-Modules effectively captured students' interest and enhanced engagement, both of which are critical for promoting active learning. The use of interactive modules allows students to learn at their own pace, integrating clinical knowledge with foundational sciences, crucial for effective learning in medical education [29]. It has also been seen in previous works that integrated modular systems are more effective than traditional methods, promoting critical thinking and innovation among students [30]. These systems allow flexibility and adaptability to individual learning needs, which can lead to improved academic performance and satisfaction [30]. Students also expressed a strong preference for a blended learning approach, advocating for e-modules as a supplement rather than a replacement for traditional teaching.

Level 2: Learning—Cognitive, Affective, and Psychomotor Outcomes

In terms of knowledge recall (remember), students in the intervention group were significantly better than those in the control group in recalling factual knowledge. However, low-achieving students did not show statistically significant improvements, likely due to difficulties in retaining information without contextual application. To enhance their learning, strategies, such as spaced repetition and adaptive quizzes, could be incorporated in e-modules to reinforce knowledge retention and provide targeted support [31].

For conceptual comprehension (understand), the e-module significantly improved comprehension for low and medium achievers, while high achievers showed minimal gains. This could be attributed to the fact that high-achieving students already have a strong conceptual foundation, making additional learning less impactful for them. To cater to this subgroup, future iterations of the module should integrate advanced case–based learning and real-world problem-solving tasks to challenge their cognitive abilities further [32]. When assessing problem-solving skills (apply), students in the intervention group showed significantly higher improvements. This finding underscores the module's effectiveness in developing clinical reasoning and problem-solving abilities. Medium and low achievers benefited the most, suggesting that structured digital learning can help bridge performance gaps and create a more equitable learning experience. The effectiveness of e-modules in promoting critical thinking and higher-order learning (analyze) was evident through significant improvements in analysis-level assessments.

The impact of e-modules varied across different student groups. Medium achievers showed the most substantial gains across all cognitive levels. Their foundational knowledge gaps were likely addressed through the structured nature of the e-modules, allowing them to engage more effectively with new learning strategies. Low achievers demonstrated notable improvements in comprehension and application, indicating that e-modules serve as effective platforms for conceptual learning. In contrast, high achievers exhibited smaller relative gains, possibly due to their prior familiarity with the concepts covered. This finding aligns with past works, which also found that digital learning tools have the most impact on students with moderate baseline proficiency, while high-achieving students experience diminishing returns [33,34]. Students with moderate proficiency are often seen to benefit from digital learning tools as they enhance essential digital skills and cater to their specific learning needs, which are crucial for academic success [33,34].

Conversely, high-achieving students may already possess the skills and motivation to excel without the additional support of digital tools, potentially diminishing their relative impact [35,36]. Also, self-directed and problem-based learning approaches are more effective for high-achieving medical students, as they provide greater cognitive flexibility and autonomy compared to structured digital modules [37]. Studies have emphasized that digital learning tools designed for high achievers should incorporate more advanced problem-solving tasks, adaptive difficulty levels, and research-oriented challenges to maintain engagement and maximize learning outcomes [38-40].

Effectiveness of e-Modules Across Progressive Levels (the Miller Pyramid)

This study's findings align with the Miller framework, demonstrating that e-modules were particularly beneficial in progressing students from basic knowledge acquisition to higher-order thinking and practical application.

Knowledge Acquisition (Knows)—Remembering and Understanding

Students in the intervention group outperformed those in the control group in both of these domains. e-Modules enhanced students' ability to recall and comprehend medical concepts more effectively than traditional lectures alone. This aligns with previous studies, where digital learning tools significantly improved retention and understanding in medical students by integrating multimedia, interactive elements, and adaptive learning [40,41].

Additionally, the effectiveness of e-learning in knowledge acquisition has been reported in studies on flipped classrooms [42]. Students who engaged with online modules before in-person sessions demonstrated better long-term retention compared to those relying solely on lectures.

Application of Knowledge (Knows How)—Application and Analysis

Low achievers and high achievers have performed significantly well in the intervention group, suggesting that e-modules facilitated deeper learning and cognitive processing, allowing

XSL•FO
RenderX

students to synthesize and apply knowledge to real-world scenarios. It was similarly found in past studies that interactive e-learning modules significantly improved students' problem-solving skills in clinical case studies [43-46]. Digital resources, when designed with active learning strategies, such as those integrated into these e-modules, enhance analytical reasoning, reduce cognitive overload [47], and improve knowledge retention and conceptual understanding [48,49].

Demonstration of Skills (Shows How)—Psychomotor Domain

The motor skills of students assessed using OSCEs were also significantly higher in the intervention group. The results suggest that interactive, visual, and simulation-based e-modules are effective in improving hands-on procedural skills, which is an essential aspect of medical training. The finding concurs with other studies that the use of computer technology enables learners to be active in the learning process, construct knowledge, develop problem-solving skills, and analyze the given situation to discover alternative solutions [50]. Studies have also found that virtual simulations and video-based learning improve students' psychomotor skills, particularly in clinical scenarios where real-life practice opportunities are limited [51,52]. Simulation-based e-learning has been found as effective as traditional hands-on training in improving procedural skills [53]. Moreover, the integration of e-modules with interactive video demonstrations likely enhanced motor learning [54].

Professionalism and Attitudes (Does)—Affective Domain

The affective domain is often neglected in traditional didactic education. Studies suggest that interactive, self-paced learning methods enhance students' motivation and self-directed learning behaviors [55], developing greater autonomy in medical education [56]. The incorporation of self-assessment, feedback, and real-life clinical scenarios in e-modules likely contributed to this improvement.

Implications for CBME Implementation

The successful implementation of the e-module demonstrates that technology can enhance medical education by making complex concepts more accessible and promoting independent learning. One of the key takeaways is the role of technology as a catalyst for learning. The e-module supports self-directed learning by allowing students to engage with content at their own pace. This aligns with the growing emphasis on student autonomy and flexible learning within medical education [56]. Another critical aspect is the scalability and adaptability of the e-module. Its modular design allows for easy adaptation across various medical disciplines.

Recommendations for Future Research

Future e-module designs should include differentiated instructions to address varied learning needs. CBME can benefit from hybrid models that combine e-modules with case-based learning and simulations, developing deeper engagement and critical thinking, particularly among high achievers. Adding gamified elements and competitive assessments may help sustain motivation across all student levels. Future research should extend evaluation to Kirkpatrick levels 3 and 4, examining behavior change during clinical postings and long-term impact on competency attainment in later MBBS phases. The integration of advanced adaptive learning, analytics dashboards, and gamification may further strengthen national-level CBME implementation.

Limitations of the Study

This study has several limitations. The study was conducted between 2015 and 2018, and some technologies used (such as Adobe Flash) are now deprecated. While this does not affect the internal validity of the study, it limits immediate scalability of the exact modules in their original form. However, as all modules were exported into Moodle-compatible SCORM packages, the instructional design and learning architecture remain fully transferable to modern authoring tools. Additionally, the literature cited in this study spans both the study period and recent years, consistent with standard academic practice for studies reporting older datasets. Contemporary sources were intentionally included to ensure that the interpretation and implications of the findings align with current developments in CBME, e-learning research, and medical education frameworks. These later references did not inform the original study design or data collection but were used solely for contextualization. It involved only first-year medical students, limiting the generalizability of the findings. The focus was on short-term outcomes (Kirkpatrick levels 1 and 2), without examining long-term behavior changes or clinical impact. While most students had access to devices and the internet, differences in internet speed or device quality were not fully considered, which may have affected learning. Instructor-related bias is also possible, as differences in teaching style could have influenced results despite standardized content. Finally, while student feedback was gathered, detailed engagement data, such as time spent, interaction frequency, or assessment attempts, were not thoroughly analyzed.

Conclusion

Well-designed e-modules, when combined with traditional teaching, can significantly enhance learning by using clear goals aligned with Bloom taxonomy and the Miller pyramid for undergraduate medical students. They helped students not only remember and understand content but also apply it and develop stronger attitudes and skills. Students across performance levels benefited, with average performers improving the most. Positive feedback and better test scores indicate that e-modules are a valuable addition to medical education, though they work best as supplements rather than replacements. These tools can be expanded to other subjects and learner levels to support more flexible and engaging learning. With CBME now uniformly implemented across India, scalable e-modules aligned with national competencies could promote more equitable learning, especially in resource-limited institutions. The findings support national strategies that use structured e-learning to strengthen and standardize instructional quality.

Abstract

Background: Motivational interviewing (MI) is a patient-centered communication approach that supports health behavior change; yet, its integration into undergraduate medical curricula remains inconsistent. Combined learning models that comprise face-to-face instruction with structured web-based components may strengthen MI training, but evidence supporting their effectiveness among medical students, particularly in Asian contexts, is limited.

Objective: This study evaluated the impact of a combined MI educational model on final-year medical students' MI knowledge, confidence, and application in real patient encounters during clinical rotations.

Methods: This study used a sequential explanatory mixed methods design. The quantitative component used a before-and-after study to evaluate changes in MI knowledge and confidence among final-year medical students enrolled in an Ambulatory Care course in 2024. All 130 students participated in a 2-hour interactive MI workshop, and 120 completed pre- and postintervention questionnaires assessing MI knowledge and self-reported confidence. Students were also provided access to a 3-hour web-based MI learning module, and learning-management system analytics were used to track engagement. The qualitative component consisted of semistructured interviews with 12 purposively selected students, conducted to explore their experiences applying MI during clinical encounters. Quantitative data were analyzed using paired-samples *t* tests, and qualitative data were analyzed using inductive conventional content analysis. Findings from both components were integrated during interpretation to provide a comprehensive understanding of the educational intervention.

Results: Students demonstrated a significant improvement in MI knowledge following the educational intervention (pretest mean 8.87, SD 2.69; posttest mean 15.04, SD 2.99; $t_{1\ 1}$ =–18.45; P<.001; η^2=0.74). After the workshop, 96.9% (126/130) of students reported applying MI with patients, and 92.3% (n=120) agreed that the combined learning approach was adequate for supporting clinical use. Learning analytics data showed that 76.9% (n=100) of students enrolled in the web-based MI module, and 51% (n=51) completed all lessons. Students most frequently applied MI when counseling patients with diabetes, hypertension, and dyslipidemia, especially related to diet, physical activity, and medication adherence. Interview findings indicated that students mainly used brief MI, were most comfortable with engaging and focusing, and developed greater empathy, confidence, and patient-centered communication skills. Challenges included limited time during consultations, clinical workload, and difficulty applying all MI processes to complex cases.

Conclusions: A combined MI learning approach integrating a short workshop with a web-based course was associated with higher MI knowledge scores and greater self-reported confidence among students, as well as reported use of MI-informed communication strategies during clinical encounters. Students perceived MI as a practical and ethically grounded communication approach that can enhance patient engagement, particularly in the management of chronic diseases. Introducing MI training longitudinally through a spiral curriculum, with opportunities for repeated practice and reinforcement, may help strengthen behavior-change communication competencies in undergraduate medical education.

Introduction

Background

Patient-centered communication is a fundamental component of effective clinical practice and plays a critical role in promoting health behavior change and improving clinical outcomes [1-5]. Physicians frequently engage in patient education during routine consultations, particularly when managing chronic diseases such as diabetes, hypertension, and cardiovascular conditions that require sustained lifestyle modification and self-management [1]. Evidence suggests that structured patient education interventions can improve clinical outcomes across a wide range of conditions, including cardiovascular disease, diabetes, respiratory disorders, and mental health conditions [1,2]. Effective patient education is typically supported by communication approaches that emphasize patient engagement, individualized counseling, and shared decision-making [6,7].

Among the various communication strategies used to support behavioral change, motivational interviewing (MI) has emerged as one of the most widely studied and evidence-based approaches [8]. MI is a collaborative, patient-centered counseling method developed by Miller and Rollnick [8] that aims to strengthen individuals' motivation and commitment to change by exploring and resolving ambivalence [9]. The approach emphasizes empathy, collaboration, and respect for patient autonomy while guiding patients toward identifying their own motivations for change. Over the past 3 decades, MI has been applied across a wide range of health care settings and clinical conditions [9,10].

A growing body of evidence demonstrates that MI can effectively support improvements in health behaviors and clinical outcomes [9-15]. Systematic reviews and meta-analyses have shown that MI interventions are associated with increased physical activity, smoking cessation, weight reduction, improved glycemic control, and reductions in alcohol consumption and other health-risk behaviors [11-14]. MI has also been successfully implemented in primary care settings, where physicians frequently counsel patients on lifestyle modification and chronic disease management [15-17]. However, despite its demonstrated effectiveness, studies indicate that motivational and patient-centered communication techniques remain underused in routine clinical practice, partly due to insufficient training among health care professionals [16,17].

Recognizing the importance of behavior-change communication, medical education programs have increasingly explored ways to incorporate MI training into undergraduate curricula [1]. Previous studies have shown that MI can be successfully taught to medical students and other health professional trainees using a variety of instructional strategies, including workshops, role-play exercises, coaching, and supervised practice [18,19]. These educational interventions have been associated with improvements in students' communication skills, confidence, and readiness to support patient behavioral change [20-22]. In addition, training in MI may help students develop transferable clinical communication skills such as reflective listening, open-ended questioning, and affirmation, which are valuable across many areas of clinical practice [6,23].

Despite these promising findings, several challenges remain in integrating MI training into medical curricula. Existing educational programs vary widely in duration, teaching methods, and assessment approaches, and there is no widely accepted standard model for MI education in undergraduate medical training [1,18,19,24-26]. In many programs, MI instruction is limited to short workshops without sufficient opportunities for reinforcement, practice, or longitudinal integration. As a result, the sustained application of MI skills in clinical practice remains inconsistent [10,24,25].

Multifaceted or combined educational methods comprising face-to-face instruction with web-based learning modules have been proposed as a promising strategy for improving MI training [14,27]. Such approaches allow learners to acquire foundational knowledge through flexible online learning while using in-person sessions for interactive practice and feedback. Emerging evidence suggests that combined educational methods can enhance learner engagement, knowledge retention, and skill development compared with traditional teaching methods alone [18,19,28]. However, relatively few studies have examined the effectiveness of combined MI training models among undergraduate medical students, particularly in Asian and low- and middle-income educational contexts [18,19,26].

Although MI training has been studied in medical education, relatively little research has examined how combined educational approaches comprising in-person workshops with web-based modules can be implemented within undergraduate medical curricula in resource-constrained educational settings. This study therefore evaluated the implementation of a combined learning approach for introducing MI to final-year medical students in Thailand and explored students' learning experiences and reported application of MI during clinical training.

Our Medical School Curriculum

Our medical school, located in northeastern Thailand, enrolls approximately 310 students annually. The 6-year undergraduate medical curriculum consists of a premedical phase, a preclinical phase, and a clinical phase, totaling 259 academic credits [29,30]. The first year focuses on premedical education (38.5 credits), while the second and third years emphasize preclinical sciences (76.5 credits). Clinical education occurs during years 4 to 6 and comprises 96 credits during years 4 and 5, followed by 48 credits during the final-year clinical rotations [30].

The learning outcomes of the curriculum are categorized into 3 domains: fundamental knowledge, professional competency, and professionalism. Communication skills are included as a core competency under the professionalism domain. Communication training is integrated throughout both preclinical and clinical courses; however, structured training specifically focused on behavior-change communication techniques has not been mandatory in the curriculum.

Before the 2024 academic year, some students may have been exposed to MI informally during clinical rotations in psychiatry. Beginning in the 2024 academic year, MI training was formally introduced as a compulsory component of the final-year

XSL•FO
RenderX

curriculum within the Ambulatory Care in Primary Care Setting course, where this study was conducted.

Final-year medical students participating in this course have already completed core clinical rotations and are actively involved in outpatient care under faculty supervision. During these rotations, students conduct patient interviews, participate in clinical decision-making, and provide counseling for chronic disease management. This clinical environment provides opportunities for students to apply behavior-change communication techniques such as MI during real patient encounters.

Methods

Study Design

Overview

This study used a sequential explanatory mixed methods design consisting of 2 complementary phases. In the first phase, a quantitative before-and-after evaluation was conducted to assess changes in final-year medical students' knowledge in MI following participation in the educational intervention.

In the second phase, semistructured qualitative interviews were conducted after completion of the quantitative data collection to further explore students' experiences in learning and applying MI during clinical encounters. The qualitative component was designed to help explain and contextualize the quantitative findings, particularly regarding how students applied MI in real clinical settings and the challenges they encountered when using MI with patients. The integration of quantitative and qualitative findings provided contextual insights into students' learning experiences and complemented the quantitative results.

As the training was implemented as part of the required curriculum for all students, a comparison group was not feasible; therefore, this study was designed as an educational program evaluation rather than an experimental effectiveness study.

Participants

This study's population consisted of final-year medical students enrolled in the "Ambulatory Care in Primary Care Setting" course during the 2024 academic year (May 2024 to April 2025). This course is a required component of the clinical curriculum and includes outpatient training in primary care settings.

Students who participated in the pilot testing of the questionnaire instruments (n=28) were excluded from this study to avoid potential bias related to prior exposure to the survey tools.

Sample size estimation was conducted using G*Power (version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) for paired comparisons of pre- and posttest scores [31]. Assuming a moderate effect size of 0.5, a statistical power of 80%, and a significance level of 0.05, the minimum required sample size was estimated to be approximately 50 participants.

The assumed effect size of 0.5 was selected based on conventions for moderate effect sizes commonly used in educational intervention studies and prior research evaluating communication skills and MI training among health care trainees.

Although all eligible final-year medical students enrolled in the course were invited to participate in this study, the power analysis was conducted before data collection to verify that the available cohort size would be sufficient to detect meaningful differences in knowledge scores between pre- and posttests. As the available cohort included 130 students, the sample size exceeded the minimum requirement estimated by the power analysis.

Educational Interventions

The educational intervention was designed to introduce foundational principles of MI and to provide opportunities for students to apply MI concepts in clinical contexts. The intervention combined a face-to-face interactive workshop with a structured web-based learning module and brief MI guides, allowing students to acquire theoretical knowledge and practice communication strategies relevant to behavior-change counseling in primary care.

Workshop

A 2-hour interactive workshop on MI was provided. The students attended the workshop in small rotation groups (25 - 28 students per group; 6 rotations throughout the academic year). The workshop facilitators (IT and PN) are faculty members in family medicine and medical education with experience in behavioral counseling in primary care. They have completed formal MI training programs and are continuing professional development activities related to MI.

The workshop content included an overview of health-behavior change theory, the principles and spirit of MI, and the 4 core MI processes (engaging, focusing, evoking, and planning). Students were introduced to the use of key MI communication strategies, including open-ended questions, affirmations, reflective listening, and summaries.

Interactive learning activities were incorporated to support skill development. These included case-based discussions, role-play exercises, and guided demonstrations of brief MI techniques. Students practiced applying MI strategies to simulated clinical scenarios commonly encountered in primary care, particularly in counseling patients with chronic conditions such as diabetes and hypertension.

Web-Based Course

In addition to the workshop, students were provided access to a structured web-based MI learning module designed to reinforce key concepts and support self-directed learning. The module contained approximately 3 hours of learning material and included short lessons covering MI principles, stages of change, and practical applications in patient consultations.

The online course incorporated interactive elements such as quizzes, self-reflection exercises, and case-based learning activities to encourage active engagement. The web-based curriculum was developed following established principles for effective online education [32]. The web-based module was provided as supplementary learning material to reinforce the

XSL•FO
RenderX

workshop content. Students could voluntarily access and complete the course at their own pace through the medical school's learning management system.

Completion of the web-based module was defined according to the platform's predefined criteria, which required students to complete all lessons and associated activities in the online course.

Brief MI Guide

A brief MI guide was provided as a downloadable resource within the web-based course and distributed during the workshop. The guide summarized key MI communication principles and included practical examples of open-ended questions, reflective statements, and strategies for exploring patients' motivation for behavior change. It also provided practical prompts to help students incorporate MI-informed communication into routine outpatient consultations. The guide served as a quick reference tool during clinical training rather than a comprehensive MI training manual. The resource was adapted from the "A Taste of MI" exercise included in the MI foundational training developed by Miller, Rollnick, and Moyers [33] and has been described in our previous publication [27].

The learning objectives of the intervention were to (1) introduce students to the principles and spirit of MI; (2) familiarize students with the four MI processes—engaging, focusing, evoking, and planning—and with fundamental MI communication skills, including open-ended questions, affirmations, reflective listening, and summaries; and (3) support the initial application of MI-informed communication strategies, including brief MI techniques, during clinical encounters.

Given the limited duration of the training, the program was designed to provide introductory exposure to MI concepts and basic communication strategies rather than to develop full MI proficiency.

The interactive workshop was a required component of the Ambulatory Care course, and therefore, all enrolled students attended the workshop session. In contrast, the web-based MI learning module was provided as a supplementary self-directed learning resource, allowing students to access and complete the lessons voluntarily at their own pace through the learning management system.

Quantitative Component

A before-and-after design was applied to assess students' knowledge before and after participation in the MI training. Students completed the pretest questionnaire before participating in the MI workshop. The baseline questionnaire included demographic characteristics (age and sex) as well as information about students' prior exposure to MI and other communication strategies used in patient counseling. Additional items assessed whether students had previously received training related to MI and their experiences with behavior-change communication during clinical rotations. These baseline variables were collected to characterize this study's population and to provide contextual information regarding students' prior familiarity with MI and communication skills before participating in the educational intervention. The posttest questionnaire was administered immediately after completion of the workshop to assess immediate changes in knowledge and confidence following the instructional session. The web-based module was provided as supplementary learning material that students could access voluntarily after the workshop to reinforce MI concepts during their clinical training. The instruments were developed by the research team (IT and RM) based on the relevant literature [14] and reviewed by experts in medical education and general practice to ensure content validity. Three independent reviewers assessed each item for clarity, relevance, and necessity. The questionnaires included multiple-choice, yes or no, open-ended, and Likert-scale questions evaluating knowledge, attitudes, and self-reported application toward MI.

Knowledge scores were calculated by summing the number of correct responses to the multiple-choice questions, generating a total knowledge score for each participant in both the pre- and posttests.

For attitudinal measures, the postintervention questionnaire included items assessing students' self-reported confidence in applying MI during patient consultations. Confidence was assessed across the 4 MI processes—engaging, focusing, evoking, and planning. Participants rated their confidence using a 5-point Likert scale ranging from 1 (not at all confident) to 5 (very confident). Students also reported the extent to which they applied MI during clinical encounters using a 5-point Likert scale ranging from 1 (used the least) to 5 (used the most). The questionnaire items were developed based on the MI framework described by Miller and Rollnick and were reviewed by experts in medical education and general practice to ensure content validity. After piloting with 28 students, minor revisions were made. Internal consistency reliability was assessed for the Likert-scale items measuring confidence related to MI, yielding a Cronbach α coefficient of 0.93. The survey instrument used in this study is available from the corresponding author upon reasonable request.

Qualitative Component

Semistructured interviews were conducted with students who had completed both the pre- and posttests. The semistructured interview guide was developed by the research team based on this study's objectives, findings from the quantitative phase, and relevant literature on MI education and communication skills training in medical education. The interview questions explored several key domains, including students' experiences applying MI in clinical encounters, which MI processes or techniques they used most frequently, perceived changes in their communication style following the training, challenges encountered when attempting to apply MI during patient consultations, perceived benefits of MI for patient communication, and students' perspectives on the most appropriate timing and methods for teaching MI in the medical curriculum. All interview participants were drawn from the same cohort of final-year medical students who participated in the quantitative component of this study.

Students were informed about the qualitative component after completing the MI training and posttest questionnaire and were invited to participate in voluntary interviews. Students who

XSL•FO
RenderX

expressed interest were contacted by the research team and scheduled for an interview.

A total of 12 students were selected using purposive sampling to ensure representation from different periods of course participation during the academic year. Specifically, students were selected from early, middle, and late course rotations in order to capture a range of experiences with learning and applying MI during clinical training.

The sample size was guided by the principle of thematic sufficiency commonly used in qualitative research exploring participant experiences. During analysis, the research team observed that key themes began to recur across interviews, suggesting that sufficient depth of information had been obtained for the purposes of this exploratory qualitative component.

Interviews were conducted in May 2025 via Google Meet and lasted approximately 15‐20 minutes. The relatively brief duration reflected scheduling constraints during students' clinical rotations; however, the semistructured format enabled focused discussion of key topics related to students' experiences with learning and applying MI. All interviews were audio-recorded with participants' consent, transcribed verbatim, and returned to participants for verification to ensure transcription accuracy.

The semistructured interview guide used in this study is available from the corresponding author upon reasonable request.

Data Analysis

Quantitative Analysis

Statistical analyses were performed using IBM SPSS Statistics for Windows (version 20.0; IBM Corp). Paired-samples *t* tests were used to compare the mean knowledge scores before and after the intervention. Analyses were conducted using pairwise deletion, meaning that only participants who had both pre- and posttest responses for the relevant variable were included in the paired comparisons. Participants with missing responses in either the pretest or posttest were excluded from the paired analysis for that variable.

These measures were designed to assess students' perceived knowledge, confidence, and self-reported use of MI-informed communication strategies, rather than to provide an objective assessment of MI competency.

Qualitative Analysis

The interview data were analyzed using conventional content analysis, following the methodological approach described by Hsieh and Shannon [34]. An inductive approach was adopted, involving repeated reading of transcripts to identify initial codes, which were subsequently grouped into broader categories and themes. Initial coding was conducted by 1 researcher (IT), after which emerging codes, categories, and interpretations were reviewed and discussed with the research team to enhance analytical rigor and credibility.

Integration of Quantitative and Qualitative Data

The 2 data strands were integrated during interpretation to provide a comprehensive understanding of the intervention's impact. Quantitative findings demonstrated measurable improvements in knowledge and confidence, while qualitative insights illustrated how students experienced, applied, and reflected on MI in clinical contexts. This integration allowed qualitative findings to complement and provide contextual insights into the quantitative results, strengthening the overall interpretation of this study's findings.

Ethical Considerations

This study was approved by the Khon Kaen University Human Research Ethics Committee (project number HE631031). Participation was voluntary, and all students were informed of their rights to withdraw at any stage without academic consequences. Informed consent was obtained from all participants before data collection. Confidentiality and anonymity were maintained throughout the research process. Participants were encouraged to share honest feedback, as their insights were considered valuable for improving educational approaches in behavioral change communication training. Participation was voluntary, and no incentives were provided.

Results

Overview

Table 1 shows demographic data of the participating final-year medical students. None of the participants had prior MI training or course completion within the past 3 years. Table 2 shows student participation in components of the MI training program. All 130 final-year medical students attended the required 2-hour MI workshop as part of the Ambulatory Care course. The web-based MI learning module was offered as a voluntary supplementary learning resource. Learning-management system analytics showed that 100 (76.9%) students accessed or enrolled in the online module. Among those who accessed the module, 51 (51%) students completed all required lessons and activities according to the platform's completion criteria. Across students who accessed the module, the mean number of lessons completed was 9 of 19 lessons, indicating varying levels of engagement with the online content. Participants' enrollment time in the course ranged from 0 to 481 minutes, with a mean of 71.98 (SD 92.49). The number of completed lessons by participants ranged from 0 to 19 lessons, with a mean of 9.19 (SD 8.87). These findings indicate variable engagement with the web-based module, reflecting the self-directed nature of the online component.

[a]MI: motivational interviewing.

Table . Student participation in components of the MI[a] training program.

Training component	Values
Attended MI workshop (required), n (%)	130 (100)
Accessed or enrolled in web-based module, n (%)	100 (76.9)
Completed all web-based lessons, n/N	51/130
Lessons completed (among enrolled students; N=19), mean (SD)	9 (8.87)

[a]MI: motivational interviewing.

Most final-year medical students expressed strong needs and expectations regarding MI. Before completing the MI workshops, the majority wanted to strengthen their skills in choosing words carefully, applying stages of change, motivating patients, and enhancing communication for health-behavioral change (Table 3). Their learning expectations were consistently high, with mean scores near 4 on a 5-point scale, particularly for MI skills, knowledge, and helping patients control their diseases through MI (Table 4). Regarding specific behavioral areas, students prioritized skills related to oral medication adherence, diet and nutrition, doctor appointment adherence, and injection drug administration (Table 5). Overall, the data highlight the strong motivation among students to develop practical MI communication and counseling competencies that directly support patient self-management and lifestyle modification.

Table . Skills that participants wanted to develop to help patients with diabetes, other chronic diseases, or the general population in modifying health behaviors (before completion of the MI[a] workshops).

Skills that participants wanted to improve (n=127)	Values, n (%)
Choosing words carefully to enhance motivation	96 (75.6)
Applying the stage of change	95 (74.8)
Motivating	90 (70.9)
Communication skills to enhance motivation	90 (70.9)
Counseling	84 (66.1)
Facilitating successful health-behavioral change in patients	84 (66.1)

[a]MI: motivational interviewing.

Table . Participating final-year medical students' expectations for learning the MI[a] course.

Expectation in learning on MI (n=127)	Values, mean (SD)[b]
MI skills	4.06 (0.84)
Control patients' illnesses or diseases after applying MI with them	3.99 (0.72)
MI knowledge	3.97 (0.80)
Patients can change their behaviors after applying MI with them	3.94 (0.77)
Prompt use for MI	3.91 (0.87)
Teaching colleagues about MI	3.62 (0.91)

[a]MI: motivational interviewing.

[b]Mean was calculated using a 5-point Likert scale ranging from 1 (not at all expected), 2 (slightly expected), 3 (moderately expected), 4 (very much expected), and 5 (fully expected).

Table . Specific behaviors that the participating final-year medical students needed skills and knowledge in helping patients change.

Specific behaviors	Values, mean (SD)[a]
Oral medication administration	4.24 (0.79)
Diet and nutrition	4.20 (0.76)
Doctor appointment adherence	4.20 (0.83)
Injection drug administration	4.15 (0.84)
Exercise	4.13 (0.80)
Counseling skills for behavioral change	4.09 (0.75)
Behavioral changes in all aspects	4.06 (0.83)
Updating knowledge and skills in patient care	4.05 (0.83)
Working with the patient's family	3.94 (0.82)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (least needed), 2 (slightly needed), 3 (moderately needed), 4 (very needed), and 5 (most needed).

After attending the MI workshop, 126 of 130 (96.9%) final-year medical students reported attempting to apply elements of MI during patient encounters within the preceding 2 weeks. Most participants (n=120, 92.3%) indicated that the combination of a 2-hour workshop and web-based learning was sufficient for applying MI in clinical practice. Students perceived MI as a useful communication approach for supporting health-behavioral change (mean 4.47 of 5, SD 0.67).

After completing the MI workshop, the final-year medical students who applied MI techniques in real clinical settings predominantly used MI to support patients in improving their diet, physical activity, and medication adherence (Table 6), particularly among those with diabetes, hypertension, and dyslipidemia (Table 7). Students reported applying elements of MI during patient encounters and demonstrated moderate to high confidence in applying MI across all 4 MI processes (Table 8). The highest confidence score was observed for engaging (mean 3.73, SD 0.78), followed by focusing (mean 3.65, SD 0.74), planning (mean 3.52, SD 0.87), and evoking (mean 3.38, SD 0.90). These findings suggest that students felt relatively comfortable initiating and structuring MI conversations but reported slightly lower confidence in more advanced MI processes such as evoking change talk.

MI process (n=126)	Level of use, mean (SD)[b]	Level of confidence, mean (SD)[c]
Engaging	3.95 (0.93)	3.73 (0.78)
Focusing	3.59 (0.93)	3.65 (0.74)
Evoking	3.47 (0.97)	3.38 (0.90)
Planning	3.48 (1.10)	3.52 (0.87)

[a]MI: motivational interviewing.

[b]Mean was calculated using a 5-point Likert scale ranging from 1 (used the least), 2 (used a little), 3 (used moderately), 4 (used a lot), and 5 (used the most).

[c]Mean was calculated using a 5-point Likert scale ranging from 1 (not at all confident), 2 (somewhat not confident), 3 (neutral), 4 (confident), and 5 (very confident).

Comparing Participating Medical Students' Knowledge Scores Before and After Workshop Completion

A total of 130 final-year medical students participated in the MI workshop. Of these, 126 (96.9%) students completed the pretest questionnaire, and 120 (87.5%) students completed the posttest questionnaire. Students who did not complete the posttest were primarily absent during the postintervention data collection session or did not submit the questionnaire. Paired analyses were conducted using data from the 120 students who completed both the pre- and posttest. The proportion of missing data for the paired analysis was therefore small and unlikely to substantially affect the results. A paired-sample *t* test was conducted to examine differences in knowledge scores before and after participation in the MI training. There was a statistically significant difference in the knowledge test scores from time 1 (mean 8.87, SD 2.69) to time 2 (mean 15.04, SD 2.99), t_{119}=−18.45, P<.001 (2-tailed). The mean increase in knowledge test score was −6.18 (SD 3.66), 95% CI −6.84 to −5.51. The eta-squared statistic indicated a large effect size (eta-squared=0.74).

Insights From Participant Interviews

A total of 12 final-year medical students voluntarily participated in the semistructured interviews, representing 3 groups categorized by their enrollment period in the MI course: students who completed the course at the beginning of the 2024 academic year (May to August 2024), coded as group A; those who completed it in the middle of the academic year (September to December 2024), coded as group B; and those who completed it at the end of the academic year (January to April 2025), coded as group C. To maintain participant confidentiality while

XSL•FO
RenderX

distinguishing individual responses, each quotation is identified using a code consisting of a letter and a number. The letter (A, B, or C) represents the interview group based on the period of course participation, and the number represents the individual participant within that group.

The qualitative analysis identified several themes related to students' experiences learning and applying MI during clinical training, including experiences using MI in clinical encounters, changes in communication style, barriers to implementation, perceived advantages and benefits of MI, development of confidence, and students' perspectives on MI education.

According to the semistructured interviews (Table 9), the final-year medical students reported applying MI primarily in brief forms during patient encounters, particularly with patients managing chronic conditions such as diabetes, hypertension, dyslipidemia, and gout. They identified engaging as the most frequently used and comfortable skill, whereas evoking and planning were used less often due to time limitations and lower confidence. After completing the MI course, the students observed noticeable improvements in their communication, becoming more empathetic, reflective, and patient-centered. They perceived MI as a valuable approach that enhanced patient motivation, strengthened doctor-patient relationships, and promoted ethical and collaborative care. Nonetheless, challenges such as heavy workloads, time constraints, and communication barriers with some patients were reported. Most students expressed increased confidence in using MI and preferred learning it during their fifth year, when clinical exposure allowed sufficient opportunity for practice before the externship year. They also emphasized that effective MI instruction should integrate lectures with practical components, such as role-play, video demonstrations, and feedback sessions, ideally delivered through blended or flipped classroom models, to reinforce both theoretical and applied communication skills.

XSL•FO
RenderX

Table . The participating final-year medical students' experiences in and perceptions toward the use of MI[a] with patients.

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
Theme 1: students' experiences applying MI in clinical encounters • Final-year medical students reported applying MI during patient encounters, most often in the form of brief MI rather than the full 4-process model (A1-A4, B1-B5, and C1-C3). They most commonly used MI with patients managing NCDs[b] such as diabetes, hypertension, dyslipidemia, or gout (B1, A1, B3, C1, and C3), and in some cases to support smoking cessation (C3) or alcohol reduction (B2). • Across interviews, students identified engaging as the MI skill they used most frequently and felt most comfortable with, while evoking and planning were used less often because of limited time, clinical workload, or lower confidence in applying the full sequence (A1, B2, and B4). Many students explained that although they could not always perform all MI processes, they consistently incorporated key elements such as open-ended questioning, reflection, and affirmation into routine consultations (B5 and C3).	• "I used MI with patients with diabetes, hypertension, dyslipidemia and gout." (B1) • "In general, I try to explore the root cause of the patient's problem. I haven't had the opportunity to use the full MI process yet, but I try to engage them in talking about what happened and what consequences have occurred and tried brief MI with all patients with diabetes." (B2) • "I use every MI process and apply brief MI with all patients, mainly focusing on engaging. Sometimes patients ask, 'Will I get to see your supervisor?' or say things to make me feel like I'm not trustworthy enough, and insist that they would rather talk with my supervisor." (B4) • "Engaging is the basic process and the easiest to use. Affirmation is important for maintaining positive communication. Open-ended questions have some limitations because patients may not understand us, making them harder to use. I had already used some of these techniques before knowing MI through this course, and during the training, I felt good realizing that I had been using them already." (B5) • "Engaging is used very often, especially when adjusting medication for diabetic patients. I ask questions like, 'Why is the control not achieved?' or 'Is there anything that can be changed?'—but I haven't gone as far as the evoking process yet for the full MI but I tried to used brief MI. I also use the concept of the stages of change to assess which stage the patient is in and whether they are ready to change their behavior." (A1) • "I use Engaging in the outpatient department because we usually focus only on the patient's presenting problem. In reality, we can inspire or spark awareness in the patient. For example, a patient came with diabetes and also smoked. At first, I didn't focus on the smoking issue, but I tried to use reflection, which helped the patient realize that the number of cigarettes he smoked was quite high. When someone reflected this back to him, the patient said, 'I know it's a lot, right, doctor?' In that case, I went through all four MI processes. It felt like small talk that helps initiate the conversation." (C3)

XSL•FO
RenderX

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
Theme 2: changes in students' communication style after MI training • Final-year medical students reported clear changes in their communication style after completing the MI course, most commonly integrating engaging, open-ended questioning, and affirmation into their routine consultations (B1, B2, B4, and C1). Engaging was the MI process used most frequently, often combined with focusing to help patients better understand their condition and explore their own reasons for behavioral change (B4 and C1). Several students also described increased use of reflection and empathic listening, which helped patients express their motivations more freely and led to deeper conversations (C3). • Although evoking and planning were used less consistently, students reported feeling more confident overall and more capable of supporting patient-led change, moving away from directive advice-giving toward a more collaborative style of consultation (A1 and C3).	• "Used Engaging and tried to ask open-ended questions. Changed my way of working significantly after learning MI. After the course, I felt more confident using it and even tried applying it with my family members." (B1) • "After learning about Motivational Interviewing, what I've continued to use is open-ended questions. I ask open-ended questions to let them share, and then I practice empathic listening. Before the course, I had used affirmations occasionally, but after the course, I began using them more often. Giving affirmations helps patients feel proud of themselves and more motivated." (B2) • "The skill I continue to use regularly is engaging. I even applied it with my grandfather at home regarding his smoking. We had conversations using engaging and focusing, and as a result, he reduced his smoking. Affirmation is the skill I use the most." (B4) • "Engaging is probably the skill that has stayed with me after the course because I don't usually see patients long term. Most of the time, I see them for just one visit. So, I use engaging and focusing—patients don't always understand what they have, but we help them understand themselves better and improve their compliance." (C1) • "I use reflection more often now. At first, I would just keep asking questions and taking notes based on what the patient said. But when I started using reflection, it made me pause and think, and it also helped the patient reflect on themselves at the same time. As for affirmation, it is very important. Positive reinforcement has always worked well. What the patient gains is the feeling that someone cares and is interested in them, which helps them open up more. This makes it easier when it comes time to offer advice." (C3) • "Before and after the course, I think there's a big difference. I had never really helped patients change their behavior, but in real life, it's very important. If we can help them reach a stage where they're ready to change, it has a significant impact on the condition they are dealing with." (A1)
Theme 3: challenges and barriers to using MI in clinical practice • Final-year medical students reported several challenges when attempting to use MI in clinical settings. A major barrier was time pressure and high patient load, which made it difficult to perform all MI processes and often resulted in reverting to traditional directive advice-giving (B3, A2, and B5). Many students also noted that their limited experience and developing confidence in MI techniques led to hesitation, disrupted communication flow, or incomplete use of the approach (B1). • Students described difficulties in choosing the right wording, keeping conversations focused, and managing open-ended questions—which sometimes led patients off-topic and required more time than was available (A3 and C2). Additional obstacles included challenges communicating with older adult patients who had hearing problems or preferred to speak only with a doctor rather than a student (B4). Some students also encountered patients with fixed beliefs or preconceived online information, which made behavioral change difficult unless MI skills were used fluently and confidently (C1).	

XSL•FO
RenderX

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
	• "While using it, I couldn't think of how to proceed, so the interaction wasn't smooth. I've only just started using it and I'm not yet proficient. My skill and experience are still limited." (B1) • "How to use words so they understand us. Choosing the right words/change talks is challenging. If I could follow up with the same patient, I think I would be able to use this effectively—it would be doable if it's the same person. In real life, it takes a lot of time to listen. I believe it can be applied to everyone, but for now, I haven't used it with every patient." (C2) • "With open-ended questions, patients often talk about many things off-topic, which takes a lot of time." (A3) • "Because of the time constraints and the high number of patients, there's very little time left for each consultation. If I try to use MI, it becomes impractical—I won't be able to finish on time, and it makes other patients wait longer." (B3) • "Elderly patients often have trouble hearing, so I have to speak loudly, and they are usually not very cooperative. It takes a long time to talk with them. Patients prefer to make plans with the doctor (not with the student)." (B4) • "Because of limited time in real-life practice, I may not be able to use every step—only the basic ones. Patients may not come for counseling but rather for treatment. Some principles may not be fully understood at first, until I gain more experience using them with patients." (B5) • "If we are unable or lack the necessary skills, we may not be able to apply the principles in practice. Many patients nowadays have access to technology. They search for information on their own and come with fixed ideas or a fixed mindset. If we don't have the skills, we won't be able to help them." (C1) • "Conversations take time, and because of the large number of patients, we are unable to complete the full process. The time we have is limited, so we end up giving direct advice in the usual way—such as about alcohol or diet—which fits within the time limit, but the patients still don't change." (A2)

XSL•FO
RenderX

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
Theme 4: perceived benefits of MI for patient communication and clinical practice • Final-year medical students described multiple benefits of applying MI in routine consultations, particularly in improving communication and strengthening the doctor-patient relationship. Students perceived MI as a valuable approach for establishing shared goals and involving patients in decision-making, rather than relying on 1-way directive advice (B3 and A2). This collaborative communication style helped patients feel listened to and respected, which in turn increased trust and engagement during consultations (B2 and A3). • Many students reported that using MI enhanced patients' motivation and willingness to participate in their own care. They observed that when patients were encouraged to express their concerns and motivations, they became more confident and proactive in managing their health conditions (B4 and C3). Students noted that this approach was particularly useful in managing chronic diseases such as diabetes, where long-term behavior change is essential for effective care (B5). • Students also highlighted that MI helped them better understand patients' perspectives, emotions, and barriers to behavioral change, thereby fostering greater empathy in clinical interactions (C3 and A1). Several participants emphasized that MI aligns with patient-centered and ethical communication, helping to reduce misunderstandings and potentially decrease the likelihood of patient dissatisfaction or complaints (C1). • In addition to benefits for patient care, students reported that using MI positively influenced their own professional development. They described feeling more confident and satisfied when consultations became more collaborative and when patients responded positively to their communication approach (A1 and C3). Some students also noted that MI improved their broader communication skills, including active listening, reflective responses, and awareness of personal biases during clinical encounters (B5 and C2). • Finally, several participants suggested that MI may contribute to more efficient long-term care. They perceived that patients who felt motivated and supported were more likely to engage in self-management, which could reduce repeated consultations for the same behavioral issues. For many students, practicing MI also reinforced their sense of professional identity as a physician who communicates with empathy, respect, and patient-centered care (A1, A2, and B2).

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
	• "This was the first thing that interested me—how to speak. It helps guide me a lot when talking with patients. I think it's very important." (B1) • "This is a skill every doctor should have. Before, I would just tell patients what to do without exploring how difficult behavioral change can be or how much time it takes to change. Now I use a patient-centered approach, finding a shared middle ground together." (B2) • "MI is important. Giving advice is necessary, but advice alone is a one-way communication and then it ends. MI, on the other hand, allows patients to make their own decisions. If we do it well, good outcomes will follow—like quitting smoking and preventing disease. With better clinical practice, the results we aim for will also improve." (A2) • "We don't force the patient to do anything — we plan together and see things from their perspective. It's better than just telling the patient what to do. It helps us understand the ways that lead to change. Even though we don't follow up with the patient afterward, during the interaction we can feel that the patient understands and has goals for change. It creates a good relationship with the patient." (A3) • "MI is important because it helps us find a shared goal. If the doctor doesn't do this, the patient may not want to make any changes—it feels as if someone is just ordering them, so they don't want to follow. MI helps patients want to improve themselves and want to collaborate with our guidance. The benefit for us is that it helps us understand patients better. It's not just about applying a theory and expecting results to happen automatically." (B3) • "MI is important. It's clear that patients become more cooperative. It's evident that MI truly helps motivate patients, and it helps us understand them better — we gain more insight into their background and situation. Patients are more willing to cooperate as a result." (B4) • "Using MI in the care of patients with diabetes makes management easier, if it is used correctly and fluently." (B5) • "MI is very important. Behavior is something that stays with patients for long time. What happen is the patient is often not understood by the doctor because we've never asked about their thoughts and feelings—we still don't really know each other. MI provides a natural way for us to do this. It gives us a structure to understand the patient. Behavior is hard to change. MI helps us reach the patient's feelings and talk about their attitudes, which is extremely helpful." (C3) • "It benefits us by helping us empathize with patients and listen to them more attentively. Sometimes we don't feel like listening to patients, even when what they say affects their treatment. It reminds us not to let our own bias get in the way, and to act professionally. It also helps us observe the patient's gestures and behavior." (B5) • "MI is important, yet it's something no one has ever brought up. MI is a part of medical ethics—listening without judgment and applying the principles of patient-centered care. We didn't recognize its importance before or realize what proper ethical principles really entail—we just practiced without knowing their significance." (C1) • "The benefit for myself is that I feel, in my heart, like a good doctor. The patient is happy, and they leave the consultation with a sense of satisfaction." (A1) • "It helps patients open up to us more, as if we were talking with a family member. When we encourage them and give positive support, that positivity comes back to us. The patient is happy, and we are happy — we receive positive energy. It makes us appreciate the value of caring for patients even more." (C3) • "The benefit for ourselves is improved communication skills, which help not only with patients but in general as well." (C2) • "The outpatient setting is very important. If there is proper guidance on how to speak with patients, it helps them feel comfortable and satisfied when they listen, and they become more cooperative. That's exactly what MI does." (A1) • "Doctor–patient relationship becomes more open, allowing patients to trust the doctor and feel understood. It gives them the opportunity to think for themselves, and they feel more confident and trusting.

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
	As a result, our work improves and becomes lighter—our workload is reduced because patients understand how to take care of themselves." (A2)
Theme 5: development of confidence in applying MI • After completing the MI course and practicing its techniques during clinical rotations, most final-year medical students reported increased confidence in communicating with patients and supporting behavioral change (B1, B3, and B4). Several students noted a shift from feeling uncertain or hesitant in offering guidance before the course to becoming more comfortable and proactive in conversations involving lifestyle changes or complex emotions (B4 and C3). • Students described how MI gave them a clearer framework for patient interaction, helping them move beyond simply giving advice to learning how to guide patients through reflective discussions and motivate change (A3 and B5). A few emphasized that increased confidence was also tied to stronger medical knowledge, which enabled more fluent and effective use of MI in practice (A1). • Although confidence was not immediate for everyone, many students shared that through repeated use—both in clinical encounters and informal settings—they became more adept at integrating MI naturally into their consultations (A2 and B5).	• "More confident in giving advice to patients, more willing to speak up, and becoming more familiar with it." (B1) • "More confident, and during OPD rotations I use MI more often." (B3) • "More confident now. Before the course, I didn't dare to give advice to patients." (B4) • "I am more confident in helping patients change their behavior. At first, I didn't know there was a principle behind it, I would just give advice or tell them what to do. In the future, I will use MI in situations where it is appropriate, but there are still limitations due to the high number of patients coming to the OPD." (B5) • "To be confident in speaking and using MI, we must first be confident in our medical knowledge. Once we are confident in our knowledge, we will feel more confident during patient consultations, and the more we speak, the more fluent and confident we become in using MI." (A1) • "More confident immediately after the course, but not at the highest level yet. After practicing for a while following the course, I became much more confident. I tried using it on my own and no longer needed additional training." (A2) • "Before learning MI, everything was scattered and without direction. I didn't know what to do and had no framework. • Now, I feel more confident." (C3) • "There is now a clearer starting framework. Before, I would give advice based on the knowledge I had — 1, 2, 3, 4 — without giving patients the chance to talk about why they couldn't follow it. After learning MI, I understand patients more, can help motivate them, and can apply a more effective approach to giving advice." (A3)
Theme 6: students' perspectives on when MI should be taught in the curriculum • Most final-year medical students agreed that year 5 is the most appropriate time to introduce MI in the curriculum, as it aligns with outpatient clinical exposure and provides enough time to practice before entering the externship year (B1, B2, and B4). Students noted that by year 5, they have sufficient medical knowledge and experience to make MI training meaningful and applicable, especially during rotations involving real patient care and behavioral counseling (A3 and B3). • A few students recommended introducing MI theory earlier, in years 3 or 4, followed by more practical reinforcement in years 5 and 6 to help develop fluency over time (C1 and A2). Some felt that teaching MI too late—such as near the end of year 6—would limit the opportunity to apply and refine skills in varied clinical settings (B2 and A2). • However, a small number suggested that year 6 is ideal, viewing it as the stage when clinical confidence matures enough to fully integrate MI into patient care (B5 and C3). Overall, the majority favored a staggered approach, with early theoretical exposure followed by increasing depth and practice in years 5 and 6.	

XSL•FO
RenderX

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
	• "I would like to learn it before entering year 6, so that I can practice more and apply it across different block rotations. It could be early in year 5 or during the family medicine rotation in year 5. Since in year 5 we have OPD sessions, while in year 4 we mostly focus on history taking and physical examination, learning it in year 5 would be better. Then, by the time we reach year 6, when we are more involved in the patient management, we would be able to use it more fluently." (B1) • "In years 5 and 6, there are more opportunities to explore patient care. In year 5, there is the OPD Ambulatory Medicine course. If MI is taught in year 5 and then applied in Ambulatory Care in Primary Care during year 6, that would be ideal. However, in year 6, if a student takes the block toward the end of the year, they would learn the techniques late and have less time to practice. Therefore, learning MI in year 5 would be better." (B2) • "Years 4 - 5 are okay because that's when we start working in the outpatient department. In year 4, we have a rotation in community hospitals, and I heard that the nurses there use MI with diabetic patients. So if we could learn it in year 4, that would be good. Then in years 5 - 6, we would be able to apply it in real practice." (B3) • "Learning it in year 5 would be good because we have outpatient rotations and can apply it. By year 6, we'd have a solid enough understanding to use it directly in clinical practice." (B4) • "I think teaching it during the extern year (year 6) is suitable because students already have confidence in patient care. But if it's taught before the extern year, students may not be ready yet." (B5) • "MI should start being taught theoretically in years 3 - 4. After learning the theory, students can then observe patients, and later receive reinforcement teaching again. In year 4, the focus should be on engaging and focusing, because that year is mainly about history taking and physical examination. In years 5 - 6, the teaching should shift to evoking and planning, because students begin learning about treatment and management. This would help students understand MI more deeply. Those who already enjoy talking with patients benefit a lot when they learn MI, but those who are more academically focused, not like to listen or talk may not use it as much." (C1) • "In year 4, it can be practiced during the family medicine rotation. If students start practicing in year 4 and continue in years 5 - 6, their skills will become more complete. If it is taught near the end of the extern year, they may not have many opportunities to apply it in different wards." (A2) • "Year 6, because that's when we get to use it in real practice. In year 4, during OPD rotations, it's difficult to apply because most of the learning is through lectures and observing instructors. If we had to do it ourselves, it would be hard to apply, since the focus in that year is mainly on history taking and physical examination." (C3) • "Years 5 - 6 are suitable because by the time we reach the stage of giving advice, we already have the necessary knowledge and understand the importance of advising patients. If it is taught too early, we won't have enough information or knowledge to really help patients. If it is taught too early, we will forget it, won't see its importance, and won't be focused. In years 5 - 6, students are more likely to want to use it." (A3)

Final-year medical students' experiences in and perceptions toward the use of brief MI with patients	Comments
Theme 7: preferred educational approaches for learning MI • Final-year medical students emphasized the importance of combining lectures with hands-on practice when teaching MI. While onsite lectures and web-based modules were considered helpful for providing foundational knowledge (B1, B3, and B4), most students stressed that practice-oriented learning—especially through role-play, video demonstrations, and feedback or coaching sessions—is essential for building confidence and applying MI effectively in real clinical settings (B2, C1, and C2). • Several students recommended a flipped classroom model, where theoretical content is delivered online before in-person sessions focused on skill application and reflection (B3 and B4). They also suggested that extended or repeated practice sessions, including opportunities to rehearse full MI processes and observe expert demonstrations (eg, videos or live modeling), would help address initial confusion—particularly around more complex components such as evoking and planning (A3 and B5). • Overall, students viewed a combined educational approach—with early theoretical input, case-based role-play, instructor feedback, and opportunities for ongoing practice—as key to mastering MI during undergraduate medical training.	• "Onsite lectures are good, but there is still not enough practice. When applying it with patients, there is still a lack of feedback. I would like there to be a practice session with feedback or coaching. Video demonstrations are useful and could be added to the web-based course, or a workshop could be organized for students or physicians who are interested, perhaps as an elective." (B1) • "I was impressed by the session where we practiced brief MI. I was able to try applying it with patients myself. The lecture is important, but I would like to have hands-on practice right away. The web-based format is already detailed and complete. We could watch the online clips before, during, or after trying it with patients. For the theory part, it should be summarized briefly and concisely, and then we should move straight to practice." (B2) • "Lecture+ web-based learning is already good. But if there were a wrap-up session, it would be even better, because in the classroom I couldn't keep up. If we could study the web-based content first and have some time to digest it, we would understand the in-class session better, since this is a new topic for us. Web-based learning is helpful because I can't always follow everything during the live class. • Role-play and videos would also be useful because they make it easier to apply MI and help build confidence in using it." (B3) • "I prefer learning onsite and then reviewing it again online. • Another option is to have students learn the theory on their own through the web-based course, and then the instructor can give a brief summary in class and let students do role-play." (B4) • "The teaching format is appropriate as it is. However, the session where we practiced brief MI was too short. The session should be extended, and we should also try practicing the full MI process. I would like to add a video demonstration because the current case studies are only on paper. After this, reviewing the principles doesn't require additional courses—I think we can continue practicing on our own." (B5) • "What I remember most from the course is how to speak well with patients. Even though it's been a long time, I still remember it clearly because I saw the instructor demonstrate it during the OPD rotation, especially how to approach difficult patients. The instructor was a good role model, and seeing the correct practice has stayed with me to this day." (A1) • "Lectures alone may not be enough—there should be more practice included. Perhaps add role-play demonstrations for difficult patients, with role-play sessions that classmates can observe. Coaching is challenging, but it would be very helpful if available. The content is sufficient, but what's missing is how to apply it—how to practice correctly and in what way. Skills should be refreshed regularly through small sessions, such as annual courses or workshops, so that when we apply them in practice, we have a solid foundation to rely on." (C1) • "Organize group role-plays in front of the class and have the instructor provide feedback and advice. • For physicians who want to use it, the training is sufficient, but continuous practice is necessary." (C2) • "I could follow about 50% of the lecture. When practicing, I didn't really understand what the evoking process meant or how to use it. I was still confused when trying it, but once I understood the concept, I felt that if we practiced with roleplay first and then had a follow-up lecture, it would be better. Learning from video demonstrations is difficult if we don't immediately encounter real cases. Maybe we could divide into groups for roleplay, then go back and watch the videos, and the next day do hands-on practice—that might work better. More time should be given for learning and self-practice, with more opportunities to practice." (A3)

Discussion

Principal Findings

This mixed methods evaluation examined a combined MI training program for final-year medical students. Quantitative findings showed higher MI knowledge scores and greater self-reported confidence after participation in the training program. In addition, most students reported applying elements of MI during clinical encounters, primarily in brief interactions related to counseling patients with chronic diseases.

Qualitative findings provided further insight into students' learning experiences. Participants described increased awareness of patient-centered communication strategies, including reflective listening, open-ended questioning, and affirmations. However, students also reported challenges in applying more advanced MI processes, such as evoking and planning, due to time constraints, clinical workload, and limited opportunities for repeated practice. Together, these findings suggest that the combined learning approach was associated with improvements in knowledge and perceived communication confidence, while also highlighting practical challenges in implementing MI during routine clinical encounters.

It is important to note that these findings reflect self-reported learning outcomes and perceptions of MI use, rather than objectively measured MI competency or verified patient behavior change.

Comparison With Previous Studies

Our findings are broadly consistent with previous studies suggesting that brief MI training can increase learners' knowledge and confidence in behavior-change communication [18,19,35,36]. Similar to prior research, students in this study reported feeling most comfortable using the early MI processes of engaging and focusing, while evoking and planning were more difficult to apply without extended practice or supervision. Previous research has also suggested that blended learning approaches combining online instruction with interactive teaching may enhance learner engagement and flexibility in medical education [28].

However, it is important to note that many studies evaluating MI education rely primarily on self-reported outcomes, and evidence regarding objective skill acquisition remains limited. Therefore, while this study contributes additional evidence from a Thai undergraduate medical education context, further research using objective assessment tools and controlled study designs is needed to better evaluate the effectiveness of MI training programs for undergraduate medical students.

Consistent with qualitative findings, students perceived limited consultation time as a barrier to applying MI. These perceptions are consistent with previous reports from trainees who are newly learning MI techniques and may require additional time to formulate reflective responses and guide behavior-change conversations [27]. However, evidence from the broader MI literature suggests that when clinicians become more proficient in MI, the approach can be incorporated efficiently into routine clinical consultations without substantially increasing encounter time [9,37]. Some studies have even reported that effective MI communication may improve the efficiency of patient interactions by helping clinicians focus more quickly on patients' motivations and priorities for behavior change [9,38]. Therefore, the time-related challenges reported by students in the present study may reflect their early stage of learning rather than an inherent limitation of MI itself. As students gain more experience and practice integrating MI skills into clinical encounters, the perceived time burden may decrease.

Strengths and Weaknesses

A major strength of this study lies in its mixed methods design, which allows integration of quantitative findings with qualitative insights to provide a broader understanding of students' learning experiences. The inclusion of an entire cohort of final-year medical students reduced the selection bias and enhanced representativeness. The use of validated instruments and expert review increased internal validity.

Several limitations should be considered when interpreting the findings of this study. First, this study used a single-group before-and-after design without a control group, which prevents causal attribution of observed changes to the educational intervention. Improvements in knowledge or confidence may also reflect concurrent clinical learning experiences, maturation effects, or testing effects during the academic year.

Second, several outcomes, including students' reported application of MI in clinical encounters, were based on self-reported measures, which may be subject to recall bias or social desirability bias. These measures, therefore, reflect students' perceptions rather than objectively verified MI competence. In addition, the qualitative interviews were relatively brief (approximately 15 - 20 minutes) due to scheduling constraints during students' clinical rotations, which may have limited the depth of exploration of participants' experiences.

Third, the duration of the intervention was relatively brief (approximately 5 hours of combined learning), which may be sufficient for introducing foundational MI concepts but is unlikely to support mastery of more advanced MI skills without continued practice, feedback, and supervision [10,39].

The relatively low completion rate of the web-based module may also reflect challenges related to implementation fidelity, as not all students were fully engaged with the online component of the intervention. However, the web-based course was designed as a supplementary resource to support students who wished to review or reinforce knowledge delivered during the onsite sessions. Participation in the web-based module was optional, and therefore variations in uptake among students were expected. As this study was not originally designed to compare outcomes between students who completed the web-based module and those who did not, subgroup analyses were not conducted. Future studies may explore whether different levels of engagement with online learning components influence educational outcomes.

Finally, this study was conducted at a single medical school, and therefore, the findings may not be generalizable to other educational settings or health care systems.

XSL•FO
RenderX

Implications and Future Study

The findings of this study offer practical implications for undergraduate medical education. A combined learning structure that integrates a short workshop with a self-paced web-based module may provide a flexible approach for introducing MI concepts within a busy curriculum, although engagement with the online component varied among students. The web-based component provides flexibility, while the in-person workshop facilitates experiential learning and peer interaction.

Students' preference for learning MI during the fifth year supports the alignment of MI training with clinical exposure to maximize relevance and skill transfer. A spiral curriculum, introducing MI principles during preclinical years and reinforcing practical skills during clinical rotations, could further strengthen integration.

Addressing barriers such as workload and limited practice time will require institutional support, including formative feedback, supervision, and longitudinal reinforcement. Embedding MI within broader communication skills training and assessment frameworks may enhance sustainability.

Future research should incorporate objective measures of MI competency, such as validated behavioral coding systems or structured communication assessments, to more accurately evaluate skill acquisition. Longitudinal studies are also needed to examine the retention of MI skills and their potential impact on patient outcomes over time. In addition, multicenter and cross-cultural research in low- and middle-income countries would help determine how combined MI educational approaches can be adapted to different health care systems and educational environments.

Overall, the findings suggest that the intervention was feasible within an undergraduate medical curriculum and was associated with higher knowledge scores and increased perceived confidence among participating students, while qualitative findings illustrated how students perceived and attempted to apply MI principles during clinical training.

Conclusions

In summary, this study evaluated a combined educational approach comprising a brief workshop and a web-based learning module to introduce MI to final-year medical students. The findings suggest that the training was associated with improvements in students' MI knowledge and self-reported confidence in behavior-change communication. Students also reported applying elements of MI during clinical encounters, particularly when counseling patients with chronic diseases.

While these findings indicate that combined MI education is a feasible approach for introducing communication skills within undergraduate medical curricula, the results should be interpreted cautiously due to the absence of a control group and the reliance on self-reported outcomes. Further research using controlled study designs, objective assessment tools, and longitudinal follow-up is needed to better evaluate the impact of MI training on clinical competency and patient outcomes.

Acknowledgments

We sincerely thank the production house teams of the Faculty of Medicine, Khon Kaen University, for their invaluable support in developing and producing a structured web-based course on motivational interviewing and the stage of change. Generative artificial intelligence tools were used solely for language editing and grammatical refinement. All scientific content, analysis, interpretations, and references were developed and verified by the authors, who take full responsibility for the accuracy, originality, and integrity of this paper.

Funding

This study was supported by the Faculty of Medicine, Khon Kaen University, Thailand (IN63237).

Abstract

Background: Trauma-related mortality exhibits a marked social gradient, driven by access barriers and health inequities worldwide. These barriers jeopardize progress toward Sustainable Development Goals 3 and 4.

Objective: This study aimed to investigate the prehospital and in-hospital barriers to timely injury care as perceived by frontline trainee physicians and traffic law enforcement professionals during real-time treatment execution in Uganda. Additionally, we aimed to highlight the potential impact of these barriers on trauma outcomes.

Methods: This study used a convergent mixed methods approach. Qualitative data were collected through structured interviews and face-to-face focus groups with diverse teams of 500 frontline trainee physicians, including surgical residents, interns, medical students, and traffic law enforcement professionals. Directed content analyses for structured interviews and focus groups were conducted in NVivo (version 14, release 2023; QSR International). Quantitative data were concurrently collected using a survey questionnaire from the Motorcycle Trauma Outcome Registry, which included 1003 patients with trauma. We categorized barriers as prehospital or in-hospital barriers and as trauma team-related, patient-related, or health system–related barriers. Multilevel restricted maximum likelihood logistic regression analyses of factors associated with barriers to injury care were analyzed using Stata (version 15.0; StataCorp LLC). Odds ratios (ORs) and 95% CIs were reported; statistical significance was defined as $P<.05$.

Results: Qualitative analyses identified key prehospital barriers, including delays in emergency medical services activation, ambulance arrival, and transportation. In-hospital barriers were primarily shortage of supplies, delays in identifying life-threatening injuries, and insufficient critical care services. Quantitatively, among the 1003 audited patients with trauma, 42% (416/1003) faced barriers during treatment. The most common obstacles were delays in treatment decisions (232/1003, 23%) and securing necessary supplies (180/1003, 18%). The presence of barriers was independently associated with a 3-fold increased likelihood of unfavorable Glasgow Outcome Scale scores (OR 3.15, 95% CI 2.23 - 4.66; $P<.001$) for neurological injuries and was linked to a 4-fold increase in odds of 90-day mortality (OR 4.20, 95% CI 2.25 - 6.94; $P<.001$). After adjusting for injury severity and clustering effects by hospital teams and resources, the presence of barriers was associated with arrival by public means (adjusted OR [aOR] 1.62, 95% CI 1.09 - 2.41; $P=.02$), increasing age (aOR 1.01, 95% CI 1.00 - 1.03; $P=.01$), sustaining 1 or more injuries requiring admission (aOR 1.92, 95% CI 1.18 - 3.14; $P=.01$ vs aOR 3.69, 95% CI 1.95 - 6.98; $P<.001$), and a severe Kampala Trauma Score of ≤6 (aOR 2.71, 95% CI 1.37 - 5.37; $P=.004$).

Conclusions: Multiple barriers to trauma care are more frequent for severe injuries and are associated with poorer neurological outcomes and higher mortality. These findings indicate the need for targeted, multifaceted interventions that incorporate frontline

XSL•FO
RenderX

health workers' perspectives to improve trauma care delivery in low-resource settings facing both prehospital and in-hospital barriers.

Introduction

Globally, injury-related mortality is characterized by significant socioeconomic gradients [1]. These social inequalities manifest through suboptimal prehospital care access, fragmented health care systems, and suboptimal postcrash care, including the unmet need for physical and mental rehabilitation after injuries, in both low- and high-income countries (HICs) [2]. For instance, research highlights substantial regional disparities in trauma-related mortality rates, particularly in Europe, where Eastern Europe experiences rates nearly 3 times higher than those in Western Europe [1,3]. In the United States, compelling evidence demonstrates desperate trauma outcomes that are linked to disparities in ethnicity and insurance coverage, where uninsured persons of low socioeconomic status are the most vulnerable to adverse injury outcomes, whereas in Australia, rural geographic disparities to injury care are well documented [4]. Research from Canada mandates that issues of health care inequities be addressed by medical trainees and well-established physicians through their civic duties as patients' advocates [5].

In Asia and Africa, the burden of injury is disproportionately higher in nations with poor economies, contributing to approximately 4.5 million premature deaths annually in low- and middle-income countries (LMICs) [3,6,7]. For instance, it is estimated that 36% of injury-related deaths in LMICs are linked to delays or barriers to injury care [8]. These barriers are highlighted in the United Nations General Assembly resolution 74/299, with a rapidly approaching target deadline: to halve road traffic crash–related global mortality and ensure well-being for all individuals by 2030, congruent to Sustainable Development Goals (SDG3) [9]. However, whereas recent trends show declining inequalities in injury care access among HICs, in LMICs, socioeconomic inequities, inadequate infrastructure, and shortage of human resources for health have continued to exacerbate these challenges, resulting in disparities in access to injury care both between and within regions, for instance, in urban versus rural areas [3,6,10].

In Africa, the disparities in injury care are manifested by suboptimal emergency medical services coverage in most countries in the region [11,12]. For instance, despite the high volume of trauma cases in Uganda and Rwanda, significant challenges persist, including inadequate insurance coverage and limited resources for trauma care. These challenges also encompass a weak prehospital care system characterized by shortage of ground ambulances and evacuation of injured patients predominantly by traffic police, a scarcity of trauma specialists, and the constraints of rigid, nondecentralized referral systems [13,14]. These issues not only impact injury outcomes but also have consequences on the learning and clinical experiences of medical students and resident doctors who train in such environments, including burnouts and poor retention of the health care workforce, after graduation from medical schools [15]. Medical training and capacity building have been identified as top priorities for addressing African health system challenges [15]; however, research that positions trainee physicians as policy advocates for improving the social determinants of health at individual and practice levels, particularly through identifying barriers that impact the care of patients in their regular work environment, is limited.

Positioning medical trainees as patient advocates is essential for building a competent health workforce, particularly in LMICs where resource constraints worsen health disparities and create imbalances in geographic and specialty distributions. Current academic programs in Uganda focus primarily on biomedical education, failing to connect medical training with community-based interprofessional practice, social determinants of health, and population needs. These connections are crucial for preparing future physicians to assume progressive responsibilities aligned with community priorities. Systematic reviews indicate that integrating experiential learning, reflective practice, and feedback in education fosters long-term professional identity formation, empowering trainees to influence local and national health policies, which is vital for addressing the dual burden of disease and workforce deficits in LMICs [16,17].

We previously reported on a Motorcycle Trauma Outcome Registry (MOTOR) project that considered medical trainees and traffic law enforcement first responders as sustainable human resources for injury care in rural settings with a positive impact on injury outcomes through trauma team training [18,19]. This ancillary study formed an integral component of tertiary outcomes to supplement the MOTOR project by detailing the perspectives of these cadres regarding barriers to injury care in low-resourced contexts.

Coping with patient care demands, sufficient health system resources, and an enabling work environment are essential for the success of medical trainees and frontline health workers in their learning and patient care responsibilities. These demands intensify when caring for patients with trauma due to the emergency and life-threatening nature of their injuries. Therefore, it is crucial to understand the barriers that may hinder effective treatment of such patients from the perspectives of trainee physicians, who serve as frontline health workers, and from traffic law enforcement professionals who work in the capacity of paramedics in low-resource settings. However, existing studies often lack a comprehensive analysis of the barriers to injury care faced at the individual patient level, which

XSL•FO
RenderX

are influenced by geographical and cultural contexts [13,14,20]. In Uganda, studies that have attempted to investigate some of these barriers have limited their scope to prehospital factors mainly in urban settings and have excluded insights from frontline health care workers such as trainee physicians who predominate the health system workforce [21,22]. This phenomenon can be attributed, in part, to the challenges associated with acquiring information from key frontline stakeholders. These challenges arise from their demanding work schedules, remote geographical locations, privacy concerns, and the aspiration to manage the heterogeneity of research participants, which often proves to be realistically unattainable.

Therefore, the aim of this study was to identify the prehospital and in-hospital barriers to timely injury care as perceived by trainee physicians and traffic law enforcement professionals who are the first point of contact and are actively engaged in the care of injured patients in a low-resource context, as well as to elucidate how these barriers impact injury outcomes. We structured the identified barriers into 2 frameworks, focusing on both prehospital and in-hospital challenges, while examining both infrastructural and human resource factors. Additionally, we aimed to delineate the specific barriers encountered at both the individual-patient and trauma-team levels during the real-time execution of treatment.

Methods

Study Design

This was a convergent mixed methods study nested within a broader MOTOR project, which investigated the impact of rural trauma teams and training on outcomes of motorcycle-related injuries [18]. To effectively address the complex interconnected geopolitical, infrastructural, and human resources issues that delay the execution of lifesaving interventions, mixed methods research was essential to fully understand the specific barriers to timely injury care in low-resource settings, particularly from the perspectives of health care personnel involved in the initial patient contact. Prior research had identified mixed methods as particularly suitable for investigating complex health care systems [23]. In their recent systematic review, Whitaker and colleagues [20] have recommended that future research assessing barriers to injury care should use innovative mixed methods to investigate both prehospital and in-hospital delays, as well as the associated care processes and outcomes. In this study, we fitted a 2-framework approach into the concept of 3 temporal delays in accessing treatment within the context of LMICs, including seeking, reaching, and receiving injury care, as described by Vaca et al [24]. This theoretical framework permitted the convergence of qualitative and quantitative data to gain a deeper understanding of the obstacles to injury care and the characteristics of patients who experience these barriers. The research was documented in accordance with good reporting of mixed methods studies guidelines [25], whereas the qualitative element was reported in line with the COREQ (Consolidated Criteria for Reporting Qualitative Research) [26].

Study Settings

The study was conducted from September 2, 2019, to August 27, 2023, at 6 regional tertiary hospitals in Uganda: Jinja, Hoima, Fort Portal, Mubende, Kiryandongo, and Kampala International University Teaching Hospital, which also serve as surgical residency and internship training centers. Multidisciplinary teams of consultant surgeons, residents, interns, and medical students operate the trauma and casualty units. Patients with trauma typically arrive via ground ambulances, traffic police patrols, or public transport, where they are assessed and treated by the multidisciplinary teams. These facilities operate as level III trauma centers and collectively serve a population of 18 million across 50 districts and 3 major cities in Uganda.

Study Population and Source of Data

Qualitative data were collected from surgical residents, interns (doctors or nurses), and third- and fifth-year medical students associated with the surgery departments of the participating hospitals. Additionally, we engaged law enforcement professionals specializing in road traffic regulations, who serve as first responders to road traffic–related injuries within the municipalities that constituted the catchment areas of these hospitals. The qualitative data were collected through investigator-administered structured interviews and audio-recorded face-to-face focus groups. The structured interviews had coded predetermined themes regarding barriers to injury care identified from previous literature and featured open-ended options to cater for emerging new themes [8,20]. These interviews were administered as part of a pretest conducted prior to the development training of rural trauma teams previously described for the frontline health workers [27,28]. On the other hand, quantitative data were gathered from investigator-administered survey questionnaires for patients who sustained motorcycle-related injuries, received care at any of the participating hospitals during the study period, and participated in the MOTOR project [18,29].

Sample Size Estimation and Sampling Methods

Given the complexity of the research topic and the cultural, geographical, and professional diversity of our study population, we aimed to recruit 50-80 participants for structured interviews from each of the 6 geographically distinct hospitals. We consecutively recruited samples of surgery residents, intern physicians, nurses, medical students, and purposively selected traffic rescue police involved in immediate contact with injured individuals. Participants were contacted from those who had opted into the rural trauma team development training project to complete the 15-minute structured interviews [18]. Participants who completed the structured interviews were subsequently recruited for 40-minute focus groups, organized into 100 teams. Each focus group comprised 5 participants and was managed by 3 research team members: HL administered the interviews, MM recorded field notes, and BO moderated the group sessions, verbalizing new responses verbatim. The groups consisted of varying compositions: rescue police alone (N=20), medical trainees alone (N=20), or a mix of both (N=60). Each participant was recruited only once. This data triangulation approach aimed to further explore the context of emerging themes through follow-up questions and to stimulate new themes based on team dynamics, aligning with an initial strategy to incorporate these groups into rural trauma teams [28].

XSL•FO
RenderX

To minimize institutional and selection bias, a transparent eligibility criterion was established. Trainee participants were stratified by hospital resources capacity and by study year as a rough estimate of expertise, followed by random assignment into 5-member groups using a blinded lottery method. Additionally, bias was further mitigated by triangulating data from focus groups and interviews and by continuously assessing data saturation to ensure a diversity of experiences.

We assumed data saturation and ceased recruitment when no new information, themes, or insights emerged in the monitoring log after 3 consecutive interviews and across different groups at various study sites, in accordance with previous studies [30,31]. Theme saturation was achieved after conducting 15-17 focus groups at each of the 6 hospitals, totaling 100 groups with 434 medical professionals and 66 traffic law enforcement officers (total sample=500). Data collection was capped upon reaching saturation to optimize time and resources, thereby avoiding redundancy while ensuring the comprehensiveness of emerging themes from diverse professional contexts [32]. Systematic reviews indicate that depending on the complexity of the research question and diversity of the research population, 9-17 interviews are sufficient for qualitative studies involving homogeneous populations, while a minimum of 50 interviews may be appropriate for culturally diverse populations [30,31].

The quantitative component assessed barriers to injury care for 1003 patients with trauma treated at the 6 study sites. The quantitative sample size was derived from an open-source R Shiny application for the MOTOR trial, which was a cluster randomized, parallel controlled trial with discrete time decay correlation structures for multiple periods as described by Lule et al [18].

Eligibility Criteria

The qualitative component included trauma care frontliners, such as chief surgical residents, medical interns, traffic police officers stationed on major highways for immediate road traffic accident responses, and medical students in surgical and traumatology clinical rotations. Medical participants without prior exposure to surgery or emergency department rotations were excluded, as they were presumed to lack experiences with patients with trauma and the associated barriers to care. Additionally, participants who anticipated being unable to complete both the structured interviews and focus groups due to commitments, such as police officers on duty, were also excluded to ensure comprehensive capture of each participant's experiences regarding the studied phenomenon.

The quantitative component included patients aged 2-80 years who had sustained neurological or musculoskeletal injuries resulting from a motorcycle crash and attended the emergency departments of the 6 study sites within 24 hours during the study period. To minimize confounding from injury mechanisms and comorbidities affecting neurocognitive and musculoskeletal outcomes, we excluded participants with a documented history of stroke and neuropsychiatric disorders, as outlined in the study protocols [18,27].

Data Collection

Data were collected and precoded by global surgery and doctoral researchers HL and MM according to themes identified in the existing literature [20]. The data collection process was conducted simultaneously using pretested tools [18,28,29]. The qualitative component was part of a broader face-to-face patient-public consultative engagement for the MOTOR project [18]. After explaining the research objective and the procedure for completing the structured interviews, we asked participants to identify, assess, and rank the barriers. Subsequently, we used focus groups to gain an in-depth understanding through follow-up questions, to probe novel barrier themes, and to fully capture the experiences of participants (Multimedia Appendix 1). This information was intended to inform the establishment of emergency medical services, trauma teams, and trauma registries focused on motorcycle crash–related neurological and musculoskeletal injuries, which represent Uganda's most significant trauma burden [33].

In the quantitative component, a prospective MOTOR trial project was established at 6 regional referral hospitals in Uganda [18,19], which captured quantitative data as detailed in Multimedia Appendix 2. Consultants, surgical residents, and interns involved in trauma care documented barriers encountered during the execution of definitive injury care for 1003 patients with trauma (MOTOR participants). Data on demographics, injury severity based on the Glasgow Coma Scale (GCS), and the Kampala Trauma Score (KTS) [34] were collected at baseline. On the other hand, trauma outcomes, including all-cause mortality, the Glasgow Outcome Scale (GOS) for traumatic brain injuries [35], and the Trauma Outcome Measure Scale (TOMS) score [36] for musculoskeletal injuries, were recorded 90 days postinjury.

Quantitative data were captured using precoded paper-based questionnaires and later uploaded to the secure REDCap (Research Electronic Data Capture; Vanderbilt University) electronic system hosted by Turku University in Finland [37]. Information was captured if a barrier was encountered during the execution of treatment, and each documented barrier triggered an alert, prompting an audit of the patient's case file during weekly virtual meetings via Zoom (Zoom Communications, Inc). These 15- to 30-minute meetings, summarized in field notes, clarified the nature of the barriers and included verbatim anonymous documentation of responses from research assistants (designated 2-year experienced medical officers) and attending clinicians. Corrections were made for any inaccurate entries identified during the audits. This comprehensive approach aimed to capture a nuanced understanding of barriers affecting injury care access in real time to enhance future interventions.

Data Analysis

We analyzed data from each component of this mixed methods study independently. The basis of this approach was to enrich the interpretation of the main outcomes of the MOTOR trial project in a broader context.

XSL•FO
RenderX

Qualitative Analyses

Directed content analysis for both structured interviews and focus groups was conducted in NVivo (version 14, release 2023; QSR International). We used an iterative approach to track and document the prevalence of emerging themes using a log of nodes in NVivo. The results from primary qualitative data for both structured interviews and focus groups were consistently noncontradictory; thus, the overall triangulated results from these 2 qualitative approaches were presented. Where applicable, verbatim responses were presented as quotes to provide further context from open-ended questions.

Quantitative Analyses

Concerning prehospital barriers (delay 1), participants selected from 6 responses. Provided with scores ranging from a minimum of 1 to a maximum of 6, participants ranked the barriers using a 6-point Likert scale, where 1 indicated "not a barrier," 2 "very weak barrier," 3 "weak barrier," 4 "averagely weak barrier," 5 "strong barrier," and 6 "extraordinarily strong barrier." A barrier category was considered significant (major theme) if it attained an overall mean score exceeding the prespecified hypothesized average of 3.5; otherwise, it was classified as a minor theme.

For in-hospital team barriers (delay 2) and system barriers (delay 3), there were 4 potential responses presented to medical participants, with Likert scores ranging from 1 ("least important barrier") to 4 ("very important barrier"). While initial qualitative data collection targeted emergent themes, Likert items were incorporated with open-ended questions in a mixed methods design to enrich qualitative inquiry and facilitate triangulation with quantitative data. Predetermined Likert response categories (eg, "not a barrier" to "very important barrier") quantified complex qualitative constructs such as attitudes, perceptions, and preferences. These response patterns informed purposive sampling for follow-up qualitative interviews across demographic groups and clinical experience levels. This approach bridged quantitative precision and qualitative depth by elucidating reasons behind each of the numeric Likert choices. The barrier category was considered important (major theme) if it surpassed the prespecified hypothesized average of 2.5.

The overall ranking of barriers was determined by calculating weighted mean scores, derived from the sum of individual Likert component scores multiplied by the number of responses for each component, subsequently divided by the valid sample size. This methodology has been previously validated for assessing barriers to trauma care in LMICs [20]. For example, in relation to prehospital delays, responses were scored on a Likert scale as follows: 1 (not a barrier), 2 (very weak barrier), 3 (weak barrier), 4 (averagely weak barrier), 5 (strong barrier), and 6 (extraordinarily strong barrier).

$$\text{Weighted mean barrier score} = [1(n1)+2(n2)+3(n3)+4(n4)+5(n5)+6(n6)] \div N$$

where n_1=number of people responding per component, and N=sample size.

To analyze data from the MOTOR, first, we dichotomized the responses into 2 categories, that is, whether a barrier was present (yes or no). Second, whenever a barrier was identified, responses were further categorized into three categories: (1) team-related barriers that lead to delays in the identification, prioritization, or timely referral of life-threatening injuries by the emergency teams; (2) individual barriers, either from patients or from clinicians, that contributed to delays in decisions regarding surgery, initiation of treatment, or referral of injuries exceeding local capacity; and (3) in-hospital system barriers that caused delays in securing essential supplies, including oxygen, anesthetics, sutures, and blood products, or delayed access to a functional laboratory, imaging diagnostics, theater space, or intensive critical care services. These categories were subsequently represented as proportions based on their relative contribution to the total ranks. The mean rank scores for each barrier across various cadres (third- and fifth-year medical students, intern, and police) were compared with the hypothesized mean using the nonparametric Kruskal-Wallis equality of proportions rank test.

Finally, to determine factors associated with treatment barriers and their impact on injury outcomes, we assessed normality with the Levene test and performed bivariate and multilevel restricted maximum likelihood mixed-effects logistic regression analyses using Stata (version 15.0; StataCorp LLC) after adjusting for clustering effects. The mvaghermite integration method was used to explore potential correlations between barriers and injury outcomes, including all-cause mortality and morbidity at 90 days postinjury, as measured by the GOS [35] and TOMS [36]. Confounding and effect modification were evaluated using Cochran-Mantel-Haenszel statistics. Variables demonstrating a P value of <.2 in the Mantel-Haenszel strata and those with biological relevance to injury severity were included in the final model.

Recalling that the severity of injury is an important determinant of its outcome, the effects of barriers on injury outcomes were stratified by injury severity at baseline based on the GCS and KTS II for neurological and musculoskeletal injuries, respectively [34]. The selected outcome tools were chosen due to the primary focus of the MOTOR trial project on neurological and musculoskeletal trauma [18], which represent the most significant injuries resulting from motorcycle crashes [33]. For neurological injuries, outcomes were dichotomized as favorable (if GOS score 4 - 5) or unfavorable (if GOS score 1 - 3), whereas for musculoskeletal injuries, outcomes were dichotomized as favorable (if TOMS equaled or exceeded initial Trauma Expectation Factor Score) or unfavorable (if TOMS was less than Trauma Expectation Factor Score), congruent to previous studies [35,36]. A detailed description of how these tools were used to evaluate the morbidity associated with injuries, including assessments for pain, physical function, disability, satisfaction with treatment, and overall quality of life after injury, is reported in the MOTOR trial protocol [18].

Convergence

Qualitative responses were analyzed in conjunction with quantitative metrics for each construct by 2 independent researchers (HL and MM). Any contradictions identified during this analysis were addressed by a third researcher (BO). The convergence status was categorized as "convergent" if the

XSL•FO
RenderX

qualitative findings aligned with the quantitative results, "complementary" if the combined outcomes were assessed as synergistic, and "divergent" if the 2 results were inconsistent. Divergence indicated contradiction, as reflected in the notation (Qualitative≠Quantitative). In contrast, complementarity examined the different aspects of a phenomenon from multiple perspectives, leveraging the strengths of each method to cover more content than either method alone, thereby providing fuller, richer, multidimensional, yet nonoverlapping insight (Quantitative+Qualitative). Conversely, the convergent approach required consistency of outcomes across methods (Qualitative=Quantitative).

Ethical Considerations

For this research involving human participants, all methods were performed in accordance with the ethical standards stipulated in the declaration of Helsinki and its later amendments, and in accordance with the relevant local guidelines and regulations. Ethical approval was obtained from the Research and Ethics Committees of Mbarara University of Science and Technology (reference: 1/7; 05/5 - 9) and the Uganda National Council for Science and Technology (reference: SS 5082). All participants or their legally authorized representatives provided written informed consent prior to enrollment into the study. We ensured confidentiality and anonymity of participants through the use of codes and generic pseudonyms, such as "doctor," "nurse," or "police" in the reports. Each participant was compensated with transport reimbursement of US $7.50 as approved by the research and ethics committee.

Results

Qualitative Findings

Of the 500 trauma care frontliners who participated in structured interviews and focus groups for qualitative analysis (100% response rate), 27% (135/500) were females, 73% (365/500) were males, 13% (66/500) were traffic law enforcement officers, and 87% (434/500) were medical trainees.

Prehospital Barriers (Delay 1)

The 3 highest ranked barriers to accessing injury care identified in the assessment of prehospital factors were as follows: delays in the activation and mobilization of emergency medical services (105/500, 21%); delays attributable to prehospital response times, including the arrival of ambulances at the scene (95/500, 19%); and prolonged transportation times to the hospital (75/500, 15%) (Figure 1).

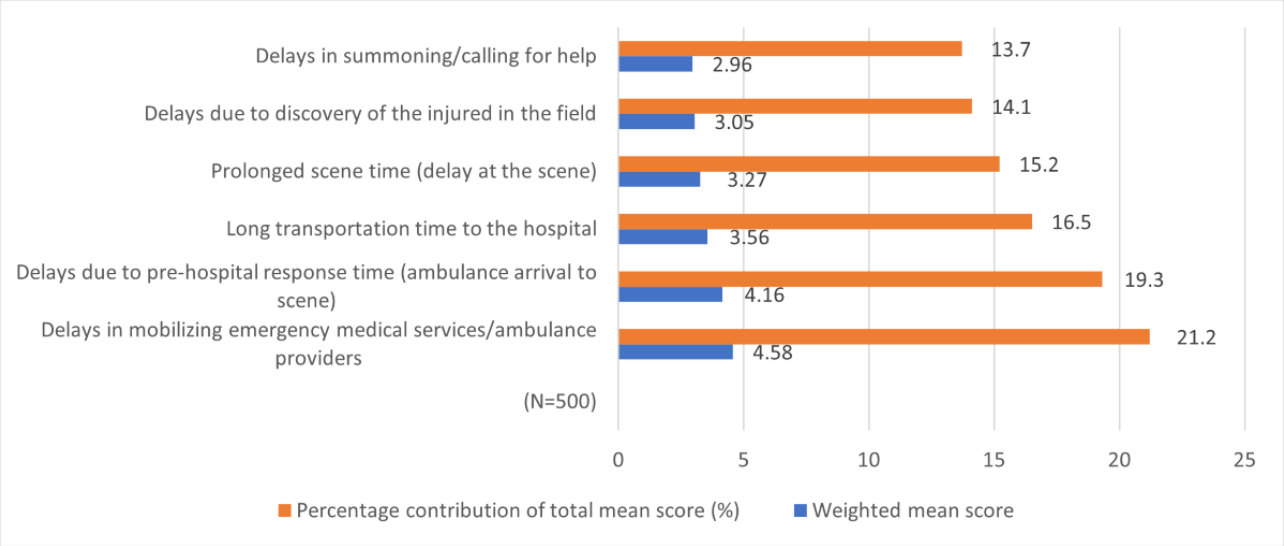
We found that while the police evacuated the patients with trauma, there were no designated rural networks of emergency rescue police to intervene for traffic crash victims.

> *The role of evacuation of traffic crash victims is not specifically designated to particular officers within our jurisdiction which means any road traffic officer on duty can oversee such cases.* [Participant no. 2, traffic law enforcement officials]

In addition, limited human resource capacity was reported as a key obstacle for the law enforcement professionals to participate in prehospital evacuation of injured patients.

> *Often we are understaffed and not able to undertake transfer responsibilities timely as this would mean leaving one's station vacant which would not be acceptable in our line of duty.* [Participant no. 36, law enforcement official]

Furthermore, a lack of key focal people concerned with coordinating emergencies at recipient hospitals and suboptimal communication technologies was cited as a key barrier to timely injury care.



> *Of course, you want to communicate timely but the poor communication technologies and network breakdown will let you down. Our intercom is not linked to that of the hospital emergency departments unless one is chanced to have physical contact there. Nevertheless, we are required to drop them (patients) by the government emergency hospital departments.* [Participant no. 11, traffic police commander]

We established that there were also concerns of bias and mistrust that led to nondisclosure of injury-related information, which could delay the emergency evacuation process and insurance compensation claims.

> *We would be delighted to have an integration of emergency evacuation rescue services that is well coordinated along with the health ministry, I guess this would increase our public trust. You want to help evacuate these accident victims, but they think you are interrogating, arresting, and prosecuting them for their traffic crimes.* [Participant no. 47, police officer]

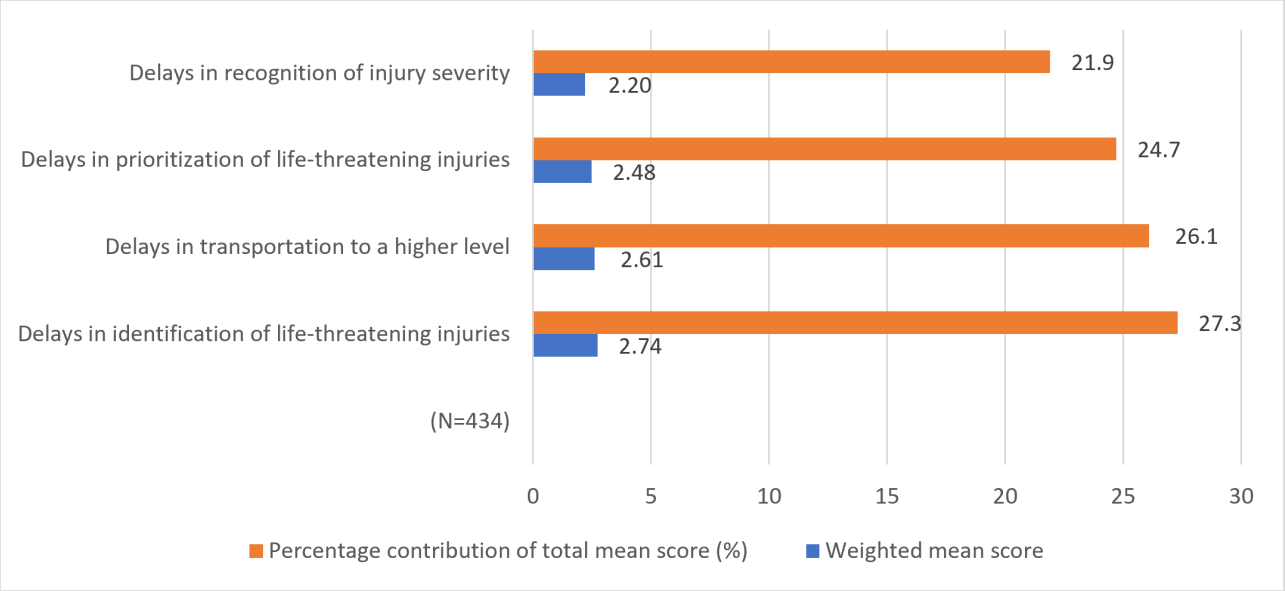
Figure 1. Overall weighted mean scores for prehospital barriers (delay 1) ranked from lowest to highest.

In-Hospital Trauma Team and Individual-Patient Barriers (Delay 2)

The highest ranked in-hospital team barriers were delays in identification of life-threatening injuries (117/434, 27%) and in executing referrals to higher trauma centers (113/434, 26%) (Figure 2).

We found that significant financial limitations prevented patients from obtaining emergency laboratory or imaging investigations that required out-of-pocket payments at private facilities, contributing to unnecessary delays. Additionally, there were no clear referral protocols linking the public to private facilities for specialized investigations or interventions that were not available in public facilities.



> *We wanted to obtain head and brain CT scans, but when the service in our government national referral hospital was down, the patient's next of kin delayed mobilizing financial resources to outsource one from private. We do not have direct referral pathways to private hospitals so then we had to wait until patients' relatives availed us with the results of the investigations before operating.* [Expert participant no. 1, attending neurosurgeon]

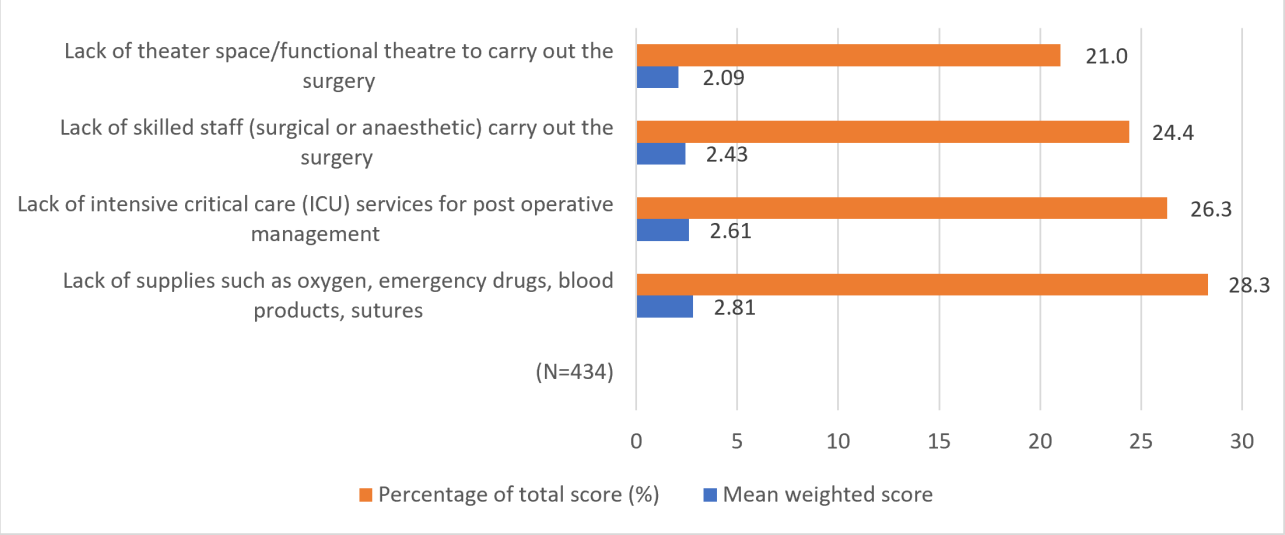
The trauma teams from qualitative clinical audits raised concerns about delays in hospital arrivals due to reliance on public transportation and dysfunctional ambulance systems. Additionally, there was limited capacity among emergency medical services staff and critical care supplies for life-threatening injuries, compounded by suboptimal health insurance coverage and communication barriers with the families of the injured individuals.

> *He arrived late in a taxi as there was no fuel in the ambulance from the referring hospital. The staff there say were understaffed and were unable to accompany the patient as no one would cover their duty. They could have placed a chest tube though, but they were out of stock. Our ICU is full though, so we plan to refer him to a private hospital after a chest tube, but we are facing difficulties with direct communication, he has no attendants available yet as his family is still mobilizing resources for ICU costs. He does not seem to be insured.* [Expert participant no. 3, attending anesthesiologist]

XSL•FO
RenderX

Figure 2. Overall mean weighted scores for in-hospital trauma team barriers (delay 2).

In-Hospital System Barriers (Delay 3)



The highest ranked in-hospital system barriers to injury care were a shortage of emergency medical supplies (123/434, 28%) and suboptimal critical care services (114/434, 26%) (Figure 3).

Qualitative clinical audits revealed a limited range of laboratory diagnostic services available in public facilities, contributing to delays in treatment decisions. Additionally, a general shortage of essential medical and surgical supplies for both pre- and postoperative care, including pharmaceuticals and blood products, was noted.

> *My role as an intern was to stabilize the patient before theatre once the decision to operate was made by the consultant. It frustrated me when I could not get the lab results and blood products on time because of having no reagents, yet my boss was on my neck. I was waiting for the relatives to bring the results from private.* [Participant no. 133, intern doctor]

> *He was supposed to get labetalol for his intracranial pressure before brain surgery; I am not sure how far his relatives have gone with lobbying for that. The orthopedic team also says he has not yet bought the implants for his fractures. There were social issues there, but I think the team will gather when the resources are available.* [Participant no. 154, surgery resident]

Quantitative Findings

Overview

Kruskal-Wallis test showed statistically significant differences in how the various cadres ranked the various barriers (Multimedia Appendix 3). Of the 1003 patients with trauma in the MOTOR for quantitative analysis, there were 82% (817/1003) males and 19% (186/1003) females. The overall median age (IQR) was 28 (22-37) years. The median (IQR) commute distance was 5 (2-10) km, and median (IQR) prehospital time was 2 (1-3) hours from accident scene to the emergency departments. Neurotrauma was prevalent in 95% (949/1003), whereas musculoskeletal injuries occurred in 80% (799/1003) of participants. A majority (745/1003, 74%) of participants sustained polytrauma. The median (IQR) baseline injury severity scores–based GCS and KTS were 14 (11-15) and 8 (7-9), respectively.

Characteristics of Patients Who Encounter Barriers to Injury Care

We analyzed 90-day complete follow-up data for 88% (887/1003) of individuals with traumatic brain injuries, and for 80% (799/1003) of individuals with musculoskeletal injuries. The characteristics of those who experienced barriers are summarized in Table 1. This group included patients who were critically ill, with 64% (272/426) presenting with a moderate to severe KTS and 45% (142/426) exhibiting moderate to severe GCS scores. Furthermore, 31% (133/426) of these individuals sustained multiple injuries that necessitated admission. For individuals with traumatic brain injuries, the proportion of unfavorable outcomes was significantly higher among those who reported barriers (84/366, 23% compared with 45/521, 9%), with χ^2_1 (N=887)=35.44 and P<.001. In contrast, for those with musculoskeletal injuries, there was no statistically significant difference in the proportions of unfavorable trauma outcomes between individuals who encountered barriers and those who did not (74/311, 24% vs 121/494, 25%), as indicated by χ^2_1 (N=805)=0.05 and P=.82. However, the mortality rate was higher among individuals who reported barriers to injury care than among those with no such barriers (55/366, 15% vs 27/521, 5%), with χ^2_1 (N=887)=24.83 and P<.001, as shown in Table 1.

In-Hospital Audit of Nature of Common Barriers to Injury Care for the Patient Participants (Delay 3)

From 1003 audited trauma cases, only 59% (587/1003) received treatment for their injuries without their clinical teams encountering any barriers in the provision of definitive care. Hospitals whose trauma teams received rural trauma team development training identified more barriers than their counterparts (256/501, 51% vs 170/502, 34%; *P*<.001). The proportion of patients who faced 1 or more barriers was 23.1% (232/1003) at the individual (patient) level, 6.3% (63/1003) at trauma-team level, and 17.9% (180/1003) at hospital-system level. Team-level barriers referred to obstacles that resulted in delays in the activation of emergency teams, as well as in the identification, prioritization, recognition, or timely referral of life-threatening injuries. Individual-level barriers were those that impeded timely decisions regarding the initiation of treatment or the referral of injuries that exceed local capacity. In contrast, in-hospital system–level barriers were systemic obstacles that caused delays in obtaining essential supplies, such as oxygen, anesthetics, sutures, blood products, and diagnostics, as well as in securing access to theater space and intensive or critical care services.

Factors Associated With Health Care Access Barriers and Their Impact on Injury Outcomes

The results of factors associated with barriers to injury care are presented in Table 2. After adjusting for clustering effects by hospital teams and resources, mixed-effects regression analyses indicated that the factors independently associated with barriers to injury care included increasing age, involvement in motorcycle-car crashes, the multiplicity of injuries requiring admission, the presence of moderate or severe injuries as assessed by both the KTS and the GCS, the occurrence of axial head lesions, and the necessity for craniotomy.

Further analysis demonstrated that the presence of barriers was independently associated with unfavorable GOS scores (odds ratio [OR] 3.15, 95% CI 2.23 - 4.66; *P*<.001) for neurological injuries and was linked to a 4-fold increase in odds of 90-day mortality (OR 4.20, 95% CI 2.25 - 6.94; *P*<.001). However, barriers were not significantly associated with unfavorable TOMS scores for musculoskeletal injuries.

Multilevel analyses identified key factors associated with barriers, including arrival by public means (adjusted OR [aOR] 1.62, 95% CI 1.09 - 2.41; *P*=.02), increasing age (aOR 1.01, 95% CI 1.00 - 1.03; *P*=.01), and sustaining 1 or more injuries requiring admission (aOR 1.92, 95% CI 1.18 - 3.14; *P*=.01 vs aOR 3.69, 95% CI 1.95 - 6.98; *P*<.001), as well as a severe KTS score of ≤6 (aOR 2.71, 95% CI 1.37 - 5.37; *P*=.004). Conversely, a negative head CT result and skull fractures were associated with lower odds of encountering barriers in both bivariate and multilevel analyses as shown in (Table 2).

[b]Not applicable.

[c]Serious injury refers to one that warrants admission on its own merit.

[d]CT: computed tomography.

Convergence

The aggregated data indicated that the components of delay 1 exhibited divergence, while convergence was observed for delays 2 and 3. A summary of the integration between qualitative and quantitative findings is presented in Table 3.

XSL•FO
RenderX

Table . A joint display summary showing the intersection of qualitative and quantitative results.

Theme/construct	Quantitative metrics	Quantitative findings	Qualitative quotes	Convergence status	Implications and overall interpretation
Delay 1: delays in decision to seek injury care	Prehospital interval in hours	Prehospital intervals of more than 1 hour were not independently associated with reported barriers to injury care (OR[a] 1.11, 95% CI 0.84 - 1.46; *P*=.48).	• "You want to help evacuate these accident victims from scenes, but they think you are interrogating, arresting, and prosecuting them for their traffic crimes." • "He arrived late in a taxi as there was no fuel in the ambulance from the referring hospital."	Divergent	Prehospital time was confounded by several factors including public mistrust, scene time, commute distance, and ambulance availability, which impacted decisions to seek injury care.
Delay 2: delays in reaching injury care	Referral decision to dispatch interval in hours	Referral to dispatch intervals of more than 1 hour were associated with lower odds of reported barriers to injury care (OR 0.62, 95% CI 0.46-0.84; *P*=.002).	• "Due to understaffing we are often unable to undertake transfer responsibilities timely." • "You want to communicate the transfer timely but the poor communication technologies and network breakdown will let you down." • "Our intercom is not directly linked to hospital emergency departments."	Convergence	Prolonged referral intervals were linked to barriers in accessing timely definitive injury care. Hospitals would delay referrals when the demands of patient care did not exceed the available local resources or when the necessary resources for executing the referrals were unavailable.
Delay 3: delays in receiving adequate injury care.	Emergency department arrival to head CT[b] imaging as a measure of in-hospital delays	Negative CT results were associated with lower odds of reporting barriers (OR 0.54, 95% CI 0.35-0.83; *P*=.01). Conversely, severe Kampala Trauma Scores ≤6 were associated with increased odds for reporting barriers to injury care (OR 2.71, 95% CI 1.37 - 5.37; *P*=.004).	• "We do not have direct referral pathways to private hospitals for CT." • "The patient's next of kin is still mobilizing financial resources to outsource CT from private." • "Our intensive care unit is full, so we plan to refer him to a private hospital, but his family is still mobilizing resources for ICU costs."	Convergence	Critically ill patients with severe injuries face obstacles in accessing injury care such as dysfunctional referral protocols and suboptimal insurance coverage compared with less severely injured individuals.

XSL•FO
RenderX

Theme/construct	Quantitative metrics	Quantitative findings	Qualitative quotes	Convergence status	Implications and overall interpretation
Injury outcomes at 90 days	Injury morbidity based on proportions of unfavorable outcomes and proportions/odds of mortality	Multiplicity of injuries was associated with increased odds of encountering barriers in the continuum of injury care (OR 3.69, 95% CI 1.95 - 6.98; *P*<.001). Encountering barriers was independently associated with 3-fold increase in unfavorable Glasgow Outcome Scores (OR 3.15, 95% CI 2.23 - 4.66; *P*<.001) and 4-fold increase in 90-day mortality (OR 4.202, 95% CI 2.245 - 6.937; *P*<.001).	• "He was supposed to get labetalol for his intracranial pressure from head injury before brain surgery; the relatives need to lobby for that. The orthopedic team also says he has not yet bought the implants for his fractures. The multidisciplinary team will gather when everything is in place." • "We had to wait until patients' relatives availed us with the results of the investigations from private before operating."	Complementary	Multiple injuries were linked to delayed access to critical surgical care interventions. These delays could contribute to undesired injury outcomes and increased mortality.

[a]OR: odds ratio.

[b]CT: computed tomography.

Discussion

Principal Findings

The objective of this study was to identify critical obstacles within the continuum of trauma care, both before and during hospital admission, as perceived by first responders. We found that there was a convergence of key themes between those reported by frontline health workers during the qualitative interviews and those elicited by the attending clinicians during the real-time execution of patient treatment in the quantitative trauma registry audit. Our results indicated notable systemic inefficiencies in the activation of emergency medical services and the arrival of ambulances, which may exacerbate the severity of injuries and negatively impact patient outcomes. Moreover, a lack of designated rural networks for emergency responses, as highlighted by the law enforcement officials, exacerbates the situation in remote areas. Furthermore, the absence of clear protocols for traffic crash victim evacuation may negatively impact the quality of care provided. Similar impediments have been earlier identified in remote settings of other LMICs, highlighting the need to strengthen rural trauma systems [20,38].

Qualitative analyses uncovered organizational and system-level factors encountered by law enforcement and referring clinicians. For instance, understaffing and the absence of clearly defined roles for emergency road traffic response personnel underscore the necessity for strategic workforce management and explicit assignment of responsibilities. The complex interplay among understaffing, role ambiguity, and task delays driven by burnouts due to heavy workload degrades emergency care processes. These effects reflect a mismatch between people, tasks, and tools, which collectively undermines the health system's ability to deliver safe, high-quality care. Within the Systems Engineering Initiative for Patient Safety, these workforce-related conditions operate as work system determinants that shape how care tasks are allocated, coordinated, and executed.

Moreover, there were reported inefficient communication technologies that impeded effective trauma coordination between emergency responders and recipient hospitals, delaying patient transfers. Research shows that such inefficiencies could result in the loss of critical information and compromise patient care [13]. In a recent scoping review of handover practices between paramedics, emergency department staff, and trauma teams, lost information due to communication gaps was associated with diagnostic errors, missed injuries, and increased mortality [39].

Furthermore, we identified psychosocial constraints to an effective emergency response framework manifested by public bias and mistrust of law enforcement trauma evacuation teams. This mistrust led to withholding valuable information regarding the circumstances of injury, which would be essential for assessing the liability and settlement of insurance claims, thereby reducing out-of-pocket expenditure. These observations reinforce the need for comprehensive community engagement and awareness campaigns to build public trust. Statutorily integrating police services with health care systems may bridge these gaps [40]. However, this unified approach requires clearly defined dispatch protocols with explicit role specifications, structured assessment checklists, and quality safeguards with clinical oversight of scope of practice to ensure patient safety and compliance with data-protection policies.

We found in-hospital barriers characterized by a shortage of surgical supplies, which delayed the identification and treatment of life-threatening injuries. Access to essential medical supplies and a competent health workforce are an integral component of World Health Organization (WHO) building blocks for resilient health systems [41]. A sustainable robust logistical framework is mandatory to ensure that clinicians can quickly assess, diagnose, and treat life-threatening conditions. In quantitative analyses, the plausible correlation between the presence of barriers, injury severity, and unfavorable outcomes further emphasizes that these systemic issues not only hinder immediate care but also have lasting implications for the recovery and survival of very critically ill patients whose care demands exceed local resources. The increased odds of mortality among those who encounter obstacles highlight the urgent need for interventions aimed at streamlining care processes and resource allocation within trauma care systems. Comparable research conducted in Rwanda, Ghana, and South Africa assessed the application of multiple data collection methods to identify context-specific blockages to injury care that contributed to mortality and disability, and our findings are consistent with these studies [38].

Finally, the obstacles identified by the frontline workers during the real-time execution of treatment, such as inadequate diagnostic resources, transportation failure, and financial difficulties, spotlight systemic challenges within the Ugandan health care sector. Sustainable health care financing is an additional core WHO building block because it protects patients from catastrophic expenditures [41]. In a recent Delphi study conducted in Malawi [42], the absence of readily available physical resources emerged as the most significant factor contributing to in-hospital delays. Moreover, the high financial cost of care and the unaffordability of emergency transport were identified as the primary factors leading to prehospital delays [42]. These challenges reflect inadequate resource allocation to trauma care and to the broader health sector, which has negatively impacted the quality of health systems in both LMICs and HICs [43,44]. For instance, a systematic review of barriers to injury care in 21 American countries revealed that a lack of resources and equipment constituted 58% (33/57) of barriers, followed by the absence of protocols, understaffing, transport and logistics challenges, and financial limitations [45]. Further research from Australia and Europe elaborates more on these challenges, highlighting rural-urban and socioeconomic disparities amid declining social support structures [46,47].

Poor-quality health care and inadequate financial risk protection are now considered the major drivers of mortality, surpassing inadequate health access, which has delayed the achievement of SDG3 targets 3.6 and 3.8 in vulnerable populations, irrespective of country-specific development index [43,48]. Furthermore, the reported inefficient communication technologies that impede effective trauma coordination, coupled with inadequate infrastructural capabilities influenced by social factors in health systems, could impede the attainment of SDG9 [48]. Thus, attaining universal health coverage should not be regarded as a stand-alone but rather a multisectoral initiative that incorporates elements of SDG9. This would foster technological innovations for medical equipment, build inclusive infrastructure such as safe road networks and accessible hospitals with functional emergency departments, and establish resilient industries that foster research development and equitable medical education to address low-quality and health access barriers [49]. Our results indicate weak connections between the formal and informal sectors, public and private sectors, and health and technology sectors. Addressing these gaps through strong advocacy by civil society organizations could meet the care demands of severely injured patients and enhance the overall learning and work environment for trainee physicians in low-resource settings, thereby improving the quality of their medical education (SDG 4).

Policy Implications

Our study has identified multiple significant obstacles present at the various stages of the trauma care continuum. Most of these identified challenges are applicable to other LMICs [20,38,42]. Consequently, the hindrances to injury care from the perspectives of trainee physicians and traffic law enforcement first responders must be addressed to accurately conceptualize their expected roles in the trauma care continuum and patients' advocacy. Addressing these barriers requires multidisciplinary approaches focusing on quality prehospital response, swift safe transportation, and robust postcrash care systems. Stakeholders, including the National Road Safety Council, Ugandan Ministry of Health, Ministry of Education, and Regional Police Commanders, should engage in planning meetings to address these critical issues.

All the financial, logistical, and system-level impediments to trauma care elicited in this study are direct obstacles to the WHO health systems building blocks [41]. This study provides context for the implementation strategies needed to address gaps in injury care. In Uganda, policymakers should strengthen the existing Integrated Disease Surveillance and Response system by adapting monitoring tools including electronic logistics management and health information systems to track stockouts of essential medical supplies, human resources observatories to monitor health workforce distribution and service delivery inequities, and national health accounts to monitor health financing, public expenditure, and financial risk protection. These measures, aligned with WHO guidance and the Global Health Observatory, would form a coherent framework for assessing and improving health sector performance regarding trauma care [41].

Regarding individual-patient and trauma-team delays, the interplay between limited insurance coverage and insufficient disposable incomes leads to substantial delays as caretakers mobilize funds for critical investigations and emergency surgical procedures. For instance, a brain computed tomographic scan can cost a substantial amount of up to US $130, commensurate to the average monthly salary of green-collar workers in Uganda [24]. Consequently, trauma teams delay surgical decisions, which may preclude high-quality surgical outcomes amidst potential threat for medical-legal litigation, as patients and families increasingly assert their autonomy in treatment decisions. The likelihood that individuals with severe injuries have high care demands, which may exceed local resources, necessitates advocacy for improvement in the health system to

XSL•FO
RenderX

adequately address these needs. To achieve this goal, stewardship that promotes good governance and team leadership, together with routine community health insurance engagement, should accompany health system performance assessments in line with the WHO building blocks for sustainable health systems.

In-hospital system delays in injury care were primarily attributed to a lack of supplies and critical care services, with these constraints ranking second in an audit of patient handling. Key supplies such as oxygen, anesthetics, and blood products, as well as access to operating theaters and intensive care units, are all mandatory requisites for the survival of patients with major trauma. Access to good-quality service delivery such as critical care underpins one of the WHO building blocks. Previous studies indicate that dual deficiencies in both equipment and human resources imply a severe hindrance to lifesaving interventions, contributing to a substantial proportion of preventable trauma deaths in LMICs [13,20]. To mitigate these adversities, investment in reliable supply chain management through private-public partnerships, improving ambulance coordination through sufficient staffing, and establishing financial support systems for uninsured patients could streamline referral pathways to ensure continuity of care in emergency situations. The use of noncontributory funding sources generated through public taxation, pooling funds across multiple public sectors, and strong accountability to track performance of the designated funds could mitigate the shortage of supplies and safeguard patients against catastrophic expenditures [48].

Strengths and Limitations

The strengths of this study dwell in its mixed methods approach, which enabled a nuanced analysis of barriers encountered at various stages of real-world injury care. Additionally, by focusing on the perspectives of frontline workers directly involved in trauma care, the study provides valuable insights into context-specific challenges encountered in LMIC settings. Moreover, the study contributes valuable evidence on the intersection of trauma systems, medical education, and health equity in low-resource settings, which is relevant to the attainment of SDGs 3 and 4.

However, there were limitations that should be recognized. First, the use of Likert scales may pose challenges for interpretation although they were applied to mixed methods to enrich qualitative inquiry and facilitate triangulation with quantitative data. While the study used parametric tests to enhance statistical power, this approach might not align with best practices for exploratory research that lacks prior hypotheses [50].

Second, the study assumes that accumulated Likert items can serve as a reasonable surrogate for continuous interval measurements. Although this assumption facilitates the computation of overall mean scores to enable objective ranking for the barriers, it may potentially compromise the precision of central tendency measures [51]. Moreover, while we endeavored to interpret the data objectively through triangulation and use of parametric tests, we acknowledge the possibility of bias arising from the integration of diverse data paradigms which used varying collection and sampling methods. This concern reflects a significant and ongoing debate within the field of mixed methods research [52].

Third, the reliance on data saturation during interviews may have unintentionally constrained the identified barriers to dominant themes, thereby silencing divergent minority opinions. This represents an inherent methodological issue in qualitative research, which often prioritizes the depth and richness of data over numerical targets [31]. Moreover, we acknowledge that recall in qualitative responses and the missing 90-day outcome data may have introduced systematic bias.

Finally, we acknowledge that aggregating injury severity into subcategories of mild, moderate, and severe, and outcomes as favorable versus unfavorable, may lead to a loss of information, contributing to residual confounding in assessing the true impact of barriers on injury outcomes. Moreover, in view of other host and environmental factors that impact injury outcomes but were not assessed in this study, patients with less severe injuries may have had minimal care needs, which could prevent attending clinicians from identifying significant in-hospital barriers during their treatment, compared with the severely injured patients, an issue that future studies should address. Nevertheless, the study assumed that stratifying trauma outcomes by injury severity categories would minimize this confounding.

Conclusions

This mixed methods study evaluated the key barriers to injury care within the context of frontline health workers in low-resource settings. We identified significant barriers in the prehospital and in-hospital trauma care continuum, which could adversely impact patient outcomes. These systemic challenges require multifaceted targeted interventions that integrate operational improvements to address system-level factors and logistical frameworks through community engagement. The results of this study warrant an urgent need to secure sustainable hospital supplies and establish clear referral protocols that link the public to private facilities. These interventions would enable timely treatment decisions to optimize trauma care delivery and treatment outcomes, especially for those who sustain severe injuries. Future research should be robust multicenter prospective cohort studies that integrate mixed methods to investigate how these barriers impact long-term injury outcomes in diverse socioeconomic settings.

Acknowledgments

The authors wish to express their gratitude to the staff at various medical referral institutions in Uganda, including Jinja, Mbarara, Hoima, Mubende, Kiryandongo, and Kampala International University Teaching Hospitals for providing space for data collection. Furthermore, the authors acknowledge all study participants for their willingness to dedicate their time to participate in this investigation and the MOTOR trial registry project investigators for permitting triangulation of the datasets used in this study.

Abstract

Background: AI tools have the potential to enhance personalized clinical care, particularly in radiology. However, their integration into clinical workflows remains complex, especially in pediatric oncology, where early cancer detection is critical. Children with Li-Fraumeni syndrome (LFS), a rare cancer predisposition disorder, undergo regular surveillance whole-body magnetic resonance imaging (wbMRI), which presents an opportunity for AI-assisted tumor detection.

Objective: We evaluated the feasibility of an AI-assisted overlay for highlighting tumor-like regions in pediatric surveillance wbMRI and explored how access to the overlay influenced radiologist workflow, candidate-lesion marking behavior, follow-up recommendations, and perceived workload.

Methods: We developed a patch-based AI segmentation model trained on augmented 2D slices from 675 surveillance wbMRI volumes of pediatric patients with LFS. The model was designed to highlight regions with high tumor probability. A reader study was conducted with 2 radiologists who independently reviewed wbMRI cases both with and without AI assistance. We measured evaluation time, number and location of reader-marked candidate lesions, type of follow-up recommendation, and subjective feedback using structured questionnaires.

Results: AI assistance altered interpretation workflows for both radiologists, with mixed effects. On average, the time required to evaluate each case increased when using the AI tool for both radiologists. However, one radiologist had an increase in the number of candidate lesion locations selected with the tool, and one had a decrease in the number of candidate lesion locations selected with the tool. Subjective feedback indicated that one of the radiologists reported lower mental demand with the AI tool, while both radiologists reported lower stress with the AI tool. Interrater variability was evident, underscoring the need for personalized calibration of AI tools.

Conclusions: AI-assisted wbMRI interpretation can improve tumor detection in pediatric cancer surveillance by reducing false negatives. However, its influence on workflow efficiency and interradiologist variability highlights the importance of careful implementation. Successful integration requires addressing challenges such as improving the predictive precision of AI models, offering intuitive end-user designs and instructions, and building trust in AI outputs. AI outputs can influence workflow and behavior in reader-specific ways. Clinical translation will require larger, randomized, multireader studies and model refinement to reduce false positives and quantify lesion-level reader performance. This can help ensure better patient outcomes in addition to reduced clinician burnout.

Introduction

Integrating AI tools into clinical practice marks a paradigm shift in health care, with the potential for enhanced diagnostic accuracy, improved workflows, and personalized patient care. In fact, a 2019 survey of health professionals found that up to 71% of surveyed physicians opined that AI would improve and impact the field of medicine within the next decade [1]. The potential of AI tools in health care extends across various domains, including radiology [2], pathology [3], dermatology [4], ophthalmology [5], general practice [6], surgery [7], neurology [8], cardiology [9], and more. By leveraging vast amounts of medical data, AI algorithms can help identify patterns and correlations that may be more difficult for human clinicians to recognize due to the size, rarity, or complexity of certain clinical conditions. As a result, this can enable earlier and more accurate diagnoses and subsequent interventions. Machine learning models have shown promising task-specific performance in selected medical-imaging applications, although performance and clinical benefit vary substantially across tasks, datasets, and implementation settings [10].

In addition to aiding in clinical diagnostics, AI tools can enhance clinical decision-making [11]. AI-based decision support systems can synthesize plans from multimodal data and can continuously learn from new data, improving recommendations over time and adapting to the latest clinical guidelines and research findings [12]. The use of AI in clinical settings also addresses the growing concern of clinician burnout caused by an increase in workload in interpreting imaging examinations without a corresponding increase in manpower [13]. Yu et al [14] further support the complexity of human-AI collaboration in diagnostic settings and indicate significant variability in how radiologists respond to AI assistance. They found that radiologists' performance was easily influenced by AI errors in their large-scale study on AI-aided chest X-ray interpretation, but conventional factors such as experience or familiarity with AI did not predict the impact of AI support. There is also inherent variability in how radiologists use and interact with AI tools, which is influenced by personal biases, cognitive strategies, and the opacity of AI algorithms [15-18].

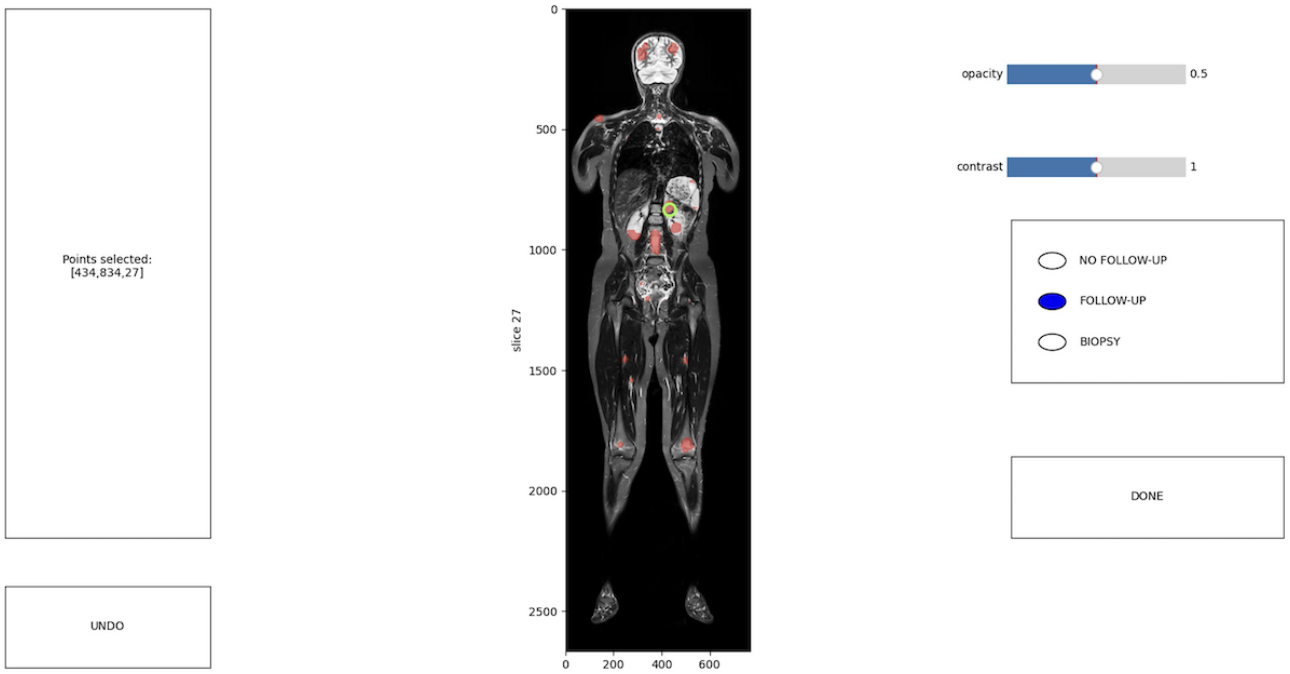
Integrating AI into clinical practice also raises concerns about data privacy [19], algorithmic bias [20], and the need for rigorous validation and regulation [21]. Ensuring that AI tools are reliable, explainable, and complement rather than replace clinical judgment is critical to ensuring their acceptance, since replacement is a significant fear in the field, for clinicians and patients receiving care alike [22,23]. Thus, a collaborative approach, where AI augments the clinician's expertise instead of acting as a substitution, is essential for the successful adoption of these technologies.

In this paper, we studied the interaction between radiologists and a specific AI tool that was developed for the interpretation of tumors in whole-body magnetic resonance imaging (wbMRI) performed as part of an imaging protocol for cancer surveillance [24]. Early detection of tumors in patients with cancer predisposition disorders such as Li-Fraumeni syndrome (LFS) through clinical-imaging protocols has been shown to improve the prognosis of patients [25]. However, the detection and segmentation of tumors in pediatric wbMRIs is challenging for many reasons. In particular, variations in the age, sex, body shape, body size, and bone density of a developing child may influence the anatomical and physiological properties that contribute to image formation. In addition, variations in tumor size, location, magnetic resonance imaging (MRI) signal brightness, type and settings of the MRI scanner, and MRI artifacts are a few of the factors that radiologists must consider when evaluating wbMRIs in search of tumors in patients with LFS [26]. Although the malignancy of a tumor cannot always be identified from an MRI examination alone, developing a tool to assist radiologists in finding tumors by highlighting areas of high tumor probability may save time, reduce the chance of missing tumors, and minimize the amount of invasive tests. However, there is a lack of tools for finding tumors in wbMRIs for the reasons outlined above. To our knowledge, AI-assisted tumor detection has been less studied in pediatric surveillance wbMRI than in adult or single-organ imaging settings. This setting is distinct because lesions are often very small relative to the full image volume, tumor prevalence is low, and the whole-body field of view introduces substantial anatomical heterogeneity. Accordingly, our contribution is both technical and human-factors-oriented: we describe a patch-based tumor-likelihood overlay for pediatric LFS surveillance wbMRI and an exploratory reader study, evaluating how the AI overlay influences workflow, candidate-lesion marking behavior, follow-up recommendations, and perceived workload.

In order to find areas of high tumor probability within wbMRIs, we use segmentation. The use of deep learning methods to perform biomedical segmentation tasks effectively, especially in low-data availability domains, has seen great strides in recent years [27,28]. In spite of this, the comparative sizes of wbMRI volumes and tumors are so vastly different that the signal-to-noise ratios are often too low for proper tumor detection and segmentation when using full volumes or generative approaches [29,30]. Patch-based approaches show promise in this regard for segmenting very small objects in large spaces [31-33].

After developing our AI tool to highlight areas of high tumor probability in wbMRIs, we performed a validation study with 2 radiologists, each reviewing several wbMRIs with and without the assistance of the AI tool, to analyze the effect of the tool on the overall evaluation time, candidate-lesion marking behavior, follow-up recommendations, and questionnaire responses. Based on our findings from this study and relevant literature, we provide insights on how to effectively incorporate AI tools into health care to navigate existing challenges and uncover unexplored opportunities. Based on these findings and relevant

XSL•FO
RenderX



literature, we discuss practical considerations for integrating such overlays into health care workflows.

Methods

AI Tool Development

We developed our AI tool, shown in Figure 1, starting from its initial conception and progressing through multiple iterations to refine it based on best practices and feedback. We carefully integrated feedback from our clinical collaborators at every stage, ensuring that both the underlying algorithm and the user-facing components aligned with real-world diagnostic needs. The model-development and reader-study components are reported separately below.

Figure 1. The app that allows scrolling through a volume with the AI tool overlaying masks onto the regions of high tumor probability (in red), selected points (candidate lesion locations) on the image (in a green circle), a list of selected points on the left, an opacity slider and contrast slider on the top right, and the a reader-selectable follow-up recommendation on the right.

We trained the AI tool to recognize areas of high tumor probability using datasets generated by obtaining 2D patches from the slices of 675 coronal Short Tau Inversion Recovery (STIR) wbMRI examinations in which volumes were assessed from patients with LFS aged 0 to 18 years, followed in the Oncology Department of a large tertiary pediatric hospital after the study received Research Ethics Board approval from our institution. Only 27 out of 675 (4.0%) volumes were tumor-positive, containing 60 tumors in total, and only 120 out of 27,437 (0.44%) slices contained tumor signal. We have approximately 40 slices per volume, with each slice being approximately 3000×800 pixels. This created an extreme class-imbalance setting, with tumor tissue representing a minute fraction of the total image area. Because the natural prevalence of tumor-containing tissue was too low for stable patch-based training, patch sampling was intentionally enriched for tumor-containing patches, as described below. The diameter of each tumor section ranged from about 10 to 100 pixels, representing only a small fraction of each wbMRI volume. We used 4-fold cross-validation and a test set while ensuring that each of the train and validation folds, as well as the test set, was separated by patient volumes. A total of 5707 patches of size 128×128 pixels were extracted after split assignment, with 3995 (approximately 70%) used for training/validation and 1712 (approximately 30%) for testing. Within each split, approximately 25% (999/3995 and 428/1712) of the sampled patches contained tumor tissue. This proportion was enforced intentionally for model development and did not reflect the natural prevalence of tumor-containing tissue in surveillance wbMRI. Positive patches were drawn primarily from tumor-containing slices and centered on annotated lesions, with additional jittered samples to vary lesion position; negative patches were sampled from tumor-free regions, tumor-free volumes, and physiologically bright STIR regions that commonly generate false positives. Data splitting was performed at the patient level before patch extraction so that all patches from a given patient remained within a single training, validation, or test partition. The results on the volume-level cross-validation set and test set were obtained by running the trained patch-based model in a sliding-window manner on each slice, with 25% pixel overlap between adjacent patches to reduce edge misses.

Ethical Considerations

The study received approval from the Research Ethics Board at The Hospital for Sick Children (SickKids) under the protocol “Machine Learning (ML) Approach to Improve Early Cancer Detection” (number 1000063239; principal investigator: AG).

Patches, Augmentations, and Synthetic Tumors

Rather than using all possible patches, we found it more efficient and effective to primarily train the model using patches that

XSL•FO
RenderX

contained tumors centrally (Figure 2). The masks for the corresponding patches were taken from the same location within the mask volumes. We also included a few patches with their centers moved around randomly to account for variations in the location of a tumor within any given patch. To improve the specificity of the tool, we also included several patches from elsewhere in the body to train the model to recognize false positives. For instance, we included patches from parts of the body that are inherently bright on wbMRI STIR sequences, to ensure that the model can differentiate between inherently bright body regions and tumors, which also appear bright. Finally, we included a few patches from volumes without tumors, which were obtained from the same general region as volumes containing tumors, in order to help the model differentiate between patches with and without tumors obtained from the same part of the body.

Figure 2. (A) A patch and mask with tumors. (B) A patch and mask without tumors.

To improve robustness, we applied augmentations intended to approximate routine manipulation during MRI review, including zoom, brightness variation, and noise modulation. We also included synthetically inserted tumors of varying size, shape, brightness, and location to increase exposure to rare small-lesion patterns [34,35].

Model and Losses

The U-Net model [28] was used along with a compound loss function containing asymmetric unified focal loss [36], Dice loss [37], contour perimeter loss [38], and contour difference loss to address extreme foreground-background imbalance and to improve lesion boundary localization. The respective coefficients α, β, γ, and δ of each of these losses were tunable hyperparameters.

$$(1) \text{Loss}_{patch} = \alpha \times \text{Loss}_{AUF} + \beta \times \text{Loss}_{D} + \gamma \times \text{Loss}_{CP} + \delta \times \text{Loss}_{CD}$$

Each of the 4 parts of the loss function (Equation 1) served a specific purpose. Loss_{AUF} and Loss_{D} dealt with the imbalance between the hard class (tumor pixels) and easy class (nontumor pixels), and Loss_{CP} and Loss_{CD} ensured that the tumor was properly localized and sized with limited overguessing or underguessing.

Radiologist Evaluation

Setup

To evaluate our AI tool designed to highlight areas of high tumor probability on pediatric wbMRIs from children with a known cancer predisposition syndrome, based on the patch-based model run across wbMRIs in a sliding window fashion as described above, we gave 2 radiologists (Olurotimi Komolafe and Sayali Joshi, each with 3 years of radiology experience after training, respectively, who were supervised by a senior radiologist, Andrea S Doria, with over 20 years of radiology experience after training) detailed instructions on how to label 25 wbMRI volumes with the aid of the AI tool and 25 wbMRIs without the aid of the AI tool. The tool provided radiologists with the option to have AI overlays of predicted masks of high tumor probability regions to potentially help them identify tumors more efficiently and accurately. This was an exploratory, nonrandomized, noncounterbalanced reader study. Each radiologist reviewed 25 cases with AI overlays, followed by 25 different cases without AI overlays.

A timer was incorporated into each wbMRI, which automatically started as soon as each radiologist began the evaluation. The first 25 wbMRIs assigned to each radiologist contained the AI-assisted tumor prediction overlays. The app, as pictured in Figure 1 (note that the red prediction mask overlay is only shown for volumes 1 - 25 and not shown for volumes 26 - 50), shows the user interface we designed for evaluation. When reading the AI-assisted MRI volumes, the radiologists had the option to scroll up and down through each volume using the up and down keys on the keyboard (or scroll using the mouse or trackpad). They also had the option to change the degree of opacity of the red prediction mask overlays using an opacity scroller, which enabled them to transition between fully transparent and fully opaque. The default opacity was set to 50%. The app also incorporated a contrast tool to alter the visual contrast of the original wbMRI from 0 to 2, where 0=low contrast and 2=high contrast. The default contrast was set to 1. To improve detail, the app also incorporated zoom in, zoom out, and pan features, whose buttons were placed on the bottom left of the screen (Figure 1). These augmentations, some of which were suggested by the participating radiologists, were incorporated to simulate the native MRI reporting tools, which the radiologists were accustomed to in reporting wbMRIs.

The primary task was to place a click at the center of each suspected lesion or other candidate abnormality within a wbMRI volume. We refer to these clicks as candidate lesion locations rather than tumors because each click represented a reader's suspicion rather than a verified lesion. Clicking on a region placed a green circle over that region, with a corresponding coordinate from the region added to a "Points selected" box (Figure 1). This box contained all the points (candidate lesion locations) selected for that specific wbMRI volume and served

XSL•FO
RenderX

the purpose of providing visual feedback of all candidate lesion locations to the radiologists. This way, they could see if any points had been selected in error. To undo any errors, an "Undo" button was provided, which deleted the previous selection circle and the corresponding error coordinates from the selection box.

After selecting all the candidate lesion locations that they suspected to contain tumors/lesions, they were then asked to choose whether the lesion required "No Follow-Up," "Follow-Up," or "Biopsy." The options to do this and finish the evaluation were provided on the right side of the screen (Figure 1). Invariably, the radiologists' choice as to whether or not a lesion required follow-up was reflective of their consideration of the lesion to be malignant, suspicious, indeterminate (biopsy or follow-up), or benign/physiological (no follow-up). After clicking on a choice of follow-up, the incorporated timer automatically stopped, and the radiologist was redirected to a short Likert survey to evaluate their reporting experience for that particular volume. The survey evaluations were not timed.

Survey

The survey consisted of the following questions, ranked on a scale from 1 ("not at all") to 5 ("a great deal"):

Q1. How mentally demanding was the task?

Q2. How hurried or rushed was the pace of the task?

Q3. How successful were you in accomplishing what you were asked to do?

Q4. How hard did you have to work to accomplish your level of performance?

Q5. How insecure, discouraged, irritated, stressed, and annoyed were you?

After concluding their reading of the first 25 wbMRI volumes, which contained tumor prediction overlays, the radiologists then read another set of 25 wbMRI volumes, following the exact same procedures, but without tumor prediction overlays. Data obtained from each MRI volume—with and without the AI overlays—included the amount of time it took to finish the labeling, the candidate lesion locations selected, the follow-up recommendation, and the survey responses.

Results

To better study the discrepancy between the performance at the patch level and the volume level, the following metrics were considered at each level. Although it is desirable for diagnostic tools to have both low false-positive and false-negative rates, there is often a trade-off in trying to minimize both.

Given the priority of minimizing false negatives, we used a threshold to check whether at least 10% of the tumor pixels have been predicted by the segmentation model. The dice score was easily affected by the amount of tumor pixels correctly predicted and therefore did not need to be rigorously optimized, as predicting the general tumor location is sufficient. Similarly, the pixel-based false-positive rate needs to be higher for the segmentation model to properly identify parts of tumors that would otherwise be missed. We achieved a 1.54% increase on average across the validation folds in the binary tumor detection score at the patch level, as shown in Table 1, with 0.9550 using U-Net without any modifications and 0.9704 using U-Net with all of the modifications discussed in this paper.

Table . Train/validation results for each additional modification to the U-Net model with the average dice score, true-positive rate (TPR), false-positive rate (FPR), and binary tumor detection score (true for a patch if TPR>10%) across the folds[a].

U-Net modifications	Dice score	TPR	FPR	TPR>10%
$Loss_D$	0.9097/0.8200[b]	0.9874/0.9391	0.0080/0.0096[b]	0.9926/0.9550
+ $Loss_{AUF}$	0.8105/0.7463	0.9796/0.9478	0.0170/0.0181	0.9911/0.9616
+ $Loss_{CP}$	0.8182/0.7439	0.9788/0.9486	0.0167/0.0440	0.9883/0.9666
+ $Loss_{CD}$	0.8328/0.7644	0.9834/0.9457	0.0179/0.0139	0.9908/0.9651
+ Augmentations	0.7703/0.7732	0.9767/0.9476	0.0229/0.0137	0.9865/0.9660
+ Synthetic tumors	0.8014/0.7577	0.9754/0.9527[b]	0.0167/0.0155	0.9858/0.9704[b]

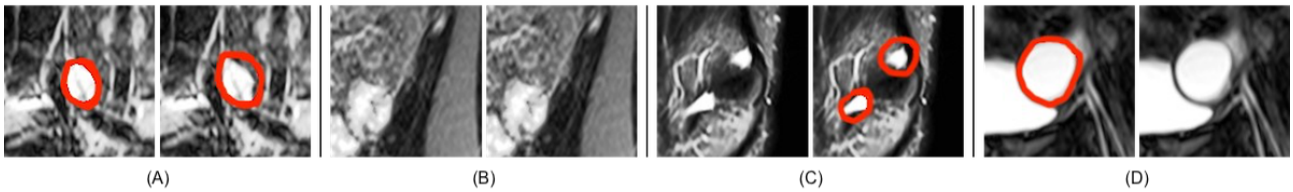
[a]We treat true-negative patches as perfect matches, which count toward the patches where TPR >10%. Each row consists of all the additions in the previous rows.

[b]We denote the best validation results for each metric. Note that the best TPR and TPR>10% come from including all of the U-Net modifications.

At the patch level, in addition to recording each of the losses and the total weighted loss, the true-positive rate (nonthresholded and thresholded at intervals of every 10% of tumor detection), the true-negative rate, false-positive rate, false-negative rate, positive predictive value, negative predictive value, accuracy, balanced accuracy, Jaccard index, false discovery rate, and false omission rate were recorded for both the training and validation sets. These epoch-based metrics were considered when selecting the best model. Figures 3 and 4 illustrate representative test-set predictions.

XSL•FO
RenderX

Figure 3. Examples of contours of the true and predicted masks (red outline) for (A) true positive, (B) true negative, (C) false positive, and (D) false negative when identifying a tumor.



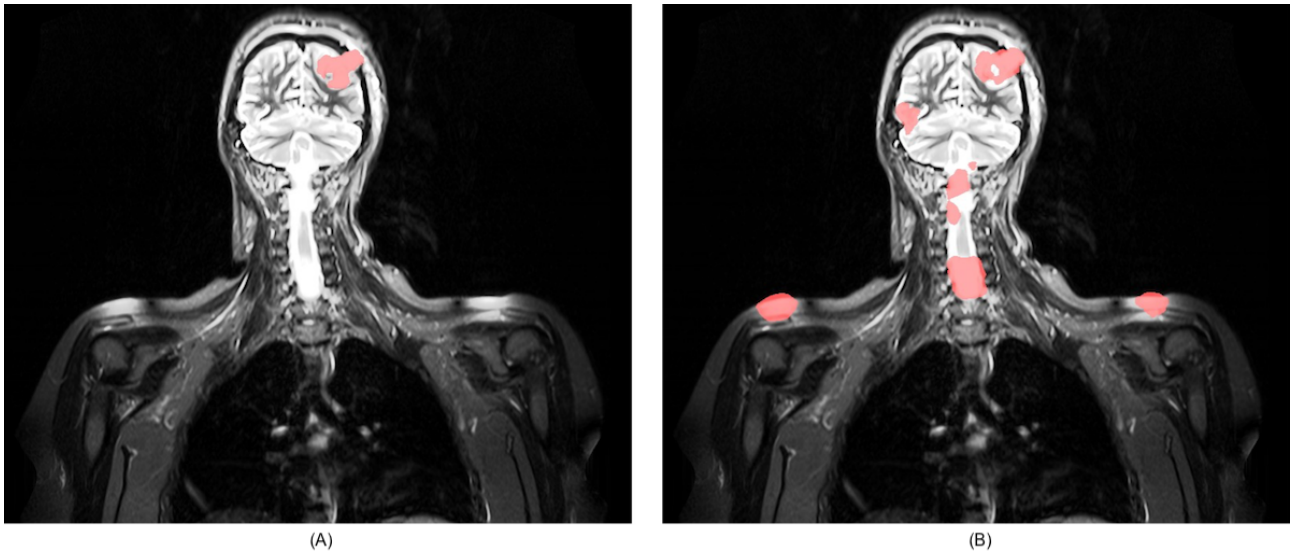


Figure 4. Representative test-set example. (A) Ground-truth tumor annotation. (B) Model output overlaid in red. In addition to the true lesion, nontumor highlighted areas are visible, illustrating the false-positive burden that radiologists would need to dismiss in clinical use.

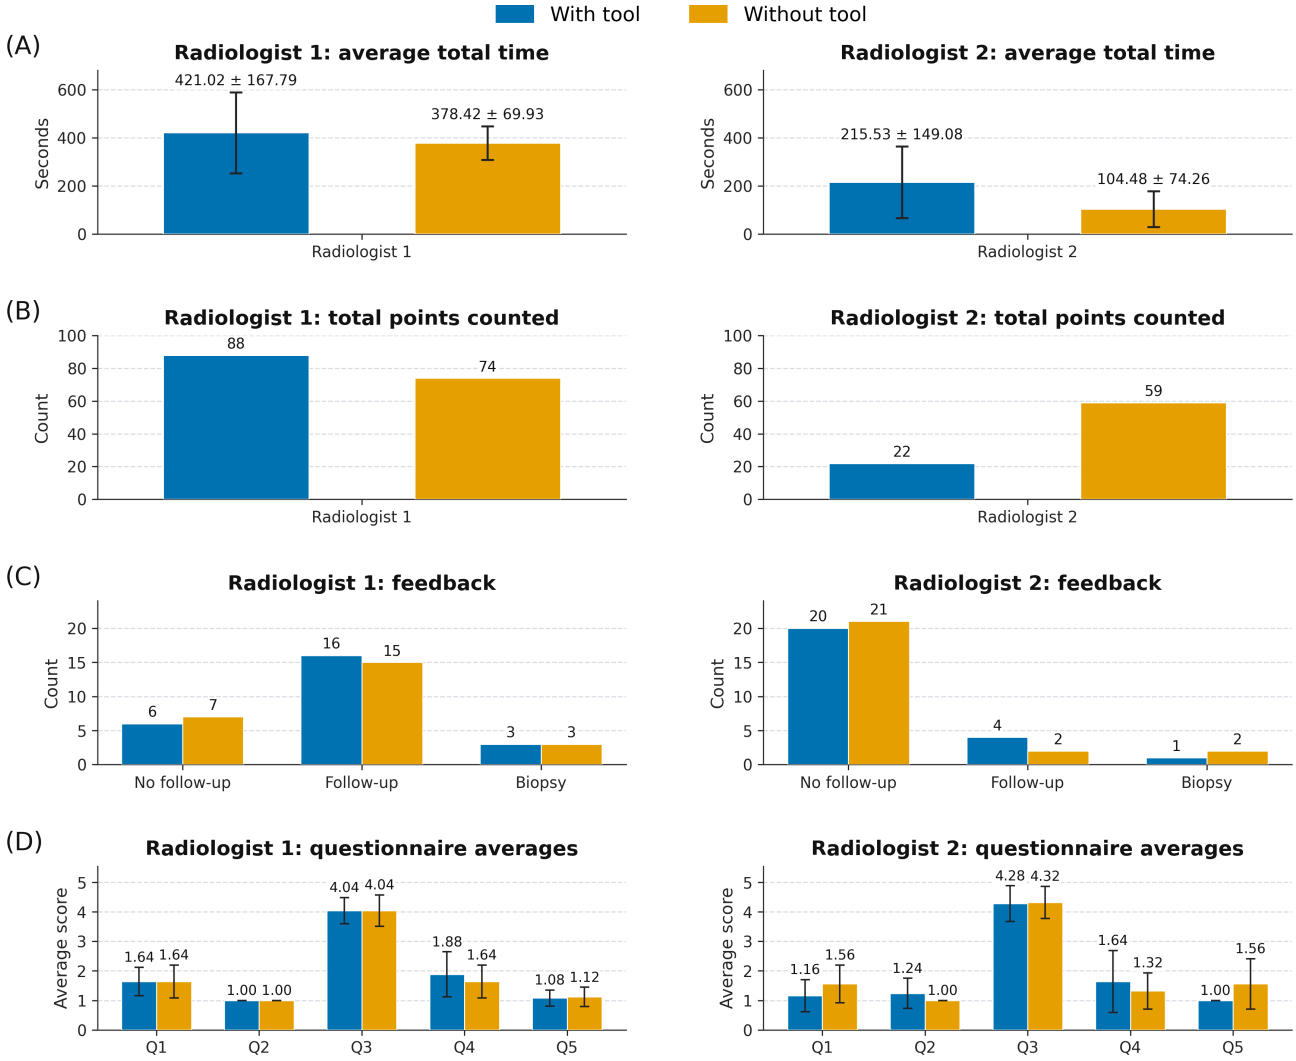

The detection rates reported below are lesion-level and tumor-positive volume-level metrics from sliding-window inference on full wbMRI volumes; a tumor was counted as detected when the model overlapped at least 10% of the annotated tumor pixels. On the cross-validation set, 27 out of 53 (50.9%; 95% Wilson CI 37.9%‐63.9%) tumors were detected in 16 out of 21 (76.2%; 95% Wilson CI 54.9%‐89.4%) tumor-positive volumes. On the held-out test set, 6 out of 7 (85.7%; 95% Wilson CI 48.7%‐97.4%) tumors were detected in 5 out of 6 (83.3%; 95% Wilson CI 43.6%‐97.0%) tumor-positive volumes. Given the very small number of positive cases, these intervals are wide and should be interpreted cautiously. The false positive rates in each volume ranged from approximately 0.5% to 2%. However, it is important to note that tumors only comprised around 0.01% to 0.0001% of each given volume. Therefore, there were 50 to 20,000 times more false positive pixels (usually brighter spots not representing tumors) than true positive pixels (representing tumors). This discrepancy between the false positive vs true positive pixels may not be an issue if radiologists are experienced and can readily dismiss clear cases of groupings of false positive pixels (such as variants of normality in bone marrow signal intensity) as false positives based on their specialized knowledge and complementary clinical and laboratory assessments. This false positive burden is an important limitation because even visually dismissible false positive regions may increase reader verification workload and influence how radiologists respond to the AI overlay.

Two radiologists, designated as radiologist 1 and radiologist 2, independently assessed pediatric wbMRIs under 2 conditions: with and without the AI-assisted diagnostic tool. We systematically analyzed their differences in labeling strategies, assessment duration, recommendations for clinical follow-up, and subjective evaluations of their workflow experience.

As shown in Figure 5, the average total time to evaluate each wbMRI for both radiologists was longer with the AI tool than without the AI tool. The use of the AI tool impacted the radiologists differently. While radiologist 1 spent more total time labeling the studies than radiologist 2, there was only a marginal time difference spent on labeling the studies with the AI tool than without the AI tool (Figure 5)—indicating that the AI tool only slightly increased the reporting times. Across both conditions, radiologist 1 marked twice as many candidate lesion locations as radiologist 2 (162 vs 81) and in the AI-assisted cases, radiologist 1 marked four times as many candidate lesion locations as radiologist 2 (22 vs 88) (Figure 5). In addition, radiologist 1 recommended follow-ups or biopsies more often than radiologist 2. The consideration of several more lesions as potentially worrisome is a rational explanation as to why radiologist 1 spent more time on labeling the studies than radiologist 2.

XSL•FO
RenderX

Figure 5. Reader-study results by radiologist and condition. (A) Mean evaluation time per volume; error bars indicate SD. (B) Total number of reader-marked candidate lesion locations across cases. (C) Counts of follow-up recommendations (no follow-up, follow-up, and biopsy). (D) Mean postcase Likert scores (1-5) for mental demand, hurriedness, perceived success, effort, and negative affect/stress; error bars indicate SD. "With tool" refers to cases read with the assistance of the AI overlay tool, and "Without tool" refers to cases read without it.

In contrast, although the AI-assisted samples had a higher mean reporting time for radiologist 2, it reduced the number of candidate lesion locations as potentially containing a tumor/lesion, in comparison to labeling without the AI tool. Given the low density of tumor slices in the volumes, the AI tool may have been helpful in reducing the number of false positives for radiologist 2 (Figure 5). Radiologist 2 also selected a smaller number of lesions for biopsy/follow-up than radiologist 1.

With regard to feedback on follow-up suggestions, the 2 radiologists overlapped 11 out of 25 (44.0%) times in their follow-up suggestions with the tool and 10 out of 25 (40.0%) times without the tool. With the tool, the 11 overlaps came from 6 overlaps in "No follow-up," 4 overlaps in "Follow-up," and 1 overlap in "Biopsy." Without the tool, the 10 overlaps came from 7 overlaps in "No follow-up," 2 overlaps in "Follow-up," and 1 overlap in "Biopsy."

Finally, the questionnaire was used to evaluate the subjective experience after each case. Reader 1 reported slightly higher effort with AI assistance (Q4) and slightly lower negative affect/stress with AI assistance (Q5). Reader 2 reported lower mental demand with AI assistance (Q1), higher hurriedness (Q2), similar perceived success (Q3), higher effort (Q4), and lower negative affect/stress (Q5). Because only 2 readers participated, these questionnaire findings should be interpreted descriptively rather than as generalized user-preference outcomes.

Discussion

This study contributes both a pediatric surveillance wbMRI tumor-likelihood overlay and an exploratory reader-study evaluation of how such an overlay may affect radiologist workflow. In addition to machine learning metrics, other considerations such as deployment scenario, human-computer interaction, and individual differences must be taken into account.

The low signal-to-noise ratio of pediatric wbMRI scans and the limited number of positive cases contributed to labeling difficulties in this study. While the AI tool aimed to mitigate the challenges of tumor detection, radiologists still seemed to double-check the AI's positive and negative suggestions, possibly subconsciously, in addition to accomplishing the

XSL•FO
RenderX

required task. This increased the time and impacted the efficiency of their assessments in different ways based on the radiologist.

Model development occurred in an extremely low-prevalence setting. The small number of tumor-positive volumes limited the diversity of tumor appearances, sizes, and anatomic locations represented in training and likely contributed to unstable performance estimates and persistent false positives. In addition, the intentionally enriched patch-sampling strategy improved learnability but does not reproduce real-world prevalence. A limitation of this study is that the model showed modest lesion-level performance with a substantial false positive burden. Radiologist behavior may reflect responses to an occasionally imperfect or noisy overlay in addition to the effect of a clinically reliable tumor-detection tool. These factors limit robustness and generalizability, and external validation in larger, more diverse, preferably multicenter cohorts is needed.

In the United States, radiologists have faced a high number of lawsuits due to missed diagnoses [39]. Therefore, radiologists generally prefer to "over-call" a finding rather than "under-call" or miss out on potentially lethal findings. For a tool designed to detect tumors to be adopted, it is crucial to have a low false negative rate. However, this does not justify the tool having a very high false positive rate, which then introduces a new challenge of differentiating between the true positives and the false positives, which in itself may also have adverse legal ramifications.

The main purpose of surveillance wbMRI in patients with cancer predisposition disorders is to avoid missed tumors. However, false positives are not a trivial trade-off in this setting. If the tool highlights many nontumor regions, radiologists must spend additional time verifying them, clinician trust in the AI overlay may decline, and patients and families may be exposed to additional follow-up imaging, biopsy discussions, or uncertainty. In Li-Fraumeni surveillance, where families already face substantial psychological burden, false positive prompts may also increase anxiety if they trigger further workup for ultimately benign findings. Reducing false positives while preserving sensitivity is therefore central to clinical adoption.

Our results reflect the nuanced impact of AI tools on clinical practice, with both radiologists demonstrating markedly different responses to the tool's guidance. The AI tool appeared to prolong the diagnostic process for one of the participating radiologists, possibly due to second-guessing the AI's recommendations, overrelying on the recommendations, or trying to verify its findings. In contrast, the other radiologist seemed to use the tool to streamline their decision-making in the sense that although more time was spent with the AI tool, the number of candidate lesion locations selected was much lower with the tool than without the tool, suggesting that the AI tool was able to root out a lot of false-positive cases. The subjective survey responses also suggest that the same AI overlay can be experienced as either helpful or effortful, depending on the individual reader, reinforcing that user experience should be considered reader-specific rather than uniform.

The divergent behavior of the 2 readers suggests that identical AI overlays may not be interpreted consistently across radiologists. One reader marked substantially more candidate lesions and recommended follow-up more often overall, whereas the other was more conservative. This variability indicates that overlay interpretation is itself a human-factors problem: the same AI output may be integrated differently depending on reader thresholds, risk tolerance, and trust calibration. Future deployment studies should therefore include reader onboarding, calibration, and interface testing rather than assuming a one-size-fits-all interaction model.

While many AI tools often achieve diagnostic results that are comparable to radiologists, their narrow task focus and need for large, annotated datasets limit their effectiveness. Furthermore, the "black box" nature of neural networks means that radiologists often second-guess AI outputs. The differences between radiologists' performance in this study suggest that some radiologists might spend extra time verifying AI outputs or modifying their usual workflow to incorporate AI feedback.

Our exploratory reader study reveals how individual radiologists' diagnostic workflows change with the introduction of AI tools in varying ways and illustrates how individual biases and preferences affect human-AI collaboration. Another study suggests that self-confidence, not confidence in AI, affects the decision to accept or reject AI suggestions the most [40]. Given that only 2 readers were studied, these differences should be interpreted as preliminary evidence of reader-specific heterogeneity rather than as a comprehensive characterization of interreader variability in clinical practice.

Our analysis revealed that the AI tool impacted radiologists differently. Radiologist 1 displayed little difference in average evaluation time with or without the AI tool, while radiologist 2 had a lower mean evaluation time labeling without the tool than with it. The AI tool appeared to streamline radiologist 2's decision-making process but also led to fewer candidates being selected, suggesting better exclusion of false positives. Despite the variance in time spent to conduct the requested tasks, the overlap in follow-up suggestions was similar for both radiologists with and without the AI tool in less than half the cases. More caution seems to be taken with the AI tool than without the AI tool with regard to the follow-up suggestions. Additionally, questionnaire results demonstrated varying subjective impacts on mental demand, hurriedness, irritation, workload, and perceived success with and without the tool.

Following the evaluation of our AI tool by 2 radiologists, we identified several challenges and opportunities in improving the usability of AI tools in health care. Based on the lessons learned from this study, the key insights are as follows:

- Different health care professionals with similar levels of training may interact with AI tools in various ways, influenced by personal biases and cognitive strategies, so calibrating AI tools to each individual represents a potentially promising future direction to explore.
- The opaque or black-box nature of many AI algorithms can lead to distrust and second-guessing of AI outputs by health care professionals; therefore, improved explainability and

XSL•FO
RenderX

interpretability may mitigate clinician skepticism and reduce redundant verification behaviors.
- Having clear and comprehensive training for health care professionals on how to effectively use AI tools is important in ensuring the proper use of the tools and improving satisfaction with their utilization.
- Poor integration of AI tools into existing workflows can disrupt routine practices and reduce overall efficiency, so employing a continuous evaluation and improvement process to refine AI tools based on real-world performance and user feedback may prove useful.
- The introduction of AI tools can increase cognitive load and mental demand if the interactive component is not up to par. Therefore, making health care professionals a part of the discussion on how to develop user-friendly AI tools that can help reduce friction with existing workflows is crucial.
- The technical complexity of AI tools can pose a barrier to their effective use by health care professionals who are not technically inclined. Therefore, it is important to create user-centric designs that serve the needs and preferences of health care professionals from a wide spectrum of experiences.
- Fostering collaboration between AI developers, health care professionals, and researchers in the development process to ensure AI tools are clinically relevant and serve precise clinical needs.
- Encouraging the use of AI tools as supportive aids, rather than replacements for human imaging interpretation, can help avoid overconfidence or underconfidence in the AI tools.

In summary, this study addresses a clinically specific and technically challenging setting, pediatric surveillance wbMRI in LFS, and shows that AI overlays can influence radiologist workflow in reader-specific ways. We did not formally disentangle appearance-driven signals from implicit contextual/location priors, so future work should test whether the model remains sensitive to tumors in less commonly represented locations. The reader study should be interpreted as preliminary. Only 2 radiologists participated, and the design was not randomized or counterbalanced. Therefore, the observed differences in timing, candidate-lesion marking, and subjective responses should be viewed as descriptive and hypothesis-generating rather than definitive estimates of clinical workflow impact or trust or as robust estimates of population-level reader effects. The nuanced relationship between radiologists and AI tools requires further research to optimize these systems for diverse diagnostic workflows. This study emphasizes the interplay between trust, validation, and interpretation in human-AI collaboration, highlighting that a one-size-fits-all strategy may be inadequate for optimizing AI tools in health care.

Abstract

Background: Image-based pill verification systems demonstrate high model accuracy. However, their effectiveness in pharmacy practice depends on how pharmacists interact with the AI output. The timing of AI advice is one design factor that influences these interactions, yet its impact on pharmacists' moment-to-moment trust dynamics during medication verification requires further investigation.

Objective: This study aims to investigate how the timing and conditionality of AI assistance shape pharmacists' trust dynamics during medication verification.

Methods: Between April and December 2024, 50 licensed pharmacists completed a browser-based simulated medication dispensing task with 2 AI types: ex-ante advice (AI advice given concurrently with clinical information) and ex-post advice (AI advice given after an initial diagnosis). Ex-post advice was further divided into the involved ex-post and the not-involved ex-post conditions. The experiment used a within-participants design with varying AI types and AI recognition patterns (right fill-correct recognition, right fill-incorrect recognition, wrong fill-correct recognition, and wrong fill-incorrect recognition). The primary outcomes were trust adjustment magnitude and trust adjustment, which were analyzed using mixed-effects linear regression models.

Results: Trust adjustment magnitude differed significantly across AI assistance conditions. The involved ex-post condition led to the highest magnitude of trust adjustment, followed by ex-ante advice (mean difference 9.65, 95% CI 8.55-10.75; $P<.001$), with the not-involved ex-post condition showing the lowest magnitude (mean difference 3.33, 95% CI 2.63-4.03; $P<.001$). Analysis by each recognition pattern revealed significant differences in trust adjustment when the right drugs were incorrectly rejected. In this pattern, the involved ex-post condition led to larger trust decrements than both ex-ante advice (mean difference −2.13, 95% CI −3.83 to −0.44; $P=.008$) and not-involved ex-post conditions (mean difference −7.32, 95% CI −13.69 to −.95; $P=.009$). A marginal difference was observed between ex-ante advice and not-involved ex-post conditions (mean difference −5.19, 95% CI −11.55 to 1.17; $P=.051$). No significant differences were observed for other recognition patterns.

Conclusions: Both the timing and conditionality of AI assistance influenced pharmacists' trust dynamics. Disagreement-based AI interventions (involved ex-post) that incorrectly challenged pharmacists led to a substantial trust decrement, whereas the not-involved AI intervention resulted in more stable trust fluctuations. These findings highlight the importance of designing AI systems that align intervention strategies with user expertise and task demands to foster appropriate trust in safety-critical workflows.

Introduction

Background

Pharmacists play a critical role in ensuring that patients receive the correct medication, particularly during medication verification, in which the medication filled inside the bottle must match the prescription label [1]. Errors at this stage, such as dispensing the wrong drug, strength, or formulation, are a major source of preventable adverse drug events, with error rates that can exceed 1% in both community and hospital settings [2-4]. These errors adversely impact patient safety and trigger emergency room visits and hospitalizations [5]. Contributing factors include high workload, fatigue, technology limitations, lack of trust in automation, and the high cognitive demands placed on pharmacists who must manage multiple tasks simultaneously [6-9]. Because medication verification is both labor-intensive and cognitively demanding, tools that reduce dispensing errors have the potential to substantially improve patient outcomes and decrease health care costs [10].

To mitigate these risks, image-based pill verification systems have been introduced [11-15]. Advances in deep learning have further improved the performance of these systems, with recent models achieving accuracies greater than 98% [16]. However, the successful integration of AI systems into pharmacy workflows depends not only on model accuracy but also on how humans perceive, trust, interpret, and act on AI output [8,17,18]. Prior human factors and human-computer interaction (HCI) research highlights two design dimensions that strongly influence human-AI interaction: (1) the amount and type of model information presented and (2) the timing of AI assistance [19,20]. These dimensions shape cognitive load, situational awareness, and the development of trust in autonomous and AI systems, defined as the belief that an autonomous or AI agent will support an individual's goals under conditions of uncertainty [21].

The amount and type of model information can play a key role in promoting clinician understanding of clinical decision support systems (CDSSs). To overcome the barrier of the "black-box" nature of many of these CDSSs, in which model outputs provide little insight into how predictions are generated, research has emphasized the importance of enhancing system transparency through explanatory feedback and uncertainty visualizations [9,22-26]. For instance, Kompa et al [26] investigated how different levels of explanation in a CDSS supporting balance disorder diagnosis influenced health care professionals' trust and reliance. Participants used either a selective CDSS that presented examination results alone or a comprehensive CDSS that additionally provided explanatory context. Their findings showed that explanations positively affected trust, whereas limited explanations led users to question the system's reliability [26]. Kim et al [9] examined how presenting model uncertainty information in a medication verification AI affected pharmacists' trust. Their pill characteristic plots conveyed match-mismatch information based on visual attributes such as imprint, color, shape, and score, and the uncertainty plot illustrated the predicted probability of each set of predictions summarized in a histogram [11]. By manipulating the presence of uncertainty visualization as a between-participants factor, they found that communicating uncertainty improved pharmacists' end trust, suggesting that transparency fosters more calibrated trust and active engagement with AI systems [9].

Another critical design factor influencing human-AI interaction is the timing of AI advice [20]. In clinical decision-making, AI systems may present recommendations before the human makes the initial decision (ex-ante AI advice) or after the human forms an initial judgment (ex-post AI advice) [19,27]. Ex-ante systems provide continuous feedback throughout the task [28,29], supporting real-time integration of AI insights, but increasing the risk of cognitive overload or anchoring when AI outputs are incorrect [30-32]. In contrast, ex-post systems require the human decision maker to commit to an initial decision before receiving AI advice [33-36]. While this approach can preserve human decision autonomy and reduce the anchoring effect, it may exacerbate confirmation bias [37-39], contribute to algorithm aversion [35,40,41], and introduce workflow interruptions when AI intervenes unnecessarily [42].

Empirical findings on the optimal timing of AI assistance remain mixed. Yin et al [27] investigated how the timing of AI advice affects doctors' diagnostic decision-making. In their experiment, they recruited and asked physicians to diagnose clinical cases. The authors compared ex-post advice with ex-ante advice. They found that physicians engaged more deeply with ex-post advice, resulting in higher diagnostic accuracy (task performance) compared with ex-ante advice. Conversely, Fogliato et al [43] explored a human-AI workflow sequence with veterinary radiologists, who reviewed X-ray images and made diagnostic judgments under two conditions: (1) a 1-step workflow (ex-ante advice), where AI inferences were shown before radiologists' diagnosis and (2) a 2-step workflow (ex-post advice), where radiologists made an initial diagnosis first, then saw the AI's recommendations. The authors reported that radiologists' diagnostic performance was better in the ex-ante advice system compared to the ex-post advice system. With the ex-post advice help, radiologists rarely revised their initial judgments and rated the AI as less useful [43].

Properties of Trust Dynamics

Trust in autonomous and AI systems has been extensively studied across domains, including health care [9,17,21]. Trust is a critical determinant of how people rely on autonomous systems and is strongly influenced by system performance [44-46].

Most existing literature has adopted a snapshot approach to trust measurement, typically assessing trust through posttask or end-of-experiment questionnaires. While informative, this approach overlooks that trust is a dynamic variable and evolves over the course of repeated, moment-to-moment interactions with autonomous systems [45,47,48].

Yang et al [45] identified and summarized 3 key trust dynamics properties. First, continuity suggests that trust at a given moment (i) is strongly associated with trust at the immediately preceding moment ($i - 1$). Trust tends to increase following automation successes and decrease following failures [9,46]. Second, negativity bias highlights the asymmetric impact of autonomy

XSL•FO
RenderX

performance, wherein trust is difficult to build but can be lost quickly. Prior studies have shown that negative experiences with automation failures exert a stronger influence on trust than positive experiences [8,49-51]. Third, stabilization refers to the tendency for trust to stabilize over repeated interactions with the same system, as users gain familiarity and form more stable expectations [52].

Present Study

Building on these findings, the present study investigates how the timing of AI assistance shapes pharmacists' trust dynamics during medication verification. We examine 2 modes of AI engagement: ex-post advice (AI advice given after an initial diagnosis) and ex-ante advice (AI advice given concurrently with clinical information). The ex-ante advice continuously displays predictive information throughout the task, and the ex-post advice intervenes only when its prediction conflicts with the pharmacist's initial decision. Ex-ante advice may support continuous decision-making but risks cognitive overload and anchoring, whereas ex-post advice may reduce unnecessary attentional demands but risks disruptive false alarms [30,32-34,36].

By comparing these timing strategies, we aim to identify how different modes of AI engagement influence trust adjustment in a safety-critical and expert-driven medication verification task.

In addition, prior empirical validations of trust dynamics properties (continuity, negativity bias, and stabilization) have relied primarily on simplified tasks and nonexpert participant populations [8,45,48]. By examining licensed pharmacists engaged in realistic medication verification tasks, the present study extends prior work and strengthens the ecological validity of trust dynamics properties in a safety-critical health care context.

Methods

Ethical Considerations

This study was exempt from institutional review board oversight by the University of Michigan (HUM#00241223). All participants provided electronic informed consent prior to the experiment, and data were collected anonymously. Participants received US $100 upon completing the study.

Participants

Pharmacists were recruited via email through the Minnesota Pharmacy Practice-Based Research Network, Pharmacy Practice Enhancement and Active Research Link in Wisconsin, and the University of Michigan College of Pharmacy Pharmacist Preceptor Network. Participants were eligible for the study if they were licensed in the United States, were at least 18 years old, and had access to a laptop or desktop computer with a webcam. Pharmacists were excluded if they needed assistive technology to operate a computer, wore eyeglasses with more than 1 power, had uncorrected cataracts, intraocular implants, glaucoma, or permanently dilated pupils, and/or had eye movement or alignment abnormalities (eg, lazy eye, strabismus, nystagmus). Fifty licensed US pharmacists participated in the study between April and December 2024.

AI Model

The AI model used in this study is a Bayesian neural network (BNN) designed to predict the National Drug Code (NDC) for dispensed pills while estimating the prediction uncertainty [11,16]. This was achieved by applying random dropout to a ResNet-34 convolutional neural network architecture [53,54]. Instead of outputting a single probability distribution for each class, the model generated 50 probability vectors for each image. The final NDC prediction was determined by averaging those vectors and selecting the class with the highest mean probability.

The model was trained on a dataset of 432,974 images representing 352 distinct NDC classes from a mail-order pharmacy in the United States, which uses a robotic system to count pills, fill and label vials, capture images of the contents, and seal the vials [55]. The dataset contains 1 year of robot-captured images of solid oral medication (ie, tablets and capsules) inside prescription vials, with each image associated with its corresponding NDC and annotated with attributes such as color, shape, size, manufacturer, tablet scoring, and imprint. The number of available images for each NDC varied from 3 to 12105, with a median of 540 (IQR 257-1291).

The medications in the dataset were categorized into 12 distinct colors: white (42.1%), yellow (12.3%), pink (9.1%), orange (7.1%), multicolor (5.9%), green (5.2%), red (5.2%), blue (4.8%), brown (3.8%), purple (3.1%), turquoise (0.7%), and gray (0.7%). Additionally, seven unique shapes were categorized: round (49.6%), oval (33.4%), capsule (16.2%), hexagon-6-sided (0.4%), triangle (0.3%), trapezoid (0.1%), and pentagon-5-sided (0.04%).

Experimental Apparatus

Overview

The study utilized Labvanced, a browser-based experimental platform, to conduct simulated medication dispensing tasks. Participants accessed the testbed through a web browser on their personal computers, which enabled the software to collect eye-tracking data through the webcam while also recording response decisions and reaction times for each task.

Experimental Task

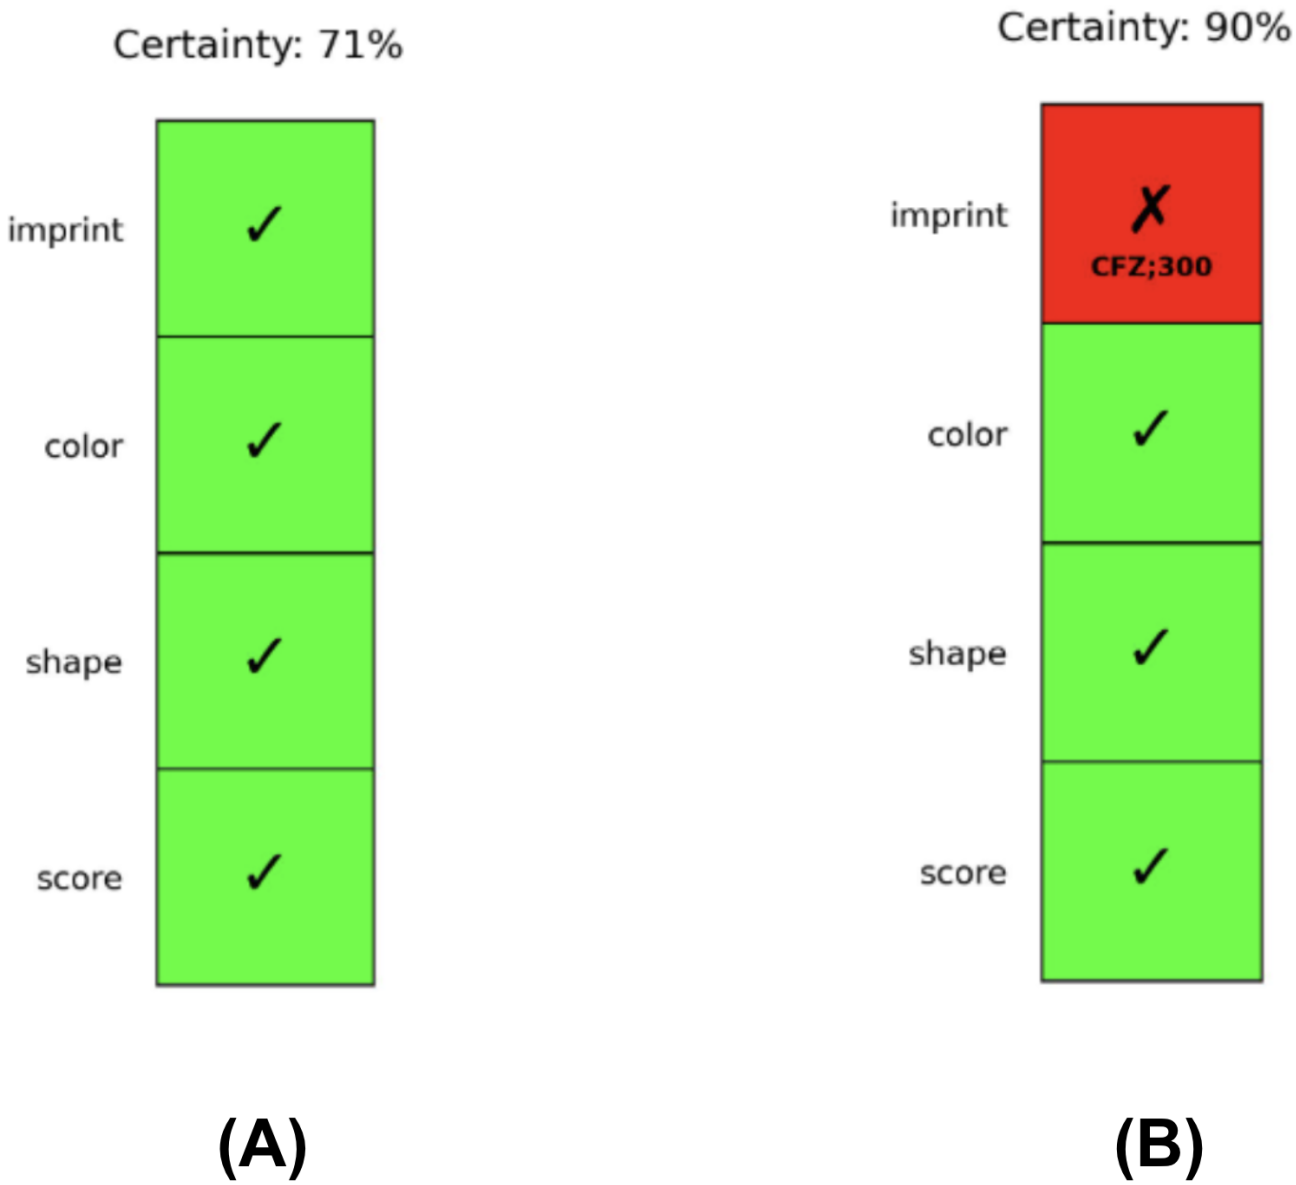
In this experiment, participants performed a simulated medication verification task supported by varying types of imperfect automated pill recognition systems [9,12,13]. The user interface displayed a reference image of prescription medication, the prescription details, and an image of the filled medication. In the 2 AI-assistance conditions, the AI-generated decision support was also presented. The objective was to determine whether the filled medication matched the prescription (ie, reference image). If the 2 images matched, the correct response was to click "accept"; if they differed, the appropriate response was to click "reject."

The experimental stimuli, including the reference NDC and corresponding filled medication images, were carefully selected from the dataset of 432,974 images. The selection prioritized a

XSL•FO
RenderX

broad representation of medication colors and shapes while excluding blurry images to ensure clarity. To reduce potential learning effects, each reference NDC was presented no more than twice during the experiment. To ensure sufficient exposure to both correct and incorrect AI predictions, we constructed a 300-image experimental dataset (representing 154 distinct NDCs) by selectively sampling from the larger dataset to increase the proportion of naturally occurring incorrect predictions, resulting in an overall AI accuracy of approximately 79%. NDCs could occur no more than twice to prevent bias. AI outputs were not artificially modified, and all predictions reflect the model's original performance. Because this sampling approach preserved the model's inherent error patterns, prediction errors were not uniformly distributed across medication characteristics (see Table 1).

Table . Distribution of medication characteristics for the experimental dataset (n=300).



Characteristics	Filled, n (%)	Reference, n (%)
Color		
White	154 (51)	160 (53)
Yellow	42 (14)	34 (11)
Pink	24 (8)	22 (7)
Orange	21 (7)	25 (8)
Multicolor	4 (1)	4 (1)
Green	14 (5)	14 (5)
Red	7 (2)	7 (2)
Blue	12 (4)	12 (4)
Brown	14 (5)	14 (5)
Purple	4 (1)	4 (1)
Turquoise	4 (1)	4 (1)
Shape		
Round	181 (60)	187 (62)
Oval	80 (27)	72 (24)
Capsule	35 (12)	37 (12)
Hexagon (6-sided)	2 (1)	2 (1)
Triangle	2 (1)	2 (1)

To characterize the nature of AI errors, the visual similarity between the reference medication and the AI-predicted medication was examined. Most incorrect predictions (93%) occurred between medications sharing the same color and shape (ie, visually similar medications with different NDCs). A small proportion involved a shape mismatch (5%) or a color mismatch (2%), and none involved mismatches in both color and shape.

Two types of AI assistance, both powered by the same underlying BNN model, were integrated into the interface. The AI model communicated its confidence (or uncertainty) and feature matches through a checkbox plot indicating 4 key pill characteristics: imprint, color, shape, and score (Figure 1A). Matching characteristics were represented using green checkboxes with checkmarks. Mismatches were represented using red checkboxes marked with an "X," along with a textual description of the AI-predicted characteristic (eg, the predicted imprint shown in Figure 1B). The AI's confidence was represented by the predicted probability of the highest-ranked NDC class.

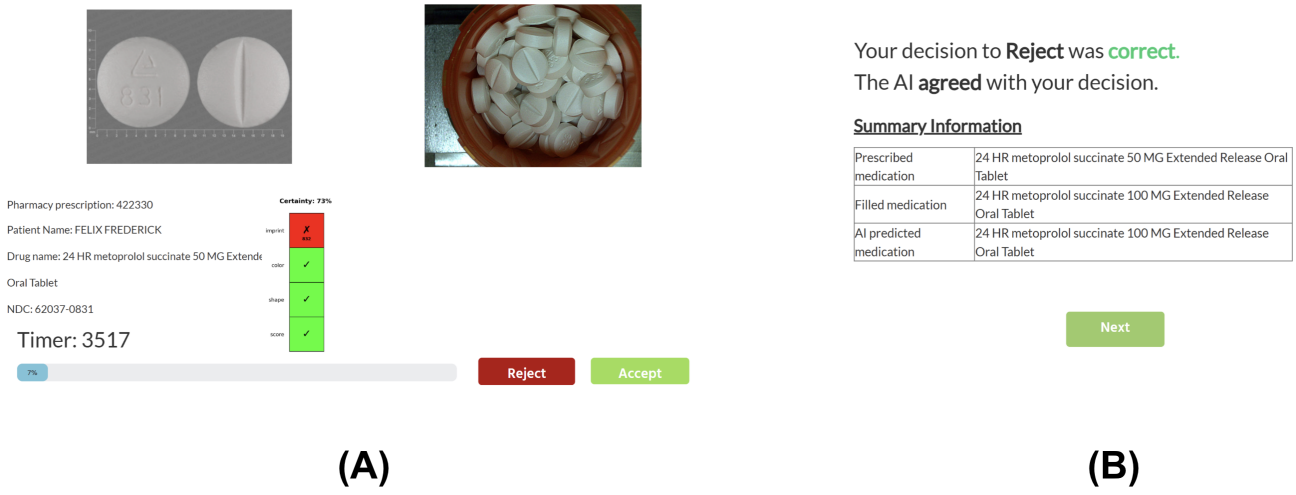
XSL•FO
RenderX

Figure 1. Checkbox plots. (A) Checkbox plot indicating a match and (B) checkbox plot indicating a mismatch. Matching characteristics were represented using green checkboxes with checkmarks. Mismatches were represented using red checkboxes marked with an "X," along with a textual description of the AI-predicted characteristic.

The ex-ante advice condition continuously displayed the checkbox plot before the participant made a decision (Figure 2A). Feedback was displayed after the participant made the decision, indicating the accuracy of the participant's selection and the AI's prediction (Figure 2B). On the other hand, the ex-post advice condition served as a "safeguard," appearing only when the participant's response contradicted the AI's prediction. For example, if the participant initially selected "accept" (Figure 3A) when the AI predicted a mismatch, the AI intervened and prompted a reverification by displaying a message, such as: "You selected Accept. The AI disagrees. Confirm or change your response" (Figure 3B). The AI assistance was intentionally imperfect, occasionally providing incorrect recommendations. Although the AI model's accuracy was 98.5%, it was deliberately lowered to 79% to ensure sufficient exposure to both AI's errors and AI's correct guidance outputs. This manipulation enabled the systematic observation of pharmacists' responses to AI successes and failures. The selected reliability level was informed by prior human factors research suggesting that when automation reliability falls below approximately 70%, its costs may outweigh its benefits, highlighting the importance of studying user responses across a range of imperfect, yet still functional, automation performance levels [56].

XSL•FO
RenderX

Figure 2. The ex-ante advice condition displayed the checkbox plot before the participant made a decision. (A) Ex-ante advice selection and (B) ex-ante advice feedback. Feedback was displayed after the initial decision.



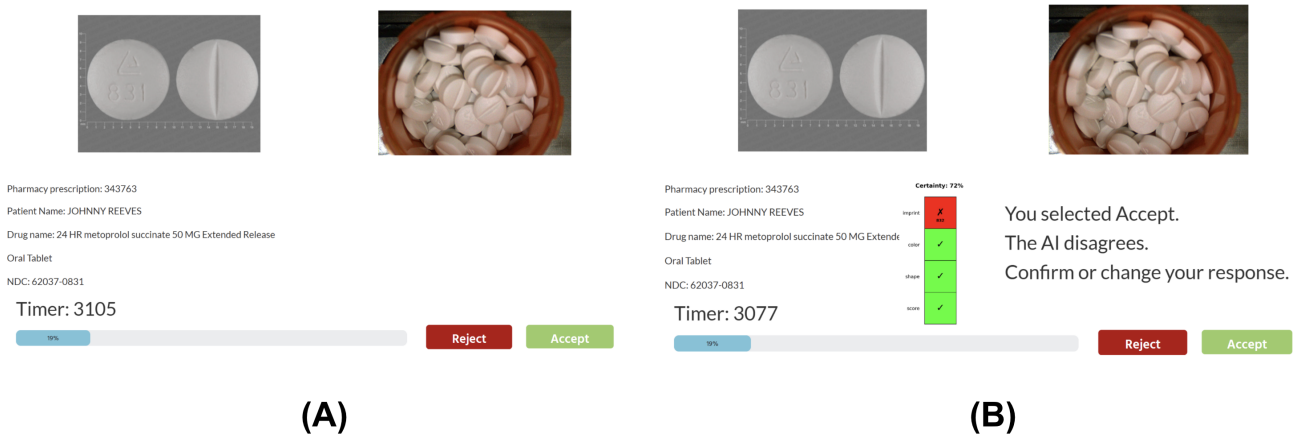


Figure 3. The ex-post advice condition served as a "safeguard," appearing only when the participant's response contradicted the AI's prediction. (A) Ex-post advice initial selection and (B) ex-post advice intervention.

Participants completed 3 blocks of 100 medication verification trials, with each block corresponding to each AI assistance condition, including a no-assistance control condition. In the AI-assisted blocks, participants received trial-by-trial feedback on indicating whether their decision to accept or reject was correct and whether the AI's recommendation was accurate (ie, "Your decision to accept was correct. The AI agreed with your decision"). Following each AI-assisted trial, participants rated their trust in the AI using a visual analog scale ranging from 0 to 100, anchored by "Not at all trust" (0) on the far left to "Completely trust" (100) on the far right. Because the no-assistance control condition did not involve AI support, no trust ratings were obtained.

Experimental Design

The experiment used a within-participants design with varying AI types (ex-ante advice and ex-post advice) and AI recognition patterns (right fill-correct recognition, right fill-incorrect recognition, wrong fill-correct recognition, and wrong fill-incorrect recognition). Within the ex-post advice condition, AI assistance was further classified as the involved ex-post condition (ex-post-AI disagreed with the human decision) and the not-involved ex-post condition (ex-post-AI agreed with the human decision). The agreement conditions depended on participants' responses and therefore could not be predetermined. Block order was counterbalanced across participants using a Latin square design. Each AI type block consisted of 100 medication verification trials randomly selected by the experimental platform from the larger trial pool, including 60 right fill-correct recognition, 16 right fill-incorrect recognition, 19 wrong fill-correct recognition, and 5 wrong fill-incorrect recognition trials.

Measures

After each trial i, participants report their $trust(i)$ in the AI. We calculate a trust adjustment as:

$$Trust\ adjustment(i) = Trust(i) - Trust(i-1), \text{ where } i = 2, 3, ..., 100$$

Since the moment-to-moment trust is reported after each trial, 99 trust adjustments are obtained from each participant.

Participant demographics, trust propensity, and eye-tracking data were also collected. Trust propensity was evaluated as a potential covariate during model development, but was not a significant predictor and did not alter the results; therefore, it was excluded from the final models. Because the present study focuses on within-participant trust adjustment, demographic and eye-tracking analyses are beyond the scope of this paper and are reported in a companion manuscript.

XSL•FO
RenderX

Experimental Procedure

Before the experiment, participants met with a member of the research team via Zoom (Zoom Communications Inc.) to verify that technical and environmental requirements were met, including a functioning webcam, adequate lighting, and a quiet workspace. Once confirmed, participants received a secure link and password to access the Labvanced software. An instructional video then introduced the mock verification process using the study interface, explaining that the objective was to determine whether an image of a filled medication vial matched the prescribed reference image.

The video also outlined the 2 AI assistance features.

Prior to starting the verification tasks, participants completed a demographic questionnaire, the Occupational Fatigue Exhaustion/Recovery Scale (OFER), and the trust propensity survey, followed by calibration procedures for the eye-tracking software [57,58].

During each trial, a "reference image" (the prescribed medication) appeared on the left, and a "filled vial image" (the dispensed medication) appeared on the right, along with relevant prescription details (Figure 2A). Participants decided whether to accept or reject the filled medication based on this comparison. Each participant completed 100 mock verification trials under the ex-ante advice condition (Figure 2A), 100 trials under the ex-post advice condition (Figure 3B), and 100 trials without AI assistance, in a counterbalanced order. The 6 block orders were assigned approximately evenly across 50 participants (4 sequences: n=8 each; 2 sequences: n=9 each). After each block of 100 trials, participants completed postcondition surveys, including the trust survey on a 5-point Likert scale, the system usability scale, the NASA Task Load Index (NASA-TLX) survey, and nonmandatory free-response feedback questions [59-61].

Analysis

We analyzed trust adjustment magnitude and trust adjustment using mixed-effects linear regression models. The models included categorical predictors and random intercepts to account for repeated measures within participants. Predictors included AI type and AI recognition pattern, forming a 3 × 4 design. We first examined differences between AI types (ex-ante advice and ex-post advice) and then further decomposed the ex-post advice into the involved ex-post condition and the not-involved ex-post condition for a 3-level comparison between interaction conditions. This decomposition was prespecified to examine the trust-dynamics associated with disagreement-triggered versus agreement-based AI interactions. Because assignment to the involved and not-involved conditions depends on pharmacists' initial decisions, these comparisons were response-contingent and are treated as exploratory analyses rather than confirmatory tests.

AI recognition patterns consisted of 4 levels: right fill-correct recognition, right fill-incorrect recognition, wrong fill-correct recognition, and wrong fill-incorrect recognition. Because the study focused on pharmacists' trust in AI-assisted decision-making, we restricted the analysis to AI-assisted conditions and excluded data from the no-AI-assistance control block.

We conducted regression 2-tailed *t* tests to compare mean trust outcomes across AI types within each AI recognition pattern. To account for multiple pairwise comparisons, *P* values for post hoc comparisons were adjusted using the Benjamini-Hochberg false discovery rate procedure. We conducted all analyses using mixed-effects linear regression models implemented in the lme4 package, applying the Kenward-Roger method to estimate degrees of freedom [62]. All analyses were conducted in the R statistical software (version 4.2.2) [63].

Results

Overview

Observations with trust-adjustment values exceeding ±3 SDs from the mean were excluded prior to analysis to reduce the influence of extreme outliers. To evaluate order effects, block order was included as a fixed-effect covariate. The likelihood ratio test showed that adding block order did not improve model fit for either outcome (trust adjustment magnitude: χ^2_9=8.88; *P*=.11; trust adjustment: χ^2_9=6.25; *P*=.28). Therefore, the results from the model excluding block order are presented.

Comparison Between AI Types

Trust Adjustment Magnitude Between Ex-Ante and Ex-Post Advice

AI type ($F_{1,9562.1}$=3.45, η^2=0.0004; *P*=.06) marginally affected the magnitude of trust adjustment. Ex-ante advice (estimated marginal mean [EMM] 6.13, 95% CI 4.28-7.97) led to marginally higher trust adjustment magnitude compared to ex-post advice (EMM 5.60, 95% CI 3.76-7.45; Table 2).

XSL•FO
RenderX

Table . Mean and SD of trust adjustment magnitude and trust change for different AI recognition patterns. AI recognition pattern to confusion matrix representation[a].

AI type and AI recognition pattern (fill accuracy - (human) AI)	Trust adjustment magnitude	Trust adjustment	Observations, n
Ex-ante advice	5.94 (15.23)		
Right-correct		2.14 (9.03)	2868
Wrong-correct		1.60 (9.90)	1088
Right-incorrect		−15.98 (26.98)	76
Wrong-incorrect		−12.78 (19.85)	800
Ex-post advice	5.37 (15.23)		
Right-correct		1.83 (8.47)	2841
Wrong-correct		1.68 (7.64)	1045
Right-incorrect		−17.84 (29.24)	90
Wrong-incorrect		−9.57 (16.71)	798
Involved Ex-Post	15.44 (26.36)		
Right-(incorrect)-correct		0.07 (13.74)	99
Wrong-(incorrect)-correct		2.75 (7.57)	95
Right-(correct)-incorrect		−18.09 (29.33)	68
Wrong-(correct)-incorrect		−8.96 (16.70)	769
Not-involved Ex-Post	2.60 (8.31)		
Right-(correct)-correct		1.90 (8.21)	2742
Wrong-(correct)-correct		1.57 (7.64)	950
Right-(incorrect)-incorrect		−11.14 (26.06)	22
Wrong-(incorrect)-incorrect		−11.45 (16.97)	29

[a]AI recognition pattern to confusion matrix representation. 472 right fill and correct recognition: correct rejection; wrong fill and correct recognition: correct detection; 473 right fill and incorrect recognition: false positive; wrong fill and incorrect recognition: false negative.

Trust Adjustment Magnitude Between Ex-Ante, Involved Ex-Post, and Not-Involved Ex-Post

When ex-post advice was further separated into involved and not-involved ex-post, the interaction condition ($F_{2,9565.1}$=380, η^2=0.07; P<.001) significantly affected the magnitude of trust adjustment.

A post hoc comparison between interaction conditions revealed that involved ex-post condition (EMM 15.78, 95% CI 13.62-17.94) led to significantly higher trust adjustment magnitude compared to ex-ante advice (EMM 6.13, 95% CI 4.15-8.11; $t_{9555.51}$=21.00, mean difference 9.65, 95% CI 8.55-10.75, Cohen d=0.72; P<.001) and not-involved ex-post condition (EMM 2.80, 95% CI 0.80-4.79; $t_{9556.27}$=27.55, mean difference 12.98, 95% CI 11.85-14.11, Cohen d=0.97; P<.001). Ex-ante advice led to a higher trust adjustment magnitude compared to not-involved ex-post condition ($t_{9554.52}$=11.46, mean difference 3.33, 95% CI 2.63-4.03, Cohen d=.25; P<.001; Table 2).

Comparison Between AI Types Within Each Recognition Pattern

Trust Adjustment Between Ex-Ante and Ex-Post Advice for Each Recognition Pattern

Recognition pattern ($F_{3,9555.9}$=811.37, η^2=0.2; P<.001) significantly affected trust adjustment; however, AI type did not influence trust adjustment ($F_{1,9548.6}$=2.47, η^2=0.0003; P=.12). However, a marginal interaction effect was observed ($F_{3,9550.7}$=2.52, η^2=0.0008; P=.06).

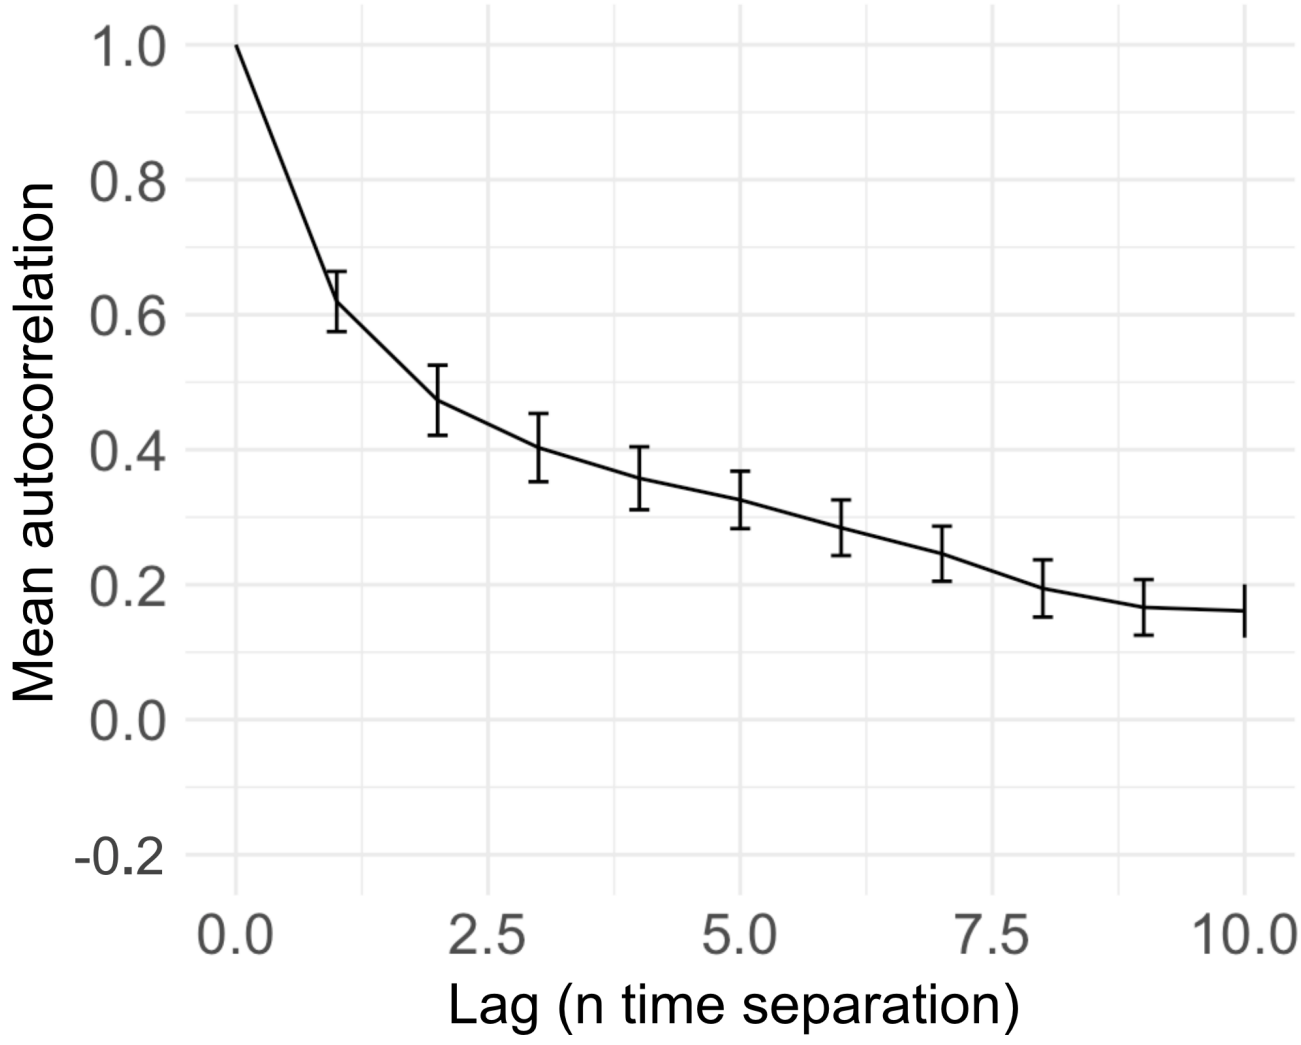
Because of the marginal interaction effect, we compare Ex-Ante and ex-post advice within each recognition pattern. Significant differences were observed when the right drugs were incorrectly rejected. Ex-post advice (EMM −17.84, 95% CI −19.06 to −16.62) showed larger trust decrement compared to ex-ante advice (EMM −15.97, 95% CI −17.19 to −14.76; $t_{9556.76}$=−2.67, mean difference −1.87, 95% CI −3.24 to −0.49, Cohen d=−0.13; P=.008). For other recognition patterns, no significant differences were observed.

XSL•FO
RenderX

Trust Adjustment Between Ex-Ante, Involved Ex-Post, and Not-Involved Ex-Post for Each Recognition Pattern

Both interaction condition ($F_{2,9558.7}$=3.89, η^2=0.0008; P=.03) and recognition pattern ($F_{3,9553.7}$=484.11, η^2=0.13; P<.001) significantly affected trust adjustment. In addition, a significant interaction effect was observed ($F_{6,9570.8}$=2.12, η^2=.0013; P=.048).

Because of the significant interaction effect, we compared interaction conditions within each recognition pattern. Significant differences were observed when the right drugs were incorrectly rejected. Involved ex-post condition (EMM −18.11, 95% CI −19.34 to −16.87) showed larger trust decrement compared to ex-ante advice (EMM −15.97, 95% CI −17.19 to −14.76; $t_{9553.27}$=−3.02, mean difference −2.13, 95% CI −3.83 to −0.44, Cohen d=−0.15; P=.008) and not-involved ex-post condition (EMM −10.79, 95% CI −15.96 to −5.61; $t_{9577.26}$=−2.75, mean difference −7.32, 95% CI −13.69 to −0.95, Cohen d=−0.52; P=.009). A marginal difference was observed between ex-ante advice and not-involved ex-post condition ($t_{9569.61}$=−1.94, mean difference −5.19, 95% CI −11.55 to 1.17, Cohen d=−0.37; P=.052). For other recognition patterns, no significant differences were observed.



Evaluating Trust Properties: Continuity, Negativity Bias, and Stabilization

To explore the key characteristics of trust dynamics, the recognition patterns were grouped into 2 categories: correct AI predictions (right drug correctly approved and *wrong* drug correctly rejected) and incorrect AI predictions (right drug *incorrectly* rejected and *wrong* drug *incorrectly* accepted).

Continuity

Comparing instances of correct versus incorrect AI predictions revealed that successful AI predictions generally increased user trust, while failures led to decreases. In addition, trust levels at a given moment (t) were strongly correlated with trust from the preceding moment (t − 1). To assess how current trust ratings relate to past ones, we calculated the autocorrelation of trust ratings. As shown in Figure 4, trust at time t closely aligns with trust at time t − 1. However, as the time interval between ratings grew longer, the average autocorrelation declined, indicating that trust correlation weakens over time (Figure 4).

Figure 4. Autocorrelation of trust as a function of time separation. The error bars represent ±2 SEs.

XSL•FO
RenderX

Negativity Bias

To test for negativity bias, we compared the magnitude of trust increases following correct predictions with the magnitude of trust decreases following incorrect ones. The results indicated a significant difference between the two: correct AI predictions (mean 2.98, SD 7.33) produced smaller changes than incorrect ones (mean 15.80, SD 23.60) (t_{4726}=30.59, mean difference −12.7, 95% CI −13.6 to −11.9, standardized effect size=−1.15; P<.001).

Stabilization

To examine the stabilization property, linear mixed models were used to analyze trust adjustments over time (sequential success [or failure] occurrence).

The findings revealed that the magnitude of trust adjustments decreased significantly across occurrences for both correct predictions (β=−.037, 95% CI −0.055 *to* −0.019, $t_{4021.10}$=−4.10; P<.001) and incorrect predictions (β=−.402, 95% CI −0.659 to −0.155, $t_{827.46}$=−3.20*;* P=.001).

Discussion

Principal Findings

This study investigated how the timing of AI assistance shaped pharmacists' trust during AI-assisted medication dispensing. We implemented two AI advice timing conditions. In the ex-ante advice condition, the AI presented recognition predictions before pharmacists' initial decision. In the ex-post advice condition, the AI provided selective, postdecision intervention. The ex-post advice was further separated into the involved ex-post condition, which intervened when disagreed with the pharmacist, and the not-involved ex-post condition, which withheld intervention when in agreement.

Overall, differences in trust adjustment magnitude across AI types were modest, with ex-ante advice eliciting slightly higher trust adjustment magnitude than ex-post advice. However, when AI generated incorrect recommendations on initially right fills, ex-ante advice resulted in significantly smaller trust decrement than ex-post advice. Further differentiation of ex-post advice revealed an ordered pattern, where involved ex-post that actively disagreed in the decision process prompted the greatest trust adjustment magnitude, followed by ex-ante advice, with not-involved ex-post yielding the smallest magnitude. This ordering was consistent across the right-incorrect recognition pattern.

In addition, pharmacists' trust dynamics demonstrated ecological validity of trust dynamics properties within a realistic verification context. The findings indicate that pharmacists' trust in AI is dynamic and influenced by the timing, level of involvement, and situational performance of AI assistance during medication verification.

Interpretation of Findings

Comparison Between AI Types

Comparison between the ex-ante and ex-post advice revealed a marginally higher magnitude for ex-ante advice compared to the ex-post advice, which aligns with the findings of Yin et al [27] that the ex-post advice resulted in superior diagnostic quality. When we further decomposed the ex-post advice paradigm into involved ex-post and not-involved ex-post to examine more nuanced trust dynamics associated with AI agreement and disagreement, the involved ex-post condition yielded the highest magnitude of trust adjustment, followed by the ex-ante advice, and then the not-involved ex-post condition. This pattern suggests that interruptive, disagreement-based interventions may exert a strong influence on trust. The ex-ante advice also required pharmacists to evaluate the AI's accuracy during verification, leading to greater trust fluctuations than in the not-involved ex-post condition, which preserved workflow continuity and imposed no extra attentional demand.

Within Recognition Pattern Comparisons

We further analyzed trust adjustment behavior across AI recognition patterns, which considered both the correctness of the filled medication (*right fill* or *wrong fill*) and the accuracy of the AI's prediction (*correct* or *incorrect*). Significant differences in trust adjustment across ex-ante and ex-post advice occurred when *the right fill was incorrectly rejected*. In this pattern, the ex-post advice led to a larger trust decrement compared to the ex-ante advice. For *the right fill was incorrectly rejected* pattern, significant differences in trust adjustment also occurred across interaction conditions. The involved ex-post condition led to the largest trust decrement compared to the other interaction conditions. The ex-ante advice showed a marginally greater trust decrement compared to the not-involved ex-post condition.

Understanding this pattern requires examining how each interaction condition responded in scenarios where AI incorrectly rejected the right drug. In the ex-ante advice condition, the AI's incorrect prediction was visible from the start. Mismatch indicators (ie, red checkboxes) may have falsely anchored pharmacists' attention toward an assumed mismatch and led to a moderate trust decrement [30,32]. In the involved ex-post condition, after pharmacists made the correct initial decision to accept the right drug, AI erroneously classified the mismatch and intervened with a false alert. This prompted the pharmacist to reconsider a correct initial decision, and the largest trust decrement was observed. This mirrors findings that incorrect ex-post alerts elicit strong trust decrements [42]. In contrast, the not-involved ex-post condition functioned as a passive agreement system. Under this condition, the AI silently agreed with the pharmacists' incorrect initial rejection of the right drug. Here, the error was shared between pharmacists and the AI, and the smallest trust decrement was observed.

Operationally, an incorrect rejection of the right drug represents an unnecessary interruption in the dispensing process. Following the AI's incorrect suggestion would require the pharmacist to reverify or refill a medication that was ready to be dispensed, introducing inefficiency. The larger trust decrement observed in this scenario likely does not stem from task consequence. When pharmacists' accurate initial decisions were falsely contradicted by the involved ex-post condition, the error was salient, yielding strong trust decrements. Conversely, when both

XSL•FO
RenderX

pharmacists and AI were wrong (not-involved ex-post), error attribution was shared, producing the smallest trust adjustment.

Validating Trust Dynamics Properties

Beyond evaluating AI interaction types, this study validated 3 trust dynamics properties—continuity, negativity bias, and stabilization [8,45,64]—with an ecologically realistic pharmacy verification environment. Prior validations have often relied on simplified tasks and nonexpert populations. By involving licensed pharmacists performing authentic pill verification, this study strengthens the ecological validity of trust-dynamics in human-AI interaction.

With licensed pharmacists, we demonstrated that trust evolves in a temporally dependent manner, such that trust at a given moment is shaped by prior interactions, strengthening following correct AI performance and declining after errors. We also observed negativity bias, reflecting the asymmetric influence of system performance, whereby trust is more sensitive to AI failures than to successes, making it difficult to build but easy to lose. Finally, pharmacists' trust exhibited stabilization, showing a tendency to converge over repeated interactions as users developed more consistent expectations of the system's behavior.

Implications

These findings underscore the need for careful design of conditional intervention systems in safety-critical workflows. Ex-post advice assistance, implemented as a disagreement-triggered intervention, carries risks of confirmation bias, low revision rates, and negative reactions to incorrect alerts [40,43]. For pharmacists, who are expert decision makers and typically accurate, false AI interventions impose unnecessary cognitive costs. Frequent exposure to erroneous interventions may lead to over-skepticism toward the AI, undermining the intended safety benefit. Conversely, ex-ante advice avoids disruptive alerts but introduces anchoring and information-overload risks of Ex-Ante paradigms [30,31]. Both modalities present distinct trade-offs between autonomy support, cognitive load, and error-correction potential.

Designers of medication verification AI must consider these dynamics when determining when and how AI assistance should be delivered. For example, hybrid approaches, such as confidence-gated alerts, adaptive interventions, or selective suppression of low-confidence interruptions, may mitigate the negative impacts observed with the involved ex-post condition.

Limitations and Future Directions

We acknowledge several limitations of this study and propose directions for future research. First, the AI system's accuracy was experimentally reduced from its operational performance (98.5%) to 79% to ensure sufficient exposure to both correct and incorrect recommendations within a feasible number of trials. Although this approach enabled systematic examination of trust adjustments, it may limit generalizability to real-world settings where AI errors may be less frequent. In high-accuracy environments, errors may be more salient and unexpected, potentially eliciting different trust dynamics. Future research should investigate how trust evolves under near-realistic levels of AI reliability.

Second, in the involved ex-post condition, AI disagreement and workflow interruption were inherently coupled. Thus, the observed aggregated trust adjustment magnitude and trust decrement may reflect not only disagreement with the AI recommendation itself but also the cognitive and attentional disruption introduced by mid-task interventions. Future work should investigate the independent effects of disagreement content and workflow interruption on trust adjustment.

Third, the present analyses focused on self-reported trust adjustment, captured through trial-by-trial trust ratings, rather than subsequent behavioral adaptation to the AI support. As a result, the study does not explicitly highlight whether the trust pattern predicts behavioral responses, such as overriding AI recommendations, changes in decision strategies, or adjustments in reaction time. The asymmetric trust pattern observed in the study (negativity bias) may also relate to the broader literature on algorithm aversion, which suggests humans might respond differently to algorithmic mistakes, to an extent that they may disregard using systems even if they outperform humans [40,65]. Future work should investigate how moment-to-moment trust dynamics influence the subsequent decision-making behavior during repeated interactions with AI systems.

Conclusions

This study examined pharmacists' trust dynamics in response to variations in AI assistance timing and conditionality during the medication verification task. By comparing ex-ante advice and ex-post advice paradigms, and further decomposing ex-post advice into involved and not-involved conditions, the findings demonstrate that both timing and conditionality influence trust. In particular, ex-ante advice resulted in greater overall trust adjustment magnitude than in ex-post advice. However, when further decomposed, disagreement-based interventions that incorrectly challenge right expert decisions produced the largest trust decrements and greatest trust fluctuations.

These results extend prior work on AI advice timing by showing that the effectiveness of ex-post advice depends on the nature of AI involvement. While ex-post advice has been shown to enhance overall decision quality, the present findings indicate that the degree to which the AI agrees or disagrees with users' initial decision plays a critical role in trust adjustments beyond the AI advice timing alone. For expert users performing safety-critical tasks, such as pharmacists performing medication verification, erroneous AI interruptions may influence trust more negatively than continuous AI support. This highlights the need to align AI intervention strategies with user expertise and task demands.

Finally, this work also validates the view that trust in AI is a dynamic, interaction-driven construct that evolves through repeated encounters with system behavior. By validating trust dynamics properties in an ecologically realistic pharmacy verification task, this study contributes to human-AI interaction research that emphasizes the importance of capturing moment-to-moment trust adjustments.

Abstract

Background: AI has the potential to enhance clinical decision-making in high-acuity settings such as intensive care units (ICUs) and emergency departments (EDs). However, despite promising performance, many AI-driven clinical decision support systems (AI-CDSSs) face poor adoption due to issues of trust, workflow disruption, and alert fatigue. Understanding the human factors that shape clinician acceptance is critical to guide safe and effective implementation of AI-CDSS in acute care. Theoretical frameworks, including the Systems Engineering Initiative for Patient Safety (SEIPS) 2.0 model and the technology acceptance model (TAM), suggest that successful adoption requires addressing sociotechnical interactions among clinician trust, system design, organizational readiness, and task complexity, yet few empirical studies have applied these frameworks to AI-CDSSs in acute care settings.

Objective: This study aimed to evaluate emergency medicine and critical care clinicians' perceptions of AI-CDSSs and to identify key factors influencing adoption, including trust, design preferences, and workflow integration.

Methods: A SEIPS 2.0–informed mixed methods study evaluated ICU and ED clinicians from Emory Healthcare on perceptions of AI in clinical practice. An expert-reviewed survey (N=57) assessed clinician perceptions, trust, and implementation preferences. Semistructured interviews (n=11) included A/B testing of AI-CDSSs and clinical sepsis scenarios to explore decision-making in context. Transcripts were thematically analyzed using the Braun and Clarke framework in ATLAS.ti (version 26, ATLAS.ti Scientific Software Development). Quantitative data were analyzed descriptively. This study assessed clinician perceptions using mock alerts and hypothetical scenarios rather than real-world AI-CDSS deployment.

Results: Trust in AI varied significantly by patient acuity (Cochran Q=30.40, *P*<.001): stable patients (43/57, 75%, 95% CI 63% - 85%), deteriorating patients (27/57, 47%, 95% CI 35% - 60%), and critically ill patients in the ICU and undifferentiated patients in the ED (25/57, 44%, 95% CI 32% - 57% for each scenario). Internal consistency was acceptable-to-good across three scales (Cronbach α: AI Perception=.891, Trust=.743, Implementation=.740; McDonald ω: AI Perception=0.895, Trust=0.782, Implementation=0.746). Barriers included overreliance, insufficient training, and data quality concerns. For the exploratory AI-CDSS design, clinicians preferred opt-in alerts (10/11, 91%), evidence-linked recommendations (7/11, 64%), and avoiding overt mention of increased AI acceptance (8/11, 73%). Thematic analysis yielded 36 themes across six domains: trust and transparency, alert usability, workflow fit, data concerns, training needs, and perceived clinical impact. Clinicians favored AI-CDSSs that preserved autonomy, minimized disruption, and provided transparent rationales.

Conclusions: Adoption of AI-CDSSs in critical care is not solely a technical issue but a human-factors challenge centered on trust, transparency, and workflow compatibility. These findings support future testing of a phased implementation approach—beginning with lower-acuity applications where clinician trust is highest, then gradually extending to higher-acuity scenarios with enhanced transparency and override mechanisms. This graduated strategy addresses the critical interdependencies among people (trust), tools (design), organizations (training), and tasks (clinical complexity) identified in this study.

Introduction

The integration of AI tools into clinical practice offers an opportunity to enhance health care delivery, particularly in high-acuity settings like the intensive care unit (ICU) and emergency department (ED), where rapid, data-driven decisions are crucial [1]. Despite the technological promise, the successful implementation of AI tools into frontline clinical practice is filled with challenges [2]. The history of health information technology is replete with examples of powerful tools that failed to gain traction due to a mismatch with clinical workflow. This mismatch is often attributed to a lack of attention to "human factors," which refer to the complex interplay between technology, users, and the clinical environment [3]. The adoption of AI is similarly challenged by significant barriers, including a lack of trust, concerns about workflow disruption, and the potential for alert fatigue [3-5]. Overcoming these barriers requires a deep understanding of clinician perceptions, needs, and priorities.

A clinical decision support system (CDSS) is a practical application that can integrate AI into clinical decision-making [4]. A targeted intervention can be suggested to the clinician through a CDSS from a validated machine learning algorithm. For instance, in the Precision Resuscitation With Crystalloids in Sepsis (PRECISE) trial, a validated machine learning algorithm identifies a subgroup of infected patients with a potential mortality benefit from balanced crystalloid instead of normal saline, and a CDSS prompts the clinician to change the order [6]. Since the integration of CDSSs into electronic health records (EHRs), there have been multiple studies on the "five rights" of CDSSs, which help guide the creation of effective alerts [7]; however, less is understood on how to effectively incorporate a CDSS that utilizes an AI recommendation. Because successful AI-based CDSS (AI-CDSS) implementation depends on more than the technical performance of the algorithm, a human factors framework is needed to examine how clinician trust, workflow, alert design, and organizational context shape adoption [8,9].

Using multiple complementary frameworks to evaluate implementation of an AI tool can provide a more holistic understanding. We primarily draw on the Systems Engineering Initiative for Patient Safety (SEIPS) 2.0 model [10], which conceptualizes health care systems as comprising five interacting components: people, tasks, tools and technologies, organization, and environment. SEIPS 2.0 emphasizes that patient safety and quality outcomes emerge from complex, bidirectional interactions among these components, making it particularly suitable for studying the adoption of AI-CDSSs, which simultaneously affects clinician cognition (people), decision-making workflows (tasks), interface design requirements (tools), implementation strategy (organization), and care setting constraints (environment). We also incorporate constructs from the technology acceptance model (TAM) [11], specifically Perceived Usefulness and Perceived Ease of Use, and Jian et al's [12] Trust in Automated Systems framework, which characterizes trust across belief, intention, and behavior dimensions. In addition, we draw on the three-layer trust model of Hoff and Bashir [13], which distinguishes dispositional, situational, and learned trust and offers an integrative lens for trust in automation. This multiframework approach responds to calls for theoretically grounded, human-centered evaluations of health care AI [8,9].

In this study, we address the gap in knowledge on applying AI-CDSSs to high acuity settings through a mixed methods evaluation to investigate ED and ICU clinicians' perceptions of AI use in clinical practice and to identify and analyze the facilitators and barriers to AI adoption.

Methods

Study Design

A mixed methods human factors evaluation was conducted at Emory Healthcare in Atlanta, Georgia. The study employed a cross-sectional, exploratory design and combined a quantitative survey with qualitative, semistructured interviews. We used a convergent (concurrent triangulation) design in which the quantitative and qualitative strands were collected in parallel and given equal priority (QUAN+QUAL). Integration occurred at the methods level, through shared constructs across the survey and interview guide, and at the interpretation level, through a joint display. The mixed methods reporting follows the Good Reporting of a Mixed Methods Study (GRAMMS) criteria [14] (Checklist 1). SEIPS 2.0 also guided the study operationally across data collection, analysis, and interpretation. Survey domains and the semistructured interview guide were developed to reflect SEIPS 2.0 work-system components, including people, tasks, tools and technologies, organization, and environment. These domains were later used as sensitizing concepts during codebook refinement, theme development, and interpretation. The objective was to explore clinician perceptions of AI-CDSSs.

Recruitment and Participants

Eligible participants included clinicians in the ICU and ED, who were actively involved in direct patient care. Recruitment was conducted from February to April 2025 through multiple channels: invitation emails distributed via ICU and ED provider listservs at all Emory Healthcare hospitals, institutional review board (IRB)–approved flyers posted in clinical units, presentations during departmental meetings, and word-of-mouth referrals among clinical staff. Flyers included a QR code directing interested individuals to the online REDCap survey platform. Participants could opt to complete the survey, participate in an interview, or both. Participation was voluntary and could be discontinued at any point.

XSL•FO
RenderX

Data Collection

Survey Procedures

The survey instrument was developed through an iterative consensus process with subject matter experts in critical care and health informatics. The instrument assessed four primary domains: (1) clinician demographics and prior experience with AI, (2) general perceptions of AI's role and impact, (3) trust in AI recommendations across different clinical scenarios, and (4) the importance of various AI usability features. The survey was administered online via REDCap (Vanderbilt University) and remained open from February 9 to April 1, 2025. Items used Likert-scale (5-point), multiple-choice, and open-ended response formats.

The survey was voluntary and distributed through ICU and ED provider listservs, IRB-approved flyers with QR codes, departmental presentations, and word-of-mouth referral. The survey was administered electronically through REDCap, and participants reviewed study information and provided informed consent before participation. No survey weighting was applied. Since recruitment occurred through both listserv-based and open-ended channels, the exact number of clinicians who received or viewed the invitation could not be determined, and a precise response rate could not be calculated. A Checklist for Reporting Results of Internet E-Surveys (CHERRIES) checklist was completed [15] (Checklist 2).

The survey items were organized into four construct groups for analysis: (1) AI perception (6 items mapping to TAM perceived usefulness: accuracy, efficiency, variability, the two complementarity items, and reliability; the negatively worded overreliance item was analyzed as a standalone item), (2) trust scenarios (4 binary items across patient acuity levels, informed by Jian et al's [12] trust-in-automation framework), (3) trust beliefs (3 Likert items: reliability, understanding-trust link, complementarity), and (4) implementation factors (6 importance-rated items mapping to unified theory of acceptance and use of technology [UTAUT]; facilitating conditions and TAM perceived ease of use [11,16]).

Interview Procedures

Clinicians who completed the survey were subsequently invited to participate in semistructured interviews conducted via Zoom (Zoom Communications, Inc) from March 20 to April 7, 2025. Interviews lasted approximately 30 to 45 minutes and followed a structured guide developed by the research team based on existing literature regarding AI-CDSS adoption. All interviews were conducted by the lead analyst (MD, who has clinical training in dentistry and informatics). The interview component is reported in accordance with the Consolidated Criteria for Reporting Qualitative Research (COREQ) [17] (Checklist 3). Interview questions explored the same domains as the survey while allowing for deeper examination of participants' reasoning and preferences. The interviews incorporated A/B testing of different AI-CDSS interface designs. Alert prototypes were derived from the AI-CDSS utilized in the PRECISE trial, which encourages clinicians to consider changing their order from normal saline to balanced crystalloid in a population of infected patients that have been shown to have a mortality benefit with balanced crystalloid using an AI algorithm [6]. Participants evaluated three distinct pairs of mock-up alerts (version A vs version B; Multimedia Appendices 1-4), each designed to assess specific aspects of usability and information framing. For each pair, participants selected their preferred design and articulated detailed reasoning for their choice. The presentation order of A/B test pairs was consistent across participants; randomization or counterbalancing was not employed, which may introduce order effects. Additionally, each A/B pair tested multiple design variables simultaneously (eg, opt-in vs opt-out combined with different action language), limiting the ability to isolate individual design effects.

Participants were also presented with a clinical case scenario designed to elicit nuanced perspectives on the practical application of an AI-CDSS. Nurses were excluded from this section since the decisions made may be outside their scope of practice. The scenario depicted a 54-year-old male with multiple comorbidities presenting with septic shock. This case was used to anchor the discussion and probe opinions across five decision points in a critical care resuscitation (Multimedia Appendix 5).

All interviews were audio-recorded using Zoom's built-in recording function, transcribed verbatim using automated transcription with subsequent manual review for accuracy, and deidentified prior to analysis. Complete survey and interview instruments are provided in Multimedia Appendices 6 and 7 respectively.

Data Analysis

Survey responses were analyzed using descriptive statistics (frequencies, proportions, means, and SDs) computed in Python (SciPy, NumPy). Proportions are reported with 95% Wilson score CI, preferred over Wald intervals for small samples and extreme proportions. Likert-type items (5-point scales) are reported with means, SDs, and 95% CIs. Internal consistency of multi-item scales was assessed using Cronbach α. The McDonald ω (total, from a one-factor model) is analyzed alongside α because ω provides a less restrictive estimate of internal consistency and is recommended as a practical complement to α [18]. Trust across four patient acuity levels was compared using Cochran Q test for related binary samples, with pairwise McNemar exact tests and Bonferroni correction (6 comparisons, adjusted α=.0083). Holm step-down and Benjamini-Hochberg false discovery rate adjustments are presented alongside Bonferroni, and a Friedman test on the full 5-point trust ratings served as a nonparametric sensitivity analysis. Medians and IQRs are reported with means and SDs for Likert-type items in a supplementary table (Multimedia Appendix 8). Associations between categorical variables (department×perception, role×AI usage, AI experience×trust) were assessed using chi-square tests or Fisher exact tests when expected cell counts fell below 5. Since more than 20% of expected cell counts were below 5 in these cross-tabulations, they were treated as exploratory sensitivity analyses, and Monte Carlo permutation *P* values (fixed margins, 100,000 simulated tables) were computed alongside the asymptotic tests. Given the exploratory sample size (N=57), we report exact counts alongside percentages and note cell-count limitations for cross-tabulations. For the multiselect item on desired AI

XSL•FO
RenderX

applications, respondents could choose any number of options, and percentages are reported as shares of all selections. Exploratory subgroup analyses compared ICU and ED respondents on each main outcome using 95% Wilson CIs, Fisher exact tests for binary outcomes, and Mann-Whitney *U* tests for ordinal items.

Interview transcripts and open-ended survey responses were analyzed using thematic analysis following the six-phase framework described by Braun and Clarke [19]. Two reviewers (MD and KC) independently coded the data using ATLAS.ti (version 26; ATLAS.ti Scientific Software Development) and Microsoft Excel. Coding was conducted both deductively, based on the structure of the interview guide, and inductively to capture emergent patterns. The reviewers first reviewed transcripts to identify recurring ideas, phrases, and concepts, which were then labeled as codes and organized into a shared codebook, through consensus discussions with a third reviewer (SP), refining the codebook across multiple coding cycles. During codebook refinement and theme development, codes and excerpts were reviewed in relation to SEIPS 2.0 work-system domains while allowing inductive themes to emerge from the data. Related codes were then collated into preliminary themes and subthemes based on recurring patterns in the interview transcripts. These preliminary themes were reviewed against the underlying excerpts, refined through consensus discussions among the analytic team, and revised to reduce overlap and improve conceptual clarity. Themes addressing similar concepts were then merged into six overarching thematic clusters based on recurrence across responses, relevance to the study aims, clinical interpretability, and alignment with SEIPS 2.0 work-system domains. The final cluster structure was validated by comparing each cluster against representative excerpts, resolving discrepancies through coder discussion, and integrating the qualitative findings with survey results. Integration types in the joint display (convergent, complementary, expansion, or emergent) were assigned through consensus discussion between the two coders. Open-ended survey responses were coded using the same codebook to ensure analytical coherence across data sources. An audit trail was maintained throughout the analytic process, and regular debriefing sessions among coders ensured analytic rigor. Intercoder agreement was assessed at early coding stages using percentage agreement, which exceeded 85% prior to consensus discussion. A third reviewer (SP) not directly involved in the clinical trial adjudicated discrepancies.

Ethical Considerations

The study received approval from the Emory University and Indiana University IRBs (IRB #STUDY00008904 and Protocol #26246 respectively), and all participants provided informed consent prior to participation and data collection. All study procedures adhered to ethical guidelines for human subjects' research. All data were deidentified, and transcripts and survey data were stored on secure, encrypted servers. Participants' identities were protected throughout data analysis and reporting.

We acknowledge that the positionality of the research team, several members of which are embedded in the PRECISE trial [6], may introduce bias toward favorable framing of AI-CDSSs. The lead analyst (MD) conducted interviews with prior knowledge of AI-CDSS design principles; however, the dual-coder approach, inclusion of clinician coinvestigators (DM, JWD, SVB) with direct patient care responsibilities, analytic debriefing, and team-based consensus review during analysis helped mitigate interpretive bias. We have attempted to present both supportive and critical clinician perspectives throughout.

Results

Survey Findings

Respondent Characteristics

Fifty-seven clinicians completed the survey (98.2% completion rate, with 1 partially incomplete). The sample comprised ICU providers (39/57, 68%, 95% CI 56% - 79%), ED providers (13/57, 23%, 95% CI 14% - 35%), and other settings or the general ward (5/57, 9%, 95% CI 4% - 19%). Respondents represented diverse clinical roles: ICU advanced practice providers (APP; 15/57, 26%), nurses (12/57, 21%), residents and fellows (9/57, 16%), intensivists (8/57, 14%), emergency physicians (7/57, 12%), and ED APPs, pharmacists, and other roles (6/57, 11%). Experience ranged from <1 year (2/57, 4%) to >15 years (9/57, 16%), with the largest group at 1 - 5 years (18/57, 32%).

Of 57 respondents, 22 (39%, 95% CI 27% - 51%) reported prior AI use in clinical practice, while 35 (61%) had not. Among AI users (n=22), usage frequency was daily (n=5, 23%, 95% CI 10% - 43%), weekly (n=11, 50%, 95% CI 31% - 69%), monthly (n=3, 14%), and rarely (n=3, 14%). Confidence in AI recommendations among users was generally positive: confident (n=8, 36%, 95% CI 20% - 57%), moderately confident (n=9, 41%, 95% CI 23% - 61%), slightly confident (n=3, 14%), and not at all confident (n=2, 9%). Combined positive confidence (confident+moderately confident) was 77% (95% CI 57% - 90%).

Perception of AI Role and Impact

Fifty-four percent (31/57, 95% CI 42% - 67%) of survey respondents perceived AI as "helpful but supplementary," 23% (13/57, 95% CI 14% - 35%) considered it "transformative and essential," 19% (n=11) were "neutral/uncertain," and only 4% (2/57, 95% CI: 1% - 12%) viewed AI as "potentially disruptive." Trust in AI varied significantly with patient acuity (Cochran Q_3=30.40; P<.001): stable ward patients elicited the highest combined trust (somewhat trust+strongly trust) at 75% (95% CI 63% - 84%), followed by deteriorating ward patients at 47% (95% CI 35% - 60%), undifferentiated ED patients at 44% (95% CI 32% - 57%), and critically ill ICU patients at 44% (95% CI 32% - 57%). Notably, strong distrust increased markedly with acuity: from 2% for stable patients to 7% for deteriorating patients to 12% for critically ill ICU patients. Overall, 68 % (95% CI 56% - 79%) of respondents expressed ethical concerns about AI in clinical decision-making. Regarding overreliance, 79% (95% CI 67% - 88%) agreed or strongly agreed that overreliance on AI poses risks to patient outcomes.

Likert-scale responses further characterized clinician attitudes: most clinicians agreed that AI enhances care efficiency (36/57,

XSL•FO
RenderX

63%) and complements clinical expertise (39/57, 68% to 43/57, 75%), while over three-quarters reported that understanding AI outputs increases trust (45/57, 79%). At the same time, concerns about overreliance on AI were common (45/57, 79%). Confidence in AI's reliability was more moderate, with 47% (27/57) agreeing that AI provides reliable insights. Internal consistency was considered good for the 6-item AI Perception scale (Cronbach α=0.891; McDonald ω=.895) and acceptable for the 3-item Trust subscale (α=0.743; ω=.782) and the 6-item Implementation scale (α=0.740; ω=.746), all exceeding the 0.70 acceptability threshold. Detailed Likert-scale statistics are presented in Table 1.

Table . Clinician attitudes toward AI-based clinical decision support system (Likert-scale responses).

Statement	Mean (SD)	95% CI (mean)	Median (IQR)	Agree and strongly agree combined % (95% CI)
AI improves accuracy of decisions	3.54 (0.78)	3.34 - 3.75	4 (3-4)	56 (43 - 68)
AI enhances care efficiency	3.79 (0.80)	3.58 - 4.00	4 (3-4)	63 (50 - 75)
AI reduces decision variability	3.51 (0.78)	3.31 - 3.71	4 (3-4)	54 (42 - 67)
AI complements clinical expertise	3.74 (0.77)	3.54 - 3.94	4 (3-4)	68 (56 - 79)
AI insights complement expertise	3.86 (0.74)	3.67 - 4.05	4 (4-4)	75 (63 - 85)
AI provides reliable insights	3.35 (0.88)	3.12 - 3.58	3 (3-4)	47 (35 - 60)
Overreliance on AI poses risks	4.05 (0.91)	3.82 - 4.29	4 (4-5)	79 (67 - 88)
Understanding AI outputs increases trust	4.14 (0.97)	3.89 - 4.39	4 (4-5)	79 (67 - 88)

Inferential analysis revealed that trust varied significantly across patient acuity levels (Cochran Q_3=30.40; *P*<.001). Pairwise McNemar tests with Bonferroni correction (6 comparisons, adjusted α=.0083) confirmed that trust in stable patients was significantly higher than in deteriorating (*P*<.001), ICU (*P*<.001), and ED (all *P*<.001) scenarios, while the three nonstable scenarios did not differ significantly from each other. Conclusions were unchanged when Holm step-down and Benjamini-Hochberg false discovery rate adjustments were used instead of Bonferroni. A Friedman test on the full 5-point trust ratings confirmed the acuity effect (χ^2_3=33.5; *P*<.001; Kendall W=0.20). In exploratory sensitivity analyses, the cross-tabulations had more than 20% of expected cell counts below 5 and are not confirmatory. The association between department and AI perception was significant under the asymptotic test (χ^2_9=17.4*;* *P*=.04) but was not robust under Monte Carlo permutation testing (*P*=.08). The association between role and AI usage was significant (χ^2_7=16.5*;* *P*=.02; permutation *P*=.01). Both findings require confirmation in larger samples. Fisher exact test for AI experience and trust in stable patients was not significant (OR 0.79; 95% CI 0.23-2.69; *P*=.76).

Barriers to AI Adoption

Among the 22 respondents with AI experience, insufficient training (n=12, 55%, 95% CI 35% - 73%) and lack of trust in AI recommendations (n=12, 55%, 95% CI 35% - 73%) were the most frequently cited barriers, followed by workflow disruption (n=7, 32%, 95% CI 16% - 53%) and other factors (n=4, 18%, 95% CI 7% - 39%). Only 2 respondents (9%, 95% CI 3% - 28%) reported no barriers. The values here are reported among AI users only, as barriers are most meaningful for those with direct experience. Given the small denominator (n=22), these proportions have wide CIs and should be interpreted cautiously.

Desired Features and Implementation Priorities

Respondents universally emphasized the importance of explainability: 75% (43/57) rated transparency as "very important" and 25% (14/57) as "important," achieving 100% combined endorsement (95% CI 94% - 100%). Furthermore, 79% (45/57, 95% CI 67% - 88%) agreed or strongly agreed that understanding how AI generates its outputs increases their trust. Implementation factor importance ratings (on a 5-point scale from "Not important" to "Essential") were: nondisruptive to workflow (mean 4.47, SD 0.66; 91%, 95% CI 81% - 96%), positive patient outcomes (mean 4.35, SD 0.81; 88%, 95% CI 77% - 94%), clear recommendations (mean 4.14, SD 0.81; 81%, 95% CI 69% - 89%), alignment with clinical judgment (mean 4.11, SD 0.75; 84%, 95% CI 73% - 92%), training provided (mean 3.91, SD 0.97; 70%, 95% CI 57% - 81%), and intuitive interface design (mean 3.89, SD 0.88; 75%, 95% CI 63% - 85%). Internal consistency for the 6-item implementation scale was acceptable (Cronbach α=0.740).

Respondents could select multiple desired AI applications, so percentages are shares of the 213 total selections. The most desired applications were antibiotic selection (41/213, 19.2%), image interpretation (37/213, 17.4%), ventilator management (30/213, 14.1%), sepsis prediction (28/213, 13.1%), deterioration prediction (26/213, 12.2%), fluid management (24/213, 11.3%), and vasopressor management (18/213, 8.5%). Preferences varied by clinical role: nurses prioritized image interpretation, deterioration prediction, and sepsis prediction, while intensivists preferred antibiotic selection and image interpretation. By department, ICU clinicians most valued antibiotic selection

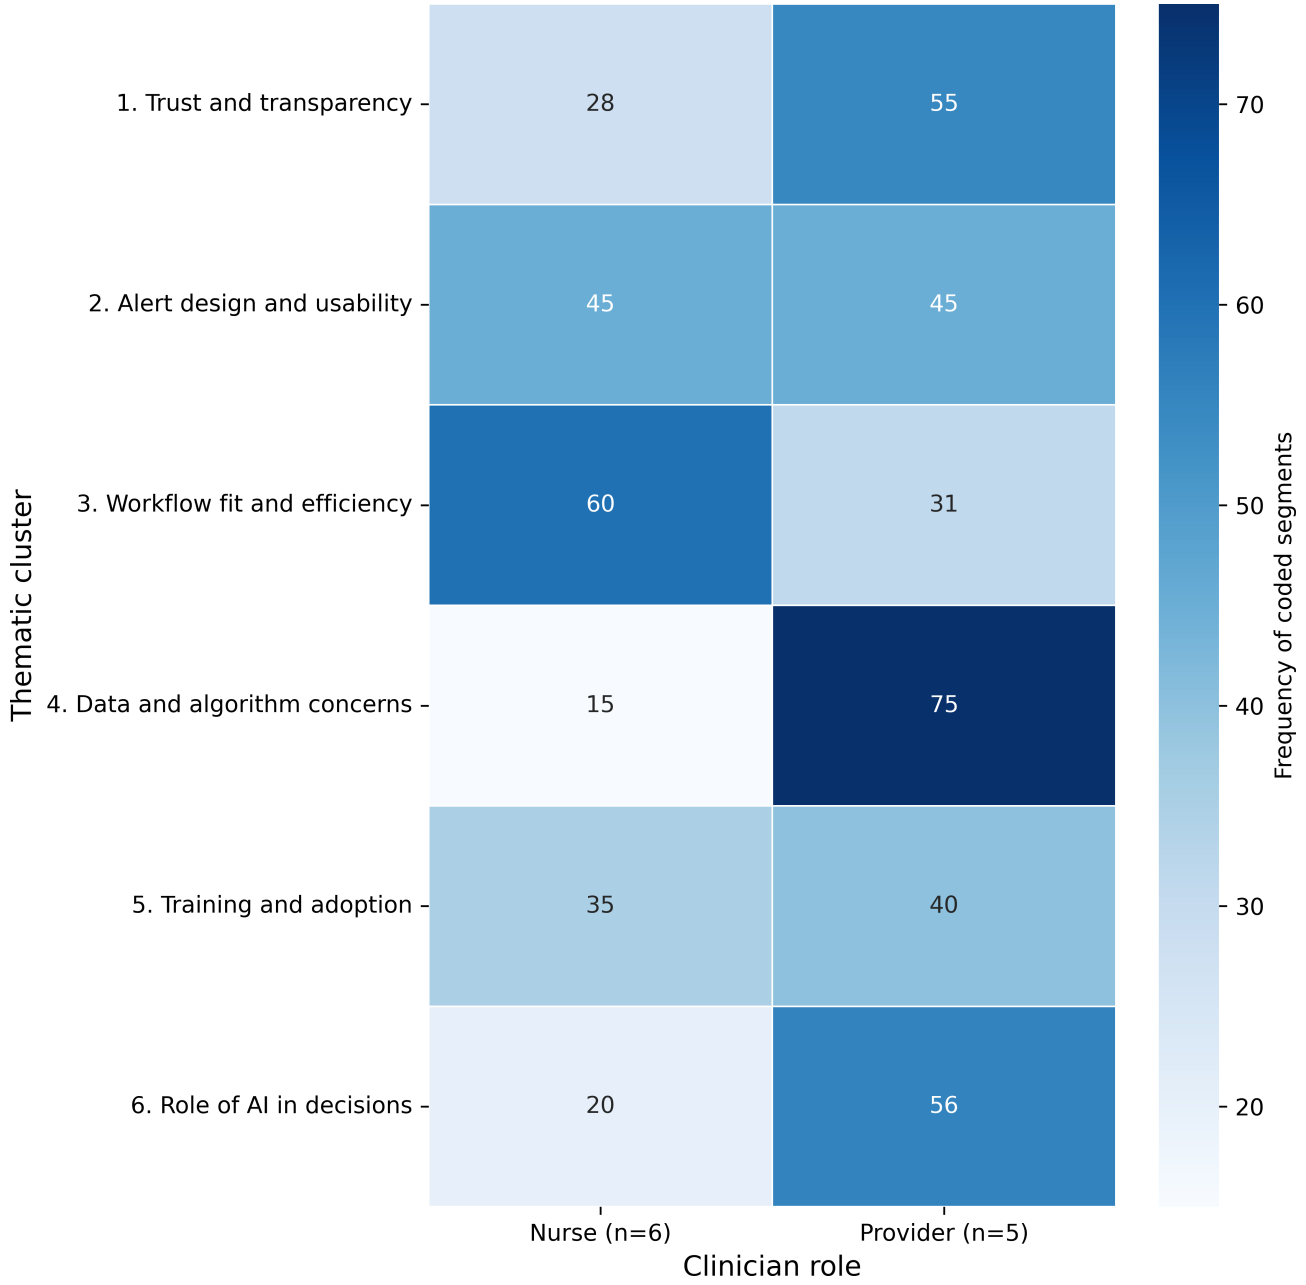
XSL•FO
RenderX

(28/136 ICU selections, 20.6%), while ED clinicians showed more evenly distributed preferences across use cases.

Exploratory ICU vs ED Subgroup Comparisons

In exploratory subgroup analysis, prior AI use was more common among ED respondents (10/13, 77%; 95% CI 50% - 92%) than among ICU respondents (12/39, 31%; 95% CI 19% - 46%; *P*=.008). No other main outcome differed significantly between the two departments. For example, combined trust for a stable ward patient was 28/39 (72%; 95% CI 56% - 83%) among ICU respondents and 11/13 (85%; 95% CI 58% - 96%) among ED respondents. Full subgroup statistics with 95% Wilson CIs are provided in Multimedia Appendix 9. The ED subgroup was small, so these comparisons are hypothesis generating only.

Interview Findings



Overview

Semistructured interviews were conducted with 11 participants, including physicians (3), APPs (2), and nurses (6). The thematic analysis for the interviews identified 36 detailed themes from approximately 690 coded segments. To support synthesis and clinical interpretability, these themes were organized into six overarching thematic clusters: (1) trust, transparency, and human control (2) alert design, interface, and usability (3) workflow fit and efficiency (4) data accuracy and algorithm concerns (5) training, rollout, and adoption barriers (6) role of AI in clinical decision making. The six clusters serve as the primary analytic structure. The 36 detailed themes, related subthemes, and representative quotations are provided in Multimedia Appendix 10.

Thematic saturation was considered achieved after the tenth interview, when no new codes or subthemes emerged. Following Malterud et al's [20] information power framework, our interview sample (n=11) was deemed sufficient given the narrow study aim, specific participant group, strong interview dialogue quality, and application of established theoretical frameworks. A frequency-based analysis of thematic codes confirmed progressive code saturation across the final three interviews. This pattern is consistent with the code saturation thresholds described by Hennink et al [21]. A frequency of thematic discussion is illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. Frequency of thematic discussion by clinician role. This heatmap shows the frequency of coded segments for each thematic cluster, compared between nurses and providers. The "provider" category includes physician, resident, and advanced practice provider participants.

Cluster 1: Trust, Transparency, and Human Control

Trust emerged as a central but conditional concept in clinician attitudes toward AI. Participants described trust as dependent on transparency, logic, and the ability to maintain control over the final clinical decision. The need for explainability was repeatedly emphasized, particularly in relation to opaque or "black-box" algorithms: This qualitative finding aligns with survey data showing that 79% (95% CI 67% - 88%) of respondents agreed or strongly agreed that understanding how AI generates its outputs increases trust, while only 47% (95% CI 35% - 60%) agreed that AI systems provide reliable and accurate insights, a 32 percentage-point gap suggesting that trust is contingent on transparency mechanisms rather than assumed reliability.

> *If it's going to be a black box in like a neural network, it needs to at least make logical sense.* [P8, Emergency Physician]

Clinicians consistently emphasized the importance of human oversight and override authority:

> *If you're thinking of a supportive tool, you should be able to override the tool's recommendation.* [P9, Nurse Practitioner]
>
> *I only trust AI 50%. I still go through the reasoning myself and apply it to the situation at hand.* [P6, Nurse]

Even among those optimistic about AI's potential, trust was framed as "trust, but verify," rooted in the belief that decisions must always align with clinical reasoning and patient context.

XSL•FO
RenderX

> *It depends on the AI system…it's a trust, but verify. It needs to make logical sense. If it doesn't, or it doesn't have robust data behind it, then I'm not gonna trust it.* [P8, Emergency Physician]

> *AI can pop up and say "Hey, this number looks weird," but it's still up to the human to say...we are going to continue with our plan of care...* [P8, Emergency Physician]

Clinicians viewed AI as an "extra set of eyes" that enhances safety but must coexist with human interpretation:

> *I think it's an extra set of eyes…an extra layer of safety. But you still need humans putting all the pieces together.* [P5, Nurse]

> *You never know who put the original information in....If there was some transparency with that, then I think the trust level would be higher.* [P6, Nurse]

Cluster 2: Alert Design and Interface Usability

Participants emphasized user control, simplicity, and relevance in the design of alerts and interfaces. The majority preferred opt-in alerts that allow deliberate review rather than automatic notifications. Concise recommendations coupled with links to supporting evidence were considered ideal:

> *Links to the study rationale as to why it's doing it are always going to be helpful.* [P8, Emergency Physician]

> *If I was in clinical settings...I'd love to have a short version, and then click to see the studies when I actually have time.* [P2, Nurse]

Clinicians highlighted the importance of balancing best-practice guidance with individualized patient care:

> *Version A [opt-in] allows the clinician to take a moment and review which one is better for the patient.* [P2, Nurse]

A subset of participants expressed fatigue toward AI branding, noting that overuse of the term "AI" could reduce acceptance or trigger trust issues:

> *I'm also feeling this myself, and I do AI research. People are just getting burnt out by the term.* [P11, ICU Physician]

> *If we see "recommended by AI" on every single thing...then that could trigger trust issues...* [P5, Nurse]

Some envisioned adaptive electronic medical record (EMR) systems that would learn user patterns to reduce redundant tasks and improve efficiency:

> *The idea of a learning EMR that adapts to my patterns and shows the information I need…without all the extra clicking, would be a real time saver.* [P11, ICU Physician]

Cluster 3: Workflow Integration and Efficiency

Several participants viewed AI as a tool to enhance administrative efficiency and relieve documentation burden:

> *AI impact on nursing workflow…most importantly clinical documentation and note-taking, because many times when you are the ICU clinician, you are busy.* [P6, Nurse]

> *Ambient listening can save time for providers in terms of summarizing notes.* [P9, Nurse Practitioner]

Clinicians repeatedly noted that workflow integration would determine whether AI-CDSS tools succeed or fail in practice. Systems that disrupt time-sensitive tasks or introduce additional clicks were viewed negatively, even if algorithmically advanced. Reliable data inputs and minimal disruption were essential for trust and adoption:

> *It's a great tool, but if you make it harder to use or make me click more, people will avoid it.* [P5, Nurse]

Participants favored AI implementations that fit seamlessly into existing workflows, augmenting rather than complicating clinical processes.

> *You have to find the right use case. If it's interrupting the flow or making my job harder, it won't be used.* [P6, Nurse]

Cluster 4: Data Accuracy and Algorithm Concerns

Across interviews, data integrity surfaced as a recurring theme. Participants questioned whether AI models could operate effectively given the variability and inaccuracies of EHR data. Concerns about algorithmic reliability often traced back to inconsistent documentation or sensor readings rather than mistrust of AI itself.

> *AI is only as good as the data it's trained on.* [P7, Physician]

> *There's a lot of garbage when it comes to vital signs, like a ridiculous amount.* [P8, Emergency Physician]

> *If you're using a model that's based on garbage…it will harm people.* [P1, Nurse]

Clinicians worried that even a well-designed algorithm could amplify inequities or generate unsafe recommendations if trained on biased or incomplete datasets.

> *It would be harmful in patient populations where we don't have a lot of data…broadly applying things that may be true for the majority may not apply to the minority.* [P11, ICU Physician]

A related barrier noted by several participants was automation bias, reflecting apprehension that clinicians might overtrust AI outputs without understanding their context or training data:

> *I worry about automation bias…people treating what AI says as golden, without knowing how it was trained or the context it's appropriate for.* [P11, ICU Physician]

Cluster 5: Training, Rollout, and Adoption Barriers

The theme of training and implementation was strongly represented across participants. Many clinicians cited past experiences with EHR rollouts that lacked context or interactivity:

XSL•FO
RenderX

> *I've had experiences where things in the clinical setting get rolled out without much explanation or any explanation at all.* [P10, Nurse Practitioner]
>
> *There was no opportunity to interact or ask questions…I would want to know the reason it was being implemented, the benefit of it.* [P2, Nurse]

Participants consistently favored peer-led "super user" programs that provided accessible, hands-on training:

> *Emory is very good at doing that, any time a new system is introduced, we have super users.* [P6, Nurse]
>
> *I think if there was a dedicated person…that would be helpful; everyone is already overburdened with work.* [P3, Resident]

Most participants rejected static, online formats:

> *I don't want to take a class, and I don't want to do an online course or PowerPoint.* [P3, Resident]

Effective rollout was described as transparent, contextualized, and supported by leadership and time allocation.

Cluster 6: Role of AI in Clinical Decision-Making

Clinicians characterized AI as a complementary aid that can enhance clinical awareness and decision-making but not replace human expertise. They underscored that human touch and situational awareness remain irreplaceable. AI was described as a diagnostic "extension," comparable to tools like ultrasound:

> *I think it should be an extension of our physical exam…just like ultrasound…but with more caution.* [P11, ICU Physician]
>
> *My ideal use is: reinforce what I already thought, or help me think in a new way.* [P8, Emergency Physician]
>
> *You can't replace the hands and body of a nurse.* [P5, Nurse]

Several participants recognized AI's emerging role in detecting subtle findings and supporting clinical intuition, expressing optimism.

> *I think it's going to be a pillar of medical care…for predicting decompensation based on vitals and labs.* [P4]
>
> *AI program caught a small subdural hematoma the radiologist missed...it was really cool to see that.* [P9]
>
> *We're still in the infancy for it….But I think this is going to be the way in which we get a better sense of personalized medicine and healthcare.* [P11, ICU Physician]

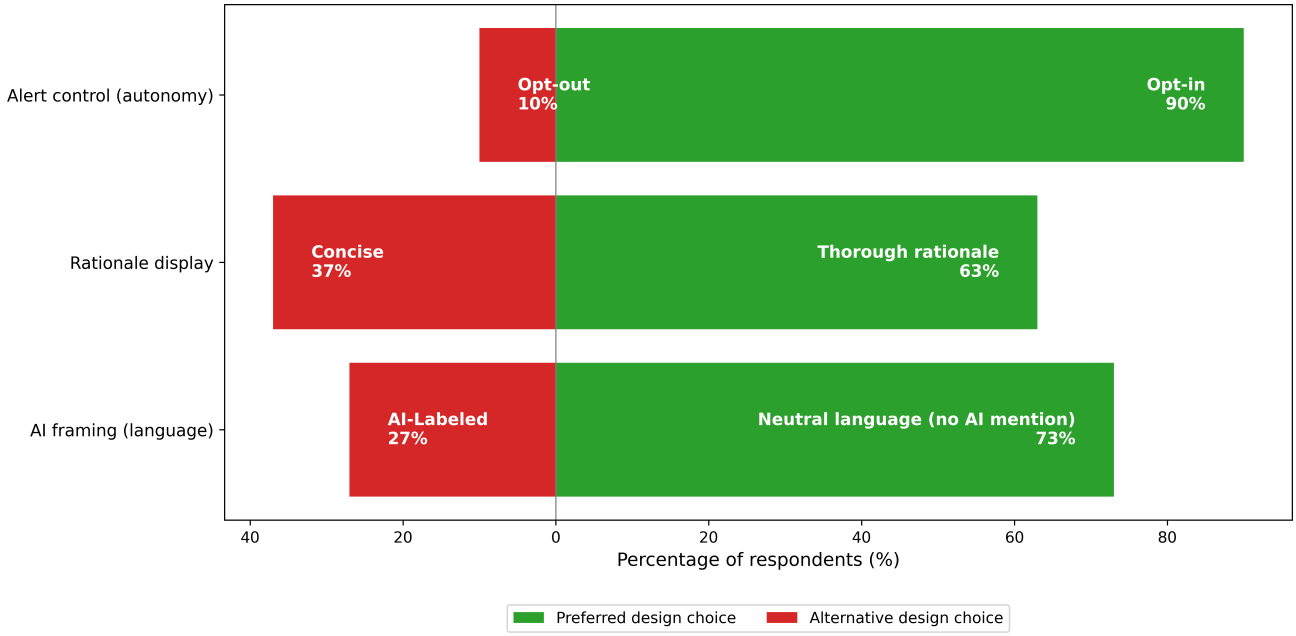
Despite optimism, clinicians cautioned that overreliance could erode core clinical skills, noting that excessive reliance on automated systems could diminish traditional clinical capabilities:

> *My clinical exam skills are not on par with my predecessors…the people coming after me, their skill sets have eroded even more.* [P11, ICU Physician]

A comprehensive summary integrating survey and interview findings is presented in Table 2.

XSL•FO
RenderX

Table . Joint display: integration of survey and interview findings.



Survey finding (quantitative)	Interview theme (qualitative)	Integration and interpretation
Trust decreases with acuity: 75% stable → 47% deteriorating → 44% each for ICU and ED (Cochran Q=30.40, *P*<.001)	Cluster 1: "I only trust AI 50%...I still go through the reasoning myself" (P6). Trust described as conditional and context-dependent.	Convergent: Both data sources confirm acuity-dependent trust. Qualitative data reveals this reflects clinicians' belief that higher-acuity decisions require greater human judgment, not blanket AI distrust.
55% of AI users cited insufficient training as barrier; 55% cited lack of trust	Cluster 5: "Things get rolled out without much explanation" (P4). Participants favored peer-led "super user" programs over online training.	Expansion: Survey identifies training as top barrier; interviews explain why past negative rollout experiences create lasting skepticism. Training format (hands-on vs online) matters more than training availability.
Exploratory A/B preference observation: 10/11 participants preferred opt-in alerts; 8/11 preferred non-AI-branded alerts	Cluster 2: "People are just getting burnt out by the term [AI]" (P11). Preference for clinician-controlled, evidence-framed alerts.	Convergent: Strong alignment between survey preferences and interview explanations. Debranded, opt-in design reflects desire for autonomy and reduced alert fatigue. These exploratory mock-alert preferences require replication and should not be interpreted as causal design conclusions.
47% agreed AI provides reliable insights; 79% concerned about overreliance	Cluster 4: "AI is only as good as the data it's trained on" (P7). Data quality concerns central to distrust.	Complementary: Survey captures magnitude of distrust; interviews reveal root cause, concerns about training data quality and EHR data integrity rather than AI capability per se.
100% rated transparency as important or very important; 79% said understanding outputs increases trust	Cluster 1: "If it's a black box...it needs to at least make logical sense" (P8). Transparency enables "trust, but verify" approach.	Convergent: Universal agreement on transparency importance. Interviews reveal clinicians want rationale not for blind acceptance but for active verification, consistent with maintaining clinical expertise.
54% view AI as "helpful but supplementary"; 68% agree AI complements expertise	Cluster 6: "It should be an extension of our physical exam" (P11). AI as "extra set of eyes," not replacement.	Convergent: Majority frame AI as augmentation tool. Both sources align on AI-as-supplement, with interviews providing the metaphor of AI as safety net.
No direct survey item on AI branding (emergent finding from interviews only)	Cluster 2: "If we see recommended by AI on every single thing...that could trigger trust issues" (P5).	Emergent: AI-branding fatigue identified exclusively through qualitative data, a novel finding that could not have been captured by survey alone, demonstrating the value of the mixed-methods design.

A/B Testing

In exploratory A/B testing of mock CDS alerts, 91% (10/11) of participants preferred an opt-in version over an opt-out version. When comparing a CDSS alert with a short, concise recommendation vs a more thorough explanation of the recommendation including a hyperlink to the study evidence, most participants (7/11, 64%) preferred the thorough explanation with the study rationale hyperlink included, while 18% (2/11) preferred having a balance of brief, concise alert messages, with a clickable hyperlink to the study evidence for reference at point of care. Seventy-three percent of participants (8/11) preferred the CDSS alert that did not mention AI in its recommendation. All respondents emphasized the importance of AI explainability (Figure 2). Further discussion of interface design considerations derived from the A/B testing results is presented in Multimedia Appendix 11. Each A/B pair varied several design features at once and the presentation order was fixed, so these percentages are exploratory preference observations. They should not be attributed to any single design element, and they require replication before generalization.

XSL•FO
RenderX

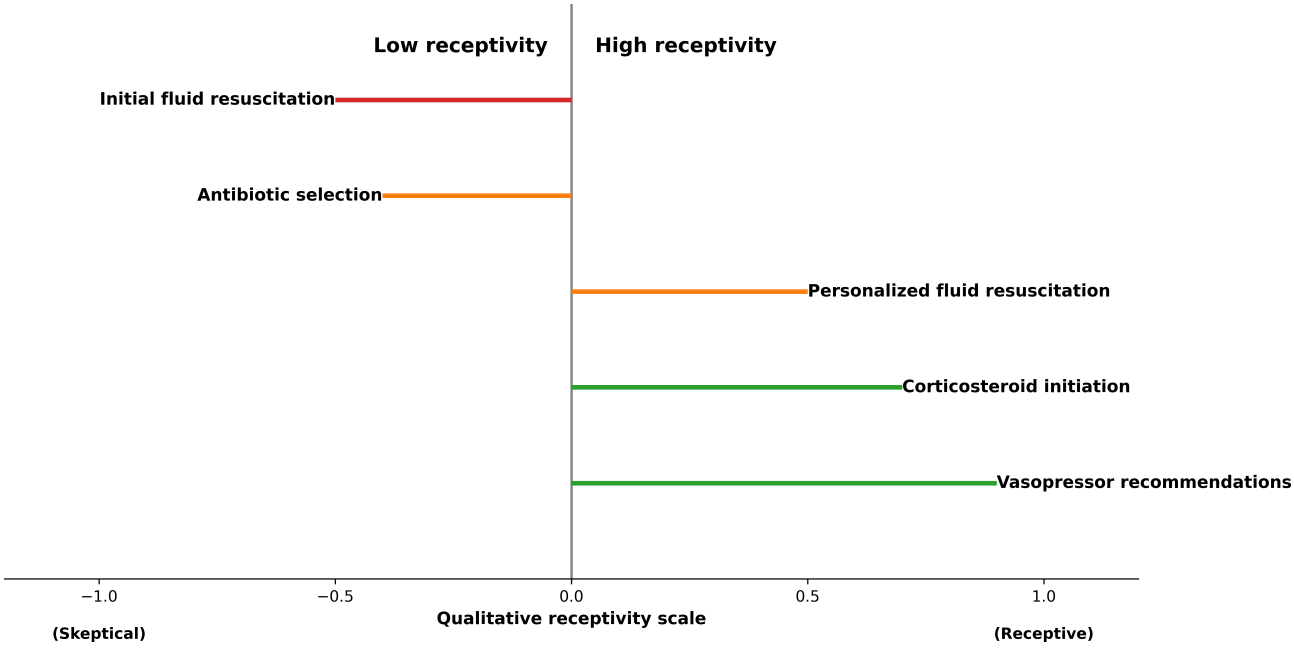


Figure 2. A/B testing preferences.

Case Scenario

A clinical sepsis scenario was presented to a subgroup of five providers (three physicians and two APPs). Their perceptions of five potential AI-driven interventions revealed a varied pattern (Figure 3). Clinicians were skeptical of AI for straightforward, protocolized tasks like initial fluid resuscitation and antibiotic selection in an uncomplicated case and were more receptive when decisions involved higher complexity like ongoing fluid management, vasopressor selection, and corticosteroid initiation, though this was often conditional on trusting the underlying data. The detailed responses are summarized in Multimedia Appendix 12. This component included only five providers and excluded nurses, although nurses participated in all other survey and interview components. It is presented as illustrative qualitative evidence rather than a basis for broader conclusions.

Figure 3. Physicians' perceptions on AI-driven clinical decision support systems in sepsis case scenarios. We created a qualitative receptivity scale (–1.0=skeptical to +1.0=receptive) to illustrate clinician responses to the five AI-driven interventions. Placement on the scale was assigned by the coding reviewers through consensus, informed by thematic coding of case scenario responses and not derived from a quantitative measure, with left indicating skepticism, center reflecting conditional acceptance, and right showing consistent openness. The scale is conceptual rather than numerical, serving to highlight relative differences in receptivity.

Discussion

Principal Findings

This study demonstrates that while clinicians in high-acuity settings are optimistic about AI's potential, their willingness to adopt these tools is contingent on a core set of principles. The AI-CDSS should be transparent in its algorithm, integrate seamlessly into complex workflows, and respect clinician autonomy and judgment. To bridge the gap between technological innovation and meaningful clinical use, the focus must shift from the capabilities of the algorithm alone to address the needs and perceptions of the clinicians for successful implementation. Our findings reflect perceived acceptability, elicited with mock alerts and hypothetical scenarios, and not actual use, implementation success, or patient outcomes. The study is therefore best understood as an early-stage formative evaluation, consistent with Phase 0 of the Developmental and Exploratory Clinical Investigations of Decision Support Systems Driven by AI (DECIDE-AI) framework [22].

Viewed through the SEIPS 2.0 framework [10], our findings map onto all five work system components: people (clinicians' trust varies by role, experience, and acuity context), tasks (AI-CDSS must fit complex, time-pressured clinical decision-making), tools and technologies (alert design preferences including opt-in mechanisms and debranded interfaces), organization (training infrastructure, rollout strategy, and peer champion models), and environment (ICU and ED contexts with distinct workflow pressures). Our results demonstrate bidirectional interactions: organizational training deficits reduce trust in the technology, while poor technology design increases task burden, illustrating why isolated interventions targeting single SEIPS components are unlikely to succeed. Interpreted through Hoff and Bashir's [13] three-layer model of trust, the acuity-dependent trust gradient reflects situational trust, and the AI-branding fatigue described in interviews reflects learned trust shaped by prior technology experiences [8]. While several of these findings converge with prior work, such as clinicians valuing transparency and explainability being important for adoption [23-31], this study identifies three distinctive insights for successful CDSS creation: preference for lower acuity scenarios, a preference-effectiveness paradox, and emphasis on training and implementation. We use the term preference-effectiveness paradox to mean that the alert designs clinicians prefer are not necessarily the designs that prove most effective in practice.

Initial AI-CDSSs should be strategic to target lower acuity scenarios while maintaining clinician autonomy to foster clinician confidence in their implementation. The demonstration of acuity-dependent trust in this study (decreasing from 75% [43/57] in stable patients to 44% [25/57] in critically ill patients) suggests a graduated, SEIPS-informed implementation strategy that accounts for task complexity. We frame this strategy as a recommendation for future testing because this study did not evaluate implementation or measure changes in confidence over time. This strategy allows a CDSS to demonstrate its reliability and value in a safer context, creating a foundation of trust before it is applied to higher acuity situations. Study participants most frequently requested AI-CDSSs for radiology and antibiotic selection, which are both lower acuity scenarios. Adaptability of AI tools at lower stakes situations has been shown to be effective in clinical scenarios like reading chest X-rays (CXRs) [32-34]. While implementation of AI assistance in CXR reading has been directed at radiologists, these applications may also have value in integration for critical care or ED clinicians. For instance, AI has the capability to effectively identify a pneumothorax, which could assist in earlier detection in resource-limited hospitals [35]. This algorithm could then, through a CDSS, prompt the provider to review or re-examine the CXR. For antibiotic selection, an AI-CDSS could make recommendations based on the hospital antibiogram and patient's former infections and antibiotic exposure. One study showed promising development of an AI algorithm that effectively detected *Stenotrophomonas maltophilia* with antibiotic resistance, and a CDSS could more rapidly alert a clinician compared to the standard practice [36]. Integration of AI in these lower acuity situations could help establish trust between the clinician and AI-CDSS [37]. As exposure to AI-CDSSs increases, these perceptions may change, and ongoing evaluation would be helpful to capture evolving attitudes and possibly allow for higher acuity applications. Our understanding of acuity with AI-CDSS recommendations remains theoretical, and future studies should compare the deployment of AI-CDSSs in variable acuity settings.

Our study demonstrated the importance of preserving clinician autonomy for acceptance of the AI-CDSS, which can be done by designing an "opt-in" over an "opt-out" system. Preserving clinician control over when and how AI recommendations are provided may support trust and perceived usefulness of the system. However, it is important to acknowledge that clinician preferences do not necessarily predict optimal AI-CDSS effectiveness in practice. Further studies are needed to compare different AI-CDSS design models in actual clinical settings. While opt-in designs may be preferred, their passive nature may result in lower compliance rates compared to more intrusive opt-out configurations in practice, as evidenced from prior clinical decision support research [5]. This demonstrates the preference-effectiveness paradox, in which autonomy-preserving designs may be preferred in fast-paced settings like the ED and ICU workflows, but optional alerts may be missed or deprioritized. Autonomy-preserving designs should therefore be paired and evaluated with monitoring of alert uptake and safety outcomes in future research. From a SEIPS perspective, this highlights an important tension between the person (clinician preferences) and organization (system effectiveness) components and underscores the need for future implementation studies to evaluate different alert design strategies in real clinical settings.

Interestingly, there was a strong preference for alerts that did not mention AI. It may reflect AI fatigue, distrust, framing effects, or concern about accountability. Debranding also creates an ethical tension with transparency because clinicians and patients may reasonably expect to know when a recommendation is AI-derived [23,26]. This exploratory finding requires replication and dedicated study before it informs design practice.

XSL•FO
RenderX

Finally, our study highlights that even a perfectly designed tool will fail if not implemented thoughtfully. "Insufficient training" was identified as a primary barrier, along with causing lack of trust. Participants reflected on prior EHR rollouts that were characterized by one-way, module-based training and minimal opportunity for feedback, which often resulted in disengagement. Conversely, interactive, peer-led "super-user" models were described as more effective and engaging. These "super-users" should have a strong understanding of the AI systems and algorithms, as well as familiarity with organizational change management processes. In addition to technical expertise, trainers should possess strong communication and listening skills to effectively engage with clinical teams and translate technical system capabilities into practical clinical use [38]. Consistent with prior studies, participants reported that training is more meaningful when it explains not only how to use the system but also why it is being implemented and what value it provides [39,40]. Participants also highlighted the importance of transparency about AI model development, including its training data and validation process [41,42]. Broader literature similarly points to the significance of addressing "change fatigue" and providing protected time for clinicians to participate in training to ensure effective engagement [43]. Training that is interactive, context-specific, and psychologically informed may mitigate resistance and improve confidence in AI-CDSS use [39,44].

Limitations and Future Directions

This study should be interpreted within the context of several limitations. First, data collection occurred within a single academic medical center, which may limit generalizability. Perceptions may differ in community hospitals and resource-limited settings with less AI exposure, and a multicenter trial is an explicit next step. Second, both interview and survey participation were voluntary, which may have introduced selection bias toward individuals with particularly strong opinions about AI. Recruitment channels were open-ended, so a response rate could not be computed, and respondents could not be compared with the underlying clinician population. In addition, the positive confidence estimates among respondents with prior AI use should be interpreted cautiously because this subgroup was small (n=22); positive selection of AI-engaged clinicians may therefore bias trust and adoption findings upward. Third, the mock alerts used in A/B testing and clinical scenarios may not fully capture the complexity of real-time clinical decision-making. In addition, these mock alerts were derived from a single AI-CDSS prototype associated with the PRECISE trial, and several members of the research team are also investigators in that trial. Therefore, findings should be interpreted as formative guidance rather than broadly generalizable evidence of AI-CDSS implementation across settings. Fourth, our sample size may have limited the power for some findings. The sample was primarily ICU based; ED findings are exploratory, and several cross-tabulations had sparse cells and are reported as sensitivity analyses. Fifth, trust in AI is dynamic and evolves with exposure [8]; our cross-sectional design captures a single time point. Future work could include a longitudinal extension, such as a resurvey of the same cohort after deployment of the PRECISE trial AI-CDSS, to capture learned trust trajectories [13,22]. Finally, this study focused exclusively on clinician perceptions of AI-CDSSs; however, the growing literature on shared decision-making in AI-augmented care emphasizes that patient perspectives are equally critical for successful AI-CDSS adoption [45]. We also note that SEIPS 3.0 has extended the model to include patient journey considerations [46]. Future directions should include multicenter replication of these findings, longitudinal evaluation of the temporal evolution of clinician trust in AI-CDSSs, and input from patient and public advocates to better understand patient-centered acceptability, transparency, and perceived benefit.

In conclusion, this study demonstrates that adoption of AI-CDSSs in critical care is not solely a technical issue but a human-factors challenge that requires focus on trust, transparency, and workflow compatibility. These conclusions are based on clinician perceptions, mock alerts, and hypothetical scenarios in a single academic medical center; the proposed implementation strategies should be interpreted as exploratory and hypothesis-generating. Their effectiveness and generalizability require validation through prospective multicenter studies and real-world AI-CDSS implementation.

Acknowledgments

We thank the clinicians from Emory Healthcare who participated in the survey and interviews, as well as the research staff who supported recruitment and data collection. We also acknowledge the contributions of the Precision Resuscitation With Crystalloids in Sepsis (PRECISE) trial team. No generative AI tools were used for any portion of the manuscript.

Funding

This study was supported by the Kaiser Permanente AIM-HI award and NHLBI R01 HL175626.

Data Availability

Deidentified survey data underlying this study are available from the corresponding author on reasonable request. Due to institutional requirements and participant confidentiality, interview transcripts cannot be publicly shared.

Abstract

Background: Robotic-assisted surgery (RAS) is increasingly being integrated into surgical services worldwide. Successful implementation of robotic surgical technologies depends not only on clinical effectiveness but also on public trust, perceptions of safety, and willingness to use technology-enabled care. In the United Arab Emirates, the adoption of RAS is expanding rapidly; however, evidence regarding public perceptions and factors influencing acceptance remains limited.

Objective: This study aims to assess awareness, understanding, perceptions, and factors independently associated with preference for RAS among residents in the United Arab Emirates.

Methods: A community-based cross-sectional survey was conducted between July and November 2025 among adults aged 18 years or older residing across multiple emirates in the United Arab Emirates. Participants were recruited using a nonprobability convenience sampling approach through hospitals, shopping malls, community events, university mailing lists, and social media platforms. A bilingual Arabic-English questionnaire adapted from previously validated robotic surgery perception instruments was administered. Descriptive statistics summarized participant responses. Associations between participant characteristics and perceptions of RAS were examined using chi-square and Fisher exact tests. To adjust for potential confounding, a multivariable Firth-penalized logistic regression model was fitted to identify factors independently associated with preference for RAS over traditional surgeon-performed surgery. Statistical analyses were conducted using R (version 4.4.1).

Results: A total of 508 participants were included. Although 85% (n=432) had previously heard of RAS, only 38% (n=195) demonstrated an accurate functional understanding of robotic surgical systems. Overall, 33% (n=169) preferred RAS, while 35% (n=178) perceived robotic-assisted procedures as safe. The most frequently reported concerns were robotic malfunction (n=360, 71%), reduced human involvement (n=239, 47%), and procedural costs (n=183, 36%). Perceived benefits included improved surgical precision (n=331, 65%) and reduced complications (n=183, 36%). In multivariable analysis, participants who perceived RAS as safe had substantially higher odds of preferring a robot-assisted surgeon than those who were uncertain about its safety (adjusted odds ratio [aOR]=3.00, 95% CI 1.56 - 5.87; *P*<.001). Conversely, participants who perceived RAS as unsafe had substantially lower odds of preferring a robot-assisted surgeon than those who were uncertain about its safety (aOR=0.08, 95% CI 0.02 - 0.26; *P*<.001). No other factors were independently associated with surgery preference after adjustment.

Conclusions: Within this predominantly highly educated convenience sample of United Arab Emirates residents, awareness of RAS was high, but accurate understanding and acceptance remained limited. Perceived safety emerged as the factor shaping preference for RAS, highlighting the importance of trust and confidence in technology-enabled health care. These findings suggest that public education, transparent communication regarding surgeon oversight, and patient engagement strategies may be important components of the successful implementation of robotic surgical services in the United Arab Emirates.

KEYWORDS

robot-assisted surgery; United Arab Emirates; health services research; human-robot interaction; technology adoption; technology acceptance; surgery

Introduction

Robotic-assisted surgery (RAS) has emerged as a major advancement in minimally invasive surgical care, transforming operative practice across multiple specialties through enhanced precision, dexterity, visualization, and ergonomic support for surgeons [1,2]. Over the past 2 decades, the global adoption of robotic platforms has expanded rapidly in general surgery, urology, gynecology, cardiothoracic surgery, and neurosurgery, supported by technological innovations and the increasing integration of AI-enhanced capabilities into surgical systems [3,4]. Contemporary robotic systems increasingly incorporate digital interfaces, image-guided navigation, machine learning–supported decision assistance, and real-time data integration, positioning RAS as an important component of the broader digital transformation of health care [5-7]. Despite growing clinical adoption and evidence supporting several perioperative benefits, including reduced blood loss, shorter hospital stay, and improved surgical precision in selected procedures, public acceptance remains essential for the successful integration of robotic technologies into routine health care delivery [8,9].

Acceptance of emerging health care technologies is influenced not only by clinical effectiveness but also by human factors, including trust, perceived safety, transparency, perceived autonomy, and comfort with human-machine interaction [10-13]. The technology acceptance model and related frameworks emphasize that perceived usefulness, perceived ease of use, and trust strongly influence willingness to adopt novel technologies [14-16]. In the context of robotic surgery, concerns regarding machine autonomy, loss of human control, technical malfunction, depersonalization of care, and ethical implications may shape patient attitudes independently of objective clinical outcomes [17-19]. Public perceptions of AI-integrated technologies are also increasingly influenced by broader societal anxieties surrounding automation and decision-making by intelligent systems, particularly in high-risk settings such as health care [13,20-22]. Understanding these human-factor determinants is therefore critical for ensuring patient-centered implementation and equitable access to advanced surgical technologies.

Existing international evidence demonstrates substantial variability in public awareness, understanding, and acceptance of RAS across different populations and health care systems. Studies from the United States and Europe have reported moderate public awareness but persistent misconceptions regarding robotic autonomy and surgeon involvement during robotic procedures [13,23]. Surveys conducted in Saudi Arabia, Kuwait, and Jordan similarly identified limited functional understanding of RAS, concerns regarding safety and technical failure, and demographic differences in acceptance, particularly across age and gender groups [10,24-27]. A recent scoping review further highlighted that public perceptions of robotic surgery are commonly characterized by uncertainty, limited trust, and confusion regarding the role of the surgeon during robotic procedures [28]. Although several studies reported positive perceptions regarding precision and innovation, many participants remained reluctant to personally undergo robotic-assisted procedures due to concerns about safety, cost, and reduced human involvement [23,24,28].

In the United Arab Emirates, rapid investment in digital health infrastructure and advanced medical technologies has accelerated the implementation of robotic surgical systems within tertiary health care centers [29]. Robotic-assisted procedures are increasingly performed across major public and private hospitals, reflecting the country's broader health care innovation agenda and strategic emphasis on AI integration within health services. Nevertheless, evidence regarding public perceptions of RAS in the United Arab Emirates remains limited. Existing studies have primarily focused on health care professionals and medical students rather than the general public [30,31]. Earlier research examining public attitudes toward robotic surgery in the United Arab Emirates reported skepticism and limited awareness; however, this study was conducted more than a decade ago and may no longer reflect contemporary perceptions within the context of rapidly evolving health care technologies and increased national investment in digital medicine [32]. This study aimed to examine public awareness, understanding, perceptions, and preference for RAS among residents in the United Arab Emirates. Specifically, the study sought to (1) assess public awareness and functional understanding of RAS; (2) examine perceived benefits, risks, and trust-related concerns associated with RAS; and (3) identify demographic and experiential factors associated with preference for RAS and perceptions of safety.

Methods

Study Design and Setting

A community-based cross-sectional survey was conducted between July and November 2025 across multiple emirates in the United Arab Emirates, including Abu Dhabi, Dubai, Sharjah, Ajman, Ras Al-Khaimah, Fujairah, and Umm Al-Quwain. The study was reported in line with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) recommendations [33].

Participants and Sampling

Eligible participants were adults aged 18 years or older residing in the United Arab Emirates who were able to read either Arabic or English. Individuals professionally involved in robotics, AI, biomedical engineering, robotic systems development, or related technical fields were excluded to minimize expert-knowledge bias and ensure that responses reflected perceptions of the general public. A nonprobability convenience sampling approach was used. Participants were recruited through both in-person and online approaches to maximize demographic and geographic diversity. In-person recruitment was conducted in hospitals,

XSL•FO
RenderX

shopping malls, community centers, and public events across multiple emirates. The online survey was disseminated through university mailing lists and social media platforms, including WhatsApp, Instagram, LinkedIn, and X (formerly Twitter).

The optimal required sample size was estimated using the single population proportion formula:

$$n=Z2P(1-P)d2$$

Assuming a 50% expected prevalence, a 95% confidence level, a 5% margin of error, and a z score of 1.96. The calculated minimum sample size was 384 participants. To account for incomplete responses and potential nonresponse, the recruitment target was increased, and a final sample of 508 participants was included in the analysis.

Data Collection Tool

The bilingual (Arabic-English) questionnaire was adapted from previously validated RAS perception surveys conducted in the Gulf region and internationally [24,27,32]. The instrument underwent expert review by specialists in public health, digital health, and RAS to assess content validity, clarity, and cultural appropriateness for the UAE context. Minor modifications in wording and terminology were implemented following expert feedback to improve comprehensibility and contextual relevance.

Translation of the questionnaire followed the World Health Organization forward-backward translation methodology [34]. The English version was initially translated into Arabic by bilingual researchers and was then independently back-translated into English to ensure semantic equivalence and conceptual consistency between versions. Pilot testing was conducted among 20 bilingual UAE residents representing the target population to evaluate readability, comprehension, cultural appropriateness, and survey flow. Feedback obtained during pilot testing was used to refine question wording and improve usability. Pilot participants were excluded from the final analysis. The questionnaire included domains assessing demographic characteristics, technology experience, awareness and understanding of RAS, perceptions and attitudes toward RAS, and prior experiences with robotic surgery. The perception and attitude items demonstrated acceptable internal consistency within the study sample (Cronbach α=0.81).

Measures

The questionnaire consisted primarily of closed-ended items divided into five domains: (1) demographic characteristics, (2) technology experience, (3) awareness and understanding of RAS, (4) perceptions and attitudes toward RAS, and (5) patient-reported experiences among participants with prior exposure to robotic surgery. Demographic variables included age, gender, nationality, educational attainment, occupation, marital status, monthly income, health insurance status, chronic disease status, and medical travel history. Awareness and understanding of RAS were assessed using items evaluating prior exposure to robotic surgery, information sources, and functional understanding of robotic systems. Participants were classified as having “good understanding” if they correctly identified that robotic surgery involves a surgeon operating robotic arms from a control console. Perceptions and attitudes toward RAS included perceived safety, trust in robotic technologies, perceived benefits and risks, willingness to undergo RAS, concerns regarding robotic malfunction or loss of human control, and beliefs regarding the future role of robotic surgery in health care.

Ethical Considerations

This study was conducted in accordance with the research standards outlined in the Declaration of Helsinki. Ethical approval was obtained from the Social Sciences Research Ethics Committee at United Arab Emirates University (reference number: ERSC_2025_5861). All participants received an information sheet explaining the study objectives, the voluntary nature of participation, anonymity, and confidentiality measures. Electronic or written informed consent was obtained before participation. Participation was voluntary, and respondents were assured of their right to withdraw at any time without consequence. No identifiable personal information was collected. All data were collected anonymously and handled in accordance with ethical research standards. Participants were not financially compensated for participation.

Statistical Analysis

Missing data were minimal (<2% across all variables). Participants with missing data for variables included in a specific analysis were excluded only from that analysis. Data were analyzed using the R statistical software (version 4.4.1; R Foundation for Statistical Computing). Categorical variables were summarized using frequencies and percentages. Exact binomial 95% CIs were calculated for key proportions.

The variable assessing participants’ understanding of RAS included 5 response options. Participants were classified as having a good understanding of RAS only if they correctly identified that robotic surgery involves a surgeon sitting at a control unit and operating robotic arms. All other responses, including “I don’t know,” were classified as limited understanding. For the ease of interpretation in inferential analyses, age was recategorized from 6 original categories (18 - 24, 25 - 34, 35 - 44, 45 - 54, 55 - 64, and ≥65 y) into 2 groups (18 - 44 y and ≥45 y).

Associations between participants’ characteristics and 2 key outcomes, including preference for and perceived safety of RAS, were assessed using the chi-square test or Fisher exact test, as appropriate. Variables examined included demographic characteristics, health insurance status, chronic disease status, medical travel history, parental status, awareness of RAS, familiarity with individuals who had undergone robotic surgery, perceived availability of RAS in the UAE, sources of information about RAS, understanding of RAS, comfort with modern technology, and frequency of technology use. Statistical significance was defined as a 2-sided *P* value <.05. To adjust for potential confounding, a multivariable Firth-penalized logistic regression model was fitted to identify factors independently associated with preference for RAS. This method was used to address sparse data and potential quasi-complete separation [35]. The primary outcome was preference for RAS versus traditional surgeon, as participants with no preference were excluded from the primary analysis. Variables were selected a priori based on theoretical relevance and included

XSL•FO
RenderX

gender, age, nationality, monthly income, knowing someone who had undergone RAS, understanding of RAS, and perceived safety of RAS. Adjusted odds ratios (aORs) and 95% CIs were reported. To assess the robustness of the findings, a sensitivity analysis was performed by redefining the outcome as preference for a robot-assisted surgeon versus all other responses (traditional surgeon or no preference) using the same multivariable Firth-penalized logistic regression model.

Results

Participant Recruitment and Characteristics

A total of 508 participants were included in the final analysis. The study sample comprised 57% (n=291) female participants and 55% (n=282) Emiratis (Table 1). Most participants (n=328, 65%) were aged 18 - 44 years, while 35% (n=180) were aged 45 years or older. The majority (n=316, 62%) resided in the Abu Dhabi Emirate, held a bachelor's degree or higher qualification (n=402, 79%), were married (n=317, 62%), and had children (n=322, 63%). Approximately one-third of participants worked in health care–related fields, including 20% who identified as health care professionals. Regarding monthly income, 31% (n=157) reported earning more than 20,000 AED (United Arab Emirates dirham; 1 AED=0.27 USD as of August 4, 2026) per month, while 13% (n=64) reported earning less than 5000 AED per month. Chronic medical conditions were reported by 22% (n=113) of the participants, 29% (n=145) reported having health insurance coverage, and 16% (n=79) reported a history of medical travel.

Perceived Safety of RAS

Overall, 35% of the participants (95% CI 31%-39%) perceived RAS as safe, whereas 22% (95% CI 19% - 26%) considered it unsafe, and 43% (95% CI 38% - 47%) reported uncertainty regarding its safety (Table S1 in Multimedia Appendix 1). Several participant characteristics were significantly associated with perceptions of safety. Male participants were more likely than female participants to perceive RAS as safe (50% vs 24%; *P*<.001). Participants aged 45 years or older were also more likely to perceive robotic surgery as safe compared with younger adults aged 18 - 44 years (42% vs 31%; *P*=.01). Emirati nationality, higher monthly income, and health care worker status were also associated with more favorable safety perceptions. Participants with health insurance coverage were substantially more likely to perceive RAS as safe than uninsured participants (51% vs 29%; *P*<.001). Participants reporting chronic medical conditions also demonstrated more positive safety perceptions compared with those without chronic conditions (41% vs 33%; *P*=.04).

Prior exposure and understanding strongly influenced safety perceptions. Participants who knew someone who had undergone robotic surgery were more likely to perceive RAS as safe than those without such exposure (66% vs 36%; *P*<.001). Similarly, participants who had previously heard of robotic surgery (38% vs 16%; *P*<.001), demonstrated accurate functional understanding of RAS (42% vs 31%; *P*=.02), or preferred robotic-assisted procedures over traditional surgery (58% vs 16%; *P*<.001) were significantly more likely to report positive perceptions regarding safety. Participants exposed to information regarding robotic surgery through television, newspapers, medical websites, medical conferences or seminars, health care professionals, or personal experience demonstrated significantly greater confidence in the safety of RAS than those without exposure through these channels. Educational attainment, having children, medical travel history, comfort with modern technology, frequency of technology use, and learning about robotic surgery through social media or university lectures were not significantly associated with perceived safety.

Perceptions Regarding the Future Role and Precision of RAS

Most participants expressed optimism regarding the future role of RAS within health care systems. Overall, 67% (n=340) believed that robotic surgery would eventually become a standard surgical approach, while 61% (n=310) perceived robotic systems to be more precise than human surgeons. Despite these favorable perceptions regarding technological advancement and precision, the willingness to personally undergo robotic-assisted procedures remained limited. Only 37% (n=188) reported that they would choose RAS if it represented the only available treatment option, whereas 31% (n=158) stated that they would still decline robotic-assisted procedures under such circumstances. Additional perception-related responses are presented in Table S2 in Multimedia Appendix 1.

Perceived Benefits and Concerns Regarding RAS

Participants reported both perceived benefits and concerns regarding RAS. The most frequently reported perceived benefit was improved surgical precision (n=331, 65%), followed by reduced complications and surgical risks (n=183, 36%). Additionally, 20% (n=102) believed RAS could reduce postoperative pain, while 20% (n=102) associated robotic surgery with faster postoperative recovery. Concerns regarding RAS were widespread, with 94% (n=478) of the participants reporting at least one concern related to robotic surgical systems. The most commonly reported concern was the possibility of a robotic malfunction during surgery (n=360, 71%). Additional concerns included reduced involvement of human surgical skills (n=239, 47%), high procedural costs (n=183, 36%), and ethical or technical concerns related to robotic technologies (n=133, 26%).

Perceived Suitability of RAS Across Surgical Specialties

Participants identified several surgical specialties they perceived as particularly suitable for RAS. General surgery was the most frequently identified specialty (n=218, 43%), followed by cardiac surgery (n=188, 37%) and neurosurgery (n=168, 33%). Additional specialties perceived as appropriate for robotic-assisted procedures included orthopedic surgery (n=152, 30%), urological surgery (n=147, 29%), and cardiothoracic surgery (n=97, 19%).

Preferences for RAS and Associated Factors

Among the 508 participants, 33% (95% CI 29% - 38%) preferred RAS, 50% (95% CI 45% - 54%) preferred traditional surgeon-performed procedures, and 17% (95% CI 14% - 21%) reported no preference (Table 2). The distribution of surgery preference differed significantly by gender (*P*<.001), age (*P*<.001), nationality (*P*<.001), monthly income (*P*=.002), having children (*P*=.023), health insurance coverage (*P*<.001), and perceived safety of RAS (P<.001). The proportion preferring RAS was higher among male than female participants (40% vs

XSL•FO
RenderX

29%), participants aged 45 years or older than those aged 18–44 years (46% vs 27%), Emirati than non-Emirati participants (39% vs 26%), participants with a monthly income of 20,000 AED or more than those with lower incomes (41% vs 28%), participants with children than those without children (37% vs 26%), and among participants with health insurance coverage than among those without coverage (42% vs 23%).

Prior awareness and exposure to robotic surgery were also significantly related to the distribution of surgery preference. The distribution differed significantly according to whether participants knew someone who had undergone RAS (*P*<.001), had previously heard of robotic surgery (*P*<.001), their functional understanding of RAS (P=.002), and whether they believed that RAS was available in the United Arab Emirates (*P*<.001). The proportion preferring RAS was higher among participants who knew someone who had undergone RAS than among those who did not (60% vs 32%), those who had previously heard of robotic surgery than among those who had not (36% vs 18%), those with good rather than poor functional understanding of RAS (35% vs 32%), and those who believed that RAS was available rather than unavailable in the United Arab Emirates (46% vs 27%). The distribution of surgery preference also differed significantly according to whether participants had learned about RAS through television (*P*=.027), social media (*P*=.009), or personal experience (*P*=.012). The corresponding proportions preferring RAS among participants with versus without exposure through these channels were 37% versus 32%, 37% versus 29%, and 57% versus 32%, respectively.

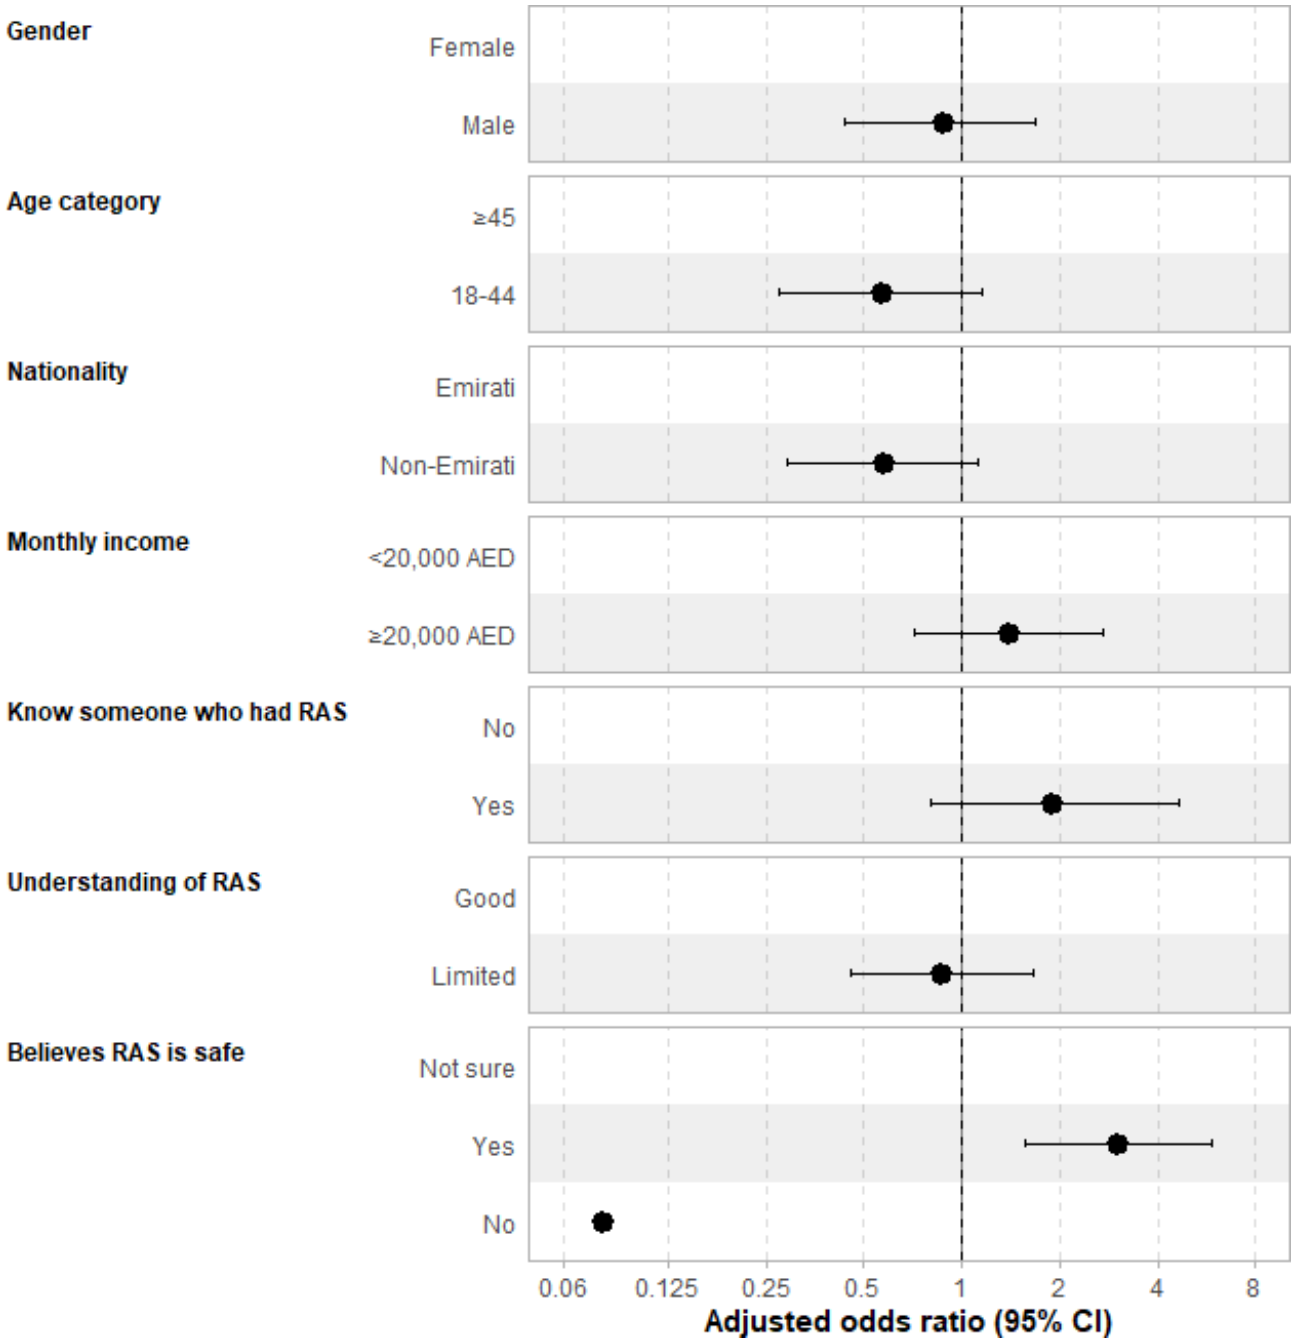
[a]Other factors explored but not found to be significantly correlated with surgery preferences include education, health care worker, having a chronic condition, medical travel, comfort level with using modern technology, frequency of technology use, other ways of learning about RAS— newspapers, medical websites, medical conferences or seminars, health care professionals, university or academic lectures, and other sources.

[b]Not applicable.

[c]AED: United Arab Emirates dirham.



[d]RAS: robotic-assisted surgery.

In the adjusted analysis using Firth penalized logistic regression, perceived safety of RAS was the only factor independently associated with preference for a robot-assisted surgeon over a traditional surgeon (Figure 1). Participants who perceived RAS as safe had substantially higher odds of preferring a robot-assisted surgeon than those who were uncertain about its safety (aOR=3.00, 95% CI 1.56 - 5.87; *P*<.001). Conversely, participants who perceived RAS as unsafe had substantially lower odds of preferring a robot-assisted surgeon than those who were uncertain about its safety (aOR=0.08, 95% CI 0.02 - 0.26; *P*<.001). No other factors were independently associated with surgery preference after adjustment.

A sensitivity analysis redefining the outcome as preference for a robot-assisted surgeon versus all other responses (traditional surgeon or no preference) yielded materially similar findings (Table S3 in Multimedia Appendix 1). Perceived safety remained the only consistent independent factor associated with preference, although younger age (18 - 44 y) also reached statistical significance in the sensitivity analysis.

XSL•FO
RenderX

Figure 1. Multivariable logistic regression analysis of factors associated with preference for a robot-assisted surgeon over a traditional surgeon. Odds ratios are adjusted for all variables shown. Error bars represent 95% CIs. The dashed vertical line denotes the null value (odds ratio=1). RAS: robotic-assisted surgery.

Discussion

Principal Findings

This study provides insights into perceptions of RAS among a convenience sample of predominantly highly educated residents in the United Arab Emirates. Although most participants had previously heard of RAS, only a minority demonstrated an accurate functional understanding of surgeon control and robotic operation. In this sample, acceptance of robotic-assisted procedures was relatively limited: only one-third of the participants preferred RAS to conventional surgery, and approximately one-third perceived robotic surgery as safe. Concerns regarding robotic malfunction, reduced human involvement, and technical reliability were common. Nevertheless, many participants simultaneously recognized potential benefits of robotic surgery, particularly improved surgical precision and reduced complications, highlighting an important tension between perceived innovation and perceived risk. Importantly, perceived safety emerged as the strongest independent factor associated with preference for RAS. Participants who believed RAS was safe were substantially more likely to prefer robotic-assisted procedures, even after adjustment for demographic and experiential factors. These findings suggest that trust and confidence in the safety of robotic surgical technologies may play a more important role in acceptance than most demographic characteristics.

XSL•FO
RenderX

The findings of this study are broadly consistent with international literature demonstrating limited public understanding and cautious acceptance of RAS despite increasing global adoption of robotic technologies in health care [28,36,37]. RAS across multiple countries is frequently characterized by uncertainty, misconceptions regarding robotic autonomy, and limited trust in machine-assisted procedures [37]. Similar findings have been reported in studies from the United States, Europe, and Gulf countries, where awareness of robotic surgery may be moderate, but functional understanding remains poor [28,38-41].

In the present study, many participants expressed uncertainty about the surgeon's role during robotic procedures, with misconceptions about robotic autonomy and machine decision-making remaining common. These findings align with previous surveys reporting that large proportions of the public incorrectly believe that robotic systems operate independently of surgeons or possess autonomous surgical capabilities [23,25,26,42]. Such misconceptions likely reflect broader societal anxieties regarding AI-driven technologies and automation in health care settings [12,13]. These findings are consistent with the concept that acceptance of robotic surgery may be influenced not only by perceived clinical outcomes but also by trust, transparency, and understanding of human oversight within technologically mediated care [15,16].

Despite recognizing potential benefits of robotic surgery, participants in this study demonstrated relatively cautious willingness to personally undergo robotic-assisted procedures. Similar patterns have been observed internationally [17,24,36,40]. Previous studies have shown that patients may perceive robotic surgery as technologically advanced yet remain hesitant to accept it for their own treatment [17,36]. This apparent contradiction likely reflects underlying concerns regarding safety, reliability, and perceived loss of human control during surgery. In the present study, concerns regarding robotic malfunction represented the most frequently reported barrier to acceptance, consistent with previous studies identifying technical failure and loss of surgeon control as major public concerns surrounding RAS [17,18,23].

Participants in this study also perceived robotic surgery as associated with improved surgical precision and better clinical outcomes, including reduced complications, lower postoperative pain, and faster recovery. These findings align with previous international and regional studies reporting that the public commonly associates robotic-assisted procedures with enhanced precision and minimally invasive surgical benefits [25,28,42,43]. However, these perceived advantages were often offset by concerns about safety, ethical implications, procedural costs, and reduced human interaction in care. Similar concerns regarding depersonalization of care and diminished surgeon presence have been reported in qualitative studies examining patient perceptions of robotic-assisted procedures [38,44].

The present findings suggest that human factors play a central role in shaping public acceptance of RAS. Trust, perceived safety, understanding of surgeon oversight, and familiarity with robotic technologies were strongly associated with acceptance of RAS in bivariate analyses. Participants with prior exposure to robotic surgery, either through personal experience or knowing someone who had undergone robotic-assisted procedures, were substantially more likely to perceive RAS as safe and preferable to conventional surgery. This finding is consistent with previous evidence showing that familiarity and direct exposure are associated with lower uncertainty and greater trust in emerging medical technologies [28,36].

The study findings indicate that media exposure may help shape perceptions of RAS. Many participants reported learning about robotic surgery primarily through television, social media, internet sources, or word of mouth rather than directly from health care professionals. Similar patterns have been reported internationally, particularly in Middle Eastern populations [42,43]. Although media exposure may improve awareness of robotic technologies, inaccurate or sensationalized portrayals of robotic surgery may also contribute to fear, misunderstanding, and exaggerated perceptions of risk [45].

Public misconceptions regarding robotic autonomy and technical failure may therefore partly reflect the quality and framing of publicly available information regarding robotic surgery. Previous studies have demonstrated that targeted educational interventions and physician-led explanations can substantially improve patient understanding and confidence regarding robotic-assisted procedures [36,39].

Importantly, the multivariable analysis demonstrated that perceived safety was the only independent factor associated with preference for RAS. Participants who believed RAS was safe were substantially more likely to prefer robotic-assisted procedures than traditional surgeon-performed surgery, even after adjustment for demographic and experiential factors. In contrast, most demographic characteristics lost statistical significance after adjustment. These findings suggest that trust in the safety of robotic systems may be more influential than demographic characteristics in determining acceptance of robotic-assisted medical procedures.

From a health services research perspective, these findings have important implications for the implementation and adoption of technology-enabled surgical services. Successful integration of RAS into routine clinical practice may depend not only on technological capability and clinical effectiveness but also on addressing patient concerns regarding safety, reliability, and human oversight. Implementation strategies that strengthen public trust and improve understanding of surgeon control during robotic procedures may therefore play a critical role in promoting acceptance and uptake of robotic-assisted surgical services.

Limitations

This study has several limitations. First, the use of nonprobability convenience sampling may have introduced selection bias and limited the generalizability of the findings. Second, the sample included a disproportionately high proportion of participants with bachelor's degrees or higher qualifications and a substantial proportion working in health care–related fields, which may not reflect the demographic composition of the broader United Arab Emirates' population. Third, the cross-sectional design precludes causal inference

XSL•FO
RenderX

regarding factors associated with perceptions of RAS. Finally, all data were self-reported and may be subject to recall and social desirability biases. Therefore, the findings should be interpreted as reflecting perceptions within this study sample rather than the UAE population.

Acknowledgments

During manuscript preparation, the authors used ChatGPT (OpenAI) to assist with language editing, to improve readability, and to enhance the clarity and grammar of selected sections of the manuscript. The tool was not used for study conception, study design, data collection, statistical analysis, data interpretation, generation or verification of references, or formulation of the scientific conclusions. Abstract

Background: Safe integration of AI-enabled clinical decision support requires understanding whether users' trust and behavioral reliance are appropriately calibrated to recommendation quality.

Objective: This pilot study examined a 3-item vignette-level trust construct and accept or reject behavior across sequential primary care–style clinical vignettes.

Methods: A total of 68 health care professionals, including 59 (86.8%) registered nurses and 9 (13.2%) physicians, each evaluated 21 clinical vignettes from 1 of 2 series. Each series contained 10 correct and 11 intentionally incorrect AI recommendations. Participants accepted or rejected each recommendation and responded to 3 questionnaire items measuring trust, perceived transparency, and likelihood of acting on the recommendation before receiving correctness feedback and points. The unrounded item mean formed the trust composite. In the behavioral analysis, 50 unrecorded accept or reject responses were classified as rejections. A pooled cross-classified linear mixed-effects model was constructed to assess associations between the trust composite, recommendation correctness, vignette position, and participant and vignette characteristics. It included random intercepts for participant and vignette item, with case series included as a nuisance adjustment.

Results: Participants accepted 374 of 748 (50%) incorrect recommendations and rejected 112 of 680 (16.47%) correct recommendations. Incorrect recommendations received lower prefeedback trust than correct recommendations (β=−0.772, 95% CI −1.036 to −0.507; standardized effect=−0.419). Trust declined modestly across vignette positions (β=−0.027, 95% CI −0.048 to −0.005; standardized effect=−0.088), with a decline in case series A but not case series B. Baseline intention to use AI was positively associated with trust (β=0.391, 95% CI 0.110-0.672; standardized effect=0.243), whereas higher perceived diagnostic difficulty was negatively associated with trust (β=−0.474, 95% CI −0.648 to −0.301; standardized effect=−0.257). In the exploratory lagged model, trust in the preceding recommendation was associated with trust in the current recommendation (β=0.266, 95% CI 0.210-0.322; standardized effect=0.264).

Conclusions: Self-reported trust differentiated correct from incorrect recommendations in aggregate, while acceptance and rejection were not fully aligned with recommendation correctness. These preliminary findings identify a potential evaluation problem: lower trust in incorrect advice does not necessarily imply that users will reject it. The findings do not establish real-world clinical effects.

Introduction

AI-enabled clinical decision support systems (CDSS) have the potential to improve diagnostic and treatment workflows across health care settings by augmenting clinicians' productivity, particularly in environments characterized by workload and uncertainty [1-3]. Yet, the adoption of AI at the bedside has been slower than expected [4]. One major reason for this slow uptake is clinicians' trust in AI systems [5]. Clinicians must feel confident that AI recommendations are reliable and safe before they are willing to incorporate them into their clinical workflow. However, integrating AI into health care without fully understanding how clinicians interact with these systems and how their trust develops over time can create risks for patient safety [6,7].

AI performance may fluctuate depending on the clinical scenario, data quality, or system limitations [8]. If clinicians overtrust AI recommendations, they may accept incorrect advice, while undertrust may lead them to ignore useful guidance. Both situations can negatively affect patient care. Therefore, to safely and effectively integrate AI into clinical practice, it is essential to understand how clinicians develop, adjust, and act on trust in AI systems, as well as the factors that influence this trust [6,9]. In many ways, understanding these trust dynamics is just as important as improving the technical performance of AI algorithms themselves [10].

In clinical environments, which are high-paced and high-stakes work systems, maintaining appropriate trust in AI systems is critical. Health care workers (nurses and physicians) often need to make rapid decisions while managing multiple sources of information, and in such settings, clinicians must quickly determine when to accept, question, or override AI recommendations. While they commonly adopt a trust-but-verify approach when working with residents or colleagues, AI systems differ in that they lack shared accountability and interactive clarification. Trust in AI can be confounded with a user's self-confidence [11,12]. If a user lacks self-confidence, they may report lower trust in the AI not because the AI is unreliable, but because they doubt their own capacity to use it safely. Distinguishing self-confidence from trust is necessary to identify the right remedies (improve model explanations vs improve user training). Additionally, positive past performance may gradually increase trust in AI recommendations [13]. At the same time, as trust grows, users may become less likely to critically scrutinize AI outputs, allowing erroneous recommendations to pass through the decision-making process without sufficient evaluation. Conversely, negative past experiences with AI may make users more skeptical of the system, reducing their willingness to rely on AI recommendations even when they are accurate [5,7,14-16]. These dynamics highlight the importance of understanding how nurses' and physicians' trust evolve through repeated interactions with AI systems. Although AI decision support tools often perform with high accuracy, infrequent errors can hinder trust in the technology.

Real-world clinical work is demanding, and trust in automation is known to vary with workload, uncertainty, and perceived task difficulty [17-19]. A growing literature has examined global attitudes toward AI in health care, yet far fewer studies have explored how trust in AI can change in a clinical setting [10,20]. Existing work has largely focused on isolated psychological or demographic predictors such as prior trust, confidence, or experience without simultaneously examining how these individual characteristics interact with contextual pressures such as time constraints and perceived diagnostic complexity [21,22].

Building on trust calibration and human-automation reliance frameworks, we conceptualized trust as a dynamic evaluation that should ideally correspond to the perceived trustworthiness and observed reliability of the AI system. Foundational trust-in-automation theory argues that trust guides reliance when users cannot fully inspect or understand an automated system, and that safe human-automation interaction requires "appropriate reliance" rather than either blind acceptance or blanket rejection of automation [23,24]. Automation-reliance research further distinguishes subjective trust from observable patterns of use, misuse, disuse, and overreliance, emphasizing that users may behave in ways that do not perfectly match their stated trust. This distinction is especially important in clinical decision support, where automation bias can occur when clinicians overrely on CDSS recommendations and reduce independent information seeking or verification [25]. Recent health care AI studies and reviews similarly emphasize that clinicians' trust in AI-CDSS is shaped by clinical reliability, transparency, validation, usability, prior experience, and professional expertise, and that trust should be examined separately from behavioral reliance on AI advice [16,26,27]. Therefore, appropriate reliance occurs when clinicians accept useful or correct AI recommendations and question or reject recommendations that are unsafe, incorrect, or insufficiently supported; overreliance and underreliance represent mismatches between AI reliability and clinician behavior. In repeated AI-assisted decisions, trust may be influenced by dispositional attitudes toward AI, the visible plausibility of each recommendation, feedback from prior clinical vignettes, and task conditions such as difficulty and time constraints [13]. Therefore, this pilot study distinguished reported trust-related evaluation from behavioral acceptance of AI recommendations.

This experimental pilot study had 3 aims. The primary aim was to characterize how the vignette-level trust composite changed across 21 sequential AI-assisted clinical vignettes and how it was associated with recommendation correctness, vignette position, baseline AI attitudes, participant characteristics, and perceived diagnostic difficulty. The second aim was to describe whether behavioral reliance, measured by accepting or rejecting

XSL•FO
RenderX

recommendations, aligned with programmed correctness. The exploratory aim was to examine the association between trust in consecutive recommendations.

Methods

Study Design

This online experimental pilot study used repeated observations across 2 fixed series of 21 clinical vignettes. For each clinical vignette, participants reviewed a fictional patient presentation and a large language model (LLM)–generated diagnosis and recommendation, indicated whether they accepted or rejected the recommendation, and rated their trust. The same response process was repeated sequentially for all 21 clinical vignettes in the assigned series. No real patient encounters or patient outcomes were evaluated.

Clinical Vignettes

Before generating any study materials, the authors provided Current Medical Diagnosis and Treatment 2010 [28] to ChatGPT (GPT-4; OpenAI) as reference material. ChatGPT was then used to draft short, fictional clinical vignettes and their associated diagnoses and recommendations. The clinical vignettes concerned common adult presentations intended to be understandable without subspecialty knowledge. They were not drawn from real patient records. The generation tasks involved creating the patient descriptions and associated reference diagnoses and recommendations, with intentionally incorrect participant-facing alternatives included where required by the experimental design.

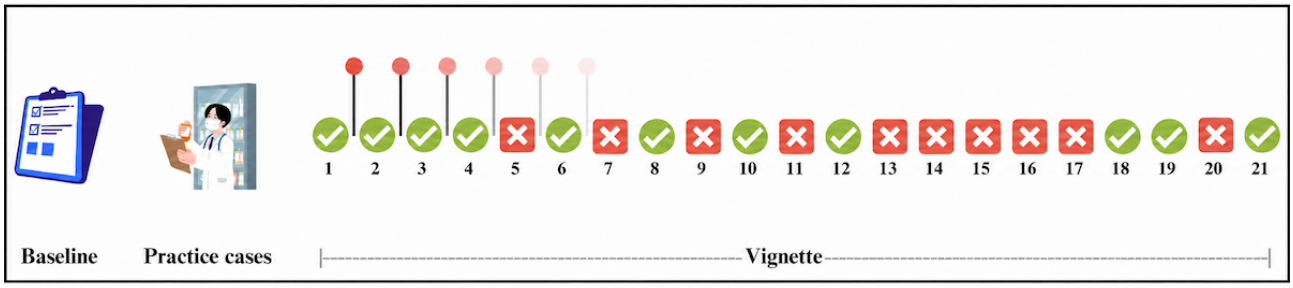
The authors reviewed the generated materials before expert physician review. They compared the initial diagnoses with the textbook and checked the clinical vignettes and recommendations for readability, completeness, clinical coherence, and internal consistency. A physician subsequently conducted the expert physician review, assessing the plausibility of each presentation, the compatibility of the proposed diagnosis with the clinical information, and the consistency of each participant-facing recommendation with its intended correct or incorrect status. She finalized the reference diagnoses and approved the materials for use in the experiment. No corrections to the initial reference diagnoses were required during either the authors' textbook-based review or the physician's review.

The absence of diagnosis-level corrections should be distinguished from the deliberately incorrect recommendations used in the experiment. Reference diagnoses established what was considered correct for each clinical vignette; participant-facing recommendations could intentionally differ from those diagnoses to implement the planned correctness sequence. These incorrect recommendations were experimental stimuli, not diagnostic errors left unaddressed during review.

Multimedia Appendix 1 describes the production and review procedure and provides prompt templates for reference-guided vignette generation, diagnosis and recommendation generation, and intentionally incorrect alternatives.

Participant Recruitment

Participants were recruited between August and September 2025 through Centiment, a paid online audience-panel service [29]. The survey was distributed to the provider's health care worker panel. Eligibility was based on self-reported professional designation as a registered nurse (RN) or physician and reported clinical experience. RNs were included because they are important users of digital clinical information and decision support and routinely contribute to assessment, monitoring, triage, escalation, and care coordination [21,22]. The clinical-vignette task examined evaluation of AI recommendations and reliance behavior; it was not intended to test participants' independent diagnostic or prescribing competence.



No independent credential, licensure, employer, or National Provider Identifier verification was performed. Centiment applies proprietary quality procedures, including duplicate and automated-response detection, device or browser fingerprinting, ReCAPTCHA, and fraud scoring. These procedures were performed by the panel provider; the research team did not receive IP addresses or device identifiers. The number invited, prescreened, or excluded by the provider and the numerical fraud-score threshold were not available to the research team.

Study Procedures

The 42 clinical vignettes were allocated to two 21-vignette series of broadly comparable scope and expected difficulty, without formal matching on independent prestudy difficulty ratings. Each series included 10 correct and 11 intentionally incorrect recommendations, giving a programmed accuracy rate of 47.62%. Both began with 4 correct recommendations followed by 2 incorrect recommendations; later correctness positions differed. Figure 1 shows the series-specific sequences. Check marks (✓) indicate recommendations classified as correct; cross marks (x) indicate intentionally incorrect recommendations. The two case series shared the same status through Trial 8 but differed at selected later trial positions. Accept or reject decisions and ratings were submitted before correctness feedback, and points were displayed for each trial. Participants rated the perceived difficulty of every clinical vignette so that variation in subjective difficulty could be described and included in the analysis.

XSL•FO
RenderX

Figure 1. Actual programmed sequence of AI recommendation correctness across the 21 analyzed cases.

Participants completed the study in one Qualtrics session and were randomly assigned to case series A or B. The session included electronic consent, task instructions, baseline questions, a demonstration vignette, and the 21 analyzed clinical vignettes. A programmed attention-check screen appeared between the fifth and sixth analyzed clinical vignettes. The demonstration vignette and attention-check screen were excluded from the analyses. Case series A had no fixed response window; case series B used a 45-second response window.

On each clinical-vignette screen, participants reviewed the patient presentation and AI recommendation, indicated whether they accepted or rejected the recommendation, and responded to 3 trust questionnaire items and a perceived-difficulty question. The accept or reject item preceded the trust questions to prioritize eliciting behavioral reliance before explicitly asking participants to reflect on trust. All responses appeared on the same screen and were submitted before correctness feedback or points were displayed.

After submission, participants received feedback about the programmed correctness of the AI recommendation. They received +10 points for accepting a correct recommendation or rejecting an incorrect recommendation and −10 points for the opposite decisions. Feedback and scores from preceding clinical vignettes were intentionally available to inform responses to subsequent recommendations. In case series B, the page advanced when the 45-second response window expired; the analytic handling of unrecorded decisions is specified below under the “Analysis” section.

Outcome Measurement

The primary outcome was vignette-level trust in the AI recommendation. Trust was operationalized through 3 investigator-developed questionnaire items addressing perceived trust, perceived transparency, and likelihood of acting on the recommendation. These items were specified as indicators of the study’s trust construct rather than as 3 separate primary outcomes; their unrounded mean was the trust composite. The conceptual framing drew on trust-in-automation literature [23,24]. The observed accept or reject response was a separate behavioral-reliance outcome. Baseline measures are summarized in Table 1, and the clinical-vignette measures are given in Table 2.

XSL•FO
RenderX

Table 1. Baseline participant measures.

Construct	Survey items	Scale or scoring
Professional designation	What is your professional or academic background?	• Registered nurse • Physician
Clinical experience	How many years of experience do you have in your current field or line of work?	• <1 year • 1-2 years • 3-5 years • 6-10 years • >10 years
Prior AI use	In the last 6 months, have you ever used AI in medical practice?	• Yes • No
Baseline trust in AI (3-item composite)	General trust in AI, perceived transparency of AI recommendations, and likelihood of acting on an AI recommendation.	• Each item: 1=none at all to 7=completely • Composite=unrounded mean of available items (minimum 2 of 3)
Intent to use AI	I would like to use AI in my clinical practice.	• 1=strongly disagree to 5=strongly agree
Self-confidence	Nine retained items: I handle new situations with relative comfort and ease; I feel positive and energized about life; I keep trying even after others have given up; If I work hard to solve a problem, I will find the answer; I achieve the goals I set for myself; people give me positive feedback on my work and achievements; when I overcome an obstacle, I think about the lessons I have learned; I believe that if I work hard, I will achieve my goals; I have contact with people with similar skills and experience whom I consider successful.	• Each item: 1=not at all to 5=very often • Mean of 9 retained items

Table 2. Clinical-vignette measures completed before correctness feedback.

Construct	Survey item	Scale
Perceived diagnostic difficulty	• How difficult do you think it would be to diagnose this patient case based on the information provided without AI assistance?	• 1=very easy to 5=very difficult
Vignette-level trust in the AI recommendation (3-item composite)	• How much do you trust the AI-based recommendation? • How transparent do you find the AI-based recommendation? • How likely are you to act upon the AI-based recommendation?	• Each item: 1=none at all to 7=completely • Composite=unrounded mean of the 3 items

Separate 1-factor confirmatory factor analysis (CFA) summaries based on polychoric correlations were aligned to the 21 analyzed clinical-vignette positions. Average variance extracted (AVE) ranged from 0.76 to 0.92, coefficient omega from 0.90 to 0.97, and Cronbach α from 0.87 to 0.96. The 3 items showed strong internal consistency; these results do not make the self-reported composite equivalent to observed acceptance or rejection. Vignette-specific factor loadings and reliability estimates are reported in Multimedia Appendix 2.

Baseline trust was calculated as the unrounded mean of the corresponding 3 baseline items, using at least 2 available responses, as specified in Table 1. Cronbach α was 0.938 among participants with complete baseline items. Self-confidence was the unrounded mean of the 9 retained 1-5 items in Table 1, informed by self-efficacy theory [30]. The supplied self-confidence CFA reported AVE=0.65, coefficient Ω=0.94, and Cronbach α=0.91 (Multimedia Appendix 2).

Data Collection

Before the clinical-vignette sequence, participants reported their professional designation, clinical experience, prior AI use, baseline trust, intention to use AI, and self-confidence. During each clinical vignette, the accept or reject decision was elicited as a binary choice, the three trust items as 1-7 ratings, and perceived diagnostic difficulty as a 1-5 rating. Responses were linked by anonymous study record, case series, and clinical-vignette position for repeated-measures analysis.

The first 20 eligible participants formed a pilot test to assess survey access, clarity of instructions, screen functioning, and whether participants could understand and answer the questions. They met the same eligibility criteria and completed the same consent process, measures, clinical-vignette sequence, and feedback procedure as the remaining participants. No technical or comprehension problems were identified, and no changes were made; these responses were retained in the final analytic sample.

XSL•FO
RenderX

Analysis

The hypotheses concerned the trust composite: H1a predicted a difference between correct and intentionally incorrect recommendations after accounting for vignette position and participant and vignette variability; H1b predicted a positive association between trust in consecutive recommendations; H2 predicted higher trust among participants with stronger baseline intention to use AI; and H3 predicted lower trust for clinical vignettes perceived as more difficult.

The demonstration vignette and attention-check screen were excluded. All 3 trust items and perceived-difficulty responses were complete for the 68 analyzed participants across 21 clinical vignettes, yielding 1428 participant-vignette observations. The data were organized in long format. The 5-point difficulty rating was categorized as lower difficulty (very easy or easy) or higher difficulty (moderate, difficult, or very difficult); a sensitivity model retained the original 1-5 score. Perceived difficulty was treated as a concurrent subjective task-context predictor rather than as a preexposure causal confounder.

Recommendation correctness was coded separately for each case series using the programmed status and cross-checked against Qualtrics task-score fields. Clinical-vignette position was centered at position 11. Correctness remained partly linked to vignette content, position, and the fixed reliability sequence; coefficients involving correctness were therefore interpreted as adjusted associations rather than causal effects.

The primary analysis pooled all 68 participants. A parsimonious cross-classified linear mixed-effects model assessed associations with the trust composite and included random intercepts for participant and vignette item, with 42 distinct vignette items. Fixed effects were recommendation correctness, centered clinical-vignette position, case series, professional designation, baseline trust, intention to use AI, self-confidence, clinical experience (≤10 vs >10 years), and perceived difficulty. Continuous participant-level predictors were mean-centered. Case series was a nuisance adjustment because vignette content and response window varied together; between-series differences were not attributed to response timing.

The primary model was fitted separately within each case series, and a pooled vignette position × case series model examined differences in sequence slopes. A secondary interaction model examined whether the incorrect-versus-correct trust difference varied with vignette position, baseline trust, intention to use AI, self-confidence, experience, or perceived difficulty. These interactions were excluded from the parsimonious primary model and interpreted as hypothesis-generating. An exploratory lagged model used positions 2-21 to relate trust in the current recommendation to trust in the immediately preceding recommendation while adjusting for current correctness, vignette position, case series, difficulty, and participant variables. Models with and without preceding-vignette trust were compared by maximum likelihood; the lagged coefficient was interpreted as a temporal association rather than evidence of a causal mechanism.

The study and analyses were not preregistered. Models were estimated by restricted maximum likelihood in Python 3.13 (Python Software Foundation) using *statsmodels* (version 0.14.6). Maximum likelihood was used for the lagged-model comparison. All reported models converged. Estimates were summarized using coefficients, SEs, 2-sided Wald tests, and 95% CIs. Standardized effects came from parallel models with z-standardized outcomes and continuous predictors, retaining the original categorical coding. Marginal R^2 described variance explained by fixed effects; conditional R^2 included fixed and random effects. Trust-composite end point frequencies were also examined.

Behavioral reliance was summarized by acceptance and rejection relative to programmed recommendation correctness. A total of 50 case series B observations had no recorded accept or reject response. For the primary descriptive analysis, these observations were assigned to the rejection category under the assumption that participants who trusted a recommendation sufficiently to act on it would record acceptance within the 45-second response window. This rule retained all presented clinical vignettes and treated unrecorded decisions as nonacceptance; it did not establish that participants actively rejected or distrusted the recommendation. A descriptive sensitivity summary excluded unrecorded decisions instead of recoding them; the resulting counts and denominators are reported in Multimedia Appendix 3.

Ethical Considerations

The West Virginia University (WVU) Institutional Review Board (IRB) approved the study under the WVU Flexibility Review Model (protocol number 2502117081). All participants provided electronic informed consent before beginning the survey. The study did not request names, contact information, IP addresses, licensure identifiers, employer information, or other direct identifiers; the analytic dataset contained anonymous responses. Study files were stored in password-protected locations accessible only to authorized research personnel. Participants were recruited and compensated through Centiment according to the provider's panel procedures; the exact participant payment was not available to the research team.

This was an online clinical-vignette experiment without real patient encounters or patient outcomes. Applicable CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) reporting principles informed descriptions of eligibility, allocation, participant flow, recommendation presentation, human-AI interaction, and analysis [31].

Results

Participant Flow and Characteristics

A total of 113 individuals participated in the survey. Sixty-eight met the eligibility and completeness criteria and were included in the analysis. The panel provider did not supply the number invited or prescreened, the number excluded through provider-level fraud or quality procedures, or sufficient information to distinguish ineligible from incomplete records among the remaining 45 participants. The final sample included 59/68 (86.76%) RNs and 9/68 (13.24%) physicians, with 34 participants assigned to each case series. All 68 analyzed

XSL•FO
RenderX

participants provided complete responses to the 3 trust questionnaire items and the perceived-difficulty item across 21 clinical vignettes.

Baseline descriptive statistics, reported as means and SDs, are presented in Table 3. The mean baseline trust composite was 4.37 (SD 1.64); mean intention to use AI was 3.35 (SD 1.16); and mean self-confidence was 4.02 (SD 0.70).

Table 3. Participant characteristics and baseline measures[a].

Characteristic	Case series A (n=34)	Case series B (n=34)	Total (n=68)
Professional designation, n (%)			
Registered nurse	31 (91.18)	28 (82.35)	59 (86.76)
Physician	3 (8.82)	6 (17.65)	9 (13.24)
Experience (years), n (%)			
<1	2 (5.88)	0 (0.00)	2 (2.94)
1-2	1 (2.94)	3 (8.82)	4 (5.88)
3-5	8 (23.53)	2 (5.88)	10 (14.71)
6-10	10 (29.41)	4 (11.76)	14 (20.59)
>10	13 (38.24)	25 (73.53)	38 (55.88)
Prior AI use, n (%)			
Yes	16 (47.06)	16 (47.06)	32 (47.06)
No	18 (52.94)	18 (52.94)	36 (52.94)
Baseline trust composite, mean (SD)	4.28 (1.66)	4.46 (1.64)	4.37 (1.64)
Intent to use AI, mean (SD)	3.41 (1.08)	3.29 (1.24)	3.35 (1.16)
Self-confidence, mean (SD)	3.95 (0.66)	4.09 (0.74)	4.02 (0.70)

[a]The baseline trust composite is the unrounded mean of general trust, perceived transparency, and likelihood-to-act items. Self-confidence is the unrounded mean of 9 retained items.

Perceived Diagnostic Difficulty

Of the 714 difficulty ratings in each series, 342 (47.90%) were categorized as higher difficulty in case series A and 355 (49.72%) in case series B. The position-specific distributions are shown in Multimedia Appendix 3.

Trust Across Clinical Vignettes

The trust composite varied across the 21 clinical vignettes in both series (Figure S2 in Multimedia Appendix 3). Case series A increased from a mean of 5.04 at position 1 to 5.38 at position 4, decreased to 3.56 at the first incorrect recommendation at position 5, and ended at 3.21. Case series B began at 4.80, decreased to 3.54 at position 5, and ended at 4.32. Grouped means by case series, difficulty, and correctness are shown in Multimedia Appendix 3.

Across 1428 trust composites, 123 (8.61%) were at the minimum of 1 and 177 (12.39%) were at the maximum of 7; 300 scores (21.01%) occurred at either end point. Scores of 2 or lower accounted for 17.72%, and scores of 6 or higher accounted for 27.03%.

Behavioral Reliance

Across both series, 374 of 748 (50%) incorrect recommendations were accepted, and 112 of 680 (16.47%) correct recommendations were in the rejection category. Each series contributed 714 decision instances: 374 with incorrect and 340 with correct recommendations. Incorrect recommendations were accepted 185 times in case series A (49.47% of incorrect recommendations; 25.91% of all series A observations) and 189 times in case series B (50.53%; 26.47% of all series B observations). Correct recommendations were in the rejection category 52 times in case series A (15.29% of correct recommendations; 7.28% of all series A observations) and 60 times in case series B (17.65%; 8.40%).

At clinical vignette 5, the first incorrect recommendation in both series, 16 participants in case series A accepted and 18 rejected the recommendation; in case series B, 12 accepted and 22 responses were classified in the rejection category. Acceptance was above zero for every incorrect recommendation. When both series returned to a correct recommendation at position 17, 25 participants in case series A and 28 in case series B accepted it. Position-specific counts are shown in Multimedia Appendix 3.

Of the 50 unrecorded case series B decisions, 26 occurred for correct and 24 for incorrect recommendations. When only recorded responses were counted, incorrect recommendations were accepted in 374 of 724 (51.66%) observations, and correct recommendations were explicitly rejected in 86 of 654 (13.15%) observations. In case series B alone, explicit rejection of correct recommendations was 34 of 314 (10.83%) recorded responses, compared with 60 of 340 (17.65%) under rejection-category coding. Complete denominators for both summaries are provided in Multimedia Appendix 3.

RenderX

Primary Mixed-Effects Model

Table 4 presents the pooled parsimonious cross-classified model. Incorrect AI recommendations were associated with lower prefeedback trust than correct recommendations (β=−0.772, 95% CI −1.036 to −0.507; standardized effect=−0.419). Trust also declined modestly across clinical vignettes (β=−0.027, 95% CI −0.048 to −0.005; standardized effect=−0.088). Intention to use AI was positively associated with trust (β=0.391, 95% CI 0.110-0.672; standardized effect=0.243), whereas higher perceived difficulty was negatively associated with trust (β=−0.474, 95% CI −0.648 to −0.301; standardized effect=−0.257). CIs for the remaining fixed effects included zero. The sensitivity model retaining the original 1-5 difficulty score yielded the same substantive pattern; each 1-point increase in difficulty was associated with a 0.404-point lower trust composite (95% CI −0.495 to −0.312).

Table 4. Parsimonious cross-classified mixed-effects model predicting the vignette-level trust composite[a].

Predictor	β (SE)	95% CI	*P*	Standardized effect
Intercept	4.795 (0.249)	4.307 to 5.283	<.001	—[b]
Vignette position (centered)	−0.027 (0.011)	−0.048 to −0.005	.02	−0.088
AI recommendation incorrect	−0.772 (0.135)	−1.036 to −0.507	<.001	−0.419
Case series B vs A (nuisance adjustment)	0.174 (0.300)	−0.414 to 0.762	.56	0.094
Professional designation (physician)	0.243 (0.401)	−0.542 to 1.029	.54	0.132
Baseline trust composite	0.072 (0.095)	−0.114 to 0.259	.45	0.064
Intent to use AI	0.391 (0.143)	0.110 to 0.672	.006	0.243
Self-confidence	0.047 (0.198)	−0.341 to 0.435	.81	0.018
Experience >10 years	0.007 (0.294)	−0.569 to 0.583	.98	0.004
Perceived diagnostic difficulty: higher	−0.474 (0.089)	−0.648 to −0.301	<.001	−0.257

[a]N=1428 observations from 68 participants and 42 vignette items. Reference categories: correct recommendation, case series A, registered nurse, ≤10 years of experience, and lower perceived difficulty. The case series was included only as a nuisance adjustment. Marginal R^2=0.176; conditional R^2=0.500. Standardized effects were obtained from a parallel model in which the outcome and continuous predictors were z-standardized; categorical predictors retained their original coding.

[b]Not applicable.

Sensitivity Analyses by Case Series

Sensitivity analyses showed that lower trust for incorrect recommendations was evident in both case series: case series A, β=−0.850 (95% CI −1.197 to −0.502), and case series B, β=−0.676 (95% CI −0.996 to −0.356). The longitudinal pattern differed across vignette sets. Trust declined with vignette position in case series A (β=−0.056, 95% CI −0.085 to −0.027) but not in case series B (β=0.004, 95% CI −0.022 to 0.030). In the pooled vignette position × case series model, the case series B slope was 0.064 points per clinical vignette less negative than the case series A slope (95% CI 0.027-0.102). Higher perceived difficulty was negatively associated with trust in both series, whereas intention to use AI was positively associated with trust only in case series B (Table 5).

XSL•FO

Table 5. Parsimonious models fitted separately within each case series[a].

Predictor	Series A			Series B		
	β (SE)	95% CI	*P* value	β (SE)	95% CI	*P* value
Intercept	4.918 (0.269)	4.390 to 5.446	<.001	4.846 (0.458)	3.948 to 5.744	<.001
Vignette position (centered)	−0.056 (0.015)	−0.085 to −0.027	<.001	0.004 (0.013)	−0.022 to 0.030	.77
AI recommendation incorrect	−0.850 (0.177)	−1.197 to −0.502	<.001	−0.676 (0.163)	−0.996 to 0.356	<.001
Professional designation: physician	1.144 (0.642)	−0.113 to 2.402	.07	−0.354 (0.564)	−1.459 to 0.752	.53
Baseline trust composite	−0.060 (0.131)	−0.317 to 0.198	.65	0.134 (0.128)	−0.118 to 0.385	.30
Intent to use AI	0.236 (0.203)	−0.163 to 0.634	.25	0.619 (0.211)	0.205 to 1.033	.003
Self-confidence	−0.211 (0.273)	−0.745 to 0.324	.44	0.045 (0.313)	−0.568 to 0.657	.89
Experience >10 years	−0.305 (0.367)	−1.024 to 0.414	.41	0.173 (0.486)	−0.780 to 1.126	.72
Perceived diagnostic difficulty: higher	−0.604 (0.144)	−0.887 to −0.321	<.001	−0.344 (0.103)	−0.546 to −0.141	<.001

[a]Each model included 34 participants, 714 observations, 21 vignette items, and random intercepts for participant and vignette item. Marginal or conditional R^2=0.178/0.438 for case series A and 0.323/0.601 for case series B. The pooled vignette position × case series model is summarized in the text.

Exploratory Interaction Model

The exploratory model suggested that sensitivity to incorrect recommendations varied with several characteristics. The incorrect-versus-correct difference was more negative among participants with more than 10 years of experience (interaction β=−0.703, 95% CI −0.998 to −0.407) and at higher self-confidence (interaction β=−0.360 per scale point, 95% CI −0.571 to −0.150), but less negative on clinical vignettes categorized as higher difficulty (interaction β=0.327, 95% CI 0.045-0.609). Interactions with vignette position, baseline trust, and intention to use AI had CIs that included zero. Because this interaction-heavy model was secondary and participant-level power was limited, these findings are considered hypothesis-generating. Full model estimates are reported in Multimedia Appendix 3.

Exploratory Lagged Model

In the exploratory lagged model, the preceding clinical vignette's trust composite was positively associated with current-vignette trust (β=0.266, 95% CI 0.210-0.322; standardized effect=0.264). Incorrect current-vignette recommendations remained associated with lower trust (β=−0.753, 95% CI −1.037 to −0.469; standardized effect=−0.405), intention to use AI remained positively associated with trust, and higher perceived difficulty remained negatively associated with trust. Vignette position and the remaining participant-level variables had CIs that included zero. Adding preceding-vignette trust improved model fit relative to the otherwise identical model without the lagged term. Full coefficients and model-fit statistics are reported in Multimedia Appendix 3.

Hypothesis Summary

H1a was supported because incorrect recommendations received lower vignette-level trust than correct recommendations. H1b was supported statistically because the preceding clinical vignette's trust composite was positively associated with current-vignette trust, although this result is interpreted as a temporal association rather than evidence of a causal carryover mechanism. H2 was supported because baseline intention to use AI was positively associated with vignette-level trust. H3 was supported because higher perceived diagnostic difficulty was negatively associated with vignette-level trust.

Discussion

Principal Findings and Contributions

Participants assigned lower trust to incorrect than to correct AI recommendations, yet accepted half of the incorrect recommendations and rejected approximately 1 in 6 correct recommendations under the stated behavioral coding rule. This aggregate pattern identifies a potential gap between self-reported trust and reliance calibrated to recommendation correctness; it does not establish that individual participants recognized errors before accepting them. Trust in consecutive recommendations was positively associated; baseline intention to use AI was associated with higher trust, and greater perceived difficulty with lower trust. The pooled decline across vignette positions was evident in case series A but not case series B.

Together, these results suggest that clinical AI evaluation should focus on 2 related but distinct questions: whether users can judge the quality of individual AI recommendations and whether those judgments lead to appropriate reliance. The findings should nevertheless be interpreted as preliminary because they were obtained from a small, nurse-dominant sample completing simulated primary care–style tasks.

Dynamic Trust and Recommendation Correctness

Participants gave substantially lower trust ratings to incorrect recommendations than to correct recommendations. Because the trust questions were completed before current-vignette feedback was shown, this difference suggests that participants were, on average, sensitive to features of the vignette and the

XSL•FO
RenderX

apparent plausibility of the AI recommendation. The average difference was therefore present before explicit feedback about that recommendation. This result is consistent with recent repeated-interaction studies. Kahr et al [32] found that people reported greater trust and reliance when AI advice came from a more accurate model, while Yang et al [33] showed that users adjust trust from one interaction to the next and react particularly strongly to automation failures.

The pattern of trust across the 21 clinical vignettes was less consistent. Trust declined in case series A but remained comparatively stable in case series B. This qualification is important because it means that the pooled decline should not be interpreted as a universal process in which trust steadily erodes whenever users encounter AI errors. Instead, the course of trust appears to depend on which cases users see, how convincing the recommendations appear, and where correct and incorrect recommendations occur in the sequence. This result is consistent with Rittenberg et al [34], who found that trust did not always rise and fall in direct proportion to automation reliability. In their experiments, trust sometimes declined even when system reliability improved, and trust was difficult to rebuild after users had experienced a poorly performing system. Kahr et al [32], by contrast, observed increasing trust when participants repeatedly interacted with high-accuracy AI advice. Considered together, these studies and the present findings indicate that there may not be one standard trust trajectory. Trust depends on reliability, but it is also shaped by starting impressions, the order and type of errors, task characteristics, and the user's ability to evaluate each recommendation. Because recommendation correctness, case content, and vignette position were not independently randomized in this study, the lower trust assigned to incorrect recommendations cannot be attributed solely to correctness. Some of the difference may also reflect the particular cases used or their position in the sequence. The main conclusion is therefore that participants showed aggregate sensitivity to recommendation quality, while the way trust changed over time remained dependent on the specific case series.

Trust in Consecutive Recommendations

Trust in the immediately preceding clinical vignette was positively associated with trust in the current clinical vignette. In everyday terms, participants appeared to carry part of their recent impression of the AI into the next case rather than evaluating every recommendation in complete isolation. This makes sense in repeated AI use: after seeing several useful recommendations, a person may approach the next recommendation more favorably, whereas recent errors may create greater caution. This finding is consistent with evidence from Kahr et al [32], Yang et al [33], and Rittenberg et al [34] that early reliability experiences can influence later trust and its recovery. This study extends this work to repeated clinical-vignette tasks. However, the lagged finding should not be described as proof of trust inertia. Consecutive ratings from the same participant will often resemble one another potentially because individuals have relatively stable response styles and general attitudes. The most defensible interpretation is that trust showed temporal continuity where the previous rating provided useful information about the next rating, but the study cannot determine whether this occurred because of memory of previous AI performance, accumulated feedback, a stable personal response pattern, or another cognitive process.

The practical implication remains important. Trust in AI should be studied as a developing process rather than as a one-time opinion.

Reported Trust and Behavioral Reliance

One of the most important contributions of this study is the separate examination of reported trust and actual accept or reject behavior. Lower average trust for incorrect recommendations coexisted with frequent acceptance of those recommendations. This finding supports prior concerns about automation bias in clinical decision support. Gaube et al [35] found that inaccurate advice reduced physicians' diagnostic accuracy and that substantial subgroups of both radiologists and physicians with less radiology expertise repeatedly followed incorrect advice. This study identifies a related concern in a different task: lower average trust for incorrect advice did not coincide with uniformly low acceptance of that advice. A recommendation may be accepted because it appears plausible, reduces the effort required to reach a decision, or is difficult to verify independently.

At the same time, the present behavioral pattern differs from findings reported by Küper et al [27]. In their 2025 study of 223 dermatologists, participants relied more strongly on correct than incorrect AI advice, but overall reliance on AI was low and self-reliance was high. In this study, by contrast, half of the incorrect recommendations were accepted. This difference may reflect several features: Küper et al [27] studied specialists performing dermatology image-classification tasks, whereas this study included a nurse-dominant sample evaluating short primary care–style vignettes.

The binary accept or reject decision used in this study provides a clear behavioral indicator, but actual clinical reliance may be more complicated. Sivaraman et al [9] found that intensive care unit (ICU) clinicians did not always simply accept or reject AI treatment advice; they often accepted some parts, rejected others, or delayed action, a process described as negotiation. Thus, the current findings clearly demonstrate misalignment between reference correctness and behavior, but future studies should allow more nuanced responses that better reflect how health care professionals use recommendations in practice.

Together, the aggregate findings support measuring trust and behavioral reliance separately rather than assuming that lower self-reported trust ensures rejection of incorrect advice. The present analyses did not directly test a within-participant causal pathway from trust to the accept or reject decision.

Baseline AI Attitudes and Perceived Difficulty

Participants who entered the study with a stronger intention to use AI generally reported higher trust across the individual cases. This finding is consistent with recent reviews showing that perceived usefulness, openness to technology, previous experience, and expectations about AI influence health care professionals' acceptance of AI systems [5,6,16]. This study extends that literature by showing that a general willingness to

XSL•FO
RenderX

use AI was related not only to overall acceptance, but also to evaluations of specific recommendations during repeated interactions. However, the baseline trust composite itself was not clearly associated with vignette-level trust after the other variables were considered. This suggests that general trust and intention to use AI may not represent the same thing. A participant may express general trust in AI but remain unwilling to use it because of workflow, accountability, or professional concerns. Conversely, someone may be willing to use AI as a helpful tool without assuming that every recommendation is trustworthy. This distinction should be studied more directly in future work.

Participants also reported lower trust in cases they perceived as more difficult. This finding suggests that difficult or ambiguous cases may make participants less certain not only about their own judgment, but also about the quality of the AI recommendation. It complements the finding reported by Gaube et al [35] that the effect of inaccurate clinical advice varied across individual cases and was especially concerning when cases involved difficult-to-recognize diagnostic features. Because perceived difficulty was measured during the same clinical vignette, this study cannot conclude that difficulty caused lower trust. A case may have seemed difficult because the vignette was ambiguous, because the AI recommendation appeared inconsistent, because the participant lacked relevant knowledge, or because several of these factors occurred together. The appropriate takeaway is that participants trusted AI recommendations less on cases they personally experienced as more difficult.

Limitations and Future Research

Several limitations constrain interpretation. First, the study used short primary care–style clinical vignettes rather than real encounters. The cases were drafted with LLM assistance, anchored to a 2010 textbook, and reviewed by one physician, but were not independently adjudicated by multiple practicing primary care clinicians. They may not reflect current guidelines, contemporary diagnostic pathways, or the complexity of clinical practice.

Second, the sample was small and nurse-dominant. Registered nurses represented 86.76% (59/68) of participants, whereas physicians represented 13.24% (9/68). Although nurses are important users of clinical information and decision support, they do not ordinarily make all primary care diagnoses or prescribe treatments independently. The mismatch between the simulated task and usual RN scope may have affected perceived difficulty, trust, and reliance, limiting ecological validity and generalization to either physician diagnosis or routine nursing practice.

Third, professional designation was self-reported and was not independently verified through licensure, employer, or National Provider Identifier records. The third-party panel did not provide complete counts for invitations, prescreening, or provider-level quality exclusions. Fourth, the participant-level sample limited power for professional-group comparisons and the exploratory interaction tests; their estimates should be interpreted as hypothesis-generating.

Fifth, the two case series differed in vignette content, later correctness positions, and response window. These features were not independently varied, so between-series differences cannot be attributed to response timing or case characteristics. The differing clinical vignette slopes demonstrate that the pooled longitudinal pattern was sensitive to vignette set. Sixth, correctness followed fixed series-specific sequences rather than being randomized or counterbalanced, leaving correctness partly linked to vignette content, vignette position, and reliability phase.

The handling of unrecorded decisions is an additional limitation. Classifying the 50 unrecorded case series B responses as rejection represented nonacceptance, not a verified active decision. It may overstate deliberate rejection and understate acceptance among participants who provided an explicit response. This matters particularly for apparent underreliance: 26 unrecorded responses to correct recommendations contributed to the rejection category. The recorded-response sensitivity summary illustrates this dependence on coding but cannot establish what the unrecorded decisions would have been. Future studies should retain timeout or nonresponse as a separate behavioral outcome rather than assume that it is equivalent to rejection.

Conclusions

This nurse-dominant pilot study illustrates why clinical AI evaluation should examine both self-reported trust and observed reliance across clinical vignettes. Incorrect recommendations received lower trust on average, but half were accepted; approximately 1 in 6 correct recommendations fell into the rejection category under the stated coding rule. These findings identify a potential evaluation problem rather than a demonstrated patient-safety effect. Larger studies using independently validated, role-aligned clinical vignettes, counterbalanced experimental factors, and separate recording of active rejection and nonresponse are needed to determine how recommendation quality, feedback, and difficulty shape appropriate reliance.

Acknowledgments

The authors gratefully acknowledge Dr Zaira Chaudhry for her expert physician review and finalization of the clinical vignettes, reference diagnoses, and AI recommendations following the authors' textbook-based checks. Her review assessed clinical coherence, plausibility, and consistency with each recommendation's intended correctness status before deployment. The authors declare the use of generative AI (GenAI) in the research and writing process. According to the GAIDeT (Generative AI Delegation Taxonomy; 2025), the following tasks were delegated to GenAI tools under full human supervision: literature search and systematization, code generation, reproducibility testing, proofreading and editing, and summarizing text. The GenAI tools used

XSL•FO
RenderX

were Apple AI and ChatGPT 5.6. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes. The declaration was submitted by all authors.

Abstract

This single-arm pilot study of a psychological, app-based intervention (platoniq) found significantly reduced loneliness after 4 and 8 weeks.

Trial Registration: German Clinical Trials Register DRKS00038467; https://drks.de/search/en/trial/DRKS00038467/details

(JMIR Hum Factors 2026;13:e99374) doi:10.2196/99374

KEYWORDS

loneliness; social health; digital health; pilot study; digital mental health

Introduction

Loneliness, the subjectively perceived lack of social relationships, is affecting a significant share of people across countries and age groups [1]. As this is associated with numerous adverse health consequences [2], effective interventions to tackle loneliness are highly needed. Although a substantial body of evidence has examined such interventions and found that psychological approaches in particular can effectively reduce loneliness [3], considerably more research is still required. Loneliness is linked to hypervigilance and negative social cognition, reinforcing withdrawal in a cycle [4], which cognitive-behavioral techniques such as social skills training and cognitive restructuring aim to break. Particularly, low-threshold digital interventions are an interesting yet underinvestigated approach with few available studies [5]. Consequently, the objective of this preregistered [6] pilot study was the evaluation of a digital app-based intervention against loneliness.

Methods

Ethical Considerations

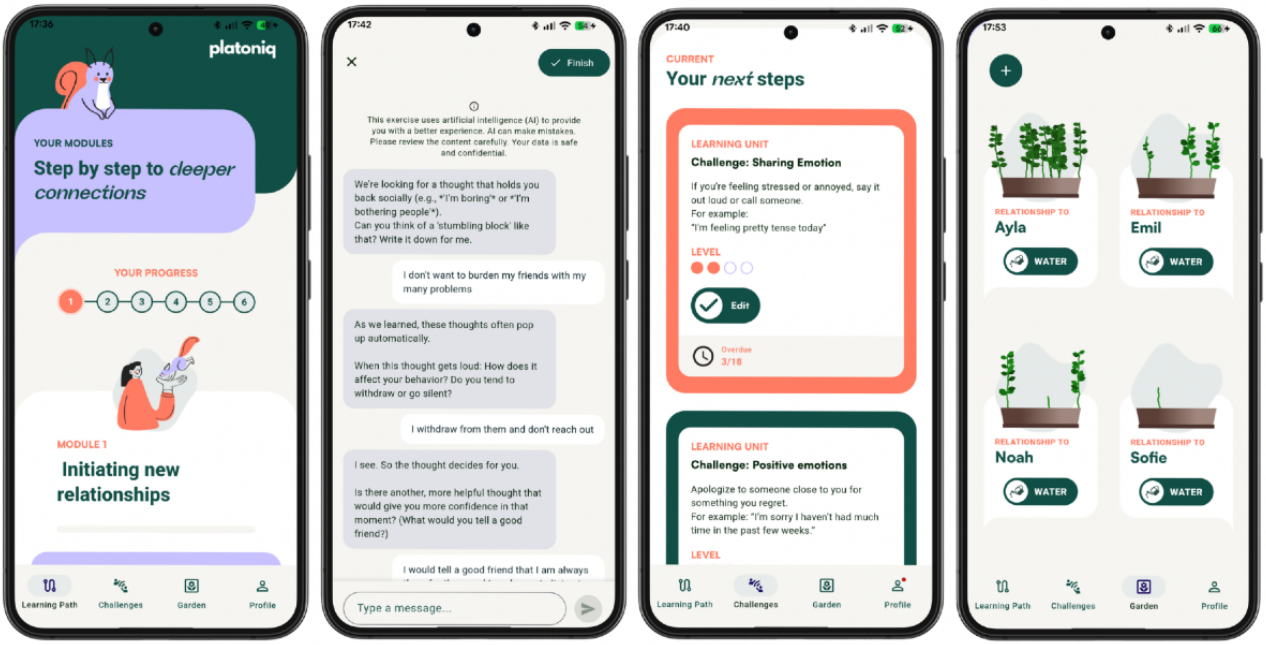
Ethical approval for this study was granted by the ethical committee of the Institute for Psychology of the Humboldt University Berlin (identifier: 2025 - 58).

Study Design

This pilot study was designed as a one-arm, noncontrolled trial. Loneliness, the primary outcome, was assessed using the 9-item version of the UCLA Loneliness Scale (UCLA-9) [7] at baseline, 4 weeks, and 8 weeks. Additionally, perceived social support [8], perceived stress [9], and social competencies [10] were measured at baseline and at week 8 as secondary outcomes.

Sample

Study participants were recruited through convenience sampling via several channels, such as social media and university newsletters. A total of 72 participants matched our inclusion criteria (UCLA-9 score ≥18, reflecting preexisting low-to-moderate loneliness; ≥18 years old; German-speaking; no acute mental health crisis; and not currently seeking treatment), completed at least 1 of the follow-up questionnaires, and accessed the intervention with their phone. The median age was 35 (IQR 27.0-48.75; mean 39.3, SD 14.23) years and 60 (83.3%) participants were female. Of the 72 participants, 10 (13.9%) reported a migration background; 40 (55.6%) were employed full-time; and the sample was highly educated, with the majority (n=50, 69.4%) holding a university degree.



Intervention

The app-based intervention platoniq (SHS Social Health Solutions UG) was used in this study. The digital intervention is structured into 6 modules, addressing diverse aspects of social relationships and loneliness. Exercises are adapted from social skills training and cognitive behavioral therapy, following a

XSL•FO
RenderX

cognitive model of loneliness [4]. One new module is unlocked each week, covering the following topics in sequence: initiating relationships, deepening relationships, emotional support, conflict management, setting boundaries, and social relationships and own needs. Within each module, exercises have to be completed in sequential order (see Figure 1). In addition, the app includes a tracking mechanism for social relationships, allowing participants to monitor their social interactions over the course of the program. Notifications reminded participants to use the app, and chat support was available for technical questions.

Figure 1. Screenshots of the intervention app, platoniq, which includes exercises (eg, social skills training and cognitive restructuring), behavioral experiments, and a tracking mechanism.

Results

Out of the 72 included participants, 67 (93%) provided answers to the UCLA-9 after 4 weeks from the intervention start. UCLA-9 scores decreased from baseline (mean 25.6, SD 3.7) to week 4 (mean 23.5, SD 4.2). A paired *t* test showed a significant medium-to-large effect for loneliness (t_{66}=5.8; *P*<.001; *d*=0.71), with an average reported decrease on the UCLA-9 of 2.2 (SD 3.1). Approximately 75% (50/67) of participants reported a decrease, and 45% (30/67) of all participants reported a decrease of at least 3 points. This has been considered clinically meaningful in past work, following a reliable change index derived for the UCLA-9 in a comparable sample [4]. Higher baseline UCLA-9 scores were associated with greater reduction (*r*=0.25; *P*=.04). The effect remained stable for the 44 participants who responded to the questionnaires after 8 weeks, with scores decreasing from baseline (mean 26.2, SD 4.2) to week 8 (mean 24.0, SD 5.2; t_{43}=3.8; *P*<.001; *d*=0.57), reporting an average reduction of 2.21 (SD 3.9). Additionally, effects were found for interpersonal competencies (t_{43}=−3.1; *P*=.004; *d*=−0.46) as well as perceived social support (t_{43}=−2.4; *P*=.02; *d*=−0.37). However, while there was an average decrease of 0.77 (SD 6.8) in perceived stress, this effect was not statistically significant (t_{43}=0.75; *P*=0.45; *d*=0.13). No significant baseline differences were found between completers and noncompleters (ie, no 8-week questionnaire) at 8 weeks across demographic or clinical variables, suggesting limited attrition bias. Noncompleters showed markedly lower overall engagement (mean 14.8, SD 13.3 vs 30.9, SD 20.1 events; $t_{69.87}$=4.10; *P*<.001).

On average, the included participants used the app for approximately 128 (SD 119) minutes, corresponding to a weekly usage of around 21 (SD 19.8) minutes. On average, 25 (SD 19.3) exercises were completed, as well as 6 (SD 4.6) behavioral experiments, and the tracking mechanism was used 18 (SD 19.3) times. The small (*r*=0.14) correlation between usage time and reduction was nonsignificant in the given sample (*P*=.24).

Discussion

In this uncontrolled pilot study, an app-based digital health intervention targeting loneliness in individuals with at least low-to-moderate levels of loneliness showed preliminary signals of reduced loneliness. The observed within-group effect size (*d*=0.71) falls within the range reported across existing internet-based interventions (*d*=0.33 to *d*=1.47) [5], corroborating the general promise of this intervention format. However, given the single-arm design, this interpretation is limited, and randomized controlled trials are needed to confirm the intervention's effectiveness.

The sample was predominantly female and highly educated, with considerable dropout, limiting generalizability. Additionally, user satisfaction and barriers to use were not systematically assessed. Finally, the association between

XSL•FO
RenderX

baseline severity and reduction may partly reflect regression to the mean. Interestingly, contrary to our initial hypothesis, the effect on perceived stress in this study was not significant. This may be due to limited statistical power to detect small effects. Taken together, these preliminary results suggest app-based cognitive behavior therapy interventions may offer a promising approach to addressing loneliness as a pressing public health challenge.

Generative AI Use

The authors used Claude (Anthropic) to assist with language editing and wording of the manuscript. The tool was not used to generate scientific content, analyze data, or interpret results. All authors reviewed and edited the output and take full responsibility for the content of this publication.

Funding

The article processing charge was funded by the Open Access Publication Fund of Humboldt-Universität zu Berlin.

Data Availability

Due to legal and privacy restrictions, the user data used in this study cannot be shared. Access to the data is limited to authorized researchers under strict confidentiality agreements.

Authors' Contributions

SH conceptualized the study, developed the methodology, conducted the data collection, curated and analyzed the data, administered the project, and wrote the original draft of the manuscript. JS contributed to the conceptualization, data collection, and project administration. LS and DS contributed to the development of the intervention and provided resources. TK advised on the study design and methodology. UL supervised the project. All authors critically reviewed and approved the final version of the manuscript.

Conflicts of Interest

SH, LS, and DS are cofounders and stakeholders of SHS Social Health Solutions UG, which provided the intervention that was evaluated in this study. JS, UL, and TK report no conflicts of interest.

Abstract

SSEndoSim, a free, open access, mobile, web-based endodontic diagnostic simulation application for undergraduate dental education, demonstrated favorable usability rated on a System Usability Scale (SUS) witht a composite 100-point score (mean 75.30, SD 14.72) and high perceived educational value (PEV) on a 5-point scale (mean 4.62, SD 0.40) in a cross-sectional usability evaluation of final-year bachelor of dental surgery (BDS) students at Liaquat University of Medical and Health Sciences (LUMHS), Jamshoro, Pakistan, in April 2026, establishing usability and learner acceptability.

(JMIR Hum Factors 2026;13:e100407) doi:10.2196/100407

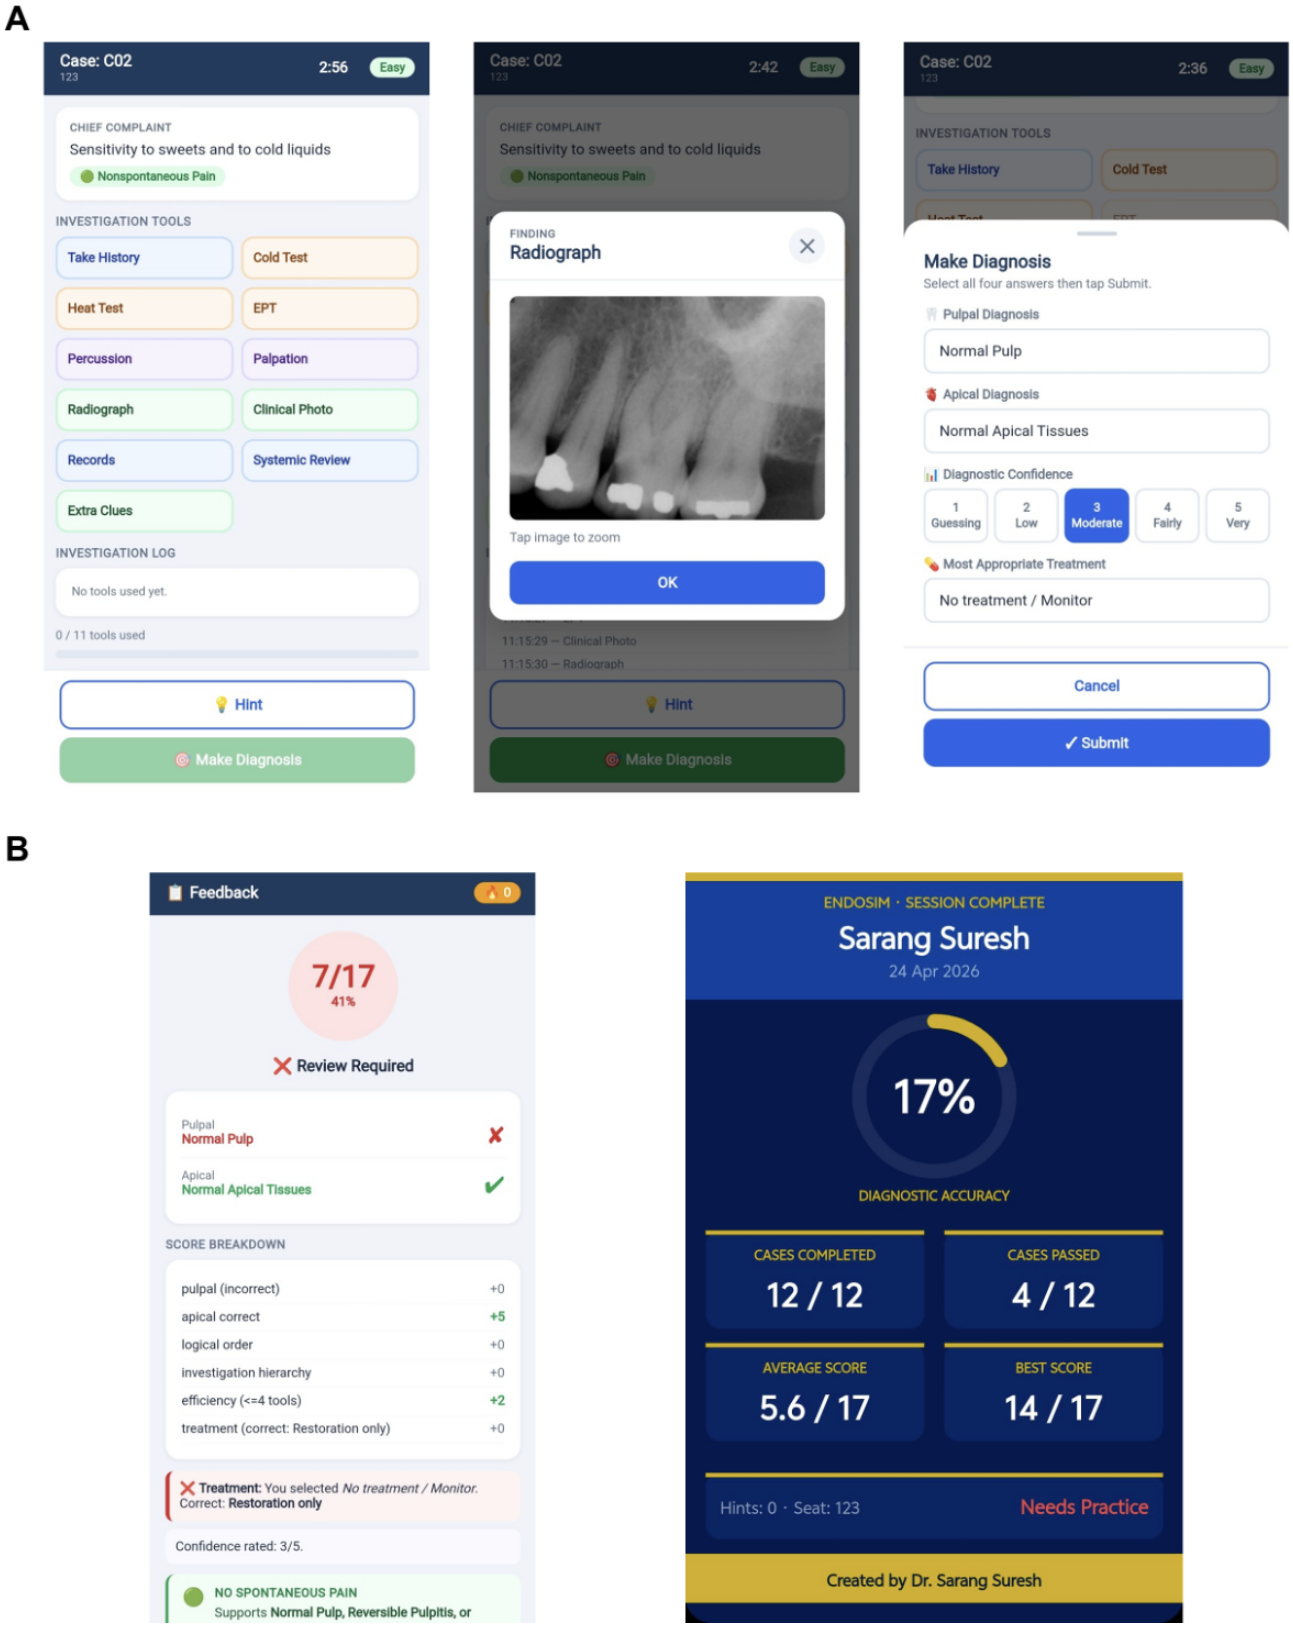
KEYWORDS

dental education; endodontic diagnosis; gamification; mobile learning; simulation; serious game; System Usability Scale

Introduction

Endodontic diagnosis requires simultaneous pulpal and periapical diagnoses using American Association of Endodontists terminology [1], with treatment following the European Society of Endodontology S3-level guideline [2]. Undergraduate diagnostic accuracy is variable, and lectures and clinical exposure alone are insufficient to develop it consistently [3]. Simulation enables repeated engagement with curated cases as well as immediate feedback [4]. Free, browser-based tools may help where commercial simulation platforms are inaccessible.

We report the development of SSEndoSim, a free, web-based endodontic diagnostic simulator with automated scoring and structured feedback, and an initial evaluation of its usability and perceived educational value (PEV) among final-year bachelor of dental surgery (BDS) students ahead of a planned trial of learning effectiveness.



Methods

Application Development

SSEndoSim [5] was designed so that every case demands a simultaneous pulpal and periapical diagnosis per American Association of Endodontists terminology, and every submission receives immediate, objective feedback. It runs in any web browser without installation. The student selects investigations, submits both diagnoses, chooses treatment, and rates their confidence in the diagnoses. A 17-point rubric scores the diagnosis (10 points), treatment (2), and guideline-consistent investigation (5, with deductions), and feedback follows immediately (Figure 1). Rubric weights and difficulty labels were set by investigator judgment, and 2 senior endodontists reviewed the cases and rubric (expert review, not formal content validation). The 12-case bank spanned 6 of 7 pulpal and 4 of 6 periapical categories (4 easy, 6 moderate, and 2 hard). Cases were sampled without replacement within a session; reloading or changing difficulty began a new sequence, so cases could recur across sessions. Twenty postgraduate trainees and faculty piloted SSEndoSim informally beforehand (verbal feedback only), and their prewindow records were excluded from this study by date. SSEndoSim is for education with simulated cases, not diagnosis of real patients. Multimedia Appendix 1 details SSEndoSim's development, rubric, case bank, and log definitions.

(A) Case investigation and diagnosis workflow: investigation tool panel, radiographic finding display, and combined pulpal diagnosis, periapical diagnosis, confidence, and treatment selection panel. (B) Automated postcase feedback (diagnosis result and score breakdown) and end-of-session summary card.

Participants and Measures

All 75 students in the eligible final-year BDS cohort at Liaquat University of Medical and Health Sciences (LUMHS), Jamshoro, Pakistan, were invited to participate in this study by institutional email; those who volunteered were included. Participation was voluntary, uncompensated, and without effect on teaching, assessment, or educational opportunities. Data were collected from April 12 to 26, 2026. Usability was measured with a standard, unmodified 10-item System Usability

XSL•FO
RenderX

Scale (SUS) in English [6]. PEV was measured with an exploratory 5-item investigator-developed scale (Table 1); all 15 items were scored on a scale of 1 to 5 (1=strongly disagree, 5=strongly agree). The PEV composite (participant means averaged; Cronbach α=.61) is exploratory; item-level results are primary. Sessions were reconstructed from log time using a 30-minute inactivity threshold, on which the session count depends. Because the questionnaire (roll number) and application (seat identifier) used different identifiers, individual SUS scores could not be linked to usage, so the SUS could not be examined by exposure level. Free-text comments were grouped into recurring topics by 1 investigator (descriptive summary; Multimedia Appendix 1). Analyses are descriptive (Python, version 3.11; Python Software Foundation), and no sample-size calculation was conducted.

Table . System Usability Scale (SUS)[a] and perceived educational value (PEV)[b] item results 33 final-year dental students at Liaquat University of Medical and Health Sciences (LUMHS), Jamshoro, Pakistan.

Item	Statement	Mean (SD), scale of 1 to 5
SUS1	I think that I would like to use SSEndoSim frequently.	4.61 (0.83)
SUS2	I found SSEndoSim unnecessarily complex.	1.85 (0.97)
SUS3	I thought SSEndoSim was easy to use.	4.06 (1.17)
SUS4	I think I would need technical support to use SSEndoSim.	1.91 (1.16)
SUS5	I found the various functions in SSEndoSim were well integrated.	4.00 (0.97)
SUS6	I thought there was too much inconsistency in SSEndoSim.	2.03 (1.13)
SUS7	I would imagine that most people would learn to use SSEndoSim very quickly.	4.21 (1.14)
SUS8	I found SSEndoSim very cumbersome to use.	2.21 (1.24)
SUS9	I felt very confident using SSEndoSim.	4.09 (0.98)
SUS10	I needed to learn a lot of things before I could get started with SSEndoSim.	2.85 (1.48)
PEV1	SSEndoSim helped me understand endodontic diagnostic classification better than reading alone.	4.36 (0.86)
PEV2	The immediate automated feedback after each case was educationally valuable.	4.76 (0.50)
PEV3	The scoring system motivated me to think carefully before submitting a diagnosis.	4.70 (0.64)
PEV4	I would recommend SSEndoSim to fellow dental students for self-directed learning.	4.76 (0.44)
PEV5	SSEndoSim should be included as a formal component of the endodontics curriculum.	4.52 (0.71)

[a]SUS composite score (0 - 100): mean 75.30, SD 14.72.

[b]PEV composite score (1-5, exploratory): mean 4.62, SD 0.40.

Ethical Considerations

The research ethics committee of LUMHS, Jamshoro, approved this study (LUMHS/REC/1575; March 15, 2026). Invitations were sent and subsequent written electronic consent sought through the institutional email and questionnaire system. Roll numbers, used only to screen duplicates, were deleted before analysis. Deidentified data were held by the principal investigator alone, who lectured the cohort, had no assessment role, and did not know who participated.

Results

Of 75 invited students, 33 (44%) attempted at least 1 case and submitted a complete questionnaire; of these, 17 (52%) completed all 12 cases. Logs recorded 43 sessions and 423 scored case attempts, comprising 301 unique user-case combinations and 122 repeats, with 16 users (48%) repeating at least 1 case. The median number of unique cases attempted was 12 (IQR 5.5 - 12), and the median time spent using the app was 22.4 minutes (IQR 10.7 - 29.0).

The mean SUS score was 75.30 (SD 14.72; 95% CI 70.08 - 80.52; median 80.0, IQR 66.2 - 87.5; range 45.0 - 100.0). The distribution showed no strong evidence of

XSL•FO
RenderX

departure from normality (Shapiro-Wilk *P*=.35). Individual scores were as follows: 3 (9%) scored below 51, 7 (21%) score from 51 to 67, 6 (18%) scored from 68 to 79, 10 (30%) scored from 80 to 89, and 7 (21%) scored 90 or above (Multimedia Appendix 1). Item means are shown in Table 1; among the negatively worded items, the onboarding item scored highest (2.85, SD 1.48). PEV was high (mean 4.62, SD 0.40), with automated feedback and peer recommendation scoring highest (both 4.76). Of the 19 free-text comments received, the most common topics were feedback and scoring clarity (n=4; Multimedia Appendix 1).

Discussion

SSEndoSim's mean SUS score (75.30, SD 14.72) is comparable to other endodontic and dental diagnostic education tools evaluated with the SUS: the Endo 10 endodontic diagnosis app (median 77.5) [7], an endodontic e-learning application (81.4) [8], and a virtual scenario–based clinical-reasoning system for dental students (70.14) [9]. Samples and administration differ, so values are broadly consistent, not directly comparable. Participants rated the feedback favorably, and immediate feedback is one component associated with deliberate practice [4]; however, these data do not show that use of the app resulted in corrected diagnostic errors in users. Score-based elements may encourage use, but engagement alone does not establish learning benefit [10,11], and high recommendation and curricular-integration ratings reflect learner perception, not curriculum readiness. The open-ended data and scores for the onboarding item point to onboarding as the clearest usability target, and strengthening introductory guidance is the immediate development priority.

This single-institution study used a voluntary, self-selected sample of participants who were possibly more receptive to mobile learning than nonparticipants. Because the developer taught the cohort, perceived-authority and social-desirability effects cannot be excluded. The PEV measure was not pretested and showed modest internal consistency. Logs could not be linked to questionnaire responses, exposure varied, and only 17 participants completed all 12 cases. There was no comparator group or pre-post learning measure. The findings, therefore, concern usability and learner perception, not educational effectiveness.

A free, web-based, guideline-aligned simulator was usable and well regarded by final-year BDS students in a resource-constrained setting. Its browser-based architecture and teacher-editable case bank may be adaptable to other areas of dental education, although this was not examined here. Whether SSEndoSim improves diagnostic competence remains to be tested.

All 15 items were scored on a 5-point Likert scale (1=strongly disagree, 5=strongly agree). Values are raw item means (SD) and are not transformed for display. SUS items 2, 4, 6, 8, and 10 are negatively worded: lower raw means indicate more favorable responses, and these items are reverse scored only when computing the SUS composite. The PEV composite is the mean of each participant's 5 PEV items, averaged across participants, and is exploratory (Cronbach α=.61). All values are descriptive; no hypothesis tests were performed. Full response distributions can be found in Multimedia Appendix 1.

Acknowledgments

The authors used Claude (Anthropic) to assist with coding the SSEndoSim application and for language editing of the manuscript. The clinical content of the application was drawn from published guidelines and authored by the investigators; it was not generated by AI. The authors independently checked all statistical calculations against the raw data. Generative AI was not used to create study data, results, or references. The authors reviewed and approved the final manuscript and took responsibility for its content.

Funding

The authors declared no financial support was received for this work.

Data Availability

The deidentified item-level questionnaire dataset and the aggregate application-log summaries analyzed in this study are available from the corresponding author on reasonable request.

Authors' Contributions

SS conceived the study, developed the application, analyzed the data, and drafted the manuscript. PR contributed to data collection, data analysis, and technical refinement of the application. FK designed and supervised the study. All authors reviewed and approved the final manuscript.

Conflicts of Interest

SS developed the SSEndoSim application and declares this nonfinancial developer interest. The authors declare no financial conflicts of interest.

Abstract

Background: Internet hospitals are playing a significant role in medical care with their potential to provide widely accessible outpatient service delivery via information technologies. Current research on patients' satisfaction with internet hospitals mainly focus on physician-patient relationship and patient demand, and less is considered about the whole process of online consultation.

Objective: This study aims to identity the factors influencing patient satisfaction considering the entire process of online consultation to help physicians deliver better online medical services and to help physical hospitals operate internet hospitals more effectively.

Methods: Based on the service quality (SERVQUAL) theoretical model, questionnaire items were designed for the 5 dimensions of reliability, assurance, responsiveness, empathy, and tangibility. The research samples for data collection were 355 patients on the internet hospital platform operated by a tertiary general hospital in Beijing. Confirmatory factor analysis was performed for dimensions of the measurement model, and path analysis was performed for the structural model.

Results: The current consultation process of internet hospitals, as perceived by patients, did not yet meet their expectations, and the overall satisfaction rate of patients was only 7.15. The 5 dimensions of reliability, responsiveness, empathy, tangibility, and assurance had different positive predictive effects on patient satisfaction in internet hospitals to a certain extent. Among them, tangibility exerted the greatest impact on patient satisfaction in internet hospitals (β=0.25) but obtained the lowest score among the sampled participants (mean=6.78).

Conclusions: Internet hospitals and physicians should focus on the factors of the above dimensions, especially the tangibility of medical services in the multistage online consultation, thus better serving patients and promoting the sustainable development of internet health care.

Introduction

The internet hospital is a new medical model that realizes online disease diagnosis and treatment services by using information technology to provide services to patients with common diseases or chronic diseases or living in remote and rural areas [1,2]. On such platforms, patients can consult physicians about their disease diagnosis, treatment plan, and prognosis without the limits of time and space [3,4]. In June 2024, the number of internet medical users in China had reached 418 million, accounting for 37.7% of the total internet users. There are 3340 internet hospitals in China, and the annual volume of internet-based medical services provided exceeds 100 million medical visits. The convenience, accessibility, and continuity of medical services in internet hospitals have injected great momentum into the development of China's public health services [5,6].

Internet hospitals have developed rapidly and become an important part of China's medical service system [7]. Many entity hospitals have set up their own internet hospital to provide web-based medical services. Compared with physical hospitals, internet hospitals can reduce patients' waiting time, increase doctor-patient interaction efficiency, and improve the accessibility of medical service quality [8]. Patient satisfaction is an important basis for evaluating health care quality, and patients will have high satisfaction when they are treated in an expected way and receive high service quality [9]. However, despite the convenience and accessibility of online health care services, there is still room for improvement in patient satisfaction with internet hospitals [3].

Existing research on patients' satisfaction primarily focus on online physician-patient interaction [4,10] and physician provision [7,11] and tends to examine offline physical hospitals [12,13]. For example, Li et al [4] evaluated the impact of internet hospitals on physician-patient relationship during outpatient visits and suggested improving physicians' online communication skills and strengthening the level of trust between physicians and patients from a patient perspective. Chang et al [10] investigated how physician-patient online interaction affects the integration of online and offline health services. Wu et al [7] studied patient satisfaction from the perspective of physicians and proposed that physicians' response, detailed style, and emotional comfort positively affects patient satisfaction. Yang et al [11] explored the effect of physicians' appearance, smile, and positive emotions on patients' selection and evaluation behavior and reported interesting and valuable conclusions. However, these studies have only focused on patient satisfaction at a specific stage, without exploring the whole process of patient diagnosis and treatment in internet hospitals.

Online consultation in internet hospitals is a complex and dynamic process, which includes preconsultation, consultation, postconsultation, and online and offline integration [14]. When patients have diagnosis and treatment needs, they can apply to internet hospitals for online consultation services. In the preconsultation stage, the patients need to decide which physician to choose by comparing information displayed in the internet hospitals [15]. Then, patients will communicate with the selected physician to conduct diagnosis and treatment in the consultation stage. In the postconsultation stage, medicines purchased online will be delivered on time without damage. Online and offline integration needs to be performed when the patient's condition is unusual or serious [10].

Patient satisfaction is often linked with health care service quality. Parasuraman et al [16] initially developed a service quality model to explain the potential causes of service quality issues and help managers improve service quality. The model was further improved as a measurement tool, the service quality (SERVQUAL) questionnaire, which consists of 5 dimensions: reliability, assurance, responsiveness, empathy, and tangibility, to measure users' expectation and perception of the service quality provided by the entity and reflects their attitude toward the service provider [17]. Previous studies have evaluated the quality of medical services in hospitals based on the SERVQUAL questionnaire [18-20]. Han et al [3] evaluated patients' expected and perceived service qualities of internet hospitals by using the service quality questionnaire with a national representative sample. In this study, we designed measure items of the questionnaire based on the 5 dimensions of the SERVQUAL theoretical model to evaluate the service quality from a multistage online consultation process such as preconsultation, consultation, postconsultation, and online-offline integration. The measurement dimensions in each phase of the diagnosis and treatment process can correspond to the SERVQUAL model.

This study aims to identify and clarify the factors influencing patient satisfaction in internet hospitals in Beijing across the multistage online consultation process. Exploring this problem can help such platforms optimize service design, thereby guiding internet hospitals to better serve patients and attract more users. We expect that problems existing in the online diagnosis and treatment process of internet hospitals can be uncovered from the perspective of patients, and suggestions on upgrading and improving internet hospitals can be put forward. Ultimately, internet diagnosis and treatment can better meet the needs of patients in the process of use and management, improve patients' satisfaction with internet hospitals, and thus promote the development of internet diagnosis and treatment.

Methods

We conducted a web-based cross-sectional survey of patients from an internet hospital platform of Beijing Chaoyang hospital, a tertiary general hospital which provides an integration of online and offline medical services for patients.

Ethical Considerations

According to the "Ethical Review Measures for Human Life Sciences and Medical Research" (approved by the National Science and Technology Ethics Committee) issued by the National Health Commission and the Ministry of Science and Technology of the People's Republic of China on February 27, 2023 (Document No. GWNJ-KE-2023-4), and according to Article 32 of Chapter 3 of the Ethical Review Regulations [21], this study was exempted from ethic review.

XSL•FO
RenderX

Before the questionnaire survey, the professional staff from the information center of the Beijing Chaoyang hospital carefully verified the questionnaire dimensions to ensure compliance with ethical standards. The survey data were anonymized and kept confidential for the respondents. During the data collection stage, our data was collected through the form of online questionnaires. All participants signed the "Informed Consent Form", clearly informing them of the research purpose, confidentiality terms, and the right to withdraw voluntarily. In the questionnaire we clearly stated that the collected data would only be used for academic research. We strictly abide by the Personal Information Protection Law. The questionnaires were anonymous and did not involve patients' names. Consequently, this study did not require ethical approval. Participants who completed a questionnaire could receive a reward of $0.80 USD. During the data processing process, we strictly abided by data protection regulations and took measures to ensure data security.

Instrument Development

Combining the existing scale of patient satisfaction in offline hospitals and the operating status of internet hospitals in Beijing, questionnaire items were designed based on the 5 dimensions of the SERVQUAL model. Our questionnaire consisted of 2 parts: basic information and satisfaction evaluation. The basic information included characteristics of the patients such as gender, age, education, monthly income, occupation, and the frequency of using internet hospitals. Satisfaction evaluation covered all stages of the patient's internet online diagnosis and treatment process, including prediagnosis, diagnosis, postdiagnosis, payment, purchase of medication, and online and offline referrals, with 4 items on reliability, 5 items on guarantees and responsiveness, 4 items on empathy, 3 items on tangibility, and 4 items on overall patient satisfaction, totaling 25 questions. Multimedia Appendix 1 lists the 25 items used in this study. The items were measured using a 10-point Likert scale (1=strongly disagree, 2=disagree, 3=slightly disagree, 4=somewhat disagree, 5=indifferent, 6=general, 7=somewhat agree, 8=slightly agree, 9=agree, 10=strongly agree).

Data Collection

To ensure the scientific aspect and rationality of the questionnaire scale, we adopted snowball sampling to conduct a small-scale pretest for patients who have used the internet hospital of a tertiary hospital in Beijing; a total of 44 questionnaires were issued, and 30 valid questionnaires were obtained after eliminating invalid questionnaires, with an effective rate of 68%. The sample data were tested for reliability and validity using SPSS software (version 24.0; IBM Corp). The Cronbach α coefficients of each dimension were greater than 0.7, and the overall Cronbach α coefficient was greater than 0.9, indicating that the internal consistency of the items was better and the overall reliability of the sample was higher. The Kaiser-Meyer-Olkin value was 0.75 and the *P* value was less than .001, meaning that the validity of the sample was acceptable. Therefore, this questionnaire can be used in subsequent studies.

In the formal survey, the questionnaire was released to the internet hospital platform of a tertiary hospital in Beijing, and convenient random sampling was adopted to distribute the questionnaires. To ensure data quality, we implemented a rigorous data screening procedure. Given that it takes 86 seconds at least to read the questionnaire from the beginning to the end, 20 questionnaires with the answer time of less than 86 seconds were excluded. Additionally, 23 questionnaires that selected one option for all questions and 6 questionnaires that failed an attention check were excluded. Finally, 355 valid questionnaires were obtained, with an effective rate of 87.9% (355/404).

Data Analysis

SPSS (version 27.0) and AMOS (version 23.0; IBM Corp) software were used for data analysis. We first employed descriptive statistics to analyze the demographic information of the patients and descriptive statistics of 25 observed variables. Structural equation modeling was then employed to examine the relationships between measurement items and structural variables to identify the causal relationships between structural variables [22,23]. Among them, confirmatory factor analysis was performed to ensure the reliability and validity for the measurement model, and path analysis was performed to estimate the influencing relationships for the structural model [24].

Results

Descriptive Statistics

Table 1 presents the demographic characteristics of the respondents. Among the respondents, males and females were evenly divided, with slightly more females than males. The largest number of people were in the 26-45 years age group, accounting for 31.5% (112/355) of the total sample. Respondents below the high school/secondary school level accounted for nearly half (174/355) of the total sample. Respondents with a monthly income of less than US $409.80 accounted for 38% (135/355) of the total sample. The frequency of using internet hospitals is measured as often (more than 3 times a month), frequently (2-3 times a month), occasionally (once a month), rarely (almost never). More than half (295/355, 83.1%) of the population employed internet hospitals at an average frequency.

XSL•FO
RenderX

Table 1. Demographic statistics of the sample (N=355).

Demographic characteristics, categories	Values, n (%)
Gender	
Female	167 (47.1)
Male	188 (52.9)
Age (y)	
<18	27 (7.6)
18-25	51 (14.4)
26-45	112 (31.5)
46-60	108 (30.4)
>60	57 (16.1)
Education	
High school or below	174 (49)
Junior college	70 (19.7)
Undergraduate	76 (21.4)
Postgraduate	35 (10)
Monthly income	
Less than US $409.80	135 (38)
US $409.90-US $819.70	130 (36.6)
US $819.80-US $1366.10	58 (16.3)
US $1366.20-US $2049.20	20 (5.6)
More than US $2049.20	12 (3.4)
Frequency of using internet hospital (frequently)	295 (83.1)

Table 2 provides a descriptive statistics for these items, including item mean and standard deviation, skewness, kurtosis, minimum, and maximum values. The skewness of each item ranged from –0.10 to –1.03, and the kurtosis ranged from 0.30 to 1.75. Since all values fell within the absolute value of 2, the data of each construct were normally distributed [25]. The mean value of each item was greater than the median 5.5, demonstrating that most patients using internet hospitals had a strong sense of identity with the potential variables set by the research. The 5 dimensions of reliability, assurance, responsiveness, empathy, and tangibility proposed in this paper could be regarded as core variables and the following detailed analysis was performed according to the data. However, the average score values of the 5 dimensions were not very high (only around 7), indicating that patients are not very satisfied with the whole process of diagnosis and treatment in the internet hospitals.

Measurement Model

We tested the internal reliability, convergent validity, and discriminant validity for confirmatory factor analysis to evaluate the fitness between the 5 constructs and their indicators. The values of composite reliability, average variance extracted, Cronbach α, and factor loadings were calculated to assess the internal reliability and convergent validity. As shown in Table 3, the factor loading values were all greater than 0.84, reaching the desired level of estimation. The *P* value of the unstandardized coefficients was less than .01, meaning that the observed variables were significant for the latent variables. The reliability coefficients, composite reliability, and Cronbach α were all above the threshold value of 0.7, and average variance extracted were greater than 0.71, indicating that all reflective constructs exhibited good reliability and convergent validity [26,27].

f3	0.84	.01	0.70			
f4	0.85	<.001	0.72			

[a]Not applicable.

For discriminant validity, the square root of average variance extracted for each construct on the diagonal was much larger than the correlation coefficients of the other constructs, indicating good discriminant validity of the measurement model, as shown in Table 4. The correlation coefficients of assurance, reliability, responsiveness, empathy, tangibility, and overall patient satisfaction were 0.88, 0.88, 0.84, 0.85, 0.87, and 0.51, respectively, with *P* values of less than .001, indicating that there was a significant positive correlation between the constructs and patient satisfaction.

Tangibility	0.35	0.40	0.33	0.35	0.87	—
Overall satisfaction	0.36	0.42	0.39	0.39	0.43	0.51

[a]Not applicable.

Structural Model

We performed absolute fit, added fit, and reduced fit to verify the fit degree of the structural model. The fitting effect of the structural model is shown in Table 5, with a chi-square of 321.6, a df value of 260, and chi-square minimum/df of 1.24, which was between 1 and 3. The goodness-of-fit index, measuring how much of the variance and covariance of the observed data can be explained by the model, was 0.93 greater than the threshold of 0.90 and the root mean square error of approximation value, which measures the gap between the theoretical model and the perfect fitting model, was 0.03 less than the threshold of 0.05, indicating that the model had a good absolute fit. The normed fit index value, incremental fit index value, Tucker-Lewis Index, and comparative fit index explain the degree of fit of the hypothetical model and the independent model from various aspects, whose values were all greater than the threshold of 0.90, meaning that the model had a good added fit with the actual data. The Parsimony-adjusted normed fit index value, Parsimony-adjusted comparative fit index value, and Parsimony-adjusted goodness-of-fit index explain the simplicity of the model based on the assessment of fit. The values were all greater than the threshold of 0.5, indicating that the model had a reduced fit [28]. Overall, the fitness of the structural model was good.

Table 5. Goodness-of-fit test.

Indicators	Model indicator values	Reference standard	Whether or not fit
Absolute fit			
Chi-square minimum/df	1.24	<3	Fit
Root mean square error of approximation	0.03	<0.05	Fit
Goodness-of-fit index	0.93	>0.9	Fit
Added fit			
Normed fit index	0.96	>0.9	Fit
Incremental fit index	0.99	>0.9	Fit
Tucker-Lewis index	0.99	>0.9	Fit
Comparative fit index	0.99	>0.9	Fit
Reduced fit			
Parsimony-adjusted normed fit index	0.83	>0.5	Fit
Parsimony-adjusted comparative fit index	0.86	>0.5	Fit
Parsimony-adjusted goodness-of-fit index	0.75	>0.5	Fit

The results of structural model are reported in Table 6, which presents the estimated coefficients, the standardized and nonstandardized coefficients, standard error, critical ratio, and the associated *P* values. The coefficients represented the factor loading from patient satisfaction to the 5 dimensions of reliability, assurance, responsiveness, empathy, and tangibility. Standard error was used to judge the relationship between different variables in the model, as well as its strength and direction, the smaller and better the standard error, indicating that the parameter estimation was more reliable, and vice versa, indicating that the parameter estimation of the uncertainty was greater. Critical ratio was used to judge whether the variables in the model had a good continuity. If it was greater than or equal to 1, it showed that the model had good continuity and could be considered existing important and stable relationships between the variables. On the contrary, it meant that the model had a large uncertainty and need to be further modified. A *P* value of less than .05 indicated that the dimension had a positive effect on patient satisfaction.

XSL•FO
RenderX

Table 6. Path coefficients and significance level analysis.

	Standardized coefficient	Nonstandardized coefficient	Standard error	Critical ratio	*P* value
Reliability	0.15	0.13	0.05	2.39	.02
Assurance	0.12	0.11	0.05	2.10	.04
Responsiveness	0.15	0.14	0.06	2.56	.01
Empathy	0.15	0.13	0.05	2.50	.01
Tangibility	0.25	0.22	0.05	4.28	.01

As shown in Table 6, the standardized coefficients of the 5 dimensions of assurance, reliability, responsiveness, empathy, and tangibility on patient satisfaction were all greater than 0, and the *P* value was less than .05, which proved that there was a significantly positive correlation between all 5 dimensions on the overall satisfaction of patients in the internet hospitals, that is, the improvement of the 5 dimensions could correspondingly affect the improvement of overall patient satisfaction. The standard errors were all positive and small in value, indicating that there was a positive effect of the 5 dimensions on overall satisfaction, and the parameter estimation of the path was reliable. The critical values were all greater than 1, indicating that the model had good continuity and there was an important and significant relationship between the 5 dimensions and overall patient satisfaction. In summary, it could be seen that the 5 dimensions played a positive role in predicting overall patient satisfaction.

Discussion

Main Findings and Suggestions

This study aims to investigate the factors influencing patient satisfaction in the multistage online consultation process based on 5 dimensions of the SERVQUAL theoretical model. To summarize, the current consultation process of internet hospitals as perceived by patients did not yet meet their expectations, and the overall satisfaction rate of patients was only 7.15. We will discuss this in detail from the following aspects.

First, our study reveals a critical paradox: among the various dimensions measuring the service quality of internet hospitals, tangibility received the lowest patient ratings, but it was identified as the most influential factor affecting overall satisfaction. The results are similar to other studies using the SERVQUAL model that emphasized the importance of tangibility [19,20]. The intangible nature of the service remains a primary bottleneck for the development of internet health care, while successfully making the virtual service tangible can yield significant returns in terms of patient trust and satisfaction. However, improving tangibility necessitates a profound experience redesign. The online user interface should evolve beyond basic functionality to become a communication medium itself, which can be achieved through visual service flow maps and multidimensional presentations of the medical teams, thereby making the intangible diagnostic and treatment process clear, predictable, and structured [10]. Besides, hospitals should integrate online and offline support systems to create a seamless chain of trust by establishing end-to-end tracking systems for prescription approval, medication delivery, and offline examination appointments. In summary, the future development of internet hospitals should not solely focus on stacking technological features but must strive to transform cold online interactions into a warm and perceptible service experience. By implementing the proposed 2-pronged strategy for enhancing tangibility, internet hospitals can effectively mitigate their inherent disadvantage of service intangibility, which will pave the way for building robust patient satisfaction and achieving sustainable growth.

Second, the findings clearly show that reliability is a core factor driving patient satisfaction in internet hospitals. Reliability assesses the ability of internet hospitals to deliver services accurately and dependably [4,18]. To strengthen reliability, internet hospitals must strive to consistently fulfill their promises to patients throughout the entire process from preconsultation, during consultation, to postconsultation. First, preconsultation focuses on establishing clear expectations, requiring physicians to adhere strictly to appointment times and ensuring complete fee transparency through detailed cost breakdowns. Second, during and postconsultation, the emphasis shifts to delivering a high-quality service loop. Previous studies have shown that online physicians are a key factor in improving patient satisfaction [11]; internet hospitals should be aware of the importance of physicians' appearance and smile on patients' selection and evaluation behavior. Physicians should communicate with professionalism and empathy (eg, a smile) to build trust and compensate for the lack of face-to-face interaction. Concurrently, drug delivery must be punctual, accurate, and with intact packaging, representing the final fulfillment of the service promise. Finally, underpinning all services is technical assurance. Internet hospitals must prioritize network security and patient privacy protection, maintained by dedicated IT teams to ensure system stability and data security [8]. In essence, by standardizing processes, ensuring transparency, and rigorously honoring commitments within this framework, internet hospitals can systematically build reliability, leading to a significant increase in patient satisfaction.

Responsiveness also demonstrated a significant positive impact on patient satisfaction in internet hospitals. Notably, among the 5 SERVQUAL dimensions, responsiveness received the highest score from the participants. This dimension pertains to the service efficiency of internet hospitals, reflected specifically in the promptness of staff replies to patient inquiries and whether the exact time for each service is communicated in advance [29]. To continuously improve responsiveness, internet hospitals need to optimize multiple aspects. First, IT support should be strengthened to ensure that medical staff can promptly address patient needs during consultations and provide quick feedback

XSL•FO
RenderX

and solutions to postconsultation issues. Second, in response to patient-reported problems such as difficulty contacting doctors and delayed responses, root causes such as network latency, system lag, or unreasonable interface design should be thoroughly analyzed and addressed through technological upgrades and process optimization. Additionally, internet hospitals should focus on enhancing service synergy, reducing communication delays, and avoiding consultation interruptions or efficiency losses due to poor communication. On the other hand, internet hospitals should further expand the application scenarios of responsiveness. For example, timely push of hospital resource information (eg, doctor schedules, latest services) and the implementation of rapid response mechanisms for payment, refunds, and other processes can comprehensively improve service efficiency and patient experience. In the future, internet hospitals can leverage intelligent technologies (eg, AI pre-replies, smart triage) to enhance responsiveness, reducing the workload of medical staff while further improving service efficiency and patient satisfaction.

Fourth, a significant positive correlation exists between empathy and patient satisfaction in internet hospitals. Improving the empathy of internet hospitals needs to focus on whether patients feel cared for in the whole process of diagnosis and treatment [30]. When internet hospitals provide personalized services, demonstrate genuine concern, and proactively address patient needs, patients feel valued, which fosters positive emotions and, consequently, increases their satisfaction [3]. For instance, internet hospitals should cater to the needs of special patient groups such as older adults and persons with disabilities. Implementing dedicated application modes such as an “Elderly Mode” with optimized font styles and sizes can directly address their specific requirements and reflect a commitment to inclusive, humanistic care. Furthermore, as internet hospitals primarily serve patients with chronic conditions or those facing mobility challenges, the scheduling system must be patient-centric. The allocation of appointment slots and the number of available time slots should not only align with patient demand but also be balanced reasonably with physicians' available consultation hours. Additionally, offline hospitals can enhance empathy by establishing dedicated service counters for their internet hospital services. These counters could assist patients with practical tasks such as printing electronic prescriptions or reports and serve as an introduction point for first-time users, guiding them through the platform's features. This integration of online and offline support embodies a holistic and empathetic approach to patient care.

Finally, among the 5 service quality dimensions, assurance was found to have the least impact on patient satisfaction, a finding that aligns with practical realities. In the context of this study, assurance primarily pertains to the technical competence of online physicians and the effectiveness of the treatment received. Patients who generally lack professional medical knowledge and face information asymmetry are often unable to directly evaluate this dimension, making the sense of assurance less tangible in an internet hospital setting. Nonetheless, it is indisputable that physicians' professional knowledge remains the cornerstone of a credible internet hospital service [14]. Therefore, entities operating these platforms, including traditional hospitals, must prioritize the rigorous selection and training of online physicians. Deploying high-caliber medical talent is essential to enhance the perceived assurance and, consequently, patient satisfaction. To this end, offline hospitals should assign their most qualified medical teams to online duties, ensuring that the quality of consultation achieves parity with in-person visits. Furthermore, strengthening the integration between online and offline services is crucial. By creating seamless referral channels and strategically shifting appropriate follow-up care burdens from offline to online platforms, health care providers can build a cohesive and trustworthy system. This integration not only enhances assurance but also encourages patient adoption and sustained use of internet hospitals throughout their entire health care journey.

Conclusion and Limitations

This study analyzes patient satisfaction in the multistage online consultation process in internet hospitals. Based on the SERVQUAL model, we designed questionnaire questions for the 5 dimensions of reliability, assurance, responsiveness, empathy, and tangibility, and collected data from patients of the internet hospital of a tertiary hospital in Beijing. We found that the 5 factors of reliability, responsiveness, empathy, tangibility, and assurance all had different positive predictive effects on patient satisfaction in internet hospitals to a certain extent. Our results provide patients, physicians, and online health communities with guidelines that support them in widely adopting internet hospitals and effectively improving their decision-making.

This paper has some shortcomings while achieving certain results. First, this paper determined 25 observed variables of the 5 dimensions according to previous literature and the actual situation of a tertiary hospital internet hospital in Beijing. However, the operation mode of each internet hospital is different, and the applicability of the variable selection is worth considering. Second, the cross-sectional design limits the ability to establish causal relationships between the 5 dimensions of SERVQUAL theoretical model and patient satisfaction. Future research could use longitudinal studies to examine the pathways of causality and the possible changes in patient satisfaction over time. In addition, the survey respondents were patients using online health services in Beijing. As an emerging thing, patients in different regions may present different satisfaction levels due to ethnic and cultural differences, and future research could explore patients in different regions.

Abstract

Background: Although telemedicine grew rapidly during the COVID-19 pandemic, instruments to assess general practitioners' (GPs) attitudes and behavioral intentions to use it are scarce. In Sweden, the Physicians' Attitudes and Intentions to use Telemedicine (PAIT) questionnaire was developed from the "theory of planned behavior" in 2019 and translated into English in 2022.

Objective: The aim of this study was to explore similarities and differences between behavioral intentions and predictors of intentions to use telemedicine among GPs in England and Sweden.

Methods: This study compared attitudes, behavioral intentions, and self-reported use of telemedicine after the COVID-19 pandemic among 52 GPs in England and 101 GPs in Sweden. The PAIT questionnaire has 33 items with 7-point Likert scale options ranging from "strongly disagree" to "strongly agree," examining 3 predictors of intentions: attitudes (12 items), subjective norms (6 items), perceived behavioral control (9 items), and "intentions" (6 items) to use telemedicine; 22 items assess use of telemedicine tools, general questions about telemedicine, training experience, free-text comments, and demographic and background questions.

Results: Both English and Swedish GPs reported little training and low use of telemedicine after the COVID-19 pandemic. Swedish GPs had significantly higher mean scores for intentions to use telemedicine in daily practice compared with English GPs. More positive attitudes and higher perceived behavioral control were significantly associated with higher behavioral intention scores in both English and Swedish GPs.

Conclusions: While our results are exploratory due to sample size constraints, these findings provide insights into the similarities and differences between English and Swedish GPs regarding telemedicine adoption—attitudes, behavioral intentions, and self-reported use of telemedicine assessed by the PAIT questionnaire—which proved useful for cross-country comparisons and could be used for further international studies.

Introduction

Background

Telemedicine has developed at a rapid pace and increased in use worldwide in recent years [1,2], partly due to social distancing policies introduced during the COVID-19 pandemic [3-6]. Current telemedicine technologies are available at a low cost, accessible to those living in rural areas, and they have the potential to decrease the workload for general practitioners (GPs) [7,8].

Telemedicine is defined by the United Kingdom's National Health Service as "The use of telecommunication and information technology providing remote health assessments and therapeutic interventions" [9]. Another definition is "health care service delivered by health care providers in a patient-centered manner, from a geographical distance using ICT (information and communication technology)" [10].

XSL•FO
RenderX

Telehealth is a broader term encompassing the integration of telecommunication in the practice, promotion, and management of health care. Methods of communication in telemedicine include video consultations, telephone calls, emails, as well as mobile apps to monitor chronic diseases (mobile health), digital diagnostic algorithms, triage, and web guideline support for treatments [7,8,11,12].

While studies in the United Kingdom have shown that GPs have a positive attitude toward telemedicine, some have criticized the lack of IT integration with existing medical systems and reported a lack of telemedicine experience, especially before the COVID-19 pandemic [3,7]. Surveys in the United States and Sweden have shown similar conclusions: positive attitudes toward telemedicine but little use of it [11,13-16]. The main obstacles for use have been reported to be a lack of experience and understanding of the use of these communication methods and technologies [13,16]. The increased use of telemedicine in health care [2,6] has raised concerns about both GP workload increase and decrease [13], with Salisbury et al [17] warning of an increase in GPs' workload when integrating telemedicine as a means of digital consultation before face-to-face consultation. Workload is only decreased if at least half of digital consultations are nonurgent matters, and it depends on the demand and requirements of the consultations [17]. There has been a call for research on telehealth and telemedicine to evaluate how they could improve medical consultations and disease monitoring [1,14]. In this study, telemedicine refers to remote clinical consultations between patients and clinicians, such as by telephone, video, chat, or secure email. It does not include remote monitoring devices, digital diagnostics, or triage algorithms.

Theoretical Framework

Over the past few decades, several theories have emerged to explain end-user acceptance and adoption of new technologies [10,18-22]. One of the most commonly applied frameworks for understanding telemedicine adoption among health care staff is the theory of planned behavior (TPB).

The TPB explains how behavioral intentions influence the likelihood of performing an action. According to the theory, these intentions are shaped by an individual's attitudes toward the behavior, subjective norms—defined as the individual's perception of social expectations regarding behavior change—and perceived behavioral control, which reflects the individual's belief in their ability to perform the behavior [23].

The TPB is widely recognized for its practical applicability and predictive validity. A validated manual is available for implementing the TPB, enabling the development of questionnaires designed to assess behavioral intentions [23].

This study aims to build upon the Swedish study by Pikkemaat et al [11], conducted in 2019 before the COVID-19 pandemic. That study examined physicians' attitudes and intentions toward using telemedicine, using a newly designed survey instrument based on the TPB. The Swedish-language instrument, known as the Physicians' Attitudes and Intentions to use Telemedicine (PAIT) survey, was distributed to 820 potential respondents across 160 health care centers in 2 southern Swedish regions, yielding 198 (24.1%) responses. The study found high levels of intention and positive attitudes toward using telemedicine, with perceived behavioral control emerging as the strongest predictor of telemedicine adoption. Given that the COVID-19 pandemic accelerated the use of telemedicine, the study suggested that intentions to use digital tools in primary care may have increased since 2019, warranting further exploration across different contexts.

To date, no studies have examined the intentions of English GPs to adopt telemedicine. Building on insights from the Swedish study conducted before the COVID-19 pandemic [11] and the assumption that telemedicine adoption may have shifted in primary care following the pandemic, we decided to collect new survey data from Sweden and compare it with data from England, both within the primary care setting.

The objective of this study was to explore and compare the intentions of English and Swedish GPs to use telemedicine using the TPB-validated questionnaire. Additionally, the study aimed to assess how attitudes, subjective norms, and perceived behavioral control influence the intentions of GPs in both countries to adopt telemedicine.

Methods

Survey Design

The PAIT survey instrument was originally designed and written in Swedish by Pikkemaat et al [11], based on the manual from the University of London Institutional Repository for creating questionnaires using the TPB, constructed by Francis et al [24]. The PAIT survey includes questions about experiences with digital contact methods, chronic disease monitoring with digital tools, and participant demographics. Digital contact methods encompass the various telemedicine approaches GPs might use to communicate with patients, such as telephone, online chat, video consultation, and email.

The original PAIT-Swedish survey instrument also included questions regarding experiences with artificial intelligence (AI) in telemedicine, focusing on diagnostic algorithms, triage, and support for treatment guidelines. However, as responses from the Swedish survey indicated very low use and experience of AI technologies among GPs [11], these questions were excluded from the English survey.

Translation and Validation Process

The PAIT survey was translated into English by a Swedish-English bilingual master's student, with minor cultural adaptations to suit the UK health care context. To ensure linguistic equivalence and conceptual accuracy, the English version underwent back-translation into Swedish, followed by a detailed comparison with the original Swedish version. This process was overseen by the research team, ensuring that no essential meaning was lost during translation.

The newly adapted English-language version, named "Behavioural Intentions towards Telemedicine" (BIT), was designed to yield scores comparable to both the pre–COVID-19 pandemic PAIT-Swedish survey [11] and the results from a

XSL•FO
RenderX

repeat PAIT-Swedish survey conducted following the COVID-19 pandemic (Multimedia Appendix 1).

Validation and Reliability Testing

The translated BIT survey was validated following established guidelines, including the Checklist for Reporting Results of Internet E-Surveys (CHERRIES), as recommended by the *Journal of Medical Internet Research* [25] (Checklist 1). The PAIT-Swedish version had previously undergone rigorous testing for construct validity and reliability using the Churchill Paradigm and COSMIN (Consensus-based Standards for the Selection of Health Measurement Instruments) guidelines. This involved a pilot test with 24 participants and evaluation by 5 proficient physicians in telemedicine to ensure the questionnaire accurately captured the research questions.

Internal consistency was assessed using Cronbach α, with items scoring below an acceptable threshold removed to improve the instrument's reliability. The final version demonstrated Cronbach α scores ranging between 0.6 and 0.95. Temporal stability was further tested by administering the questionnaire to the same 24 respondents after 2 weeks, with 12 respondents completing the retest. The Pearson correlation coefficient for test-retest reliability was 0.63, prompting minor adjustments to question structures for the final version.

Survey Distribution

The anonymous web-based BIT survey was distributed to GPs located in southwest England between March and May 2023. We contacted GPs through email and social media (Twitter and Facebook), as well as through the Royal College of General Practitioners, the British Medical Journal, GP magazine, Pulse magazine, Local Medical Committees, "GP online," "eLearning," "GP survival," and Somerset GP Education. An introductory email, including the survey or a request to share it, was sent to the managers of these groups, explaining the purpose of the research. The survey was only distributed if the group managers agreed to facilitate its circulation.

The survey for Swedish GPs was distributed between March and May 2022 to managers at the same 160 primary health care centers in southern Sweden as in the 2019 survey.

Statistics

Given the small English sample size (n=52) that limited the power of the study, analyses were exploratory. Likert scale responses were converted to numerical scores, and demographic responses were coded accordingly. Likert scale scores ranged from 1 to 7, where 1 represented "not at all," "harmful," "bad," "unpleasant," or "useless," and 7 represented "to a great extent," "beneficial," "good," "pleasant," or "useful."

We converted respondents' years of practice into 3 categories (<15 years, 15 - 29 years, and ≥30 years). For each respondent and topic, we calculated the mean intention scores from questions 17 and 18, covering email and/or online chat, video consultation, and digital tools for chronic disease monitoring.

We also calculated scores for the core concepts of the TPB that influence behavioral intentions. This included mean scores for subjective norms (questions 15 and 16), perceived behavioral control (questions 12 to 14), and attitudes (questions 6, 8, and 11). Self-reported current use of telemedicine included using different digital tools (email, chat, and video). Data were analyzed using SPSS (version 28.0; IBM Corp). Descriptive statistics were generated separately for English and Swedish GPs across the various outcomes. Group differences between English and Swedish GPs were tested using the 2-tailed Student *t* test.

To explore the association between predictor scores and behavioral intentions to use telemedicine among English and Swedish GPs, we performed a split-sample multiple regression analysis.

Data analysis followed a consistent approach for both the English and Swedish surveys, with one exception: in the Swedish survey, respondents could select "I don't know" for Likert scale questions. These responses were categorized as "Not Applicable" during the analysis.

Ethical Considerations

The English ethical review was conducted by the University of Exeter Medical School's Research Ethics Committee. Ethics approval was granted by the review board in March 2023 (845606). The study was carried out in accordance with the Declaration of Helsinki (Fortaleza, Brazil, October 2013), the UK Policy Framework for Health and Social Care Research (2020), and the general principles of Good Clinical Practice E6 (R2). Data storage complied with UK General Data Protection Regulation requirements and was securely maintained within the University of Exeter database. The study was deemed to pose no risk and did not involve the collection of any personal, health, or sensitive data.

The Swedish Ethical Review Authority provided an advisory statement confirming that, according to the Swedish Ethical Review Act (SFS 2003:460), ethical vetting was not required for this type of study because it involved anonymous data and did not inquire about participants' own health or other sensitive topics. The statement provided by the Swedish Ethical Review Authority in November 2018 states the following: "In accordance with current ethical and data-protection standards, the project does not require formal ethical review, as no personal data are processed and the information utilized cannot be linked to identifiable living individuals. Should it later become evident that personal data are involved, only the processing of sensitive personal data—such as information pertaining to racial or ethnic origin, political opinions, religious or philosophical beliefs, trade union membership, or data relating to health or sexual life—would necessitate formal ethical approval."

All participants who returned questionnaires provided informed consent to participate in the study. No monetary compensation was offered to the participants.

Results

We received 52 responses from English GPs and 101 responses from Swedish GPs. The demographics of the respondents varied significantly between the two groups (Table 1). The mean age

XSL•FO
RenderX

of English GPs was 51.2 years, compared with 47.8 years for Swedish GPs.

Table . Demographic characteristics of respondents.

Characteristics	English GPs[a] (n=52), n (%)	Swedish GPs (n=101), n (%)
Gender		
Women	37 (71.2)	51 (50.5)
Men	15 (28.8)	48 (47.5)
Nonbinary	0 (0.0)	1 (1.0)
Training in telemedicine		
Yes	17 (32.7)	37 (36.6)
No	35 (67.3)	64 (63.4)
Practice (years)		
<15	8 (15.4)	57 (56.4)
15 - 29	23 (44.2)	36 (35.6)
≥30	21 (40.4)	8 (7.9)

[a]GP: general practitioner.

Gender distribution also differed, among 52 English GPs, 15 (28.8%) identified as men and 37 (71.2%) as women, while among 101 Swedish GPs, 48 (47.5%) identified as men and 51 (50.5%) as women.

Regarding telemedicine training, 17 (32.7%) English GPs reported having received such training, compared with 37 (36.6%) Swedish GPs. Additionally, English GPs had more years of practice on average than their Swedish counterparts.

Swedish GPs had significantly (P<.001) higher intentions to use email and/or online chat, video consultations, and digital tools to monitor chronic diseases compared with their English counterparts (Table 2).

The theoretical predictors of behavior derived from the TPB revealed significant differences between English and Swedish GPs, with Swedish GPs scoring higher for both intentions and predictors of behavioral intentions to use telemedicine (Table 3).

Table . Comparison of intentions to use different telemedicine tools between English and Swedish general practitioners (GPs).

Topics	English GPs (n=52), mean (SD)	Swedish GPs (n=101), mean (SD)	*P* value
Email and/or online chat	3.6 (2.3)	4.9 (1.8)[a]	<.001
Video consultation	2.8 (1.9)[b]	4.7 (2.0)[c]	<.001
Digital tools to monitor chronic diseases	4.3 (1.9)	5.6 (1.8)[d]	<.001

[a]n=99.
[b]n=50.
[c]n=100.

[c]n=99.

XSL•FO
RenderX

Overall, the self-reported use of telemedicine was low among both English and Swedish GPs (Table 4). However, the mean scores for self-reported current use indicated that English GPs were significantly more likely to use email and/or online chat (P=.006). There were no significant differences between the two groups regarding the use of video consultations (P=.76) or digital tools for monitoring chronic diseases (P=.73).

For both English and Swedish GPs, significant associations were observed between attitudes, perceived behavioral control, and intentions to use telemedicine (Table 5). The model had a higher explanatory power for the English GPs (R^2=0.664) than for the Swedish GP (R^2=0.258). However, given the modest sample sizes, particularly in the English cohort, the multivariable regression analyses should be interpreted cautiously as they may be underpowered to detect smaller effect sizes.

Table . Self-reported current use of email and/or online chat, video consultations, and digital tools for chronic disease monitoring among English and Swedish general practitioners (GPs).

Tools	English GPs (n=52), mean (SD)	Swedish GPs (n=101), mean (SD)	*P* value
Email and/or online chat	2.2 (1.2)	1.7 (1.0)	.006
Video consultation	2.0 (1.5)	1.9 (1.3)[a]	.76
Digital tools to monitor chronic diseases	2.2 (1.7)[b]	2.1 (1.6)[c]	.73

[a]n=96.

[b]n=50.

[c]n=98.

Table . Split sample multiple regression analysis with intention scores from English and Swedish general practitioners (GPs) as dependent variables.

Predictors[a]	Intentions of English GPs[b]		Intentions of Swedish GPs[c]	
	U-B[d] (95% CI[e])	*P* value	U-B (95% CI)	*P* value
Subjective norms	0.082 (−0.139 to 0.303)	.46	0.042 (−0.174 to 0.258)	.70
Attitudes	0.783 (0.453 to 1.113)	<.001	0.4 (0.124 to 0.676)	.005
Perceived behavioral control	0.497 (0.141 to 0.853)	.007	0.52 (0.244 to 0.796)	<.001
Constant	−1.58 (−2.765 to −0.387)	.01	0.451 (−1.303 to 2.204)	.61

[a]R^2 indicates the proportion of variance in the dependent variable (intention to use telemedicine) explained by the independent variables (attitudes, subjective norms, and perceived behavioral control).

[b]R^2=0.664.

[c]R^2=0.258.

[d]U-B represents the unstandardized B value, testing whether the coefficient is equal to zero.

[e]The 95% CI reflects the range within which the true B value is likely to fall.

Discussion

Principal Results

A major finding in this study is the low self-reported use of telemedicine among both English and Swedish GPs, even after the COVID-19 pandemic. Practitioners from both countries also reported limited training in telemedicine. Despite this, Swedish GPs demonstrated significantly higher mean scores for intentions to use telemedicine in daily practice compared with their English counterparts. More positive attitudes and greater perceived behavioral control were significantly associated with higher behavioral intention scores among both English and Swedish GPs. In addition, the consistently low levels of reported training in both countries suggest that insufficient training may itself be an important contributor to lower intentions to use telemedicine, underscoring the need for more structured educational efforts.

Strengths and Limitations

A major strength of this study is the use of a validated, theory-based questionnaire (PAIT), adapted and applied in both Swedish and English primary care contexts. The questionnaire was developed based on the TPB framework and had previously been validated among Swedish GPs, demonstrating strong internal consistency and construct validity. The English version, adapted for the UK health care setting, underwent a translation and back-translation process, ensuring linguistic equivalence and conceptual accuracy. This adaptation enhances the study's ability to compare findings between English and Swedish GPs while maintaining methodological robustness.

Another strength lies in the use of theory-based survey items that have been previously used in other primary care studies, ensuring that the measured constructs are relevant and reliable. The exclusion of questions related to AI, which had shown limited relevance in the original Swedish survey, further streamlined the questionnaire for the UK primary care context.

XSL•FO
RenderX

However, the study has several limitations. The small English sample limits generalizability, so the findings should be considered exploratory. Future studies should recruit larger samples. One key limitation is the difficulty in estimating the response rate due to the recruitment methods used. As the survey was distributed through various GP networks and professional organizations, the total number of GPs who received the invitation remains unknown. Consequently, it is not possible to draw firm conclusions regarding the generalizability of the results.

Additionally, the sample of English respondents was not fully representative of the national GP population. Of the English participants, 71.2% (37/52) were female, compared with 57% of the GP workforce in England as of May 2023. This overrepresentation of female GPs may have introduced bias in the findings.

Another limitation was the challenge of identifying the specific GP groups that responded to the questionnaire. The distribution method involved contacting GP organizations and networks across southwestern England, with responses collected anonymously. While anonymity is crucial for encouraging honest responses, it also means that duplicate responses could not be detected. Nevertheless, given the time constraints faced by GPs and the voluntary nature of participation, the risk of duplicate responses is believed to be very low.

Comparison With Prior Work

The low self-reported use of telemedicine in this study is an interesting finding, despite expectations of increased use after the COVID-19 pandemic. One explanation might be that, during the COVID-19 pandemic, practices had a vital role in providing physical contact to organize and manage accurate diagnostics [18] with the purpose of avoiding hospitalization.

Our study shows that Swedish GPs had significantly higher mean scores for predictors and behavioral intentions to use telemedicine compared with English GPs, which might have several explanations. Since 2014, patients in all geographic areas in Sweden have been broadly introduced to video consultations mainly through private health care providers of digital care, leading to substantially increased costs for the regions, raising concerns regarding accessibility, inequity of care, continuity of care, and effective resource use [2]. Today, video consultations, chat-based digital tools, and a national digital contact platform are available across most Swedish regions. Many private digital health care providers have also acquired previously established primary care centers, offering integrated “digi-physical” care.

While the United Kingdom has made significant progress in health care IT, it faces ongoing challenges related to interoperability, adoption, and funding. Although access to telemedicine and digital services is improving, it remains inconsistent across regions, potentially influencing English GPs’ lower intentions to adopt telemedicine. In contrast, Sweden has developed a more integrated health care IT system with higher levels of telemedicine use, prioritizing patient convenience and accessibility.

Other Swedish studies have shown positive attitudes toward telemedicine in primary care, reporting that medical staff seem to appreciate the flexibility of working in a digital context [19], but few consider this a full-time career option [4]. While psychologists report higher intentions to use video consultations compared with physicians and nurses in a similar theory-based survey [15], physicians stress the need for evaluation of telemedicine tools regarding clinical usefulness, patient safety, and involvement of end users in the implementation process [13]. There are few studies discussing English GPs’ intentions to use telemedicine, with similar findings [3,7]. In this study, English GPs responded with low intentions to use telemedicine and little self-reported experience and training on the topic. Telemedicine and its use have been widely debated recently, regarding the practical benefits and setbacks and the optimal methods to achieve adoption [1,20]. Greenhalgh et al [26] discuss the importance of the correct adoption method of telemedicine to remain considerate of both GPs and patients, to maximize the benefits of telemedicine and minimize the setbacks.

Telemedicine appears to have a significant positive effect on many challenges that primary care faces today, such as accessibility or increased patient-centeredness [27]. There is therefore a need for a validated and efficient method of testing GPs’ intentions of using telemedicine to understand predictors of behavioral intentions and allow successful implementation.

Implications for Research and Practice

Before a more positive attitude toward the use of telemedicine can develop, it is essential to have seamless integration of telemedicine platforms with existing health care systems; comprehensive training for GPs and staff to use telemedicine tools effectively; access to remote diagnostic devices (eg, digital stethoscopes and blood pressure monitors) for patients to use at home; and increased funding for telemedicine infrastructure and services. GPs need to be involved in the development and refinement of telemedicine systems to ensure that the tools meet their needs. A cultural shift is unlikely to occur until skepticism among GPs has been addressed by promoting telemedicine’s ability to enhance accessibility and reduce unnecessary in-person visits.

The method of this study could be used for further studies either in England among English GPs or in other English-speaking countries, or it could be translated and used in other countries to strengthen the knowledge of GPs’ intentions to use telemedicine. This could help better understand the demand and benefits of certain telemedicine adoption methods in either local or global implementation structures and provide a better understanding of simple intentions. Future studies with larger and more representative samples should include training as a formal predictor of behavioral intentions, given its potential relevance for shaping GPs’ intentions to adopt telemedicine.

Conclusions

This study showed that English GPs reported lower intentions to use telemedicine compared with Swedish GPs. Practitioners from both countries also had little training in telemedicine. The behavioral intentions to use telemedicine among both English

XSL•FO
RenderX

and Swedish GPs were mainly influenced by attitudes and perceived behavioral control. The PAIT questionnaire provided valuable insights into similarities and differences between English and Swedish GPs regarding attitudes, behavioral intentions, and self-reported telemedicine use. The PAIT could serve as a useful tool for cross-country comparisons of telemedicine adoption, enabling assessments of attitudes, intentions, and perceived behavioral control across health care systems and jurisdictions. This potential is further enhanced by the recent translation of the PAIT survey into Latvian and Turkish languages by collaborating researchers, broadening its applicability for international studies.

Acknowledgments

The authors would like to thank the master's student Oliver Ras attending the medical school at the University of Exeter who translated the Swedish survey into the English context and distributed the survey to the English general practitioners. The authors are also thankful to the Swedish and English general practitioners who answered the surveys.

Abstract

Background: Social media is one of the most accessible and extensive sources of data for tracking and understanding public reactions to COVID-19 policies. Cultural differences between the United States and Japan have resulted in highly distinctive policies and public reactions in each country.

Objective: This study aims to analyze the public opinions surrounding COVID-19 mask mandate through 1,102,876 and 560,873 geo-tagged tweets from the United States and Japan during the period from 2020 to 2022. We conducted 3 stages of analysis—relevance to COVID-19 masks, stance for or against masking, and whether the tweets indicate users wearing masks—to understand individuals' stance towards the mask mandate and their actual mask-wearing behavior.

Methods: We adopted a semisupervised approach to enhance BERT (Bidirectional Encoder Representations from Transformers) classification results due to data imbalance, which were then visualized through time series and map representations.

Results: In the United States, our data showed that individuals with a bachelor's degree or higher, as well as those living in states with higher household incomes, are positively correlated with positive attitudes toward mask-wearing. In contrast, in Japan, those with higher education levels or individuals aged 65 years and older were positively correlated with tweets categorized as having a stance against the mask mandate. Key events in Japan, such as the announcement of the state of emergency and the Olympics, served as major triggers for the number boost in public opinion.

Conclusions: Our analysis of over 1.6 million tweets from the United States and Japan revealed that public opinion shifted notably in response to major events and policy changes during the COVID-19 pandemic. While some trends align with previous research, correlations with education, age, and income suggest that social media data may reflect underlying societal divisions and algorithm-driven biases.

Introduction

Countries around the world have adopted a diverse strategy for managing the COVID-19 pandemic, as summarized in the government responses index in 2020 when COVID-19 first impacted the globe [1]. The implementation of different types of policies by countries is influenced by various factors, including demographics and geographical considerations. Among the measures taken to curb the spread of the disease, the mask mandate is recognized as one of the most widely adopted policies in several countries. Early in the pandemic, the Centers for Disease Control and Prevention (CDC) advised people in the United States to wear masks as a preventive measure [2], which was also adopted in a few other countries [3]. While the Japanese government did not mandate mask-wearing, its population had already been accustomed to wearing masks even before the COVID-19 outbreak, during the pandemic, and after [4].

The comparison between the United States and Japan is a frequently studied topic among researchers due to cultural contrasts and variations in Western and Eastern societal conventions [5,6]. Cultural views also contributed to how people in the 2 countries reacted differently as a response to health

XSL•FO
RenderX

policies during the pandemic [7]. During the COVID-19 outbreak, both countries displayed contrasting attitudes regarding policy creation to control the spread of the disease and adhere to mask mandates. Undoubtedly, the vast number of social media posts is often viewed as a valuable resource for comprehending, analyzing, and even informing policymakers about societal perceptions or attitudes toward an occurrence. However, a significant obstacle for cross-cultural comparison studies is handling data from multilingual social media data. From the process of data labeling, classification, and processing, the differences between the characteristics of the 2 languages might provide interesting results to be analyzed.

Social media serves as a cost-effective and accessible alternative for assessing public responses in addition to surveys [8]. Changes in people's behavior during pandemics can be observed on social media platforms like X (formerly Twitter), as demonstrated during the 2009 H1N1 pandemic [8,9] and the COVID-19 pandemic [10]. X reflects real-time insights into individuals' reactions [11,12], making it a convenient yet highly sensitive tool for assessing the risk associated with events or interventions that may have downstream effects on policy-making and implementation [13,14]. Social media might also show declining sentiment on topics related to COVID-19 restrictions throughout the pandemic, as described in the results of a study using tweets in the 3 cities in the United States [15]. Other than previously mentioned studies, the content from social media posts, such as tweets, can also be used to assess possible outbreaks by using tools such as large language models [16].

The debate surrounding masking has generated one of the most widely discussed topics throughout the pandemic, which could be clearly traced and documented on X posts [17]. Previous studies using location information in X have been conducted, such as to predict the prevalence of ZIKV cases in the United States by filtering tweets [18]. The studies used a bounding box as the boundary of the observed area, excluding tweets from Canada and Mexico. Spatial mapping shows similar patterns observed across the United States. Another study also uses geotagged tweet data, covering discussions about the #MeToo movement in the United States [19]. The results show further discourse about the movement, including the descriptions of abuse often related to the case. These existing studies suggested that geotagged tweets might provide information about ongoing social media discussions in a certain area.

This study aims to compare the discussion about masking in COVID-19 between the United States and Japan on social media and its changes throughout the pandemic stages. In the COVID-19 period, the 2 countries have different approaches to the response to the pandemic, resulting in different policies and rules. This difference was also reflected in how people responded, which can also be seen on social media. Mask-wearing, as one of the policies during COVID-19, generates a lot of discussion among the public. Some are supporting, and some are against mask-wearing. Despite their small number, people who did not want to wear masks are a vocal minority in sharing their opinion [20]. Due to all those differing opinions, while mask-wearing is indeed an important effort to mitigate the spread of COVID-19, there are still many debates about the necessity of masks [14,21]. A geographical focus in the analysis was also interesting to explore, as a survey showed that mask-wearing as a public health behavior might exhibit spatial heterogeneity, suggesting a different approach in the area based on country-level analysis in the United States [22].

In this study, we discussed the public opinions surrounding the COVID-19 mask mandate through geo-tagged tweets from the United States and Japan during the period from 2020 to 2022 in 3 stages of analysis: starting from its relevance to COVID-19 masks, stance for or against masking, and whether the tweets indicate users wearing masks. By discussing the factors and correlation of the observed tweets, we aim to understand individuals' stance towards the mask mandate and their actual mask-wearing behavior.

Methods

Ethical Considerations

This study did not require participants to be involved in any physical or mental intervention. This research also did not use personally identifiable information, thus exempted from institutional review board approval in accordance with the Ethical Guidelines for Medical and Health Research Involving Human Subjects stipulated by the Japanese national government.

Data

The data in this study consists of geo-tagged tweets collected between January 1, 2020, and December 31, 2022, using Academic Research Access (discontinued in mid-2023). This dataset comprised 1,102,876 English tweets and 560,873 Japanese tweets. Note that we used the same dataset as our previous study on multilanguage data annotation [23]. Examples of paraphrased tweets showing their opinion about mask-wearing are shown in Textbox 1.

XSL•FO
RenderX

Textbox 1. Example of tweets in English and Japanese.

English:

- Against: Wearing this mask at work is exhausting. I'm sweating like crazy even from the smallest tasks.
- Not against: Unexpected perk of wearing a mask: it keeps your face nice and warm in freezing weather! \#MaskUp \#StayWarm \#WinterHack

Japanese:

- Against: 普段あまりこういうことは言わないようにしてるけど, どうしてまだみんな外でマスクをしてるの？室内でも特に必要とは思えないし, もう外してもいいんじゃないかな, 本当に。 (I usually try not to say things like this, but why is everyone still wearing masks outside? I don't really see the need for them indoors either. Isn't it okay to stop wearing them already? Honestly.)
- Not against: それに, マスクをしていない人の割合もかなり高め。ちょっと気が緩みすぎてない？ (Besides, the number of people not wearing masks is pretty high. Aren't people getting a little too careless?)

Demographic data were accessed from the Portal Site of Official Statistics of Japan [24] and Census Bureau data of the United States [25], obtained from the 2020 census. Previous studies have indicated that demographic characteristics such as sex, ethnicity, age, marital status, and employment status affect participation in preventive behaviors in the United States [26]. In this study, we focused on several demographics for population characteristics at the state/prefecture level: total population, population by age, education level, information on foreign members/race, and income (Table 1). For Japan, the education level was obtained from the number of employed persons aged 15 years and older.

Table . Demographics variable used in correlation calculation.

Demographics	Variable
Population[a]	• Total population • Population of working age[b] • Population of elderly (older than 65 years)
Education level[c]	• Population completed bachelor or higher
Income	• Household income
Race information	• Race index (the United States), Number of foreign residents (Japan)

[a]Total population from 2020 census.

[b]Percentage of people aged 18 - 64 years (the United States) and 15 - 64 years (Japan).

[c]Percentage of people completed bachelor or higher from population aged older than 25 years (the United States) from American Community Survey (2021) and population of employed person aged older than 15 years (Japan) from 2020 census.

Preprocessing of Tweets

The first preprocessing step involved validating each tweet's location tag. Given the various types of location information in geo-tagged tweets, we focused on city-level information found in the "full-name" entity of the tweets. Instances where the geo-tagged location did not match the city lists in the United States and Japan were removed [27,28]. Next, we applied basic preprocessing steps, including changing usernames to common handles, addressing links, converting emojis to text, and removing duplicates and NAs.

Finally, we ensured that the tweets contained the keyword "mask" for English tweets and "マスク" (mask in Japanese) for Japanese tweets. In some cases, these keywords appeared as usernames or links, providing insufficient information or relevance to the topics and were thus eliminated in the process.

Data Annotation

The annotation for our 1100 pairs of tweets was done by 4 annotators, 2 for each English and Japanese. We used Cohen kappa as the measure to evaluate interannotator agreement between annotators [29] and interpret the agreement results [30]. The complete detailed approach and evaluation are explained in Ferawati et al [23]. To combine the annotated label between the annotators, we assigned the agreed label as the final label and assigned the disagreed label as not relevant, not against, and unknown for each stage.

Classifier Training

X studies often use human annotators with the aid of machine learning classifiers [31,32]. We designed a multilingual guideline to obtain a suitable data annotation for this study [23]. The results of the annotation show a case of imbalanced data, with one category having a much smaller number of tweets compared with another. However, due to the time and resources required for human annotation, it is not practical to annotate a large number of tweets. To address this issue, we propose a semisupervised approach by using the BERT (Bidirectional Encoder Representations from Transformers) score from BERT-based classification method as additional data for training. By including additional training sets from predicted tweets, we hope to improve the performance of the classifier to

XSL•FO
RenderX

solve the cases, especially in public perception and attitudes for COVID-19 masking in the 2 countries.

An existing study explained that BERT surpassed traditional machine learning algorithms, such as Logistic Regression, Support Vector Machine, Random Forest, and Naive Bayes, where BERT was supported by its ability to understand contextual information appearing in social media [33]. BERT was also widely used to analyze and derive conclusions. Based on the results of these studies, we decided to use BERT-based models for our study. We trained the annotated datasets using BERT-based classifiers, RoBERTa base model [34] for English tweets and BERT base Japanese [35] for Japanese tweets. To evaluate the models, we set aside 15% of the annotated data as the test set and applied 5-fold cross-validation to the remaining data. The final model was selected from the fold with the best results on the test set, evaluated using F_1-macro to address data imbalance.

Due to the limited number of annotated data, we included all 1100 annotated tweets. For each language, tweets annotated with the same categories by both annotators were assigned to those categories. In cases of conflicting annotations—for example, where annotator 1 marked a tweet as not relevant while annotator 2 marked it as relevant—we categorized the tweet as not relevant. The same approach was applied for the stance stage (categorized as unclear, then assigned to not against) and mask-wearing (categorized as unknown).

Semisupervised Approach

We observed an imbalance in the categories of our annotated data, which likely contributed to the low performance of our models. Due to constraints in obtaining additional annotated data, we implemented a semisupervised approach for the stance and mask-wearing stages of the tweets. The semisupervised approach was a common measure taken to obtain more annotated data without a significant increase in annotation costs [36]. In this study, we stored the BERT outputs from the predictions and filtered them based on determined thresholds for each category. We considered 2 methods of adding pseudo-labeled data: adding an equal number of tweets to both categories and adding tweets only to the minority category. Using softmax-transformed values of the BERT output for each class, we selected a set of data to be added to the training. The objective for implementing the approach is to obtain labels with a higher confidence from the obtained softmax-transformer values as an additional sample for training. We maintained the chosen split of training and validation from the previous step in classifier training.

The selected tweets from this step were then included as additional training data using the same parameters and model as in the previous subsection. The data for validation and testing remained the same as the baseline. We experimented with several combinations of thresholds for each class in each stage (against and not for stance; no, yes, and unknown for mask-wearing), while endeavoring to keep the number of selected additional tweets balanced. When determining the threshold value for the selection, we selected a certain value to balance our objectives: retaining sufficient confident predictions for the reliability of our pseudo-label and having enough additional samples to meaningfully expand our dataset. The threshold was set by observing the transformed BERTScore from the prediction results, plotting them into a histogram with the aid of descriptive statistics of the score to determine the appropriate threshold for filtering. We then compared the results of each training.

Correlation

We calculated the correlation between the predicted percentages and demographic data from the 2 countries, the United States and Japan, using Pearson correlation. In this study, we considered 3 levels of significance for the P values with a significance level of .05, .01, and .001.

Results

Interannotator Agreement

For the annotation phase, we used only a subset of the entire dataset. Considering the reasonable workload of our annotators, we selected 1100 tweets from each language, as reported in another publication focusing on the annotation of a multicultural dataset [23]. Although the agreement levels for stance and mask-wearing stage are still less than <0.60—a score that was categorized as moderate by Cohen (1960) [29] but inadequate by McHugh (2012) [30]—they are deemed acceptable for our study (Table 2).

Table . Cohen kappa for the annotation results. The percentage in each round shows the number of samples annotated. The agreement is calculated for each round and each part of the samples.

Stage	Language	
	English	Japanese
1: Relevancy	0.79	0.92
2a: Stance	0.46	0.59
2b: Mask-wearing	0.55	0.47

The number of tweets varies substantially across the country, with certain states or prefectures having far more tweets than others. The difference in number is primarily observed in densely populated areas, such as the capital or popular destinations. Among tweets identified as relevant to COVID-19, California leads the United States in mask-related discussions, while Tokyo tops the list in Japan. A list showing the top and bottom tweet counts for states (in the United States) and prefectures (in Japan) is provided (Table 3).

XSL•FO
RenderX

Table . Top and bottom 3 of tweet counts in the United States and Japan.

Ranking	United States		Japan	
	State	Tweet count	Prefecture	Tweet count
Top 3				
	California	113,148	Tokyo	85,836
	Texas	75,517	Kanagawa	27,737
	New York	60,317	Osaka	26,725
Bottom 3				
	Vermont	1314	Kochi	1197
	North Dakota	1079	Tottori	1149
	Wyoming	776	Shimane	1049

Classifier Training

We fine-tuned roberta-base and bert-base-japanese-v3 with our annotated tweets to predict the rest of the data, a method commonly used for social media data [37,38]. We trained the classifier using this annotated data and then used it to predict the remaining tweets. The parameters for our final model used the AdamW optimizer, with a batch size of 32, 10 epochs with early stopping callback, learning rate of 0.00002, and weight decay of 0.01.

We used the entire sample of 1100 tweets for relevancy classification (Table 4). In the first stage of relevancy classification, we achieved the highest F_1-macro scores for both English and Japanese texts compared with the majority baseline. However, the stance and mask-wearing stage did not yield similar results, showing only a marginal increase from the majority baseline. This indicates that the models are still unable to correctly predict the minority categories. These results also mirror the annotation results, where annotators struggled to achieve higher interannotator agreement.

Table . Results of BERT (Bidirectional Encoder Representations from Transformers)-based classifier. Only tweets annotated as relevant by both annotators are included as a sample for Stage 2a: Stance and Stage 2b: Mask-wearing. As the category is heavily imbalanced for all the stages, we calculated the majority baseline by assigning majority classes as the predicted category in each stage: relevant for relevancy, not against for stance, and unknown for mask-wearing.

Stage	Language	Number of samples, n	Majority baseline	F_1-macro
1: Relevancy				
	English	1100	0.44	0.78
	Japanese	1100	0.39	0.75
2a: Stance				
	English	880	0.47	0.61
	Japanese	706	0.45	0.69
2b: Mask-wearing				
	English	880	0.31	0.31
	Japanese	706	0.29	0.40

Semisupervised Approach and the Final Classifier

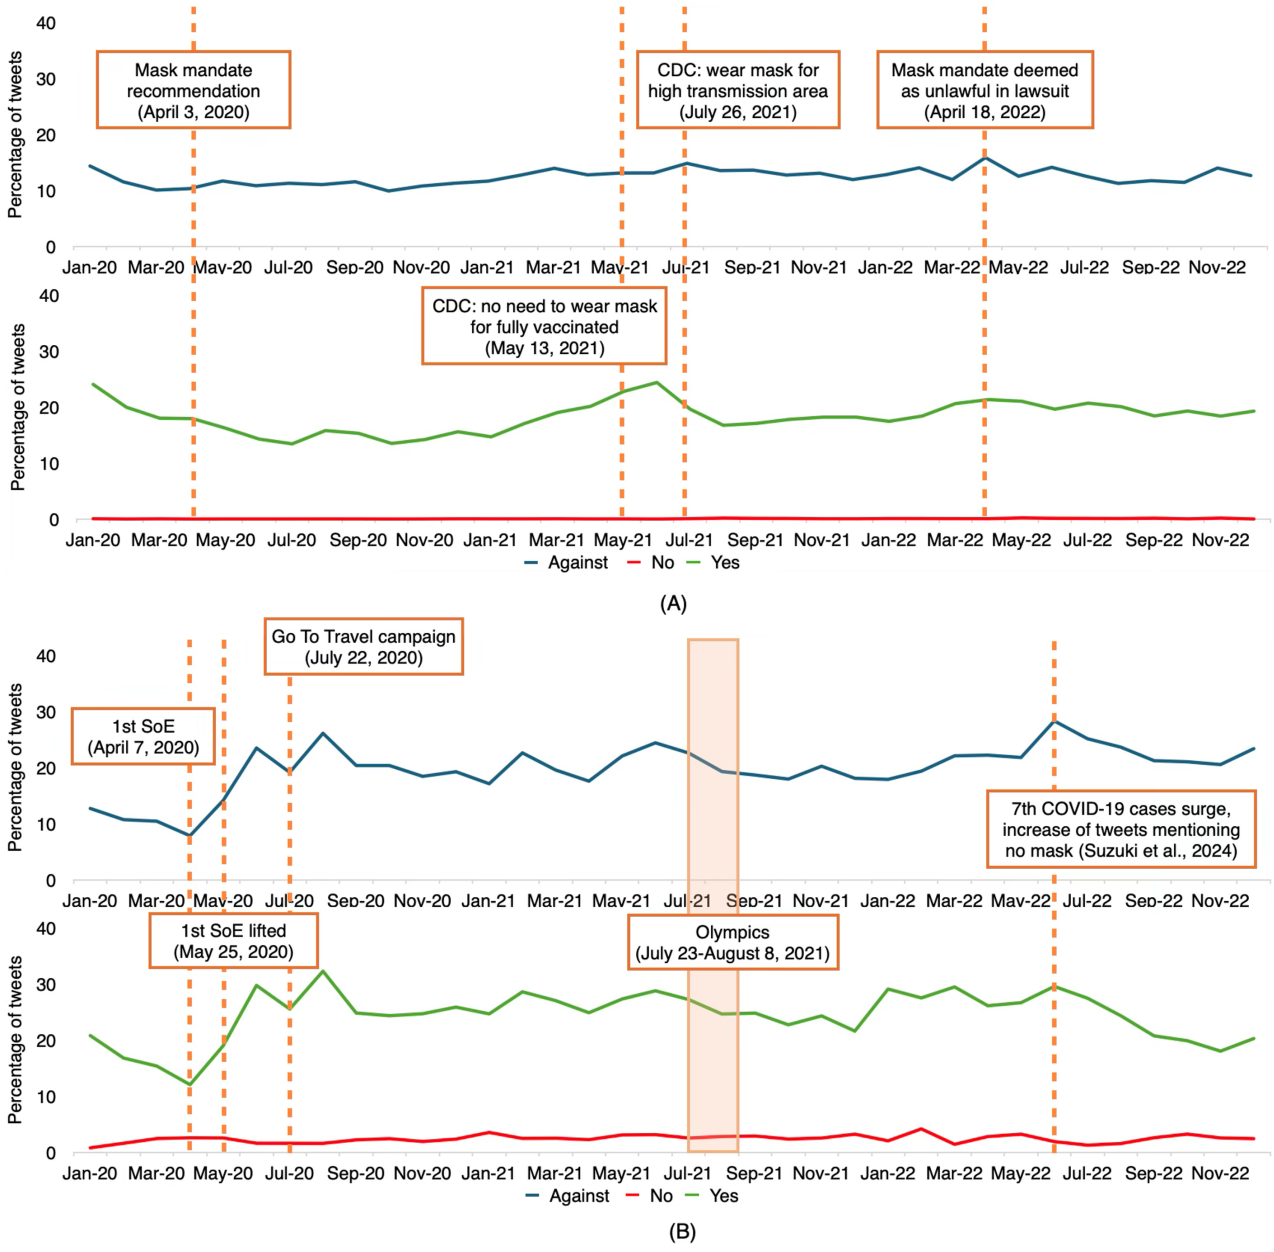
By adopting a semisupervised approach to train our classifier, we were able to improve second-stage F_1-scores that were nearly as high as those from the first stage—0.68 for English tweets and 0.72 for Japanese tweets.

Based on the results for the stance stage, the chosen threshold with a more balanced number of tweets in each category (eg, an additional 650 in the "against" category, bringing the total to 755 "against" and 775 "not against" for English data) achieved a better F_1-macro score than other alternatives.

When it comes to classifying mask-wearing behavior, maintaining a balanced sample for re-training is challenging due to the imbalance of labels in the annotated data. In English tweets, only 46 tweets were predicted as "not wearing mask" out of the entire dataset, so we included all the predicted tweets in the model. The best result was an F_1-score of 0.487, a substantial increase from the previous score of 0.301 with the original annotated data. For Japanese tweets, our best model only yielded an F_1-score of 0.48.

For the mask-wearing stage, the distribution of BERT score outputs was much more skewed than for stance in both languages. Because it was challenging to maintain balanced numbers for each category, we experimented with various threshold combinations to assess performance. Due to the difficulty in balancing the numbers, the improvement in the

XSL•FO
RenderX



model performance seems rather limited. Therefore, it should be considered the best our classifiers could achieve and is acceptable to be used in our following tasks.

The final classifier model was trained on a combined dataset of the original annotated data and the semisupervised data. The remaining tweets were classified using the final model. We deemed the F_1 -score from the previous semisupervised results acceptable for our study and used it as a basis for generating a map of stance toward the mask mandate and actual mask-wearing behavior from related tweets in the United States and Japan, using both English and Japanese tweets.

Time Series Observation of the Classification Results

The tweets were collected over a 3-year period, capturing the trend from early, peak, to post-peak periods of the COVID-19 pandemic. Throughout this time, various events and policies occurred, potentially influencing tweet volume and content (Figure 1). In the figure, no observable trend in the stance against COVID-19 masking is evident in the United States, suggesting little change in people's opinion about mask-wearing from early 2020 to the end of 2022. Both countries show a decreasing trend in tweets against masking from January 2020 to April, followed by an upward trend after relevant departments released recommendations about mask-wearing.

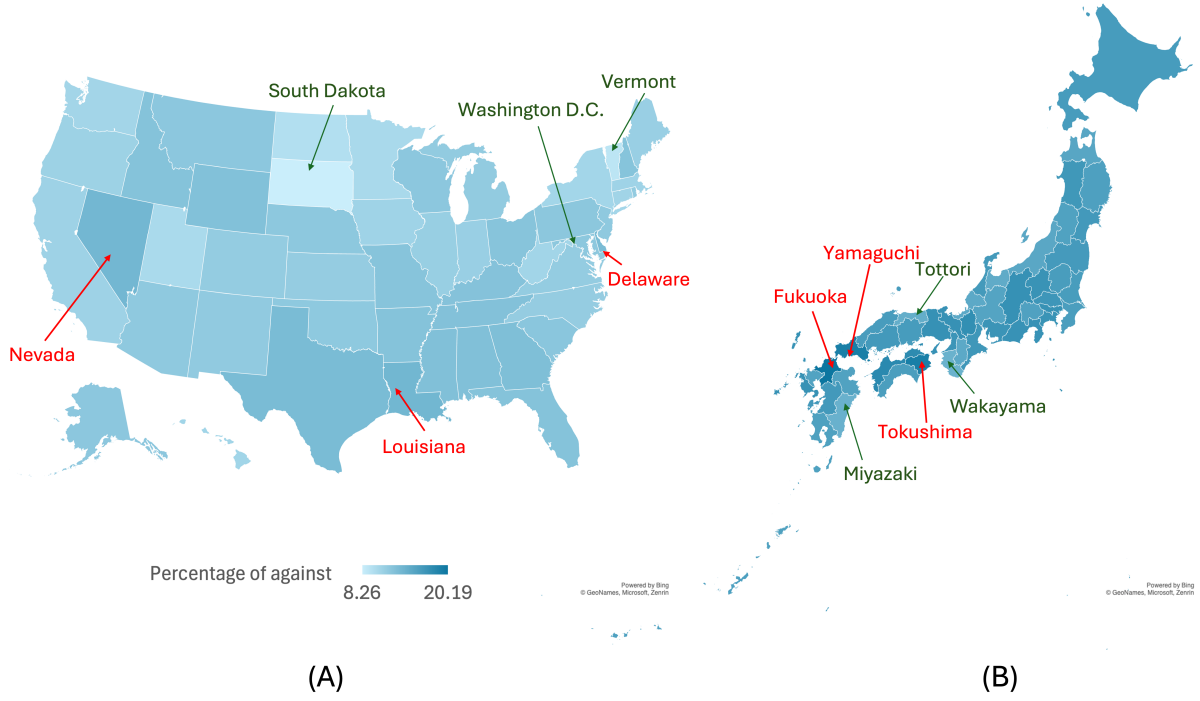
Figure 1. Time series plot of tweets against masking in (**A**) the United States and (**B**) Japan. Some events and policies happening throughout the period are highlighted in the figure. The upper part of the graph shows the percentage of tweets against mask-wearing, while the lower part shows tweets mentioning users wearing a mask (green) and not wearing a mask (red) [39]. CDC: Centers for Disease Control and Prevention; SoE: state of emergency.

Throughout the observed period, the CDC released several guidelines on the utilization of masks as a preventive measure. They initially mandated the use of masks in April 2020 and later revised the recommendation after the development of vaccines, such as lifting the recommendation to wear masks for fully vaccinated individuals in May 2021. In the month

XSL•FO
RenderX

following CDC's revision of their mask-wearing guidance to no need to wear a mask if vaccinated, tweets classified as "not wearing mask" reached their lowest point, while tweets classified as "wearing mask" peaked (Figure 1). Subsequently, the CDC released another recommendation to wear masks in high-transmission areas in July 2021, which is reflected in interesting changes observed in the time series plot of mask-wearing stages. The number of tweets indicating "not wearing mask" substantially increased from 0.03% in June 2021 to 0.21% in August 2021, while tweets about "wearing mask" saw a decrease from 24.41% in June 2021 to 16.76% in August 2021. In April 2022, as a result of a lawsuit regarding mask mandates deemed unlawful in Florida, nationwide mask mandates for airplanes and public transportation were no longer enforced [40]. As shown in Figure 1A, in the same month, a peak was observed in the stance against mask mandates in the United States, and tweets classified as "not wearing mask" peaked a month after the ruling, observed in May 2022.

In Japan, there are 3 noticeable fluctuations in the figure, closely related to COVID-19 policies. We observed some significant changes when the government announced a state of emergency (SoE) in April 2020 and subsequently lifted it in May 2020. After a dip in the percentage of tweets expressing a stance against masking after the first SoE in April 2020, the first peak appeared a month after the first SoE was lifted. These fluctuations are also consistent with findings from another study on responses to COVID-19 waves in Japan [41]. Another study discussed that there are indeed signs of disruptions due to COVID-19 in X, which shows top concerns during the SoE period and some impacts of the pandemic on societies in Japan [42]. The second peak appeared at the beginning of the Olympics. The Tokyo Olympics, held from July 23 to August 8, 2021, also influenced the observed changes in the figure. Before the Olympics began, in June 2021, there was a slight increase in tweets expressing a stance against mask-wearing, as shown in Figure 1B. The third peak appeared in June 2022, coinciding with the 7th surge in COVID-19 cases and an increase in "no mask" tweets, as observed by Suzuki et al [39].



Map Comparison

Tweets Against Masking

The final classifications from the selected model were presented in the form of maps, depicting the percentage of tweets classified as against mask-wearing in the United States (at the state level) and Japan (at the prefecture level). Table 3 reveals a significant discrepancy in tweet frequencies between states and prefectures. For instance, California has over 100,000 relevant tweets, while other states like Wyoming have fewer than a thousand tweets. Similarly, in Japan, Tokyo, the capital, has the highest number of relevant tweets, with over 85,000, while Tottori has the fewest tweets, with approximately 1000.

In the United States, Louisiana, Nevada, and Delaware were the 3 states with the highest percentage of tweets against masking, ranging from 13.28% to 13.75% (Figure 2). The 3 states with the lowest percentage are Washington, DC; Vermont; and South Dakota, with about 8% - 9%. On the other hand, in Japan, the percentage of tweets against masking is observed to be higher, ranging from 19.28% to 20.19% in Fukuoka, Yamaguchi, and Tokushima prefectures, with the lowest percentage observed at about 14% in Tottori, Miyazaki, and Wakayama prefectures.

Figure 2. Percentage of tweets against masking in (**A**) the United States and (**B**) Japan. The same color scale is used for both the United States and Japan. The top 3 prefectures/states with the highest percentage are marked in red text and arrow, while the bottom 3 are marked in green text and arrow.

Mask-Wearing Classification Results

The analysis and maps for mask-wearing behavior tweets were divided into 2 categories: those classified as “not wearing” and “wearing” masks (Figure 3). Since some states or prefectures have a much smaller number of tweets, the count of tweets classified as “not wearing” is reduced accordingly. For English tweets, the total count of “not wearing” tweets was very small, at 574, resulting in no tweets classified in the category in several states and causing the percentage to appear as 0. Wyoming has the highest percentage of tweets classified as “not wearing,” at 0.26% (2 out of 776). In contrast, Louisiana leads in the percentage of “wearing” mask tweets, at 19.12% (2122 out of 11,100); followed by Washington, DC (1638 out of 8845, 18.52%); and Alaska with about 18.33% (333 out of 1817). However, a careful interpretation is necessary for these figures, as the number of tweets was relatively small, especially for the tweets mentioning not wearing masks. The tweets were much smaller in the behavioral aspects of mask-wearing, so the resulting maps might not have enough data for a state-level conclusion.

On the Japan side, there were 8462 tweets classified as “not wearing” masks, a higher number compared with the United States results. However, a big portion of these tweets was still concentrated in Tokyo, with over 2000 tweets, while the other 31 prefectures had fewer than 100 tweets each. In terms of the percentage of tweets classified as “not wearing” masks, Hokkaido has the highest percentage at 3.15%. For tweets classified as “wearing” masks, Kagawa has the highest percentage at 25.87%.

Figure 3. Percentage of tweets classified as wearing a mask in (**A**) the United States and (**B**) Japan, and tweets classified as not wearing a mask in (**C**) the United States and (**D**) Japan. The state/prefecture name shown denotes the top 3 areas with the highest percentage. The same color scale is used for both the United States and Japan. Gray shows no predicted data for the area.

Correlation With Demographics Data

We calculated the correlation between stance percentages and the demographic data from the country census for both the United States and Japan (Table 5). In the United States, we observed a negative correlation of −0.384 between household income and stance against masking percentages. Although this correlation is relatively low, it is still significant within the 1% level of significance threshold. This suggests that states with higher incomes tend to have lower percentages of tweets against masking. Additionally, education level also shows a significant negative correlation, showing that with an increase in the population completing higher studies, there was an observed decrease in tweets with a negative stance towards the mask mandate. In Japan, we found that the number of people older than 65 years showed a positive correlation with the percentage of tweets against the mask mandate at the prefecture level. Similar results were observed in the number of people who completed a bachelor or higher degree.

Table . Correlation calculation of tweets percentage with the demographics data from the United States and Japan. The table only displayed a significant correlation.

Variable	Correlation	95% CI	*P* values
The United States			
Population completed bachelor and higher	−0.456	−0.653 to −0.200	.001
Household income	−0.353	−0.577 to −0.080	.013
Japan			
Population of elderly (older than 65 years)	0.295	0.009 to 0.537	.044
Population completed bachelor and higher	0.310	0.024 to 0.548	.034

Discussion

Principal Results

Key Events That Drove the Surge in COVID-19–Related Tweets

The time series plot illustrates the changes in stance against masking and mask-wearing tweets in the United States and Japan. The major fluctuations in the data points often coincide with governments announcing mask-related policies or major public events such as lockdown or the Olympics during the COVID-19 period. Such a phenomenon suggested that individuals tend to be prompted to express themselves on social media by major movements from government or public events, as previous studies also indicated [43-46]. In addition to the temporal trend, the geographical visualizations from the final results provide a general landscape of public responses to the mask-related policies divided by the municipal regions on social media (referred to as “X” in this study) in the United States and Japan. Information regarding the percentage of tweets against masking is displayed for each state or prefecture (Figure 3). Interestingly, Washington, DC, emerges as the state with the lowest proportion of tweets against masking and the highest percentage of tweets mentioning mask-wearing. This suggests that the state exhibits less resistance to mask-wearing and actively follows mask guidance.

Based on the correlation results between tweets and demographic data, education level and household income were found to be significantly correlated in the United States. Specifically, the population of people who have completed a bachelor’s degree and higher is negatively correlated with a stance against masking. This result indicates that with the increase in the higher education levels of the population in the states, we observed a decrease in the number of tweets against masking. This observation aligns with findings from a previous study based on a survey in the United States, which reported that individuals with at least a college degree are less likely to refrain from wearing face masks [47]. Additionally, the same study found that households with lower incomes were more likely to exhibit the same behavior of not wearing masks, an insight consistent with our findings.

Previous studies indicate that the behavior of older and younger people changes throughout the pandemic, with older individuals becoming more cautious about preventive measures as the pandemic progresses [48]. Although the majority of X users fall within the young adult category (aged 18 - 29 years), there are still a considerable number of older X users in the United States, as revealed by a survey conducted in 2023 [49]. Since this study calculated correlations for the entire period of data collection, these changes in opinion might not have been captured well. Throughout the study period, there have been several changes in mask-wearing rules, compliance, and when masks are mandated in some areas, which also affects how people responded and their opinion towards mask-wearing [50]. New information about mask-wearing released by the authority can also result in changes in public attitude toward mask-wearing [51], such as when people initially support mask-wearing and then change their opinion, or if they are against masking in the beginning and change to accepting masks in the later stage of the pandemic. This was also supported by results of the study, where a change in the sentiment is observed in the 3 major cities in the United States [15].

In Japan, the number of people aged older than 65 years shows a positive correlation with the number of tweets expressing their stance against masking, in line with a previous study in Hiroshima, Japan [52]. Based on existing studies summarizing responses in 27 countries, including Japan, people over 60 did not really comply with wearing masks outside of their home [53], which is also reflected in the results of this study [54]. The overall results of the correlation calculated are, however, quite small. Such a result indicated that there could be more confounding factors influencing the results. Below, we discuss some potential factors suggested in previous literature.

Health policy differences in the states within the United States might be one of the possible factors affecting the mask-wearing behavior reflected in social media. There had been observable differences, such as physical distancing rules across states and the relation of the measure to racial and socioeconomic differences in the area [55]. There was also an existing study documenting mask-wearing policy across the states and its enforcement [56]. The result indicates that overall, the mask is not strongly enforced in the states. The resistance to mask-wearing in the United States could also be viewed through cultural aspects of people living in the country [57]. A study focusing on the cultural and political aspects of mask-wearing

XSL•FO
RenderX

suggested that future attempts at mask-wearing policy need to consider the cultural meaning of masks to the public [58].

A difference in response to policies was observed in Japan, with results from a study showing the high trust and compliance in government policies during COVID-19 [59]. An internet survey showed that some habits of the Japanese, such as wearing masks prior to the pandemic, were also related to their responses to the preventive measures for COVID-19 [60]. These policies and behavioral insights might serve as additional variables to further explain the observed web-based behavior in X. The insights can be used in handling information dissemination in social media, for example, by the government in countries to design the most effective way to communicate with the public on social media.

Interpreting Conflicting Correlations: Mobility, Social Media, and Educational Shifts

Most of our findings aligned with previous research. However, unexpectedly, individuals with a bachelor's degree or higher also showed a positive correlation with opposition to the mask mandate, which contradicts earlier studies [48]. One possible cause for the inconsistency was the difference in the demographics between people using X and the census data used for the correlation calculation. In the United States, the percentage of X users with at least a bachelor's degree is higher than that of the general public, which is also observed in the income levels [61]. In Japan, based on a survey conducted by the Ministry of Internal Affairs and Communications, about 80% of people in their 20s were X users. The penetration rate is the highest in the younger population, but there were also users in their 60s (18.9%) [62]. According to a study conducted using X data, even within the social media users' demographics, there was a bias due to the choice to participate in a certain topic for social media discussion [63]. This disparity might affect the correlation results with tweet percentages, as the demographics being calculated are not X-specific demographics but public demographics based on census and surveys.

Another possible cause of the inconsistency in results may also have been caused by the mobility of people throughout the COVID-19 period in Japan. The tweet data were collected over a 3-year period, while the education level was obtained from the 2020 census. A previous study mentioned that before the pandemic, people were centralized in the Tokyo metropolitan area, a pattern disrupted during COVID-19 [64]. The changes in migration rates were also influenced by the emergence of remote work during the pandemic, prompting younger people to move to rural areas.

The increase in tweets mentioning "no-mask," as shown in the study by Suzuki et al [39], might also contribute to the conflicting correlation results, particularly in the latter half of 2022. Another reason might be caused by changes in the education style during the early period of COVID-19 to adapt to the changing policy. The changes to web-based education proved to be overwhelming for students, with their self-reported mental health status being worsened [65]. The anxiety and depression experienced during COVID-19 also increased students' social media usage [66]. This might be reflected in opinions about COVID-19 and its measures, such as mask-wearing, where similar cases were observed in studies about disruptions caused by COVID-19 in social media [42].

Our findings indicated that mask-wearing behavior was observed in social media discourse in both the United States and Japan. The map showing the area with a high percentage of yes and no to mask-wearing can be considered a guideline in how to communicate or release guidelines in the event of a pandemic, with more attention to the area with a high percentage of "no" in mask-wearing. Based on the number of tweets, we may also launch more information on social media to reach more people in the area. The correlation results show some significant correlations observed with population data of the states and prefectures, with some of them consistent with existing findings. These results suggest that the social media data has the potential to aid in research, with some caution due to the limited nature of the geo-tagged data in social media. Focusing on other aspects of analysis, such as other potential factors in correlation analysis or additional data, can be a future research direction to improve the results.

The Health Belief Model was believed to be useful for understanding and investigating the participation in COVID-19 preventive measures in the United States [67]. A study using the Understanding America Survey showed that the Health Belief Model results were consistent with existing studies, with mask-wearing behavior positively endorsed as one of the preventive measures. A study comparing public perceptions in different countries during the pandemic, Japan and the United States included, also showed that higher perceived effectiveness was one of the factors affecting how the public responded to preventive behavior, such as mask-wearing or handwashing [68]. To make the public more accepting of preventive measures or policies, the public needs to trust the effectiveness of the act. The role of publishing and spreading the effectiveness can be entrusted to social media, with emphasis in areas with higher percentages in the stance of not wearing masks.

Limitations

This study focuses solely on the English and Japanese languages for analyzing short and informal text, specifically tweet posts. In the second stage, we encountered numerous ambiguous and unclear tweets regarding attitude. Analyzing such stages proved challenging due to the short text and ambiguity of tweet content, which was often insufficient for accurately determining attitudes. Therefore, we chose to exclude a neutral option, limiting choices to either against or not.

Although X data might be subject to sampling bias due to its limited user base, the data were proven useful for infodemiology research, especially in identifying and monitoring public discussion topics during the pandemic [69,70]. Population-wise, our sample is restricted to individuals who voluntarily provide location information in their tweets. Despite the limitation of such data, it reflects the opinion of the users to a degree, as reported in an existing study that showed that geotagged tweets were able to display public opinion of people in the United States toward COVID-19 vaccinations [71]. Disparities in tweet counts across states/prefectures may influence the final percentage results displayed in the figures, which are based on the entire 3 years of data. We calculated the percentage based

XSL•FO
RenderX

on the tweets observed in each state as one of the measures to address the potential problems due to the location data. The number of tweets in each state varies, so we avoid general bias caused by comparing the tweets based on their count, but based on the percentage of the classified tweets. Due to the data collection period and collective analysis after, the resulting figure, especially in the form of map visualization, may not sufficiently capture early COVID-19 period changes and post-pandemic trends shown in the time series plot.

A previous study identified around 8.4% of tweets as bots from around 200,000 accounts collected in the early period of the pandemic, March to June 2020 [72]. Another study mentioned that bots focused more on political content in the COVID-19 pandemic discourse compared with health content, such as actions taken by the public during the pandemic [73]. The bots mostly discussed information related to COVID-19 or pandemic statistics. In this study, we focused on mitigating bots' influence, such as artificial amplification by removing duplicate tweets, one of which often appeared in posts by bot accounts. This action ensured that no single automated message could statistically dominate our social media dataset or skew our demographic correlations. To verify this approach, we conducted a manual audit in the annotated dataset, which was sampled randomly from the entire tweets data. We did not find apparent bot accounts during the check in our sample. Given this minimal presence, we conclude that the presence of bots does not significantly skew the overall stance analysis or correlations in our study.

The limited number of "not wearing" mask annotations constrained the number of predicted instances in the rest of the tweets. Consequently, the final predicted percentages for "not wearing" masks were also very small, only 0.07% for English tweets and 2.33% for Japanese tweets. This problem, caused by a small number of tweets annotated as "not wearing mask" was also further added by a surge in tweets mentioning "no-mask" after June 2022 [39]. This surge, as documented by Suzuki et al [39], may contribute to the disparity from previous studies and introduce bias into the correlation calculations, requiring people to interpret the results cautiously. To address these challenges, future improvements in classification and additional annotations are necessary for enhanced accuracy.

The initial score of the classification results obtained was not satisfactory. The F_1-score for stance against masking is 0.61 for English and 0.69 for Japanese. It was even smaller for the mask-wearing stage, with 0.31 for English and 0.40 for Japanese. While it is higher than the majority baseline, it is still not performing as well for the classification. There is a slight increase in the F_1-score after adding pseudo-labeled data, as observed in the stance and mask-wearing stage. However, the scores were still not as high, indicating that the topic to be classified is indeed challenging, as both human annotators and classifiers struggle to achieve a high score in classifying stance against masking and mask-wearing information of the users.

Regarding the mask-wearing stage, the number of tweets annotated as "not-wearing" masks is very small in the annotation phase (10 for English and 11 for Japanese). This small number affects the classification because when we split the data, we were working with an even smaller number of tweets for training, validation, and testing. This makes it even harder to classify the "not-wearing-mask" tweets, resulting in a low F_1-score in the testing phase. This issue is further highlighted in the classification of the remaining tweets, with only 0.07% predicted as "not-wearing" masks in English and 2.33% in Japanese out of all the predicted tweets. The low number of tweets predicted as "not-wearing" masks is also apparent in Figure 3, especially in the United States case. This limitation warrants caution in interpreting our results, especially since the annotation target was particularly challenging.

Due to the policy of X, we are unable to obtain the demographics of its users; thus, we considered using the demographics of the general population in the country. However, there are differences between the demographics of X users and the general population [61,62] which might affect the results of the correlation calculated in this study.

Conclusions

Our findings revealed a clear shift in public opinions at several key moments, often coinciding with major policy changes or public events, such as mask mandates and the Olympics, observed from 1,102,876 English tweets and 560,873 Japanese tweets from the United States and Japan between early 2020 and late 2022, covering the entire duration of the COVID-19 pandemic. Based on the correlation observed in the social media data, some variables are significantly correlated with the number of tweets, such as education levels, the population of the elderly, and household income. Some of our findings align with previous research across major social media platforms, suggesting that public opinions reflected in social media data are often interconnected. However, divisions based on education level, household income, and generational differences also indicate that social media interactions may be inherently biased, partly due to recommendation algorithms that encourage clicks and foster echo chambers.

Abstract

Background: Youth suicide is a public health crisis. In addition to suicide mortality, many youth experience and live with suicidal thoughts and behaviors (STBs). STBs have serious consequences for youth mental health and are associated with suicide. Despite recognition of the incidence and severity of STBs, barriers to accessing support are prevalent. Digital mental health (DMH) and digitally delivered measurement-based care (MBC) may improve access to treatment among youth and enhance clinical response to suicide risk and crises.

Objective: This study aimed to explore clinician perceptions of the barriers and facilitators to using DMH and MBC with youth experiencing STBs.

Methods: As part of a larger implementation science project, a DMH and MBC platform was implemented in youth-serving mental health service settings in communities across Alberta, Canada. The platform included a multidimensional assessment package and embedded an automated suicide escalation protocol that notified clinicians when youth reported STBs. In participating service settings, 32 interviews were conducted with clinicians using DMH and MBC. We used the Consolidated Framework for Implementation Research and theoretical thematic analysis to identify barriers, facilitators, and relevant themes.

Results: Four overarching themes were identified that described barriers and facilitators to using DMH and MBC with youth experiencing STBs: (1) service setting and professional practice barriers, (2) DMH platform barriers, (3) service setting and professional practice facilitators, and (4) DMH platform facilitators. Clinicians' recommendations were presented in alignment with the identified barrier themes.

Conclusions: Given the association between STBs and suicide, attending to STBs is a critical component of suicide prevention. Our findings suggest that the assessment of STBs using DMH may address the youth suicide crisis by facilitating disclosure and rapid clinical action. Moreover, multidimensional assessment may reveal important information about STBs and risk factors, with advantages for personalized care and system-level improvement. Clinicians delivering DMH and MBC must be supported by applying their recommendations and continuously strategizing to mitigate barriers and leverage facilitators for sustained implementation.

Introduction

Background

Youth suicide is a public health crisis [1-4]. In Canada, suicide is the second leading cause of death among youth and young adults aged 15-34 years [5] and accounts for approximately 25% of deaths among youth aged 15-24 years [6]. A study of the epidemiological impact of youth suicide in countries with the highest human development index found that Canada has the third highest crude suicide mortality rate among youth in the 15-24 age range [7]. Each suicide signifies a young person who matters, years of potential life lost prematurely, and exerts a heartrending impact on families, friends, and communities [8]. Beyond suicide mortality, many youth experience and live with suicidal thoughts and behaviors (STBs) [5,9]. STBs comprise all facets of suicidality: active suicidal ideation (with intent to act), passive suicidal ideation (without intent to act), deliberate self-harm, preparatory acts (eg, planning suicide), and suicide attempts [10]. Youth aged 15-19 years exhibit the highest rates of urgent care visits and hospitalization related to self-harm in Canada [5]. Notably, STBs have serious and possibly debilitating consequences for youth's physical and mental health and well-being [8].

Risk factors for STBs and suicide are heterogeneous, fluctuating, and interactive [4,5,11]. At the systemic and community level, residing in a remote or rural area [5,12], social and economic deprivation [3,5], natural disasters, and war [8,13,14] may elevate youth's vulnerability. Other powerful systemic and community influences include experiences of marginalization [4], minoritization, discrimination, prejudice, loss of cultural identity [3], and racism [5]. For youth, interpersonal factors such as negative family and peer relationships, the death of a family member or friend [3], and peer victimization [3,15] are instrumental. Experiences of child maltreatment [16-18], witnessing intimate partner violence [3], gender-based violence [5,18], and other trauma also contribute to psychosocial stress and potential self-harm. Finally, individual factors interact with and are affected by broader systemic, community, and interpersonal dynamics [4,8]. Psychological distress [19] and feelings of worthlessness, self-loathing, isolation, and other emotions [3] are associated with youth STBs. Although not all youth experiencing STBs have a psychiatric disorder (eg, posttraumatic stress disorder), mental ill-health and comorbidities increase youth's risk [10]. A personal history of STBs is a salient contributing factor to youth suicide [2,20]. Biologically, adolescence represents a period of vulnerability to developing STBs due to rapid neurodevelopmental and physical changes [4], limited cognitive control, and lower inhibition [1]. Isolation and disrupted routines during the COVID-19 pandemic interrupted typical adolescent development [4] and increased youth's risk of suicidality [1,21,22] and suicide [1,4].

Due to pervasive social inequities, risk factors and related prevalence of STBs and suicide are not equally distributed across population groups [4,5,8]. Indigenous peoples (First Nations, Métis, and Inuit) in Canada experience risk factors including intergenerational trauma, marginalization, discrimination, racism, loss of land and culture, and differential access to resources [5,23-25] (eg, mental health services, housing, and clean water) as a consequence of historical and present colonialism and oppression [23,24]. Social and health disparities resulting from ongoing injustices contribute to elevated rates of suicide among Indigenous youth [24,26]; among Indigenous youth aged 15 to 24, the suicide rate is 5 to 6 times higher than that of non-Indigenous populations [23,27]. The suicide rate among Inuit youth in this age range is 11 times higher [23,27] and may be increasing among Inuit children aged 10-14 years [24]. However, Indigenous populations are diverse [25], and suicide is not a universal phenomenon in all Indigenous communities [23,25,28]. Community contextual factors (eg, environmental location and Indigenous governance in the community) and aspects of intersectional identity (eg, gender, sexual orientation, and social location) greatly affect risk factors for suicide [28].

Among other racialized populations, collective and individual experiences of marginalization, discrimination, racism [29,30], racial trauma [31], barriers to health resources [32], and other factors also contribute to suicide risk. There is a notable lack of race-based and ethnicity-based data [29,32] documenting suicide rates, and a lack of research to better understand unique pathways to suicidality among heterogeneous racialized communities and individuals in Canada [29]. Similarly, as gender identity and sexual orientation are not typically collected in death records, suicide rates among Canadian Two-Spirit, lesbian, gay, bisexual, transgender, queer, questioning, intersex, and asexual (2SLGBTQIA+) youth are unknown [5] or underreported. Existing data demonstrate that transgender and sexual minority youth are at higher risk of suicidal ideation and attempted suicide than their cisgender, heterosexual peers [33]. As with other historically and presently marginalized populations, heightened risk of STBs among 2SLGBTQIA+ youth occurs due to external inequities and influences, such as minority stress in various forms across societal and interpersonal levels [34-36] and potential victimization [37]. Experiences of STBs are again impacted by intersectionality and within- and between-group differences [33,35,37].

Despite recognition of the prevalence of STBs and suicide in youth, and the disproportionate burden in some communities, many youth struggling with STBs are unable to access appropriate support and treatment [10,38]. Barriers to accessing youth mental health care in Canada include limited resources in remote and rural areas, long waitlists, the cost of specialized services, a lack of support for transition-aged youth, stigma toward mental health concerns, and minimal or absent culturally

XSL•FO
RenderX

competent care [39]. Among youth with access to health care systems, barriers to disclosing STBs are well documented. Many youth experience concerns about the confidentiality of their disclosure [40-42], fears of reexperiencing past harmful reactions to disclosure [42], and anxiety about hospitalization [41]. Feelings of hopelessness [40], isolation [3], and shame [41], along with fears of stigma [3], may also prevent youth from talking about STBs. Notably, 2 studies highlight that youth may not disclose STBs to clinicians if clinicians do not directly ask questions about suicidality [40,42]. A lack of clarity around roles and responsibilities for responding to suicide risk, worries about community follow-up (eg, when youth are sent to hospital but not admitted), limited time, competing priorities, and the need for training [43] may deter clinicians from initiating conversations about STBs with youth.

Digital Mental Health and Measurement-Based Care for Youth Experiencing STBs: Overview of Existing Evidence

Considering the barriers to youth mental health care and the sensitivity around discussing STBs, tools that improve youth's access to treatment and address STBs are urgently needed. Digital mental health (DMH) includes various web- and mobile-based apps that may be used to self-manage mental health concerns [38] or used in conjunction with clinician care [19,38,44,45]. Specific to STBs, DMH modalities such as telemedicine [44], videos, games, apps, supportive text messaging [38], and wearable devices [20] leverage technology to support youth experiencing ongoing suicidality and youth in acute crises. DMH may reduce barriers to treatment access by improving accessibility irrespective of youth's geographic location [19,46], eliminating waitlists, providing low- or no-cost care options, expediting access to information [45], and increasing anonymity [46]. Some research indicates that DMH may be accessible for communities experiencing systemic marginalization, provided that barriers to access are addressed, and DMH is co-designed with the community it intends to support [47-49]. Co-design enables DMH to recognize the unique experiences of diverse groups of youth, meet their self-identified needs [48,49], and improve cultural relevance and relatability [47]. Importantly, youth perceive technologies as acceptable [44,50] and even preferable [51,52] means of crisis management and intervention. Youth who have not previously shared their STBs [53] and youth with difficulties communicating verbally [52,54] may find that DMH facilitates communication and disclosure about STBs with clinicians. Furthermore, DMH can play a role in safety planning by providing psychoeducation, teaching coping strategies [38], connecting youth to crisis resources and emergency contacts (eg, clinicians and caregivers) [38,55], and enabling rapid clinical response [53].

A significant advantage of DMH is its ability to deliver assessments of STBs and subsequently facilitate measurement-based care (MBC) [56]. In mental health care, MBC involves integrating continuous measurement of a person's outcomes across one or multiple health domains into their treatment. The digital delivery of MBC through DMH apps and websites, alongside traditional services, offers a promising way to identify youth experiencing STBs and detect changes in their suicidality over time [19,53]. Clinicians monitoring youth's MBC assessments in DMH who are alerted of suicide risk can respond by initiating contact with youth, developing a safety plan, and coordinating and escalating youth's level of care. A recent mixed methods study reported that DMH and MBC improved clinicians' response to suicide risk [57]. Given that the direct assessment of STBs is associated with a higher likelihood of disclosure [41], and that youth express wanting clinicians to initiate difficult conversations about STBs [40], DMH and MBC hold potential to improve awareness of and communication about suicidality for both youth and clinicians.

A small number of studies have documented clinician concerns about using DMH and MBC with youth. For instance, responding to crises may be outside clinicians' scope of practice [58]—particularly if crisis alerts are received outside standard working hours [58-61]. This contributes to apprehension about liability due to potential delays in responding to youth at risk of suicide [58,59]. Additionally, clinicians report having limited time to implement digital tools due to low staffing availability [45], heavy workloads [58,60], and a lack of dedicated time in their schedules to review online assessments [58]. The remote nature of DMH raises concerns about clinicians' lack of control to manage crises in person (eg, being unable to direct the patient to hospital) [46]. For these reasons, implementing DMH and MBC to support youth may be challenging without changes to staffing and roles [60].

Literature exploring the perspectives of clinicians responsible for using DMH and MBC with youth experiencing STBs appears limited. While review papers summarize various types of DMH for use with this population [20,38,44,51,52], and studies with youth [19,50,53,55] and caregiver participants [55] provide valuable insights, there is a lack of implementation research specific to clinicians and digitally delivered MBC. We identified 9 relevant studies that included clinician perceptions: 2 investigated other types of DMH [45,46], 3 examined monitoring tools similar to MBC [54,61,62], and 2 considered DMH and/or MBC more broadly [57,60]. Two studies were previously conducted by our research and implementation team in preimplementation project phases [58,59].

Study Purpose

Suicide is preventable [8], and suicide prevention is a global imperative recognized by the World Health Organization (WHO) [8,63], the United Nations Sustainable Development Goals [63], and the Government of Canada [5]. Suicide prevention involves multisectoral collaboration [8], empowering communities, youth, clinicians [5], and families with mental health resources, as well as early identification and intervention [8]. Implementing DMH and MBC in youth-serving settings may support suicide prevention efforts; however, the inclusion of clinician perspectives remains a gap in the literature. In-depth qualitative research exploring postimplementation clinician perspectives is necessary to determine what clinicians need to use DMH and MBC effectively and relationally with youth. This study therefore aimed to explore clinicians' perceptions and experiences through the following research question: "What are

XSL•FO
RenderX

the barriers and facilitators to using DMH and MBC with youth experiencing STBs?"

This study is part of a larger mixed methods implementation science project evaluating the implementation of a DMH and MBC platform in youth mental health service settings in rural and urban communities across Alberta. The larger project, implementation process, and platform are described in previous publications [58,59,64-66]. Among several outcome objectives, the project is assessing the impact of implementation on emergency department use, youth mental health, and suicide attempts. This study extends our prior work by presenting data collected postimplementation, focusing explicitly on youth experiencing STBs, and using a well-established implementation science framework to identify barriers, facilitators, and clinician recommendations specific to this topic.

In this paper, unless specifically referring to MBC, we hereinafter refer to DMH and MBC collectively as "DMH."

Methods

The Innowell DMH Platform: Description and Functions for Youth Experiencing STBs

The Innowell platform (Innowell PTY Ltd) was developed in Australia through co-design with individuals with lived experience of mental illness and health care professionals [56,57,67,68]. It is web-based and contains a multidimensional assessment package of clinical questionnaires for 20 biopsychosocial domains. Youth complete the initial baseline package and can repeat all or selected questionnaires as needed. Once complete, results are presented in a dashboard with color-coded "health cards" that indicate the severity (low-high) of youth's needs. Visual graphs that reflect improvement or decline over time are generated as questionnaires are retaken. In addition, relevant apps, e-tools, and community-specific resources are provided. The platform enables MBC and encourages collaboration by allowing shared access to youth data for youth and their clinicians. Clinicians can personalize care by monitoring results according to service setting procedures, exploring questionnaire responses with youth, and engaging youth in shared decision-making about their treatment.

Innowell includes a Suicidal Thoughts and Behaviors domain and embeds an automated suicide escalation protocol [56,67,68]. In the STBs domain, questions come from 2 evidence-based measures covering current and historical STBs and their intent (eg, suicidal ideation with or without a plan or attempt): the Suicidal Ideation Attributes Scale [69] and the Colombia-Suicide Severity Rating Scale [70]. Any expression of STBs in the questionnaire immediately triggers a pop-up notification with crisis helplines and community-specific crisis resources. If the severity of risk meets a threshold determined by the service setting, a notification is also sent to the youth's clinician and any other support person monitoring their DMH profile. The notification remains "flagged" for clinicians until they have contacted the client to confirm their safety, develop a safety plan, book an appointment, or any other action deemed appropriate by the youth and clinicians. In this way, the protocol enables identification, monitoring, and rapid clinical response to suicide risk.

Service settings implementing Innowell developed procedures for responding to crises and advised clinicians not to check the platform or respond to notifications outside working hours. However, many clinicians continued to monitor the platform at other times.

Service Settings and Participant Recruitment

Participating primary care networks (PCNs), specialized mental health services, schools, and community-based organizations in Alberta implemented the platform between 2021 and 2024. Implementation was facilitated by implementation leads located in participating communities who provided DMH education, training, and support to clinicians. Clinicians invited youth aged 15-24 years to use the platform as part of their care. To recruit clinicians with differing experiences with DMH, the research and implementation team invited clinicians who used the platform extensively, moderately, and minimally to participate.

Data Collection

A semistructured interview guide was developed based on the research and implementation team's expertise in implementation science and integrating DMH in clinical practice. Three topic areas were included in the guide: (1) implementation experience, which explored participants' roles, their use of DMH, and barriers and facilitators to implementation; (2) impact, which considered the impact of DMH on workflows, supporting youth with acute care needs (including youth experiencing STBs), and youth engagement in treatment; and (3) sustainability, which addressed participants' willingness to continue using DMH and recommended changes to facilitate sustained implementation. The semistructured approach allowed participants to respond to planned topics and questions, while offering opportunities for reflections related to STBs and other pertinent issues to occur at different times. This study's topic was inductively derived from the content of the interviews.

Individual interviews were conducted online via Zoom (Zoom Communications, Inc) to accommodate participants' various locations in Alberta, and facilitated by a senior member of the research team and one research assistant (RA). Both facilitators had no prior relationship with participants. The duration of interviews varied from 60 to 90 minutes. All interviews were recorded, transcribed, anonymized, and reviewed by the research team before data analysis to ensure their anonymity and accuracy.

Data Analysis

Qualitative Descriptive Approach

This study followed a qualitative descriptive approach [71]. In contrast to qualitative methods involving recontextualization of the data [72], qualitative description seeks to explore the data using low-inference description that closely reflects participants' own words about their perceptions and experiences [71]. Descriptive methods are well-suited to health research and intervention studies, as their straightforward documentation of why the intervention did or did not work, and what could improve, can be directly applied to create clinically meaningful

XSL•FO
RenderX

change [73]. With consideration of our study's purpose, the qualitative descriptive approach was chosen to provide a rich description of participant-identified barriers and facilitators to using DMH with youth experiencing STBs.

Qualitative description is adaptable and allows for several possible means of analyzing the data [73]. We conducted our analysis in three phases: (1) deductive coding using a recognized implementation science framework [74] to systematically organize the entirety of the data; (2) rating constructs (codes) to identify what constructs served as barriers and facilitators; and (3) conducting a theoretical thematic analysis [75] to identify patterns within the constructs, group constructs into themes, and provide an in-depth description of themes in response to the research question.

Analysis Phase 1: Deductive Coding Using the Consolidated Framework for Implementation Research

The Consolidated Framework for Implementation Research (CFIR) is a highly cited implementation science resource designed to assess determinants of innovation implementation from the perspectives of involved individuals and teams [74]. Deductive coding using the CFIR can identify factors influencing implementation related to the innovation itself, larger systems, the organization, individuals delivering and receiving the innovation, and implementation processes, and inform recommendations for sustained integration. Using the CFIR enhanced our adherence to low-inference qualitative description across all phases of analysis by providing a framework in which to situate and understand our data, thereby reducing bias and overinterpretation and improving consistency between coders.

The CFIR includes 5 domains to structure research data [74] (refer to Table 1; definitions are paraphrased for brevity and adapted for relevance to this study). Each domain contains constructs and subconstructs (39 in total) with definitions for use in coding that may be understood within the implementation context and adapted as necessary.

Table . Consolidated Framework for Implementation Research (CFIR) overarching domains (adapted from Damschroder et al [74]).

CFIR[a] domain	Paraphrased description
Innovation	This domain includes factors related to the innovation being implemented (DMH[b]). CFIR constructs consider the innovation's evidence-base, design, adaptability, complexity, cost, and other innovation features that may influence implementation.
Outer Setting	This domain includes factors related to the larger setting and systems in which the inner setting is situated (eg, health care system and legal system). CFIR constructs consider local conditions, partnerships, laws, policies, financing, and other external conditions that may influence implementation.
Inner Setting	This domain includes factors related to the setting where the innovation is directly implemented (youth-serving mental health service settings). CFIR constructs consider the inner setting's structure, staffing, culture, and other internal factors that may influence implementation. Constructs also consider whether the inner setting is accepting of change, if implementation is prioritized, and the compatibility of the innovation with inner setting processes.
Individuals	This domain includes factors related to individuals involved in implementation (clinicians and youth). CFIR constructs consider the capability, opportunity, and motivation of innovation deliverers and recipients to implement and receive the innovation, and whether the innovation meets deliverer and recipient needs.
Implementation Process	This domain includes factors related to the process of implementing the innovation (DMH). CFIR constructs consider initial assessments of deliverer and recipient needs, planning, strategizing, and collaborating during implementation, engaging recipients, and other processes required to implement the innovation.

[a]CFIR: Consolidated Framework for Implementation Research.

[b]DMH: digital mental health.

Before coding, reviewed transcripts were uploaded to a qualitative data analysis platform (Taguette [Rampin]) [76]. The research team familiarized themselves with the data by reading each transcript and memoing their observations for team discussion. Transcripts were then divided between 2 RAs and independently coded using the CFIR. RAs and the research team met weekly to share their progress, discuss questions, and resolve uncoded quotes that RAs sought feedback on. If disagreements about coding arose, the team referred to the CFIR construct definitions for clarification.

The final step involved creating a copy of the larger codebook and removing all constructs that did not contain quotes related to STBs. Within the remaining constructs, any quotes with unrelated content were removed to ensure that irrelevant topics were excluded from the second phase of analysis. Domains and constructs deemed applicable to this study are defined in the "Results" section.

XSL•FO
RenderX

Analysis Phase 2: Construct Rating—Assessment of Barriers and Facilitators

In the second phase, constructs that contained quotes related to STBs were rated using the CFIR Index Manual for Administration and Scoring [77]. The CFIR Index is a practical tool for research and quality improvement designed to classify CFIR constructs as barriers and facilitators to implementation and to assess the influence, valence, and strength of the constructs. In our study, we followed the step-by-step process outlined in the manual to identify constructs as barriers or facilitators to using DMH with youth experiencing STBs.

RAs first rated individual quotes as a negative (-), positive (+), or mixed (X) factor (containing both negative and positive sentiments). Using a 5-point Likert scale, RAs then applied a number between −2 and +2 to determine the strength of the factor's influence on implementation. Most quotes related to STBs were clearly strong barriers or facilitators and rated accordingly as −2 or +2. To establish the construct's overall rating as a barrier or facilitator, RAs observed the distribution of rated quotes and rated each construct according to the majority.

Analysis Phase 3: Theoretical Thematic Analysis

After rating relevant constructs, we conducted a theoretical thematic analysis as described by Braun and Clarke [75]. Theoretical thematic analysis is a deductive method of identifying and describing patterns in the data by applying preexisting theories or frameworks to answer a research question in detail. Guided by the CFIR, completed phases of deductive coding and construct rating produced barrier and facilitator constructs that acted as the framework for interpreting the data and clustering constructs into themes [78]. We followed Braun and Clarke's [75] six-stage iterative analytic process [78] to explore data related to clinicians' perceptions and experiences of using DMH with youth experiencing STBs, contained within relevant constructs. As with previous phases, the theoretical thematic analysis remained focused on observable details in the data in alignment with the qualitative descriptive approach [71].

In the first stage, RAs refamiliarized themselves with the data by rereading coded transcripts with the research question in mind and writing memos about relevant patterns. The second stage, coding, was previously completed. In the third stage, RAs examined the constructs and their associated quotes and began to combine them into larger patterns, themes, and subthemes. This involved considering what "central organizing concept" [78] was shared by each cluster of constructs. Developing a clear understanding of what constructs and ideas fit within a particular theme led to identifying more distinct groupings. Due to the CFIR's broad definitions of constructs, some constructs contained multiple ideas and were therefore included in more than one theme. RAs ensured that ideas did not overlap between themes—despite the interconnectedness of the data overall. Subthemes captured distinct concepts but shared the same underlying concept as the theme.

In the fourth stage, themes were reviewed to confirm their central organizing concepts, ensure their relevance to the research question, and check that no key ideas in the dataset were missed. This step involved examining whether the themes told an accurate and meaningful story about the data. Finally, the fifth and sixth stages entailed defining and naming the themes and producing the paper. Exemplar participant quotes were thoughtfully selected to illustrate specific impressions in theme titles and descriptions.

Positionality

The research and implementation team includes researchers, clinicians, and clinician-researchers at various stages in their careers and with expertise in diverse disciplines (social work, psychology, psychiatry, nursing, medicine, education, and software design and development). It is vital to acknowledge that the topic of STBs and suicide is deeply significant to the authors. Some authors carry personal lived experience with STBs, have lost friends to suicide, have worked as clinicians with youth who completed suicide, and have worked in mental health advocacy alongside parents and caregivers who lost their children to suicide. Others have worked as researchers and facilitators with youth experiencing suicidality. These experiences have shaped our perspectives on life—and inevitably impacted the way we perceived and interacted with the data. We engaged in reflexivity by recognizing our unique perspectives, partaking in group discussions so that multiple perspectives were reflected in the research, and continuously referring to the data to ensure that participants' voices remained central to the analysis.

Trustworthiness and Authenticity

This study adheres to the 5 standards used to assess trustworthiness and authenticity in qualitative research: objectivity, dependability, credibility, transferability, and application [71]. Objectivity was addressed by describing our methods in detail, recognizing potential biases, and reporting our positionality. To achieve dependability, we standardized data collection by using the same interviewer and interview guide across interviews, determining data analysis procedures based on the research question, and using a credible theoretical framework (the CFIR) to guide the analysis and remain close to the data. Researcher triangulation was achieved by 2 RAs independently coding the transcripts and subsequently discussing their findings with the larger team. To assess credibility, findings were shared with implementation leads to confirm that the analysis reflected their experiences with implementing DMH and engaging with clinicians using the platform. A discussion of transferability and generalizability of the findings is included in the "Strengths and Limitations" subheading. Finally, we considered the application of the study by presenting clinician and researcher recommendations for addressing the barriers to using DMH with youth experiencing STBs (refer to "Results" section and "Practical Implications and Researcher Recommendations" subheading).

Ethical Considerations

This study was approved by the University of Calgary Research Ethics Board (REB20-1137). Potential participants were informed about the study purpose and procedures, that participation was voluntary, and that they could withdraw at any time. Before participation, all participants provided written informed consent and completed a demographic survey via

XSL•FO
RenderX

REDCap (Research Electronic Data Capture; Vanderbilt University) secure software hosted at the University of Calgary. All identifying information was omitted from the paper to protect participants' privacy and confidentiality. Monetary compensation was not provided because participation in the project entailed implementing DMH within the scope of participants' regular duties.

Results

Participant Characteristics

Clinicians (N=32) from youth-serving mental health service settings participated in interviews: 17 from specialized mental health services, 9 from schools and community-based organizations, and 6 from PCNs. A majority were from rural communities (n=21, 66%). Participants occupied varying professions, including psychology and counseling (n=14, 44%), social work (n=11, 34%), and other roles (n=7, 22%). Most participants had worked for their service setting for ≤5 years (n=19, 59%). A majority worked full-time (n=25, 78%) and had graduate-level education (n=20, 63%). Participants' ages ranged from 20 - 29 to 50 - 69 years. Most participants reported their assigned sex as female (n=25, 78%) and most identified as women (n=24, 75%). A majority were heterosexual (n=23, 72%). Just over half of participants had European ethnic origins (n=18, 56%), and others reported various ethnic origins (n=13, 41%). Several variables were collapsed into "Other" categories due to low numbers to protect participants' identities. Full participant demographics are provided in Table 2.

[a]Some variables were collapsed into an "Other" category due to low numbers. Contents of the "Other" categories are not reported to protect participants' identities. Not reported age range: during data cleaning, we identified inconsistencies between some participants' reported age (eg, ≤19 years) and education level (eg, graduate school). As such combinations were not feasible, these cases (n=2) were not reported to maintain data integrity. The extent of clinicians' platform use is not reported to protect participants' identities.

Theoretical Thematic Analysis

Overview

The CFIR delineated barriers and facilitators to using DMH with youth experiencing STBs across all 5 CFIR domains: Innovation, Outer Setting, Inner Setting, Individuals, and Implementation Process. This reflects the salience of the matter in connection with participants' service settings, professional practice, and DMH. Rated constructs that informed the theoretical thematic analysis are defined in Table 3.

XSL•FO
RenderX

Table . Synthesis of results.

Theme and subtheme[a]	CFIR[b] domain and construct included in theme, with CFIR definitions
1: Service Setting and Professional Practice Barriers	
1.1: Service setting structure does not support immediate crisis response	• Inner Setting: Structural Characteristics—Work Infrastructure (includes factors related to staffing and staff roles) • Inner Setting: Compatibility (includes factors related to the compatibility of the innovation with existing inner setting processes) • Individuals: Innovation Deliverers—Opportunity (includes factors related to the capacity, availability, and power of deliverers to effectively implement the innovation) • Individuals: Innovation Deliverers—Motivation (includes factors related to deliverers' motivation to implement and sustain use of the innovation)
1.2: DMH[c] incites tension between clinicians' responsiveness and burden of responsibility	• Outer Setting: Policies and Laws (includes factors related to laws, regulations, and professional guidelines that may affect implementation; eg, mandatory reporting laws and code of ethics) • Inner Setting: Compatibility (includes factors related to the compatibility of the innovation with existing inner setting processes) • Individuals: Innovation Deliverers—Opportunity (includes factors related to the capacity, availability, and power of deliverers to effectively implement the innovation) • Individuals: Innovation Deliverers—Motivation (includes factors related to deliverers' motivation to implement and sustain use of the innovation)
1.3: Clinicians express nuanced concerns about youth who report STBs[d] in DMH	• Implementation Process: Assessing Needs—Innovation Recipients (includes factors related to assessing the needs of recipients to inform implementation) • Individuals: Innovation Deliverers—Motivation (includes factors related to deliverers' motivation to implement and sustain use of the innovation) • Individuals: Innovation Deliverers—Opportunity (includes factors related to the capacity, availability, and power of deliverers to effectively implement the innovation)
2: DMH Platform Barriers	
2.1: Youth struggle to interpret the DMH STBs assessment and cope with results	• Innovation: Evidence-base (includes factors related to existing evidence to support use of the innovation) • Innovation: Complexity (includes factors related to the complexity of the innovation) • Innovation: Design (includes factors related to the design of the innovation) • Individuals: Innovation Recipients—Capability (includes factors related to recipients' ability and knowledge to effectively use the innovation)
2.2: Continuous DMH crisis notifications for youth with persistent or past STBs are unhelpful	• Innovation: Design (includes factors related to the design of the innovation) • Implementation Process: Assessing Needs—Innovation Recipients (includes factors related to assessing the needs of recipients to inform implementation)
3: Service Setting and Professional Practice Facilitators	
3.1: DMH supports the therapeutic relationship between clinicians and youth	• Innovation: Relative Advantage (includes factors related to whether the innovation enhances existing practice and processes) • Inner Setting: Culture—Recipient-centeredness (includes factors related to the inner setting's commitment to supporting innovation recipients) • Inner Setting: Mission Alignment (includes factors related to whether the innovation aligns with the inner setting's mission and purpose) • Implementation Process: Teaming (includes factors related to team collaboration and coordination during implementation)
4: DMH Platform Facilitators

Theme and subtheme[a]	CFIR[b] domain and construct included in theme, with CFIR definitions
4.1: DMH enables disclosure, identification, and early intervention	• Innovation: Relative Advantage (includes factors related to whether the innovation enhances existing practice and processes) • Individuals: Innovation Recipients—Need (includes factors related to whether recipients have needs that the innovation could address)

[a]All domains, constructs, and subconstructs are from Damschroder et al [74]. Definitions are paraphrased for brevity and adapted for relevance to this study.

[b]CFIR: Consolidated Framework for Implementation Research.

[c]DMH: digital mental health.

[d]STB: suicidal thoughts and behaviors.

During theming, we noted that service setting and professional practice factors were greatly interconnected. Four overarching themes were therefore identified that describe (1) service setting and professional practice barriers, (2) DMH platform barriers, (3) service setting and professional practice facilitators, and (4) DMH platform facilitators (refer to Table 3). Relevant CFIR constructs are noted in *italics* in each theme description.

Theme 1: Service Setting and Professional Practice Barriers

Overview

Theme 1 explores barriers to using DMH with youth experiencing STBs that occur in the larger organization and within clinicians' daily practice. This includes subtheme 1.1 (service setting structure does not support immediate crisis response), subtheme 1.2 (DMH incites tension between clinicians' responsiveness and burden of responsibility), and subtheme 1.3 (clinicians express nuanced concerns about youth who report STBs in DMH).

Subtheme 1.1: "Kids Don't Just Go Into Crisis Monday to Friday, 8:30 AM to 4:30 PM": Service Setting Structure Does Not Support Immediate Crisis Response

In most interviews, the structure and purpose of service settings as "not a crisis clinic" (P29) was a principal factor hindering clinicians' ability and *motivation* to use DMH with youth experiencing STBs. This service setting barrier affected participants' overall experience with DMH implementation and contributed to individual-level hurdles to integrating MBC specifically. Although DMH is accessible 24/7 and youth can complete the STBs domain at any time, participants questioned the *compatibility* of DMH that incorporates crisis notifications with their service settings and practice due to restricted clinic hours. "Time limitations" (P12) led to delayed responses to youth who scored high for STBs after clinic hours, on weekends, and during participants' holidays. One participant captured the stress shared by many clinicians: "It's terrible when you come to work and you look [at DMH] and see that they've been suicidal since Friday night, and now it's Monday or Tuesday…" (P09). Despite knowing that DMH provides immediate access to crisis resources, including crisis helplines and prompts to visit emergency services, participants felt uneasy with the situation being outside their control and being unable to guarantee that youth would receive timely and appropriate support.

Service setting structure and purpose also related to clinicians' *opportunity* to integrate DMH and crisis response into their daily workflows and processes. For many participants, DMH was considered "an unfair ask of clinicians, who don't have flexibility in their schedule" (P29) to check and respond to crisis notifications during working hours. Concerns about clinicians' limited availability were frequently tied to concerns that they may be unable to fulfill their existing roles and responsibilities if using DMH. One participant stated:

> *What happens when we get that suicidal flag? Then what? I have a full day booked with 20 patients and I don't have time to cold call this person and make sure they're doing well…* [P22]

In the context of their *work infrastructure*, such as task distribution and staffing levels, several participants consequently struggled to see DMH as a viable means to support youth in crisis.

Subtheme 1.2: "You Should Be Able to Leave Work at Work": DMH Incites Tension Between Clinicians' Responsiveness and Burden of Responsibility

Clinicians' internal conflict about receiving crisis notifications outside working hours was a significant consideration related to the *compatibility* of DMH with their practice. This involved a tension between their compassion and desire to meet youth's urgent needs, and feeling emotionally burdened by crises that occurred in their personal time. One participant articulated consequences to clinicians' mental health:

> *I can't ignore it. I don't care if it's a day off, I'm going to call that person. I don't mind doing that, because I care about my people… But for my own mental health, there were some nights where you get an email […], and I'm sitting there stressing about this individual who has just flagged as high-risk for suicide.* [P04]

Several clinicians also noted ongoing prospective anxiety about crises arising outside work, regardless of whether this transpired in reality. One participant wondered, "…in the middle of the night, are we supposed to respond? […] I would probably not sleep until I got to talk to them" (P14), and another expressed, "If something did happen where they completed [suicide], it would break your heart, that we weren't there for them" (P09). In some cases, feelings of burden negatively impacted clinicians' general perceptions of DMH and their *motivation* to continue using it. Some participants had removed or wanted to eliminate

XSL•FO
RenderX

their work email from their phone to set explicit boundaries between their practice and private lives.

Concerning clinicians' inner tension around DMH, participants shared additional worries about *policies and laws* dictating the need to attend to youth experiencing STBs within a set timeframe. Clinicians' lack of *opportunity* for crisis response meant that some participants were wary to "take on liability that I know I can't attend to" (P29). For one participant, the potential implications of not responding arose in practice and created great discomfort. They described a situation in which a client was assessed as stable during their appointment, but later scored high for STBs in DMH:

> *…it was a question of liability. I believe it was a Friday, I had very little time to follow up, and the question was 'how' and 'what if' […]. So, it was a real moral dilemma for me of, how do I follow up now that I have this information, now that it's in my hands? […] I didn't appreciate that part of my role is somehow to follow up and always be monitoring if they're scoring high on risk […]. Ultimately, we're still somewhat responsible if we do have information in between sessions if the risk changes, and I wasn't comfortable with that.* [P20]

Due to their apprehension about liability, some participants desired "…some version of this program [DMH] where it feels less like my responsibility to check in on, to be a part of […] …something that alleviates my level, or flattens and equalizes my level of responsibility with the client" (P31).

Subtheme 1.3: "How to Respond in an Effective, Timely, Equitable Way": Clinicians Express Nuanced Concerns About Youth Who Report STBs in DMH

As clinicians engaged in *assessing the needs* of youth to guide DMH implementation, they encountered unique concerns about youth who experience STBs self-reporting their symptoms. Some participants had worked with youth that they characterized as "underreporters" (P01) who revised their responses in the DMH STBs domain or stopped using DMH entirely after being flagged as high-risk. Despite prefacing that the purpose of crisis notifications is to confirm youth's immediate safety and engage in safety planning, some youth were "not very keen" (P16) about the follow-up process and "hesitant to go back" (P19) to using DMH. Participants observed that youth may minimize the severity of their STBs due to discomfort with seeing their results or fears that their caregivers would be notified. This was understood as limiting the purpose and practicality of using DMH with certain youth.

Beyond underreporting, a more prevalent issue affecting clinicians' *motivation* to continue offering DMH was their concern that some youth "overreported" their STBs to receive a quicker response from clinicians and a higher level of care to validate their experiences. Some participants felt that youth used DMH "like a bat signal" (P24) to communicate in-the-moment feelings of distress, which they did not perceive as genuine crises. One participant explained:

> *If they plot it [STBs] in the moment in which they have acuity or crisis, then it becomes real. […] Something about the fact that it now exists on that platform […], it almost enhances or amplifies what it means. Because it's available in that moment and there's that protective element of anonymity, people just shoot for the stars, so to speak.* [P31]

"Overreporting" was noted as common among youth with complex diagnoses and acute care needs, who experience "a lower level of tolerance for suicidality […] because of the structure of their thoughts" (P01). Importantly, one participant eloquently stated the "nuances" (P16) of why youth may recurrently score high for STBs in DMH:

> *…if [DMH] is the only thing that they have, that might be the only place that they're comfortable informing that 'I am in crisis'. […] If it was just left up to the platform itself… It's hard for youth to understand, and it's hard for them to not show that they're in crisis as well, if that makes sense.* [P16]

Their sentiment illustrates that DMH may sincerely reflect the perspectives of some youth, and that youth may use DMH as a cry for help.

Considering their therapeutic practice and aims, participants saw that youth reporting STBs in DMH—and the follow-up process—may inadvertently oppose distress tolerance practices learned in treatment and reinforce ineffective coping. Most participants were unsure how to manage frequent crisis notifications that they perceived did not represent youth's true level of distress, and had limited *opportunity* to do so. One participant voiced the uncertainty shared by other clinicians:

> *I felt really torn… […]. I really struggled with how to respond in an effective, timely, equitable way, while also establishing and modelling healthy attachment and healthy boundaries. I still don't know the answer. […] I don't want to ignore the button, and then one day it is a crisis and they do need immediate support […]. But, I have a full caseload now and I don't necessarily have time to take away from another client in order to respond to what I'm thinking is a crisis, but it isn't a crisis.* [P07]

Collectively, clinicians faced multilayered concerns when integrating DMH into their practice with youth with complex needs who have varying ways of communicating their suicidality and need for support.

Theme 2: DMH Platform Barriers

Overview

Theme 2 explores barriers to using DMH with youth experiencing STBs that relate to qualities of DMH itself. This includes subtheme 2.1 (youth struggle to interpret the DMH STBs domain and cope with results) and subtheme 2.2 (continuous DMH crisis notifications for youth with persistent or past STBs are unhelpful).

Subtheme 2.1: "This Doesn't Feel Safe": Youth Struggle to Interpret the DMH STBs Domain and Cope With Results

A DMH barrier for clinicians was the *design* and *complexity* of the STBs domain and its associated assessment questions. Based on their experience and feedback from youth, participants remarked that questions about STBs were poorly worded and contained "gray areas" (P30) that could be interpreted in multiple ways. One participant shared,

> *…a good example would be […], have you ever had a suicidal thought? 'Yes'. And then they're like, but it was 20 years ago, or 10 years […], it was a long time ago. When it's not relevant anymore, it's still relevant on that survey.* [P30]

Several participants commented that youth's *capability* to comprehend the questions and accurately reflect their current STBs in their responses was subsequently limited by the lack of context associated with some of the wording. Moreover, concerns emerged related to youth's capacity to understand the overall purpose and context of the STBs domain—and the necessary follow-up that may occur as a result of their responses. One participant spoke to their experience working with young clients:

> *…a lot of children […], they do make comments about wanting to end their life or feelings of wanting to die. That can be for a multitude of reasons. It's not always suicidal ideation… It can come from wishing to be with a family member that's in heaven. It could be a way of expressing, 'I just don't want to feel angry anymore', or 'I can't deal with this really big feeling' […]. So, I worry about children being on the platform and not understanding the context…* [P21]

Given the lack of clarity, some participants questioned the STBs domain's effectiveness, accuracy, accessibility, and other *evidence-base* factors. One participant expressed, "I'm going to be very blunt; I don't trust the suicide scale on the platform" (P20), and another said, "I don't think that the suicide screen available on the platform is efficient" (P21).

Another concern among clinicians was youth's *capability* to cope with reading and seeing the visual of their STBs assessment results. If youth scored high for STBs, participants worried about how youth might "interpret or sit with this information, especially if the client is presenting with challenges to stress tolerance with new information" (P25). One participant captured clinicians' fears about youth completing the STBs domain by themselves:

> *…expecting them to do all of that on their own, without any co-regulation, without any coaching… […]. This doesn't feel safe, especially if they are suicidal youth, that doesn't cope well.* [P17]

Accordingly, some participants needed to work through DMH with youth to ensure their safety during and after completing the questionnaire. This was perceived negatively due to taking additional time from youth's sessions and limiting clients' self-determination to discuss issues that matter to them.

Subtheme 2.2: "Pigeonholed and Stuck There": Continuous DMH Crisis Notifications for Youth With Persistent or Past STBs Are Unhelpful

In discussing the DMH automated suicide escalation protocol, many clinicians mentioned that the crisis notifications were "very sensitive for our population" (P24). Participants referred to the prevalence of persistent suicidality among their clients to contextualize their concerns with the *design* of the system. If youth experiencing ongoing STBs completed the STBs domain on a regular basis, clinicians were frequently notified about youth whom they were already aware of and closely monitoring. Some participants found this unnecessary and felt it did not add value to their practice. With regard to *assessing the needs* of youth with persistent STBs, participants observed that youth themselves were discouraged by being consistently flagged as "permanent high-risk" (P06). One participant explained:

> *I had some youth who got very frustrated that it always flagged, even if they weren't actively suicidal […]. The patients who have chronic suicidal ideation, I feel like they were pigeonholed and stuck there, whereas they were making incredible gains in a lot of ways, but that portion of the platform didn't depict that.* [P04]

Another participant shared their understanding of youth's thought process: "It was like, 'this is something I go through. I'm not actually gonna do it. I actually don't want to die, right now'" (P24). Regardless of how much time had passed, youth with personal histories of STBs (eg, a past suicidal episode) who disclosed this in DMH also triggered repeated crisis notifications for clinicians.

A related barrier concerning the *design* of the protocol was clinicians' perception that continuous crisis notifications impeded their delivery of strengths-based therapy. Some participants found the automated protocol to be stigmatizing, and considered this "…a barrier for the client, but as well as for me as a practitioner—I don't necessarily want to put my client in that position" (P06). Crisis notifications further distracted from other therapeutic goals that were part of youth's treatment plan. One participant described their position:

> *…when we're flagging, then all of a sudden we're re-diverting to that […]. That becomes the focus, rather than, how do we actually go backwards and look at resiliency, and how to help people grow and develop and work through things. We're always talking about the end, fearful thing…* [P17]

Although participants recognized the necessity of addressing suicidality, they highlighted that working from a strengths-based approach can underlie and support this broader intent.

Theme 3: Service Setting and Professional Practice Facilitators

Overview

Theme 3 explores facilitators to using DMH with youth experiencing STBs that occur in the larger organization and within clinicians' daily practice. This includes subtheme 3.1

XSL•FO
RenderX

(DMH supports the therapeutic relationship between clinicians and youth).

Subtheme 3.1: "You're Not Alone": DMH Supports the Therapeutic Relationship Between Clinicians and Youth

The ability for DMH to facilitate the therapeutic alliance was seen as a significant *relative advantage* of DMH for clinicians' practice, compared with traditional services alone. Across the interviews, participants consistently said that youth using DMH and clinicians' access to their results opened the door to important conversations about suicidality that may not have occurred otherwise. Participants felt that their reaching out to discuss youth's STBs was "validating for the clients" (P11) and enabled youth to "feel like they get to tell their own story—I think it made them feel like somebody gave a darn about them" (P04). When clinicians received a crisis notification, most participants found that the follow-up process also had a profoundly positive effect on their connection with youth. One participant shared their impactful experience responding to youth in crisis:

> *As a practitioner who is very relationship-based, to be able to reach out to somebody when they have identified they're in need, and to do it quickly, I just think it's such a gift […]. To be able to reach out to that person and say, 'you're not alone, these are the resources we have, we're here for you'… I can only imagine being on the receiving end […]. When I think of a youth cohort, you're often feeling unseen and unheard, and not valued or validated. For someone to be able to reach out in a time like that, I think is a huge benefit of the application. […] I feel like this tool, for me… It's been like the magic wand that has allowed me to have a different kind of relationship.* [P18]

Notably, some participants noticed that following up about youth's STBs was particularly powerful for youth who struggle to trust adults and clinicians. Responding to crisis notifications demonstrated clinicians' reliability and responsiveness to youth. One participant stated:

> *I think there was something pretty powerful of, I tell you that I'm going to get this email, and I do actually follow through with following up with you. I think that did a lot for the relationship… […] They appreciated that an adult actually did do what they say they're going to do.* [P04]

Together with one-to-one relationships, DMH aided in cultivating a positive relationship among youth and the service setting at large. Participants provided numerous examples of *teaming* in which their team was able to "reach and wrap services around" (P18) youth experiencing STBs. For instance, one participant's colleagues rapidly and effectively responded to their client's crisis notification while they were out of office. They voiced, "It was nice to know that the days you are away or not feeling well… if someone falls down, they're still going to get caught. They're still going to have a lifeline, even if you're not it" (P15). Another participant described how the alerts emphasized the strength and cohesion of their team: "…it was a success because we learned how effective our clinician team was […] …it was a good experiment in how a tool like this could unite clinicians on our team to take quick action" (P07).

Taking into account the advantages to their practice and service setting, some participants perceived a *mission alignment* between the relationship-building capabilities of DMH and the relational values of their organizations. Participants also felt that DMH and associated setting-wide collaboration to meet youth's needs contributed to their service settings' culture of *recipient-centeredness*.

Theme 4: DMH Platform Facilitators

Overview

Theme 4 explores facilitators to using DMH with youth experiencing STBs that relate to qualities of DMH itself. This includes subtheme 4.1 (DMH enables disclosure, identification, and early intervention).

Subtheme 4.1: "To Be Able to Intervene and Make Sure Someone's Life Is Safe": DMH Enables Disclosure, Identification, and Early Intervention

In a majority of interviews, clinicians noted that DMH expanded their existing awareness about youth on their caseloads who experience STBs—and the extent and urgency of their struggles. Information about youth's STBs gleaned from DMH was considered a strong *relative advantage* even among participants who faced substantial barriers to implementing DMH with youth in crisis. For youth who "barely speak" (P13), "are not forthcoming with that information" (P12), or "would never ever approach suicidality head-on" (P10), DMH created a safe space for disclosure and facilitated identification of STBs by their clinician. Participants also recognized that the STBs domain "discovered or identified" youth whom they "had no knowledge that they were suicidal" (P09), in addition to aiding identification in cases where they were already conscious of possible risk. Some participants were uncomfortable using DMH as their primary means of identification, but appreciated it as a supplementary tool alongside in-person assessment and clinical judgment.

Following disclosure and identification, clinicians stressed another *relative advantage* of DMH: "to be able to intervene and make sure someone's life is safe" (P29). Participants frequently spoke to the benefits of DMH with regard to early intervention, the provision of timely support, the ability to share internal and external resources, and how this met the *needs* of youth. Sometimes, this included expediting youth on waitlists to receive earlier and more intensive treatment to address their STBs. One participant shared that overcoming clinician discomfort to discuss STBs identified via DMH may prevent later escalation and the need for emergency services:

> *I know clinicians are generally scared about suicide, and it's always uncomfortable. But actually, when you look at it from the perspective of, let's get in there early and have that conversation. I haven't needed to send anybody to the hospital, or get any services involved immediately […]. We've gone through a suicide [safety] plan […]. It's allowed for youth to*

XSL•FO
RenderX

> *talk through what they could do, what they might do.* [P05]

Participants also felt that DMH itself had a "big role to play" (P19) in early intervention by providing resources, such as apps and e-tools, that youth can use to self-manage their STBs and reinforce coping skills between appointments.

Finally, some clinicians were optimistic that documentation about STBs in DMH might improve the quality of the youth mental health care system overall. One participant contemplated:

> *I think there's value to measurement-based care […]. The more that we're able to research, document, the better. It's actually scary, how often something happens in the medical field that we don't have proper documentation of, we don't have proper measurement of. We don't know that 70 people were suicidal. We have absolutely no idea when, why, circumstances, how suicidal they were… The more information that we have, and can collectively share, is better.* [P13]

They and other clinicians saw the potential for documentation and resultant system-level improvement as an overarching *relative advantage* of DMH—and ultimately, a gain for young people themselves who require support with their experiences of suicidality.

Clinician Recommendations

Clinicians often strategized potential solutions to the identified service setting, professional practice, and DMH platform barriers. Their recommendations are provided in Table 4 in accordance with the overarching barrier themes.

Table . Clinician recommendations for addressing the barriers to using digital mental health (DMH) with youth experiencing suicidal thoughts and behaviors (STBs).

Theme and barrier	Clinician recommendations
Service Setting and Professional Practice Barriers	
Service settings do not support immediate crisis response due to restricted clinic hours.	• Service settings implementing DMH[a] should integrate a designated crisis response professional or crisis response team from within or outside the service setting who are available to respond to youth flagged in DMH. • This professional or team should have flexible availability within and outside service setting hours.
Clinicians have limited opportunity to integrate crisis response within their schedules.	• Refer to above recommendations.
Clinicians face barriers related to responding to youth in crisis outside working hours, including feeling burdened in their personal time and concerns about liability.	• Refer to above recommendations. • Outside service setting hours, DMH should notify local and available crisis service settings instead of notifying clinicians.
Clinicians have limited opportunity to respond and are unsure how to respond to youth in crisis that they perceive are "overreporting" their symptoms.	• The DMH STBs[b] assessment should include questions that assess "bigger picture" experiences with STBs, in addition to in-the-moment feelings of distress and suicidality.
DMH Platform Barriers	
Some wording in the DMH STBs assessment can be interpreted multiple ways and lacks context.	• Revise wording to make assessment questions clearer and easier for youth to interpret. • Clinicians note that youth in crisis are not thinking clearly; ensure that the assessment and crisis resources are easy for youth to navigate.
Some youth may struggle to interpret the DMH STBs assessment and cope with reading and seeing the visual of their results.	• Complete assessment with youth in-session; however, clinicians note that this may take additional time.
Youth with persistent or past STBs are continuously flagged as high-risk in the platform.	• The assessment should clearly distinguish between past and present STBs. • DMH should include an open text box for youth to provide comments and context about STBs (eg, when they occurred—past vs present). • DMH should include an open text box for youth to provide follow-up comments and context about STBs (eg, did they access crisis resources and are they still suicidal). • If youth are no longer in active crisis and report this, DMH should "un-flag" youth. • DMH should show improvement for youth with persistent STBs who are improving yet still require close monitoring.

[a]DMH: digital mental health.

[b]STB: suicidal thoughts and behaviors.

Discussion

Principal Findings

This study explored clinicians' perceptions of using DMH with youth experiencing STBs. A theoretical thematic analysis identified barriers and facilitators related to clinicians' service settings and professional practice, and DMH itself. Our findings highlight important topics for discussion, practical implications and recommendations, and directions for future research.

In the first theme, participants shared that their service settings were not intended to provide immediate and all-hours crisis response to youth who score high for STBs in DMH. Concerns about the compatibility of DMH due to clinic hours and school closures were expressed in preimplementation focus groups conducted by our research and implementation team [58,59]. Similarly, other studies document clinician apprehension about youth reporting their STBs outside working hours [60-62], while a clinician is on leave [61,62], or if a clinician works part-time [61]. Our findings reveal additional fears that clinicians are unable to ascertain that the crisis resources provided in DMH (eg, crisis helplines or community-specific crisis resources) will adequately support youth in their moment of need. If crisis notifications occur during working hours, clinicians' ability to respond while fulfilling their existing roles and responsibilities is still limited by hectic schedules, competing demands [58], and high-acuity client caseloads [60].

The first theme also describes that clinicians' deep care for their clients' well-being extends beyond clinic hours to impact their personal time and thoughts. Although previous studies acknowledge that DMH may contribute to clinician burden [61,62], our findings more clearly define the emotional impact of crisis notifications as a unique barrier to clinicians' acceptance of DMH. This study restates another preimplementation worry that clinicians may be held legally responsible if crisis notifications are not immediately attended to due to working hours and capacity, and an adverse event occurs [58,59].

A final and noteworthy finding in the first theme is that youth experiencing STBs may under- or overreport their symptoms in DMH. Underreporting or nondisclosure of STBs may relate to fears about confidentiality [40], potential harmful reactions from clinicians [42], or other factors, which may contribute to some youth's preference for DMH that is self-guided [38]—vs DMH that provides shared access to youth's data (eg, Innowell). Our study also identifies a marked incongruity between clinicians' assessment of the criticality of youth's STBs and youth's expressed vulnerability and urgency in the DMH STBs domain. As said by one participant, frequent crisis notifications may occur if youth are only comfortable and able to alert clinicians about their STBs through online mediums [52]. Participants' perception that responding to continuous alerts may reinforce ineffective coping is consistent with Hetrick et al's [62] finding that clinicians perceive that DMH may unintentionally create learned helplessness.

Of relevance to all concerns in the first theme, 2 studies exploring both clinician and youth perspectives about DMH emphasize youth's insight into clinician barriers [61,62]. Hetrick et al [62] found that youth were understanding of clinicians' working hours, the difficulty of responding to crisis notifications after hours, and were aware that crisis resources (eg, crisis helplines) may not guarantee immediate support. Youth participants in a co-design study shared worries that monitoring risk via DMH may be burdensome for clinicians and thus may negatively impact the therapeutic alliance [61]. While mindful of clinicians' time and capacity, youth did want their clinician to know if they had used crisis resources and received support [62]. Some youth felt that automated protocols should have sufficiently high thresholds for determining the severity of risk to reduce clinician burden [61].

In the second theme, participants perceived the DMH STBs domain's complex wording and lack of context as barriers to youth using DMH and DMH accurately reflecting youth's distress. Preimplementation data similarly captured concerns that DMH may be unsuitable for youth experiencing STBs, difficult to navigate, and difficult to interpret [58,59]. This study evidences such concerns manifesting in practice and adds that, in addition to the assessment itself, results may be challenging for youth to understand and cope with without clinician support. Accessibility, ease of use [52,54], and "clear and precise questions" [54] are noted as facilitators to youth with STBs engaging with DMH.

The second theme also describes the sensitivity of the DMH automated suicide escalation protocol and frequency of crisis notifications, contextualized by participants' acute client populations. It is worth noting that a majority of our participants were rurally located. Rural communities in Canada face a higher burden of mental health crises [12], due in part to inequitable access to mental health resources, stigma, and economic pressures [79,80]. This aligns with our finding that many youth in rural areas experience ongoing STBs or have past STBs—and thereby trigger frequent alerts. Prior work explains how youth seeing their decline in DMH may create feelings of disappointment, shame, guilt, or even the urge to engage in self-harm [50]. Further, a study about best practices for working with youth experiencing STBs [40] supports our participants' concern that continuous crisis notifications may oppose strengths-based therapeutic approaches. Youth participants were uncomfortable being labeled as at-risk, felt that risk assessment may be reductive, and desired more encouraging assessment language to facilitate help-seeking [40]. Despite this, youth accentuated the importance of talking about STBs with clinicians and wanted clinicians to ask about STBs.

Findings in the third theme demonstrate that DMH can facilitate conversations about STBs between clinicians and youth. Other researchers have addressed the potential for DMH to instigate a collaborative dialogue for youth who have not yet shared their STBs [53], youth who feel ashamed and are therefore reticent to disclose STBs in-person, and youth who are more comfortable expressing themselves online [52]. In turn, conversations about STBs and safety planning may build therapeutic rapport [44,53]. Our study adds that DMH may promote a stronger relationship between youth and the service setting by uniting clinician teams to support youth in distress. In contrast to positive findings, Sundram et al [61] found that some clinicians felt that DMH

XSL•FO
RenderX

had no impact on their relationship with youth. Systematic reviews note that DMH may only promote deeper relationships for youth experiencing STBs if it is leveraged as a complement to traditional care, rather than replacing it fully [44,52].

Finally, the fourth theme illustrates the life-saving capacity of DMH by facilitating disclosure, identification, and early intervention for STBs. Disclosure of STBs may be more likely in DMH vs face-to-face assessment given youth's comfort with technology [45,52,54,60]. As a result, clinicians are better able to detect youth's urgent needs and understand the breadth of their symptoms [19,53,54,68]. Our finding that DMH supports early intervention is congruent with several studies reporting that DMH improves service settings' and clinicians' response to suicide risk by assisting clinical decision-making about youth's treatment [19,54,57,68] and escalating youth on waitlists to receive immediate care [19,53]. Additionally, previous work indicates that apps and e-tools for STBs (such as those provided in Innowell) may bridge the gap in-between sessions [52]—particularly if clinicians practice using the resources with youth to increase their comfort level [40]. This study also brings to light that information about STBs in DMH may be documented and acted upon to improve youth mental health services and targeted supports for suicidal youth.

Practical Implications and Researcher Recommendations

The fact that many of clinicians' preimplementation concerns were realized when using DMH in practice underscores the validity of their apprehension, and the need to hear and respond to their concerns. In relation to service setting and professional practice barriers, we found that adaptations are required to ensure that youth with the courage to share their STBs receive the support that they need. We echo our participants' recommendation that service settings implementing DMH should designate staff with scheduling availability and flexibility to monitor and respond to crisis notifications in DMH. Service settings might consider adding multiple clinicians or assigning a clinical team as support persons to youth's DMH profile, as well as including caregivers or other trusted adults as emergency contacts. Automatically alerting all-hours crisis service settings in the community, rather than clinicians, may also alleviate burden outside working hours—while still documenting STBs in DMH for later viewing. Concerns about liability should be addressed by providing clinicians using DMH with sufficient training and understanding of local laws, policies, and standardized clinic procedures for responding to youth in crisis. Along with procedural changes, we call for increased organizational support for clinicians whose own mental health is affected by working with youth experiencing STBs. Access to mental health resources and regular debriefing with clinician peers and leadership may support clinicians in managing stress and vicarious trauma. Regarding youth who underreport their STBs, clinicians should consider DMH as similar to paper-and-pencil assessments and rely upon their clinical judgment and relationship with youth to determine if youth are minimizing their distress. Clinicians should recognize that youth that they perceive are "overreporting" their STBs may not feel that they are exaggerating and may require more intensive treatment. Before using DMH, creating clear expectations of clinicians' availability and response times to crisis notifications may be helpful so that youth are not distressed by not receiving an immediate response.

To resolve DMH barriers, DMH developers should differentiate crisis notifications for youth who (1) are continuously suicidal or have past STBs, vs (2) youth experiencing active crises requiring urgent support. Reporting ongoing or past STBs could trigger a "secondary" alert that suggests checking in with youth in-session rather than rapid clinical action. Our participants' recommendation for DMH to include open text boxes may allow youth to comment on assessment questions they are unsure of and add context to their responses. In Sundram et al's [61] study, youth proposed a higher threshold for alerts and suggested that some youth may be capable of identifying and communicating their level of urgency in DMH.

This study emphasizes the value of implementation frameworks to assess implementation processes, identify DMH-specific barriers, and guide the design and adaptation of DMH itself. For instance, applying frameworks such as the CFIR [74] iteratively throughout DMH development and preimplementation project phases may uncover key contextual factors to address early in design (eg, outer and inner setting context, clinician capacity, and considerations for youth with ongoing or past STBs), improve alignment between DMH features and clinical processes, and increase responsiveness to user needs.

Our findings also offer practical implications for augmenting personalized care using DMH and youth's data. Considering individual risk factors for STBs and youth's unique perceptions and experiences, personalization is a facilitator to engaging with DMH [52]. Previous work highlights that multidimensional DMH assessment may detect personal underlying issues impacting STBs [50,53] and track patterns in youth's thoughts and behaviors [50]. By recognizing contributing factors beyond the symptom itself, DMH may enhance youth's self-knowledge [50] and facilitate the delivery of personalized care by clinicians [53]. We further suggest that DMH include features that enable youth and clinicians to codevelop a personalized safety plan with coping strategies, apps, e-tools, and emergency contacts.

Aligned with our larger project's outcome objectives, evidence shows that early intervention for STBs may mitigate hospitalization [81] and suicide attempts [82]. We advocate for the continued implementation of DMH in health care systems and other youth-serving institutions and organizations (eg, schools) to meet youth where they are, identify their areas of need, and intervene for STBs at early stages.

Future Directions

As digital interventions for suicidality evolve, DMH tools that assess multiple health domains remain fundamental to capturing holistic data and recognizing the multifactorial nature of risk factors for STBs. Research on DMH specific to STBs is another important area for attention and development. At present, novel approaches include (but are not limited to) natural language processing systems that detect STBs [44], real-time monitoring tools that assess STBs at the time they occur [20], machine learning [83] and continuous-time trajectory models [84] that

XSL•FO
RenderX

predict STBs, and just-in-time adaptive interventions that provide personalized in-the-moment support [11]. There is a lack of research on DMH for STBs that acknowledges and incorporates aspects of culture [52] and intersectionality. Given the compounded risk factors experienced by some populations (eg, youth who are racialized and/or 2SLGBTQIA+), community co-design of DMH for STBs is a significant and urgent area for growth, and an opportunity to support youth who are underserved and excluded by current health care systems. Trauma-informed DMH apps for youth exposed to trauma and experiencing STBs is another direction for future research. For all types of DMH, the inclusion of youth perspectives and the lived experience lens is imperative to shape accessible, inclusive, and effective resources.

All existing and future DMH developments necessitate rigorous testing and evaluation of implementation in a variety of settings. Our research and implementation team is continuing to implement DMH and share our findings of the perspectives of clinicians [58,59,64], leadership, and young people receiving care [65] to identify obstacles and practical solutions.

Strengths and Limitations

To our knowledge, this qualitative analysis is one of few studies investigating clinician perceptions of using DMH with youth experiencing STBs. The inclusion of clinicians working in PCNs, specialized mental health services, schools, and community-based organizations in rural and urban locations across Alberta, Canada, provides insights from diverse settings. Clinicians' ethnic diversity is another strength within our demographics—although we were unable to report specific ethnic origins to protect participants' identities. During data analysis, the CFIR offered a comprehensive theoretical framework for producing a rich description of themes. The involvement of researchers with lived experience of STBs and who have been affected by youth suicide aided in understanding the complexity of experiences of STBs, receiving treatment, and working with youth as clinicians.

A limitation within our demographics is that most participants identified as women. While the gender distribution is illustrative of mental health clinicians in Canada, the addition of perspectives of men and gender diversity may have enriched our findings. Our relatively small sample size of 32 clinicians in Alberta may not be representative of other communities and contexts. Finally, this paper outlines the perceptions of clinicians only; including youth along with clinicians may have resulted in different findings and recommendations.

Conclusions

This study sought to identify barriers and facilitators to using DMH with youth experiencing STBs in youth-serving mental health service settings across Alberta, Canada. Clinicians perceived service setting and professional practice barriers, including that the structure and purpose of service settings do not support immediate response to crises flagged in DMH, DMH crisis notifications create tension between clinicians' responsiveness and the emotional burden of monitoring DMH outside working hours, and clinicians are uncertain how to manage and respond to youth with complex needs who communicate their distress in DMH in differing ways. The complexity of the DMH STBs domain and continuous crisis notifications for youth with persistent or past suicidality were identified as barriers in DMH. Despite their concerns, clinicians saw that using DMH collaboratively with youth supported the therapeutic relationship and aligned with their service settings' mission and values. Disclosure, identification, and early intervention for STBs enabled by DMH significantly benefited youth and inspired clinicians to continue implementing digital tools.

Given the association between STBs and suicide, attending to STBs is a critical component of suicide prevention. Our findings demonstrate that direct assessment of STBs using DMH may address the youth suicide crisis by facilitating disclosure and rapid clinical action to support early intervention. Moreover, multidimensional assessment may reveal important information about STBs and risk factors, with advantages for personalized care and system-level improvement. Clinicians delivering DMH must be supported by applying their recommendations and continuously strategizing to mitigate barriers and leverage facilitators for sustained implementation.

Acknowledgments

We express our thanks to Marianne Barker for facilitating interviews with clinicians, and Emma Thomsen for working with youth as a Digital Navigator. We are grateful for the clinicians who invested their time in learning and implementing digital mental health (DMH) and shared their perspectives on using DMH in practice. Finally, we extend our deepest gratitude to the youth and their parents and caregivers who have profoundly impacted our lives, and our work in the mental health field. We are honored to have known you and carry your stories with us every day.

Artificial intelligence tools were not used during the preparation or writing of this manuscript.

Funding

The authors disclose receipt of the following financial support for the research, authorship, and publication of this paper. This work was supported by the Partnership for Research and Innovation in the Health System (PRIHS) Program, Alberta Health Services, the Alberta Children's Hospital Foundation, and the Canadian Institutes of Health Research (CIHR; operating grant: SPOR iCT Rewarding Success). Abstract

Background: Digital remote monitoring using smartphones and wearable devices is a promising solution for psychosis management, where precise, time-sensitive intervention is crucial. Combining active symptom monitoring (ASM) and passive sensing (PS) can support self-management by allowing remote, low-burden mental health monitoring.

Objective: This study aimed to explore (1) views on collecting data using ASM and PS methods and comfort levels with different types of data gathered via these methods, (2) views on using smartphones and wearable devices in the context of mental health care, and (3) the ownership and usage of smartphones and wearable devices.

Methods: We conducted a cross-sectional survey study with service users with psychosis in the United Kingdom between March 2023 and March 2024.

Results: A total of 309 participants completed the survey. They reported mixed views on using ASM and PS technologies for monitoring mental health, with more participants endorsing the concept than opposing it (ASM: n=145, 46.9% and PS: n=132, 42.7%). However, the type of data gathered using these methods was an important factor. Collecting personal information was deemed less acceptable (P<.001) than other data types (physical health, mental health, environment, and nonpersonal device information).

Conclusions: We found that participants were comfortable with using apps and wearables for digital remote monitoring, though personal information was less acceptable than other data types due to privacy and surveillance concerns. This highlights the importance of further exploring trust issues related to digital monitoring and ensuring that end users have choices regarding the types of data that digital systems gather and share with mental health services.

digital remote monitoring; psychosis; service user; passive sensing; smartphone; wearable

Introduction

Background

Conventional methods of monitoring and treating psychosis rely on service users recalling symptoms over the preceding period, often weeks or months, at a scheduled appointment time with a member of their care team [1,2]. However, the accuracy of symptom recall is often compromised due to infrequent clinic appointments in overstretched mental health services [3,4]. This poses challenges for psychosis management, where precise, time-sensitive treatment is crucial. In this context, mental health services are increasingly advocating for the adoption of digital tools to overcome the limitations of conventional assessment and intervention approaches [5].

Digital remote monitoring (DRM) in the context of mental health care refers to the use of digital technology to track and assess mental health symptoms remotely. It includes active symptom monitoring ([ASM]; self-reported data) and passive sensing ([PS]; sensor-derived data), enabling continuous, low-burden monitoring and the opportunity for timely, personalized interventions [3,6,7]. PS using smartphones and wearables can collect extensive sensor data, from which features can be extracted to infer clinical states [8]. In psychosis specifically, a recent systematic review found that the most used

XSL•FO
RenderX

devices for PS were accelerometers and smartphones, and the most commonly derived features were sleep duration and time spent sedentary [9]. Despite being in its early stages, recent advancements in DRM for psychosis show its potential for assessment and treatment [10]. Specifically, it has been used to monitor psychotic symptoms [11,12], functional outcomes [12], and sleep [13]. Beyond symptom monitoring, digital tools have also been used for relapse prediction. A recent systematic review found that, as of 2022, 52 studies had used ASM or PS to track early warning signs and other antecedent behaviors of relapse or symptom worsening, reflecting the rapid growth of these technologies in mental health care [14].

Numerous surveys have demonstrated a continuous increase in digital technology ownership among individuals with psychosis [15-17]. A recent survey study reported a 90% smartphone ownership rate [18], suggesting that access to devices may no longer be a significant barrier to using digital health technologies in psychosis care. Moreover, the survey indicated that most participants used instant messaging and social media multiple times per day, while health-related apps were rarely used [18]. However, despite this accessibility, service user acceptance and engagement with digital health systems have remained low, partly due to the insufficient understanding of stakeholders' preferences and needs [19]. Indeed, a recent review exploring the barriers and facilitators of engagement with digital mental health interventions (DMHIs) highlighted that successful implementation depends on the functionality of digital health systems, the relevance of their content to users' specific needs, and users perceiving value and benefit from using these interventions [20]. Additionally, demographic and other factors may affect engagement, but their effects are inconsistent across studies [20]; for example, some studies found higher engagement among older adults [21,22], while others found higher engagement among younger people [23,24] or mixed effects [25]. While previous research has explored general barriers and facilitators to engagement, there is a gap in understanding perceptions of PS technologies in this population.

Aims

This study aimed to understand the views of service users with psychosis on using personal digital devices for remote symptom monitoring. We aimed to explore (1) views on collecting data using ASM and PS methods specifically in the context of an individual's mental health care, and comfort levels with different types of data gathered via these methods; (2) broad views on using smartphones and wearable devices in the context of mental health care; and (3) how individuals with psychosis own and use smartphones and wearable devices, as well as the barriers they perceive to their use. In this study, digital health tools refer to apps, sensing features on a smartphone, wearable devices, or smartwatches that are used for monitoring and managing mental and physical health (eg, monitoring symptoms, counting steps, helping with sleep routines, and setting medication reminders).

Methods

Participants

We conducted a one-off survey study with service users with psychosis between March 2023 and March 2024. To enhance inclusivity, we deliberately applied a broad criterion for psychosis, incorporating both the use of antipsychotic medication and the presence of psychotic symptoms (ie, hallucinations, delusions, confused, and disturbed thoughts) in addition to a formal diagnosis where available. More specifically, eligibility criteria were (1) self-reported diagnosis of a schizophrenia-spectrum disorder, taking antipsychotic medication, or experiencing psychotic symptoms; (2) aged 18 years or older; and (3) provision of informed consent. Participants not sufficiently fluent in English to complete the survey were excluded from participation. To reach a broad sample, we used a wide range of recruitment methods: social media platforms (eg, X (X Corp) and Reddit (Reddit, Inc), displaying posters in mental health services, asking clinicians to identify potential participants from their caseload, recruitment via the Clinical Research Network across England, existing research cohorts of the research team, and third sector organizations.

Data Collection

The survey (Table S1 in Multimedia Appendix 1) took approximately 20 - 30 minutes to complete and gathered demographic information and explored participants' experiences with and opinions of using smartphone apps and wearable devices for mental health management. It also explored views on using digital health tools in clinical practice. The survey was developed based on a review of existing literature on DMHIs in mental health care [26-37]. To enhance participants' understanding of DRM, the survey included brief explanations of ASM and PS, accompanied by images of various digital devices. Participants could choose to complete the questionnaire in either an online or paper format based on their preference. The Qualtrics (Qualtrics, LLC) platform [38] was used to deliver the online version, accessed via a URL link or a QR code. The participant information sheet was embedded in the survey for potential participants to read, followed by a series of screening questions to assess eligibility. After participants completed the screening questions, those who were not eligible were shown a thank-you message explaining their ineligibility, and the survey ended. Eligible participants were directed to the survey questions. For participants completing a paper questionnaire, a study pack containing the paper survey (identical in content to the online version) and a return postage-paid envelope was sent. Paper questionnaire responses were then entered manually into the Qualtrics database. To monitor data integrity and minimize the risk of survey fraud, study data were reviewed monthly by the research team. Summary completion numbers were shared with participating NHS trusts, and local contacts were asked to confirm that the number of surveys received aligned with their recruitment logs. Patient and public contributors in our digital mental health group reviewed survey items for acceptability and relevance.

Data Analysis

Quantitative analysis was performed using R (R Core Team and R Foundation for Statistical Computing) [39]. Descriptive statistics, including frequencies and percentages, were calculated. To understand the differences in participants' comfort level with different features collected via DRM, we

XSL•FO
RenderX

used principal component analysis (PCA) to cluster features into high-level data-type groups (eg, personal data and health data). The clustering process was informed by a previous study on individuals' perspectives on sharing different types of digital remote monitoring data [40]. Using this as a conceptual framework, an initial grouping of features was proposed and subsequently refined through iterative discussions among authors XZ, EE, and SB. PCA biplots were examined to assess how features grouped across components, and the pair of components that provided the clearest visual separation between feature groups was used to guide clustering. Following that, we conducted the Kruskal-Wallis test to compare participants' comfort levels between data-type groups. Dunn post hoc test with Bonferroni correction was applied to identify the specific significant differences. $P<.05$ was considered statistically significant. Data visualization was created using R and Microsoft Excel [41]. We used content analysis to summarize the free-text data [42]. Initial coding was conducted by author XZ, and the results were subsequently reviewed and refined by authors EE and SB. When divergence occurred, a meeting was scheduled to discuss the discrepancies until agreement was reached. NVivo (version 12; QSR International Pty Ltd, now known as Lumivero) was used to analyze free-text data [43].

Ethical Considerations

The study was approved by the North West–Greater Manchester West Research Ethics Committee (reference: 22/NW/0246). All participants had the option to enter a £50 (US $67.40) prize draw at the end of the survey as compensation for their time. A participant information sheet was embedded in the survey for potential participants to read.

Results

Demographics

In total, 309 participants completed the survey. The median age was 38.5 (IQR 28 - 50) years. There was an approximately even gender split (male: n=145, 47% and female: n=153, 49%). Almost all participants reported their gender was the same as their sex assigned at birth (n=298, 96.4%). Most participants were White (n=244, 79%), single (n=173, 56%), and had no caring responsibilities (n=213, 68.9%). A third of participants were employed (n=99, 32%), over half were living with family (n=159, 51.5%), and nearly three-quarters had received further education or higher (n=223, 72.2%). Full sample demographic characteristics are shown in Table 1.

Views on Collecting Data Using Active Monitoring and PS Methods

As shown in Table 2, a greater number of participants endorsed using ASM and PS for remote monitoring (ASM: n=145, 46.9% and PS: n=132, 42.7%) and sharing this information with their care team (ASM: n=144, 46.6% and PS: n=134, 43.4%) compared to those who opposed it. Nevertheless, many participants felt uncomfortable using these technologies for data collection (ASM: n=56, 18.1% and PS: n=73, 23.6%) and sharing the data with their care team (ASM: n=61, 19.7% and PS: n=60, 19.4%), and a notable number of participants found these technologies unhelpful (ASM: n=45, 14.6% and PS: n=47, 15.2%). For the questions reported in Table 2, a substantial proportion of participants reported "unsure" (range 18.5% - 21.7%) or did not answer the questions (range 14.6% - 15.5%).

Neither	67 (21.68)	85 (27.51)
Missing	45 (14.56)	47 (15.21)
How comfortable do you feel with information about whether you have been sleeping, exercising, traveling, or phoning people being collected and shared with a member of your clinical or mental health team?		
Comfortable	144 (46.6)	134 (43.37)
Uncomfortable	61 (19.74)	60 (19.42)
Unsure	59 (19.09)	67 (21.68)
Missing	45 (14.56)	48 (15.53)

Figure 1 shows participants' responses regarding the acceptability of using a smartphone or wearable to collect 20 specific types of information. Only 4 out of the 20 data types or features received over 50% endorsement by participants. Specifically, heart rate (55%), fears of deteriorating (55%), sleep patterns (53%), and mood (53%) were endorsed ("agree" or "strongly agree") by participants. PCA was performed to further explore participants' comfort levels with different categories of data. Although principal components 1 and 2 explained most of the variability (66.6% and 11.1%, respectively), the clusters on the biplot of these 2 components were not clear (refer to Figure S1 in Multimedia Appendix 1). Instead, we used the biplot of principal component 2 and principal component 3 (which explained 4.3% of the variability) to guide the clustering (refer to Figure S2 in Multimedia Appendix 1). Features were clustered into 5 data types: physical health information (eg, heart rate), mental health information (eg, mood), personal information (eg, location), environmental information (eg, weather), and nonpersonal device information (eg, battery level). The Kruskal-Wallis test showed that participants' comfort levels differed significantly between data-type groups (P<.001). Dunn post hoc test for pairwise comparisons showed that participants were significantly less comfortable sharing personal information compared to all other data types (P<.001). Participants felt significantly more comfortable sharing mental health and physical health data than for all other data types (P<.05), except for environmental data (no significant difference between mental health data and environmental data; P≥.99). There was no significant difference in comfort levels between sharing mental health data and physical health data (P=.24), nor between environmental data and nonpersonal device data (P=.57; refer to Table 3).

XSL•FO
RenderX

Figure 1. Acceptability of collecting specific types of information using a smartphone or wearable device.

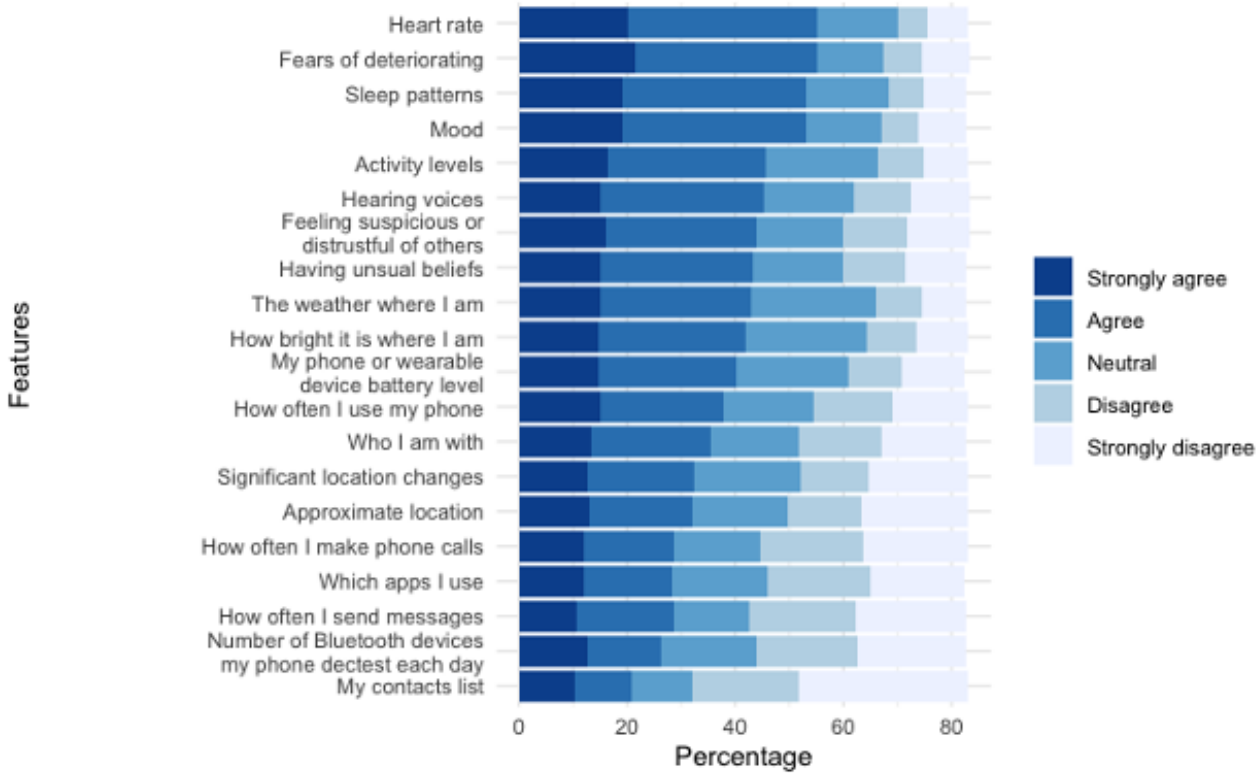

Table . Pairwise comparison of participants' comfort level with sharing different types of data with researchers.

Comparison	*z* value	Unadjusted *P* value	Adjusted *P* value[a]
Environmental information–nonpersonal device information	1.91	.06	.57
Environmental information–mental health information	−1.17	.24	≥.99
Nonpersonal device information–mental health information	−3.45	.001	.006
Environmental information–personal information	8.08	<.001	<.001
Nonpersonal device information–personal information	5.67	<.001	<.001
Mental health information–personal information	12.94	<.001	<.001
Environmental information–physical health information	−2.87	.004	.04
Nonpersonal device information–physical health information	−4.96	<.001	<.001
Mental health information–physical health information	−2.25	.02	.24
Personal information–physical health information	−13.31	<.001	<.001

[a]*P* values were adjusted for multiple comparisons using the Bonferroni correction.

Participants were also asked to share any other concerns not listed in the survey in a free-text question (refer to Tables S2 and S3 in Multimedia Appendix 1). The top concerns about ASM were "risk of data misuse" (29/91 free-text responses, 32%), "feeling uncomfortable with being monitored" (19/91, 21%), and "tracking symptoms making people feel worse" (14/91, 15%). For PS, participants expressed concerns such as "feeling uncomfortable with passive sensing" (19/57 free-text responses, 33%), "it is invasive and unhelpful" (13/57, 23%),

XSL•FO
RenderX

and "preferring to use it collaboratively rather than being monitored by a clinician" (9/57, 16%).

Views on Using Smartphones and Wearable Devices in the Context of Mental Health Care

The concept of using an app or a wearable device to support mental health between appointments was highly acceptable. A notable 59.9% (n=185) were willing to use an app, while an even higher 65% (n=201) expressed interest in using a wearable device. When it comes to integrating apps or wearables into mental health management, the most favored option was a blended approach of either an app (n=124, 51.7%) or a wearable (n=102, 41.1%) combined with face-to-face care. Moreover, the preferred method for receiving prompts to complete symptom monitoring tasks was a combination of prescheduled prompts and self-initiated responses, rather than relying solely on either method. Participants preferred this approach for both smartphone apps (n=86, 35.8%) and wearable devices (n=74, 29.8%).

Regarding the perceived impact of using apps and wearables, more than half of the participants reported that using such technologies would have no negative impact on their mood (apps: n=135, 56.3% and wearables: n=140, 56.5%) or psychotic symptoms (apps: n=117, 48.8% and wearables: n=144, 58.1%). However, when asked about the positive impact, half of the participants expressed a neutral stance on the statement that using a smartphone app (n=121, 50.4%) or a wearable device (n=128, 51.6%) makes them feel happy. Over half (n=130, 54.2%) reported that using smartphone apps could help them feel connected with others, whereas slightly fewer (n=122, 49.2%) participants reported this for wearable devices. In terms of impacts on overall mental health and well-being, 40.8% (n=98) and 37.9% (n=94) either "agreed" or "strongly agreed" that using smartphone apps and wearable devices, respectively, could help their overall mental health and well-being. A small proportion of participants considered using smartphone apps (n=48, 20%) or wearable devices (n=50, 20.2%) to be unhelpful for overall mental health and well-being.

As shown in Table S4 in Multimedia Appendix 1, the ranking of advantages, based on the total percentage of participants who reported "agree" or "strongly agree," was consistent across both smartphones and wearables. Top advantages were the ability to be used at any time, in any location (app: 189/240, 78.8% participants and wearables: 193/248, 77.8% participants), sharing information in real time with the care team (app: 180/240, 75% participants and wearables: 180/248, 72.6% participants), the ability to identify triggers and patterns (app: 171/240, 71.3% participants and wearables: 172/248, 69.4% participants), and being able to record and reflect on symptoms and experiences over time (app: 176/240, 73.3% participants and wearables: 168/248, 67.7% participants). Additional advantages specific to smartphone apps are shown in Table S5 in Multimedia Appendix 1. When participants were asked the extent to which barriers might impact their likelihood of using smartphone apps or wearable devices for mental health care (refer to Table S6 in Multimedia Appendix 1), the primary concern for apps was that they might be used as an excuse to replace face-to-face care (141/240, 58.8% participants). In contrast, cost was the main barrier for wearables (144/248, 58.1% participants).

Ownership and Usage of Smartphones and Wearable Devices

Of the 309 participants, 276 (89.3%) owned or had access to a smartphone; in contrast, 95 (30.7%) participants owned or had access to a wearable device. The percentages of iPhone (n=138, 44.7%) and Android (Google LLC; n=141, 45.6%) smartphone users were comparable. For participants using a wearable device, Apple Watch was the most used device (n=32, 10.4%), followed by Fitbit (n=28, 9.1%) and Samsung (n=16, 5.2%). Most participants reported that they faced no barriers to owning or using a smartphone (n=191, 61.8%). For those who did encounter barriers, paranoia or suspiciousness related to technology (n=37, 12%), affordability (n=32, 10.4%), and digital literacy (n=27, 8.7%) were the top reasons. Most participants (n=215, 69.6%) identified barriers to owning or using a wearable device. The primary barrier was a lack of interest (n=94, 30.4%), followed by affordability (n=82, 26.5%) and a perceived lack of need to use it (n=45, 14.6%). In terms of frequency of use, smartphones and smartphone apps were the most frequently used digital tools, with 77% (n=238) and 60.2% (n=186) of participants, respectively, reporting using these multiple times a day. In contrast, in line with the ownership rates, 60.5% (n=187) stated they did not use wearable devices. Nearly half of the participants (n=147, 47.6%) had used health-related apps. Among those, physical health apps were the most used (n=99, 32%), while just over a quarter (n=80, 25.9%) reported using mental health apps.

Regarding participants' preferences for the appearance of wearable devices, we selected Fitbit as an example of a consumer-grade device and the Empatica E4 as an example of a research-grade device. These 2 devices were chosen because they are frequently used in digital mental health research [9]. More participants chose the Fitbit (n=168, 54.4% participants) with a black strap (n=106, 50.7% participants) due to its more stylish design compared to the Empatica E4 (n=41, 13.3% participants), Fitbit with steel blue strap (n=52, 24.9% participants), and Fitbit with lunar white strap (n=49, 23.4% participants). Regardless of which type of device they selected, most participants were willing to use it daily (E4: 25/41, 61% participants and Fitbit: 121/168, 72% participants) and for longer than 1 year (E4: 21/41, 51.2% participants and Fitbit: 87/168, 51.8% participants). Participants identified the most important features of wearable devices as privacy (n=186, 89% participants), physical comfort (n=185, 88.5% participants), reasonable price (n=181, 86.6% participants), long battery life (n=181, 86.6% participants), and ease of use (n=174, 83.3% participants). A full list of features, ranked by importance, is shown in Table S7 in Multimedia Appendix 1.

Discussion

Principal Findings

We conducted a one-off survey with a large sample of individuals in the United Kingdom who self-reported a diagnosis of schizophrenia-spectrum disorder, were taking antipsychotic

XSL•FO
RenderX

medication, or were experiencing psychotic symptoms, to gather their perspectives on DRM of symptoms, including ASM and PS, using smartphone apps and wearable devices. Both smartphone apps (59.9%) and wearable devices (65%) were considered acceptable tools for digital monitoring in mental health care. Most participants preferred a blended approach that combined digital tools with in-person support and were willing to use wearable devices daily and for longer than a year to manage their mental health. Nevertheless, although more participants accepted than rejected the use of ASM and PS technologies for monitoring than those who opposed it, the acceptance rate was still below 50%. This suggests that user-level barriers must be addressed to facilitate the adoption of these methods in mental health care. Consistent with previous studies [17,18,44], smartphone ownership rates were high, and smartphones were frequently used, with participants reporting few barriers to owning or using one. In contrast, wearables were less commonly owned, less frequently used, and participants faced more barriers (eg, cost) to owning or using them. To further investigate the persistent barriers to accessibility and acceptability of digital interventions, qualitative studies, or the incorporation of qualitative interviews alongside quantitative surveys in mixed methods research would be valuable for elucidating nuanced contextual factors that may influence uptake.

Our sample was predominantly White (79%), with fewer participants from ethnic minority groups (eg, Black, 5.8%), which is less representative of the ethnic diversity typically observed in populations experiencing psychosis [45]. Additionally, 32% of participants were employed, which is higher than the employment rate reported in the broader psychosis population, which ranges from 1% to 18.5% [46]. Although the gender distribution in our sample was relatively balanced, we recruited slightly more females than males (49.5% vs 46.9%), diverging from the general trend in psychosis incidence, which is typically higher among males [47]. These differences suggest the need for further research to better understand the views of underrepresented groups on the use of personal digital devices for remote symptom monitoring.

Participants expressed varying levels of comfort with sharing different types of data with a research team. The most acceptable data types to be collected from a DRM tool were “physical health data” and “mental health data,” such as heart rate, fears of deteriorating, sleep patterns, and mood. Conversely, the least acceptable types of data were “personal information,” including contact lists, frequency of sending messages, and app usage. This is in line with a previous survey study on the general population’s comfort levels with sharing PS data for assessing depression and anxiety [40]. The study, which examined preferences for data sharing with clinicians, electronic health records (EHRs), and family members, found that participants were significantly more comfortable sharing health-related information (physical activity, mood, and sleep) than personal information (communication logs, location, and social activity) across all 3 recipient groups [40]. One explanation is that people might be more comfortable sharing health-related data because they see it as clinically relevant, whereas passive monitoring of personal behaviors (eg, communication and location) may feel more intrusive and less clinically relevant. Additionally, free-text responses in our survey study revealed that some participants were concerned about data misuse, disliked being monitored, and felt that monitoring was invasive and unhelpful. Taken together, the findings also indicate that privacy concerns remain a significant issue for people and pose a barrier to implementing digital monitoring in clinical practice. Some researchers have argued that training and explanation of the purpose of tracking to end users may reduce concerns [48]. However, our findings suggest that building trust may be more difficult than simply explaining the nonharmful nature of data tracking. Additionally, the complexity of methods such as machine learning, which is used to analyze large volumes of data collected from digital tools, makes it challenging even for clinicians to fully understand how the data will be used [49]. As the field moves toward collecting large-scale data from diverse populations, building trust between service users and digital systems is crucial.

Regarding common concerns about the potential negative effects of digital technologies on mental health, over half of the participants reported that using apps and wearables did not worsen their mood or psychotic symptoms. More participants found these technologies helpful for mental health and well-being rather than unhelpful and found that apps and wearables fostered a sense of connection, though a substantial proportion did not endorse such statements. These findings are consistent with a previous survey study [18], highlighting the complex relationship between technology use and mental health. Furthermore, serious negative effects, such as adverse events, remain an area of uncertainty. A recent review noted that while adverse events are rarely recorded and reported in DMHI trials, it is unclear whether this is due to a lack of occurrence or inadequate reporting [50]. Therefore, continued research is needed to better understand and monitor potential risks, ensuring the safety of digital health technologies in different populations.

Many participants had not used any health-related apps (42.4%). This finding echoes a previous US survey, which found that service users with psychosis rarely used their digital devices for health-related purposes, such as mental health symptom monitoring (14%) and sleep tracking (14%) [51]. Additionally, we found that for participants who had used a health-related app, physical health apps were more commonly used than mental health apps. Similarly, previous studies have identified high levels of interest in using physical health apps among young people with psychosis [52,53]. Given the increased risk of physical health conditions in individuals with severe mental health problems [54], and the frequent neglect of these issues in current mental health services [54,55], integrating both mental and physical health features in the same app may be preferred by service users. Moreover, most participants preferred DRM tools to be blended with face-to-face care. This is consistent with recent research highlighting the growing emphasis on blended care models, where digital tools complement traditional in-person services to enhance accessibility, engagement, and continuity of mental health support [56-58].

Despite the high rates of device ownership, a substantial proportion of participants reported that they faced barriers to owning or using smartphones and wearables. Specifically, for

XSL•FO
RenderX

smartphones, paranoia or suspiciousness related to technology, affordability, and digital literacy were the top reasons, whereas for wearables, top barriers were a lack of interest, affordability, and a perceived lack of need to use them. These findings suggest that wearables may be perceived as less essential for daily life compared to smartphones. However, affordability was reported as a barrier for both technologies, suggesting that cost limits access to digital technology for individuals with psychosis. A recent systematic review indicated that providing supportive infrastructure to users, including devices and free internet access, is a potential solution for advancing digital health equity [59]. For example, in the United Kingdom, the NHS could directly provide devices through its funding, as using personal health budgets for device provision is feasible in NHS City and Hackney [60]. Therefore, device provision in standard practice should be considered if digital mental health becomes an essential component of mental health care.

Strengths and Limitations

We reached a large, geographically diverse sample, enhancing the robustness and generalizability of our findings. We explicitly asked individuals who experience psychosis about their perspectives on PS, a rapidly developing subfield of digital mental health that has been largely unexplored in previous research. Regarding limitations, we relied on participants to self-report their diagnosis or experience of psychosis without independent validation. Also, this self-selected sample may have been more familiar, interested, and comfortable with using digital tools than the wider clinical population, as individuals who choose to participate in research are often more engaged with services. Moreover, the missing data rate of some questions was substantial, ranging from 1.3% to 15.5%, which can affect the reliability and validity of the findings. Additionally, although the survey included some free-text items, most data were quantitative, collected through structured response formats. As such, the study may not capture the depth or nuance that qualitative methods typically provide when exploring service user views in detail. Finally, our sample lacked ethnic diversity, with most participants being White, and almost all participants were in contact with mental health services. The findings may not be generalizable to individuals from diverse backgrounds, who may have different experiences, preferences, and barriers related to digital health technologies. Future research should aim to include more diverse samples to ensure that DMHIs are equitable and accessible to all service users.

Conclusions and Clinical Implications

Given that certain types of personal information (eg, contact lists, message frequency, and app usage) are perceived as less acceptable for collection, DRM should prioritize transparent data governance, user consent, and customizable privacy settings to build trust and alleviate concerns about surveillance and data misuse. Developers need to adhere to regulatory standards, such as the Digital Technology Assessment Criteria [61], throughout the process of designing and developing DRM tools. Additionally, service users should have control over the data they share, with whom, and for what purpose, for instance, through implementing digital dashboards to present key health metrics to service users and allow for their active participation in care management and decisions over data sharing with clinical teams. Alongside this, clinicians should also play a role in explaining the purpose of DRM (what data is being collected, why, and what it will be used for), emphasizing its clinical benefits and safety profile while addressing potential privacy-related apprehensions. Although most participants did not perceive DRM as harming mental health, a substantial proportion expressed concerns. Therefore, clinicians should proactively assess potential unintended effects, such as increased anxiety, paranoia, or distress related to feeling monitored, and implement strategies to ensure the safe and supportive use of these technologies. The higher reported usage of physical health apps compared to mental health apps highlights the potential for developing integrated platforms that address both mental and physical health needs. Given the high prevalence of physical health problems in psychosis, combining mental health tracking with physical health features (eg, activity tracking, sleep monitoring, and medication reminders) could enhance user engagement and support holistic care. To ensure the practical integration of such platforms into existing clinical workflows, it is essential to leverage established digital infrastructures, particularly EHRs. Integrating digital health apps with EHRs would allow clinicians to seamlessly access and interpret integrated data on both physical and mental health, supporting comprehensive and person-centered care. Adopting interoperability standards would further support data exchange across health care settings, enabling the holistic management of physical and mental health within routine practice. By incorporating these considerations, integrated platforms have the potential to significantly enhance service user outcomes by enabling the early detection of both psychiatric symptom deterioration and cardiometabolic risks, thereby facilitating more personalized and timely interventions. Blended approaches, using DRM alongside face-to-face care, should be considered as a priority for clinical implementation, as it appears to be participants' preference. Finally, should digital technologies become important in improving clinical care, they should be provided at no cost to service users, especially wearables, as cost appears to be a main barrier to owning or using this technology.

Acknowledgments

The authors would like to thank the participants who took part in the survey study, as well as the health care professionals and researchers who supported the study. We also thank individuals within the respective National Health Service (NHS) services for their assistance. No AI tools were used in the preparation of this manuscript.

Abstract

Background: Tobacco smoking is viewed as a behavioral risk factor for psoriasis initiation and progress, even among those undergoing biologic treatment. However, evidence regarding the association between tobacco smoking and treatment response to biologics among patients with psoriasis is limited.

Objective: This study aimed to explore the impact of tobacco smoking on the efficacy of biologic treatment in patients with psoriasis.

Methods: Patients with psoriasis undergoing biologic treatment were recruited from 2022 to 2024 at the Shanghai Skin Disease Hospital. Demographic characteristics and smoking habits were collected using a structured questionnaire. Clinical features and treatment efficacy were assessed and recorded by dermatologists at baseline and weeks 4, 8, 12, 24, and 48 after treatment, and the Psoriasis Area and Severity Index (PASI) 75 and PASI 90 measures were calculated for treatment efficacy evaluation.

Results: A total of 192 patients with psoriasis were included, of whom 78 (40.6%) were tobacco smokers, with a higher smoking prevalence observed in male patients (74/154, 48.1%). The PASI 75 response rates at weeks 4, 8, 12, 24, and 48 were 29.2% (56/192), 54.2% (104/192), 78.6% (151/192), 84.5% (153/181), and 82.7% (134/162), respectively. The PASI 90 response rates increased from 13.0% (25/192) at week 4 to 62.4% (113/181) at week 24 and 59.9% (97/162) at week 48. Logistic regression analysis indicated that nonsmoking patients with psoriasis had a high PASI 75 response rate. The adjusted odds ratios were 2.57 (95% CI 1.19 - 5.53), 2.61 (95% CI 1.34 - 5.08), 2.62 (95% CI 1.13 - 6.04), 2.27 (95% CI 0.89 - 5.75), and 2.75 (95% CI 1.01 - 7.49) at weeks 4, 8, 12, 24, and 48, respectively. Moreover, nonsmoking patients with psoriasis also had a higher PASI 90 response rate than those who smoked. The odds ratios ranged from 1.32 (95% CI 0.49 - 3.54) to 2.59 (95% CI 1.21 - 5.55). Correlation analysis showed that both tobacco smoking duration and daily cigarette consumption were negatively correlated with the reduction in PASI score at weeks 4 to 48 after treatment (P<.05).

Conclusions: Tobacco smoking was negatively associated with treatment response among patients with psoriasis undergoing biologic treatment, especially among patients with longer tobacco smoking duration and higher daily cigarette consumption.

KEYWORDS

psoriasis; tobacco smoking; biologics; treatment response; Psoriasis Area and Severity Index; PASI

Introduction

Psoriasis is a chronic and inflammatory skin disease, and most patients with psoriasis have some detriment to their quality of life [1]. Most patients with mild to moderate psoriasis can control their condition with topical medications or phototherapy, but these may not be sufficient for moderate to severe cases [2]. The emergence of biologics has brought about a major breakthrough in the treatment of psoriasis, particularly playing a positive role in patients with moderate to severe psoriasis. Biologics precisely target certain cytokines in inflammatory pathways during the pathological process of psoriasis, such as tumor necrosis factor, interleukin (IL)-17, and IL-23, to prevent inflammatory reactions and achieve efficient clearance of psoriasis lesions [3,4].

XSL•FO
RenderX

In recent years, guidelines on the treatment of psoriasis in Europe and the United States have shown growing emphasis and stronger recommendations for biologics [2,5]. The guidelines for the diagnosis and treatment of psoriasis in China also increasingly recommend biologics in clinical treatment, and the "Guidelines for the treatment of psoriasis with biologics and small-molecule drugs in China" were published in 2024, providing recommendations for clinicians on the use of biologic therapies [6,7]. With the increasing accessibility of biologics and support from medical insurance policies, more and more patients with psoriasis benefit from biologics. Previous studies have shown that biologics are efficacious in the treatment of psoriasis and are associated with greater improvements in quality of life compared with other treatment modalities [3,8,9]. However, some patients still fail to achieve satisfactory therapeutic responses in clinical practice, and factors such as genetics, obesity, tobacco smoking, alcohol consumption, and disease-related features (eg, disease duration and age at diagnosis) may contribute to the heterogeneity of responses to biologics [10,11].

Tobacco smoking is a widespread unhealthy lifestyle habit, with approximately 1.14 billion current smokers worldwide (approximately 30% in China), resulting in enormous health and economic consequences [12]. The impact of tobacco smoking on health has been extensively studied, and smoking is recognized as being closely associated with the development of various cardiovascular diseases, pulmonary diseases, and cancers [13-15]. The association between tobacco smoking and psoriasis is also receiving increasing attention. Previous studies have demonstrated that tobacco smoking elevates the risk of psoriasis and exacerbates disease severity, making the condition more difficult to control [16-18]. However, the impact of smoking on the efficacy of biologic treatment in patients with psoriasis remains inconclusive. Some studies have reported that smoking has a negative impact on the efficacy of biologic treatment for psoriasis [19-25], whereas other studies have failed to detect a significant effect of smoking on treatment outcomes [26-28]. Therefore, this study aimed to explore the impact of tobacco smoking on the efficacy of biologic treatment among patients with psoriasis in Shanghai, with the expectation of providing valuable insights for clinical practice regarding psoriasis treatment.

Methods

Study Population

A hospital-based prospective observational study was conducted in Shanghai Skin Disease Hospital from 2022 to 2024. Patients with psoriasis vulgaris aged ≥18 years, both male and female, and without a migration plan within a year were included and followed up on for 48 weeks, and patients who were unable to provide informed consent or who had neurological or psychiatric disorders were excluded. In this study, we extracted data from 192 patients with psoriasis who received biologic treatment with secukinumab.

Data Collection

Data were collected through a self-designed questionnaire administered by dermatologists after receiving uniform training. The main contents of the questionnaire were as follows: (1) demographic characteristics, including age, gender, educational level, monthly income, residence, marital status, and BMI; (2) information on tobacco smoking status, including smoking initiation age, smoking duration, and number of daily consumed cigarettes; and (3) information on psoriasis duration and severity. The severity of psoriasis was assessed by dermatologists using the Psoriasis Area and Severity Index (PASI), body surface area (BSA), and Physician Global Assessment (PGA) at baseline, week 4, week 8, week 12, week 24, and week 48.

Definition and Classification

In this study, the age of patients with psoriasis was classified as <35, 35 to 45, 46 to 60, and >60 years. Educational level was categorized into 4 groups (primary school or lower, junior high school, senior high school, and college or higher) based on the highest level of education completed. Monthly income (in CNY) was categorized into <¥3000, ¥3000 to ¥5000, ¥5001 to ¥10,000, and >¥10,000 (¥1=US $0.14). Residence was classified as urban and rural, and marital status was classified as married; unmarried; and divorced, widow or widower, or other. The BMI of patients with psoriasis was categorized as <23.9 kg/m^2 (lower or normal weight), 24.0 to 28.0 kg/m^2 (overweight), and >28.0 kg/m^2 (obesity).

A smoker was defined as a person who had smoked at least 100 cigarettes in their lifetime. Smoking initiation age was classified as <25 years and ≥25 years. Smoking duration was calculated as the age at the time of the study minus the smoking initiation age and then stratified into <20 years and ≥20 years. The number of daily consumed cigarettes was categorized as <20 and ≥20.

The PASI 75, PASI 90, and PGA (1/0) rate were calculated and used to evaluate the treatment response. The PASI 75 and PASI 90 were defined as patients with a reduction in PASI score of ≥75% and ≥90%, respectively, calculated using the formula [(PASI at baseline – PASI at week *t*)/PASI at baseline] × 100%. The PGA (1/0) rate referred to the proportion of patients with a PGA score of 1 or 0 among all patients.

Statistical Analysis

Data analysis was performed using the SAS software (version 9.4; SAS Institute). Descriptive statistics were presented as means and SDs or medians and IQRs as appropriate for quantitative variables and frequency counts and proportions for qualitative variables. The 2-tailed Student *t* test, Mann-Whitney *U* test, or Pearson chi-square test was performed to examine the statistical difference between groups. The temporal trend of treatment response (PASI 75, PASI 90, and PGA [1/0]) at different weeks among patients with psoriasis was evaluated using the Cochran - Armitage trend test. Logistic regression was applied to calculate the odds ratios (ORs) and 95% CIs to explore the association between tobacco smoking and treatment response among patients with psoriasis at weeks 4, 8, 12, 24, and 48. Scatterplots and quadratic polynomial regression were used to explore the association among smoking duration, daily cigarette consumption, and PASI score reduction. A *P* value of less than .05 (2 tailed) was considered statistically significant.

Ethical Considerations

This study was approved by the institutional review board of Shanghai Skin Disease Hospital (2022-25). Informed consent was obtained before starting the study, and the study was strictly performed in accordance with the Declaration of Helsinki. Patient participation in this study was voluntary, and patients could withdraw at any time. Participants' privacy and confidentiality were strictly protected. All data were deidentified before analysis and were accessible only to the researchers of this study. No compensation was provided to participants.

Results

Overview

A total of 192 patients with psoriasis undergoing biologic treatment were included in the final data analysis, of whom 154 (80.2%) were male. The average age of the patients was 41.2 (SD 18.2) years, with 41.1% (n=79) of patients aged >45 years. Among the patients, 49.0% (n=94) had a college or higher educational level, whereas 56.8% (n=109) reported monthly incomes exceeding ¥5000. Approximately 66.7% (n=128) of patients were urban residents, and 58.9% (n=113) of them were married. The average BMI of patients was 25.8 (SD 4.3) kg/m^2, and 65.1% (n=125) were overweight or obese. The median disease duration was 13.5 (IQR 7.0-21.0) years, and the median values of the PASI, BSA, and PGA scores at baseline (week 0) were 12.2 (IQR 9.8-18.6), 18.5 (IQR 12.0-33.3), and 3.0 (IQR 2.0-3.0), respectively. Data in Table 1 indicate that female patients were older (t_{190}=–2.64; P=.009) and had higher educational levels (χ^2_1=5.4; P=.02), higher incomes (χ^2_3=15.2; P=.002), and longer disease duration (z=–2.18; P=.03), and there was a higher proportion of married individuals in this group (χ^2_2=11.8; P=.003) but a lower proportion of overweight or obesity (χ^2_2=11.1; P=.004) and lower PGA scores than among male patients (z=–3.73; P<.001). The differences were all statistically significant (P<.05; Table 1).

Disease duration (y), median (IQR)	13.5 (7.0-21.0)	12.5 (7.0-20.0)	19.5 (11.0-25.0)	.03
PASI[a] at week 0, median (IQR)	12.2 (9.8-18.6)	12.3 (10.0-19.2)	11.3 (8.0-16.8)	.30
BSA[b] at week 0 (%), median (IQR)	18.5 (12.0-33.3)	18.5 (12.0-32.0)	16.8 (11.0-33.5)	.62
PGA[c] at week 0, median (IQR)	3.0 (2.0-3.0)	3.0 (2.0-3.0)	2.2 (2.0-2.7)	<.001

[a]PASI: Psoriasis Area and Severity Index. The PASI indicates the severity of psoriasis, with a higher value representing a more severe condition (0-72).

[b]BSA: body surface area. BSA indicates the affected body surface, with a higher value representing a more severe condition (0%-100%).

[c]PGA: Physician Global Assessment. The PGA indicates the physician's overall evaluation of psoriasis, with a higher score representing a more severe condition (0-5).

Tobacco Smoking Among Patients With Psoriasis

As shown in Table 2, of the 192 patients with psoriasis undergoing biologic treatment, 78 (40.6%) were tobacco smokers, including 74 (94.9%) male and 4 (5.1%) female patients. The prevalence of tobacco smoking was higher in male patients (74/154, 48.1%) than in female patients (4/38, 10.5%), and the difference was statistically significant (χ^2_1=17.8; *P*<.001).

Table . Tobacco smoking characteristics among patients with psoriasis (N=192).

Variable	Total	Male patients (n=154)	Female patients (n=38)	*P* value
Tobacco smoking, n/N (%)				<.001
Yes	78/192 (40.6)	74/154 (48.1)	4/38 (10.5)	
No	114/192 (59.4)	80/154 (51.9)	34/38 (89.5)	
Smoking initiation age (y), mean (SD)	24.0 (4.9)	24.0 (4.8)	24.0 (6.7)	.99
Smoking initiation age (y), median (IQR)	24.0 (20.0-26.0)	24.5 (20.0-26.0)	21.0 (20.0-28.0)	.67
Smoking initiation age (y), n/N (%)				.64
<25	40/78 (51.3)	37/74 (50.0)	3/4 (75.0)	
≥25	38/78 (48.7)	37/74 (50.0)	1/4 (25.0)	
Smoking duration (y), mean (SD)	21.2 (16.1)	20.5 (15.7)	32.8 (21.6)	.14
Smoking duration (y), median (IQR)	20.0 (9.0-35.0)	19.0 (9.0-35.0)	35.0 (14.5-51.0)	.21
Smoking duration (y), n/N (%)				.64
<20	38/78 (48.7)	37/74 (50.0)	1/4 (25.0)	
≥20	40/78 (51.3)	37/74 (50.0)	3/4 (75.0)	
Cigarettes consumed per d, mean (SD)	16.9 (7.9)	17.1 (8.1)	13.8 (4.8)	.42
Cigarettes consumed per d, median (IQR)	20.0 (10.0-20.0)	20.0 (10.0-20.0)	12.5 (10.0-17.5)	.30
Cigarettes consumed per d, n/N (%)				.34
<20	31/78 (39.7)	28/74 (37.8)	3/4 (75.0)	
≥20	47/78 (60.3)	46/74 (62.2)	1/4 (25.0)	

The average and median age of smoking initiation was 24.0 (SD 4.9; IQR 20.0-26.0) years, and 51.3% (40/78) of patients began tobacco use at <25 years. The mean smoking duration was 21.2 (SD 16.1) years, and the median duration was 20.0 (IQR 9.0-35.0) years. A total of 51.3% (40/78) of patients had smoked for more than 20 years. The mean daily cigarette consumption among patients was 16.9 (SD 7.9) cigarettes, with a median of 20 (IQR 10.0-20.0) cigarettes. In total, 60.3% (47/78) of patients smoked more than 20 cigarettes per day. The differences between male and female patients who smoked tobacco in smoking initiation age (t_{76}=0.01 and *P*=.99; *z*=–0.42 and *P*=.67; χ^2_1=0.2 and *P*=.64), smoking duration (t_{76}=–1.48 and *P*=.14; *z*=–1.26 and *P*=.21; χ^2_1=0.2 and *P*=.64), and daily cigarette consumption (t_{76}=0.80 and *P*=.42; *z*=–1.04 and *P*=.30; χ^2_1=0.9 and *P*=.34) were not statistically significant (Table 2).

Treatment Outcomes Among Patients With Psoriasis

Table 3 illustrates the longitudinal outcomes of PASI, BSA, and PGA scores, along with the achievement of PASI 75, PASI 90, and PGA (1/0) at weeks 4, 8, 12, 24, and 48 after treatment. During the treatment period, the achievement of PASI 75, PASI 90, and PGA (1/0) showed an increasing trend (*Z*=9.42 and *P*<.001; *Z*=8.53 and *P*<.001; and *Z*=3.14 and *P*=.002, respectively). The response rate increased from 29.2% (56/192) at week 4 to 82.7% (134/162) at week 48 for PASI 75, from 13.0% (25/192) at week 4 to 59.9% (97/162) at week 48 for PASI 90, and from 47.4% (91/192) at week 4 to 69.8% (113/162) at week 48 for PGA (1/0; Table 3).

[a]PASI: Psoriasis Area and Severity Index. Indicates the severity of psoriasis, with a higher value representing a more severe condition (0-72).

[b]BSA: body surface area. Indicates the affected body surface, with a higher value representing a more severe condition (0%-100%).

[c]PGA: Physician Global Assessment. Indicates the physician's overall evaluation of psoriasis, with a higher score representing a more severe condition (0-5).

Stratification by gender revealed that, in male patients, the PASI 75, PASI 90, and PGA (1/0) response rates all showed an increasing trend (Z=8.35 and P<.001; Z=7.84 and P<.001; and Z=2.85 and P=.004, respectively). In female patients, only the PASI 75 and PASI 90 response rates increased with biologic treatment at different weeks (Z=4.47 with P<.001 and Z=3.47 with P<.001, respectively) but not the PGA (1/0) response rate (Z=1.42; P=.16; Figure 1). Moreover, data in Figure 1 also indicate that female patients typically achieved better response rates (PASI 75, PASI 90, and PGA [1/0]) than male patients at the same evaluation time points.

Figure 1. Treatment responses (Psoriasis Area and Severity Index [PASI] 75, PASI 90, and Physician Global Assessment [PGA] [1/0]) of male and female patients at weeks 4, 8, 12, 24, and 48.

Association Between Tobacco Smoking and Treatment Response

Logistic regression analysis indicated that patients with psoriasis who did not smoke tobacco had higher PASI 75 response rates than those who smoked tobacco, and the ORs were 2.57 (95% CI 1.19-5.53), 2.61 (95% CI 1.34-5.08), 2.62 (95% CI 1.13-6.04), 2.27 (95% CI 0.89-5.75), and 2.75 (95% CI 1.01-7.49) at weeks 4, 8, 12, 24, and 48, respectively, even with the adjustment of potential confounders. Patients who did not smoke tobacco also had higher PASI 90 response rates than those who smoked. The ORs were 1.32 (95% CI 0.49-3.54), 1.78 (95% CI 0.85-3.71), 1.71 (95% CI 0.88-3.33), 1.38 (95% CI 0.70-2.71), and 2.59 (95% CI 1.22-5.55) at weeks 4, 8, 12, 24, and 48, respectively. For PGA (1/0), patients who did not smoke tobacco tended to have higher response rates than those who smoked tobacco at weeks 4, 8, 12, 24, and 48. The ORs were 1.08 (95% CI 0.57-2.05), 1.14 (95% CI 0.58-2.24), 1.55 (95% CI 0.70-3.39), 1.52 (95% CI 0.69-3.31), and 1.18 (95% CI 0.54-2.59), respectively (Table 4).

Table . The association between tobacco smoking and treatment response (Psoriasis Area and Severity Index [PASI] 75, PASI 90, and Physician's Global Assessment [PGA] [1/0]) among patients with psoriasis at weeks 4 to 48.

Variable	Response rate (nonsmokers vs smokers; %)	OR[a] (95% CI)		
		Model A[b]	Model B[c]	Model C[d]
PASI 75				
Week 4	36.8 vs 17.9	2.67 (1.34-5.33)	2.56 (1.23-5.31)	2.57 (1.19-5.53)
Week 8	64.9 vs 38.5	2.96 (1.63-5.38)	2.54 (1.35-4.78)	2.61 (1.34-5.08)

Week 8	67.5 vs 60.3	1.37 (0.75-2.50)	1.13 (0.60-2.14)	1.14 (0.58-2.24)
Week 12	78.2 vs 74.3	1.23 (0.63-2.45)	1.43 (0.69-2.99)	1.55 (0.70-3.39)
Week 24	80.8 vs 68.4	1.94 (0.98-3.85)	1.55 (0.74-3.22)	1.52 (0.69-3.31)
Week 48	72.7 vs 66.2	1.36 (0.70-2.67)	1.21 (0.58-2.50)	1.18 (0.54-2.59)

[a]OR: odds ratio.

[b]Model A: univariate logistic regression.

[c]Model B: multivariate logistic regression with adjustment for age and sex.

[d]Model C: multivariate logistic regression with adjustment for age, educational level, sex, marital status, monthly income, and BMI.

Among the 40.6% (78/192) of patients with psoriasis who smoked tobacco, the PASI score at baseline was positively correlated with tobacco smoking years (r=0.39; P=.03) and daily cigarette consumption (r=0.31; P=.04). Moreover, the PASI score reduction at weeks 4, 8, 12, 24, and 48 from baseline (week 0) was negatively correlated with tobacco smoking years (Figure 2) and daily cigarette consumption (Figure 3).

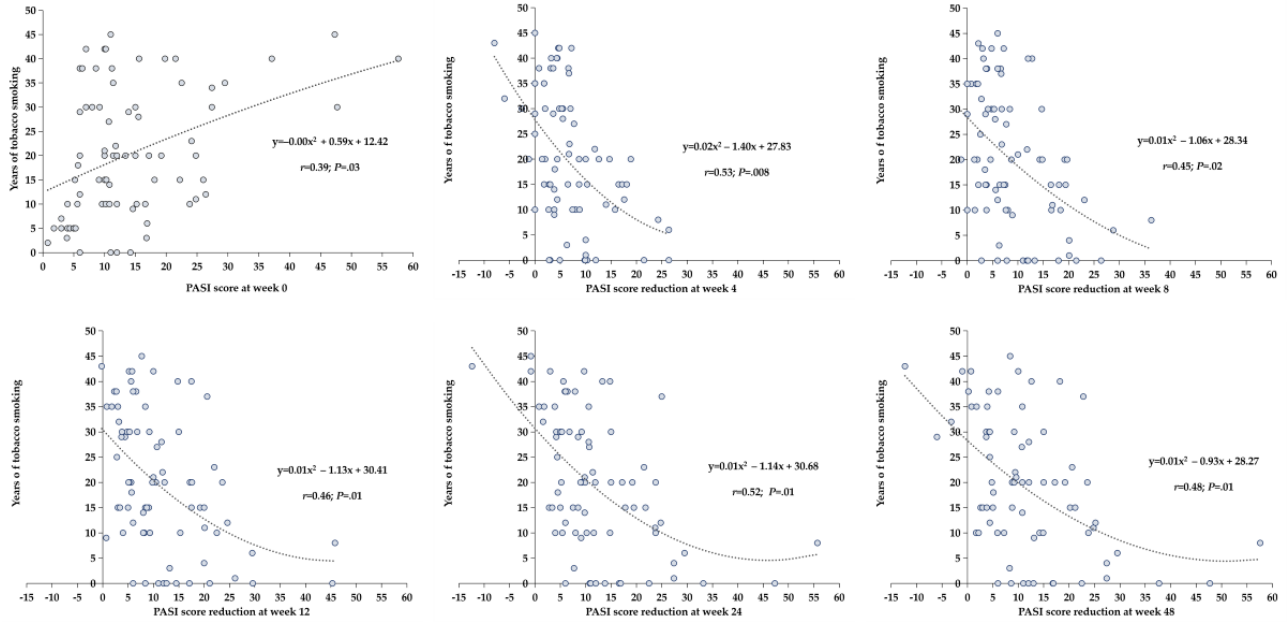

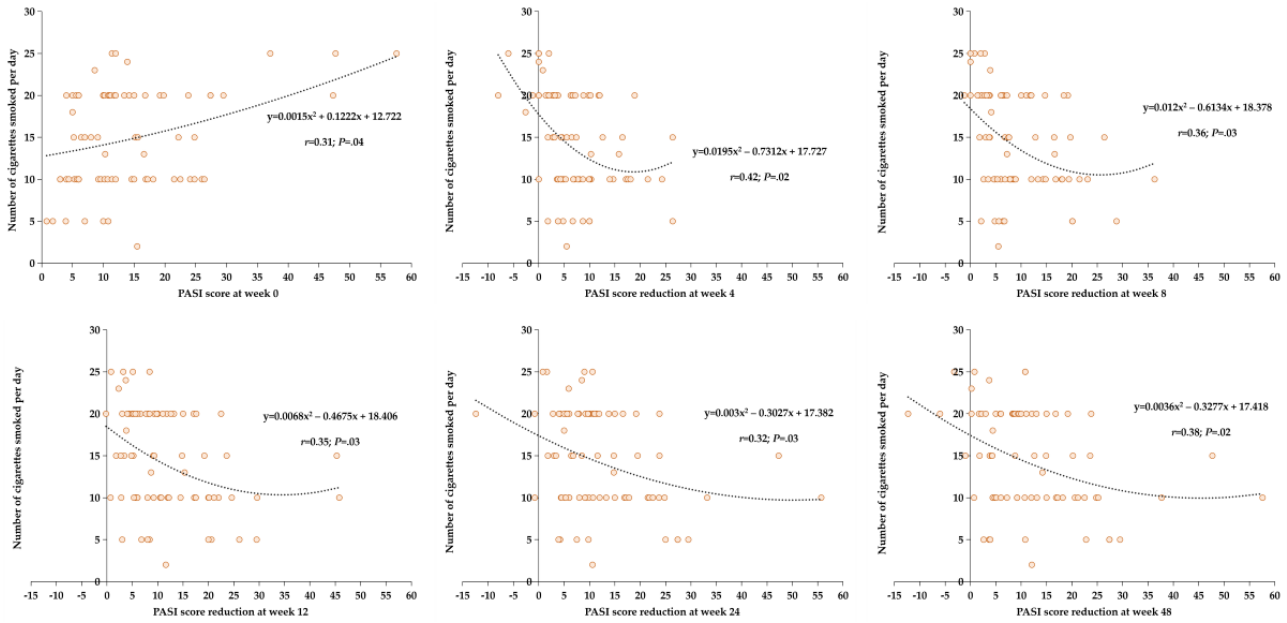

Figure 3. Correlation analysis between the Psoriasis Area and Severity Index (PASI) score at week 0 or PASI score reduction at weeks 4 to 48 and the number of cigarettes smoked per day.

Discussion

Principal Findings

This study explored the impact of tobacco smoking on the treatment efficacy of biologics in 192 patients with psoriasis based on real-world clinical data. In this study, the smoking prevalence among patients with psoriasis was 40.6% (78/192), which was consistent with that in previous studies [29-31]. The findings of this study indicated that patients with psoriasis who did not smoke had better treatment response than those who smoked, especially in the PASI 75 evaluation. Moreover, the reduction in PASI score at weeks 4, 8, 12, 24, and 48 from baseline was negatively correlated with both tobacco smoking years and number of daily cigarettes consumed.

Rapid clearance of skin lesions is the greatest treatment need among patients with psoriasis in China [32]. The emergence and application of biologics have brought about a qualitative leap in the treatment goals for psoriasis, with PASI 90 and PASI 100 becoming the new therapeutic targets for the biologic treatment of psoriasis [2,5,6]. In a previous study, based on data from the Psoriasis Study of Health Outcomes, Lynde et al [33] reported that the response rates for the primary end point (static PGA [0/1] and/or PASI 90) at week 12 were 71.4% and 58.6% for patients receiving anti–IL-17A biologics and other biologics, respectively. Pinter et al [34] compared the long-term treatment effectiveness of different biologics, including ixekizumab, risankizumab, and ustekinumab, and indicated that the response rates for PASI 90 were 40.5% to 64.3% at month 6 and 41.7% to 61.4% at month 12. In this study, we observed similar results,

XSL•FO
RenderX

with overall PASI 75 response rates of 78.6% (151/192), 84.5% (153/181), and 82.7% (134/162); PASI 90 response rates of 54.2% (104/192), 62.4% (113/181), and 59.9% (97/162); and PGA (1/0) rates of 75.5% (145/192), 75.1% (136/181), and 69.8% (113/162) at weeks 12, 24, and 48, respectively. The response rates for PASI 75 and PASI 90 at week 24 were slightly higher than those at week 48, which might be attributed to an increased rate of treatment discontinuation after receiving 24 weeks of treatment among patients.

Tobacco smoking is recognized as an important risk factor for psoriasis [35,36]. In this study, we noticed that tobacco smoking was negatively associated with treatment response at weeks 4, 8, 12, 24, and 48 among patients with psoriasis undergoing treatment with biologics. Compared to patients who smoked tobacco, patients who did not smoke tobacco had 2.75 and 2.59 times higher odds of achieving PASI 75 and PASI 90 at week 48, respectively, which is consistent with most previous studies. Two meta-analyses have reported that patients with psoriasis who smoke exhibit poorer response to biologics [20,23]. In a multicenter longitudinal cohort study, Warren et al [24] found that smokers had reduced odds of achieving PASI 90 at 6 and 12 months after initiating biologic therapies. These studies all suggest a negative impact of tobacco smoking on treatment response to biologics for psoriasis.

Previous studies have indicated that smoking intensity and duration are positively correlated with the severity of psoriasis in a dose-dependent fashion [17,18,37]. In this study, we observed consistent results demonstrating that PASI score was positively correlated with tobacco smoking years and number of daily consumed cigarettes. Moreover, we focused on the relationship between smoking and treatment efficacy among patients with psoriasis undergoing treatment with biologics during the 48-week follow-up period. The results showed that the reduction in PASI score was negatively correlated with tobacco smoking duration and tobacco smoking intensity. However, the specific mechanism of how tobacco smoking affects the efficacy of biologics for psoriasis still requires further research and exploration.

In this study, we also noticed that female patients had better treatment responses than male patients in the PASI 75, PASI 90, and PGA (1/0). There are several possible explanations for this gender disparity. First, female patients in this study had lower disease severity than male patients at baseline, which may have made it easier for female patients to achieve disease improvement. Second, BMI may also play a role in this difference. In this study, the average BMI of female patients was significantly lower than that of male patients, and higher BMI is considered to be associated with increased disease severity and reduced treatment response in psoriasis [38]. Pharmacokinetic studies have shown that excessive body weight can have a negative impact on drug clearance and volume of distribution [38]. Third, the proportion of female patients with a college education or higher was higher than that of male patients, and a higher educational level often leads to a better treatment adherence and a subsequently better treatment response [39]. Fourth, the lower tobacco smoking proportion might have also contributed to the better treatment response among female patients with psoriasis.

A key strength of this study was that the clinical data of patients with psoriasis were extracted directly from the health information system, eliminating recall bias, which ensured high data quality. The collection of data for over 48 weeks, allowing for the assessment of the impact of tobacco smoking on biologic efficacy at multiple time points, was another strength. Additionally, we used a variety of evaluation tools to assess patient outcomes, including the PASI, BSA, and PGA, thereby providing more and multidimensional data support for the study results.

Limitations

This study has several limitations. First, the 192 patients were recruited from only 1 hospital, which ensured high internal authenticity; however, the generalization of the findings to other patients with psoriasis is limited. Second, the smoking status of patients was self-reported, which may be subject to social desirability bias and recall bias. The lack of information on secondhand smoke and e-cigarette exposure may have underestimated the impact of smoking on treatment efficacy to some extent. Third, the number of female patients included in this study was relatively low, especially among smokers, which may have resulted in the findings more strongly reflecting the situation of male patients. Future studies should consider conducting investigations with larger sample sizes to comprehensively assess the impact of smoking on treatment response in patients with psoriasis with different demographic characteristics.

Conclusions

The prevalence of tobacco smoking among patients with psoriasis undergoing biologic treatment was high, especially among male patients. Tobacco smoking was negatively associated with treatment response among patients with psoriasis undergoing biologic treatment, especially among those with longer tobacco smoking duration and higher daily cigarette consumption. Therefore, we recommend that dermatologists actively assess tobacco smoking status among patients and encourage them to quit smoking to improve their treatment response.

Acknowledgments

The authors would like to thank the dermatologists at Shanghai Skin Disease Hospital for their data collection support in this study.

Abstract

Background: Pain drawing (PD) body charts are widely used in back pain research, but the representation of sex in these charts has not been systematically evaluated.

Objective: This study aims to evaluate sex representation in PD body charts used in back pain research, assess the perception of a newly designed sex-neutral body chart, and explore user preferences for sex representation in PD body charts.

Methods: We conducted a multimethod study comprising: (1) a scoping review to assess sex representation and the reporting of sex in PD body charts in back pain literature, (2) an expert opinion study where anatomy experts evaluated the perceived sex of extracted body charts, and (3) a survey among a representative sample of UK adults with and without back pain to assess the perception of a newly designed sex-neutral body chart and explore preferences for sex representation in PD body charts.

Results: From 349 full-text papers, 108 articles met the inclusion criteria. Most (103/108, 95.4%) did not report the sex of the body charts used, and only 5.6% (6/108) included both male and female charts. Experts showed fair to moderate agreement (Fleiss κ=0.306; Gwet AC1=0.456) in assessing the sex of charts, with most charts assessed as male based on majority ratings (59/108, 54.6%) and classified as male-biased relative to the sex distribution of study participants (76/108, 67.7%). The newly designed sex-neutral body chart was perceived as sex-neutral by 68.5% (204/298) of survey participants across diverse groups. However, perceptions varied by racial group: 73% (181/248) of White participants viewed it as sex-neutral, compared to 42.5% (17/40) of participants from smaller racial groups (χ^2_2=15.9; *P*=.001). Female participants slightly preferred female charts (85/154, 55.2%); male participants preferred sex-neutral ones (88/144, 61.1%). Nonetheless, most female participants (82/154, 53.3%) and male participants (107/144, 74.3%) considered the option to choose between male, female, and sex-neutral chart versions unimportant.

Conclusions: Our study reveals reporting gaps and a predominant male bias in the representation of sex in PD body charts used in back pain research. The newly developed sex-neutral body chart was widely perceived as sex-neutral, offering a promising step toward more inclusive pain assessment. However, variations in perception across racial groups highlight the need for cultural considerations in design. These findings underscore the potential of sex-neutral and culturally sensitive body charts to enhance the inclusivity and equity of back pain research and clinical practice.

KEYWORDS

pain drawing; pain map; body chart; sex; gender; sex/gender bias; back pain

Introduction

A pain drawing (PD) is an illustration of the human body that allows individuals to draw the location and extent of their pain. These visual tools support the assessment of subjective pain, may help determine appropriate treatment strategies, and facilitate communication between patients and health care professionals [1]. Since their introduction in 1949, PDs have evolved from traditional paper-and-pencil formats into digital and, in some cases, 3D representations [2]. The body charts used in these PDs vary considerably [2], with some representing male or female figures, while others may be perceived as sex-neutral.

The first sex-specific body charts, featuring both male and female versions, were introduced in 1988 by Uden et al [3], marking an important advancement in acknowledging the need for diversity in pain reporting tools [2]. However, despite this progress, subsequent research has largely neglected the role of diversity in body chart design. Most studies have examined how a participant's sex influences pain depiction by comparing PDs from female and male participants [4,5], while overlooking whether the sex of the body chart itself influences pain reporting. In addition to this gap, it remains unclear to what extent male, female, and sex-neutral body charts are currently used in pain research.

The sex of body charts used in pain research is often poorly documented, and the prevalence of different sex representations remains largely unknown. Preliminary studies suggest that male or sex-neutral charts with male features are more commonly used than female or truly sex-neutral alternatives. Most body charts are described using terms such as "human body outline," without explicitly identifying them as male, female, or sex-neutral [6]. This ambiguity raises important questions about how a "universal" human body is visually represented across sexes and genders, and how individuals perceive and interpret these depictions. A prevailing assumption among researchers is that most body charts are sex-neutral with distinctly male features, while truly sex-neutral representations are rare [1,7]. However, this perspective is not grounded in a comprehensive review, highlighting the need for further investigation into potential sex and gender biases in body chart design.

Another important consideration is whether individuals prefer male, female, or sex-neutral body charts. While some studies indicate a preference for sex-specific body charts [1,8,9], their findings may be limited by the fact that body charts intended to be sex-neutral are not always perceived or interpreted as such. Understanding individuals' preferences is critical, as these preferences may influence how users engage with the charts, their comfort in using them, and the accuracy of their pain reporting. When individuals feel represented by the body chart, they may be more likely to provide accurate and detailed pain descriptions, potentially leading to improved diagnostic outcomes [1]. Exploring these preferences also supports the development of inclusive, user-centered tools that reflect the diversity of patient populations—an essential step toward more equitable health care.

This study examines how sex is represented in PD body charts within the back pain literature, analyzing both the descriptions provided in published articles and anatomy experts' assessments of the perceived sex of the charts. Furthermore, we evaluated a newly developed sex-neutral body chart, designed by an interdisciplinary team of illustrators, computer scientists, physicians (specializing in anatomy, orthopedics, radiology, and integrative medicine), and psychologists [10]. Our aim was to determine whether this chart is perceived by individuals as truly sex-neutral, in alignment with its intended design. We also explored a range of individual factors that may influence these perceptions, alongside participants' preferences for sex-specific versus sex-neutral body charts. Taken together, this study sought to address the following research questions:

1. What is the prevalence of male, female, and sex-neutral PD body charts in the back pain literature—from its inception to the present—as reported in the articles and as assessed by experts? Additionally, what is the level of agreement among experts in their sex-based classifications of the charts?
2. How do individuals perceive a body chart explicitly designed to be sex-neutral, and what individual factors influence whether they interpret the chart as male, female, or sex-neutral?
3. In the context of back pain assessment, do individuals prefer male, female, or sex-neutral body charts, and how important is having a choice to them?

Throughout this paper, we use the terms *sex* and *gender* in accordance with the SAGER (Sex and Gender Equity in Research) guidelines [11]. We define *sex* in body charts based on anatomical characteristics, including primary and secondary sexual organs typically associated with male and female bodies, and in humans as sex assigned at birth. *Gender* refers to socially constructed roles, behaviors, and identities in humans.

Methods

Study Design

This research adopted a multimethod design comprising a scoping review, an expert opinion study, and a survey—each focusing on different aspects of sex representation in PD body charts within the context of back pain. The expert opinion study incorporated insights from anatomy experts across various medical and health sciences disciplines, while the survey gathered responses from individuals both with and without back pain. This inclusive approach ensured the integration of diverse perspectives throughout the study. We submitted the study synopsis to the Ethics Committee of Zurich, Switzerland, and after review, they stated that the study does not fall under the regulation of the Human Research Act of Switzerland (ethics ID: 2022 - 01475). The scoping review protocol was registered

XSL•FO
RenderX

in the Open Science Framework on July 1, 2024, prior to starting the process of selecting studies for the review [12].

Ethical Considerations

The study was conducted in accordance with ethical standards. Privacy and confidentiality were ensured by pseudonymizing all data in the expert opinion study and by collecting anonymized data in the survey, with no personal identifiers recorded. All data were securely stored. Participation was voluntary, and participants were informed of their right to withdraw at any time. Participants provided electronic informed consent. Each participant received £0.75 (US $1) as compensation for their time.

Inclusion Criteria

Review

The scoping review considered studies that have used, designed, or evaluated PDs with a full-body or torso template in paper or digital format. Studies were included if they assessed pain location and involved adults (aged ≥18 y) with back pain, regardless of participants' demographic characteristics (such as age, sex, or pain type and severity). The review considered all primary research studies published in English or German, conducted in any country or clinical setting. Secondary studies—including systematic reviews, narrative reviews, clinical practice guidelines, and consensus documents—were excluded.

Expert Opinion Study

The expert opinion study included experts with academic qualifications and professional expertise in medicine or related health sciences, with an equal distribution of male and female experts.

Survey

The survey included English-speaking adults aged 18 years or older who resided in the United Kingdom, had provided informed consent, and either had or had not experienced back pain, regardless of its type or severity. To ensure that the sample was approximately representative of the UK population, participants also had to meet demographic criteria for sex, age, and race based on simplified UK Census data.

Recruitment Procedure

Review

The search strategy for the scoping review aimed to identify relevant published studies. An initial, limited search of PubMed was conducted to locate key articles, followed by an analysis of the text words in titles and abstracts, as well as the index terms used to describe those articles. Insights from this analysis informed the development of a comprehensive search strategy incorporating the identified keywords and index terms, as outlined in Multimedia Appendix 1. The final search was conducted by a health librarian (CC-A) in the MEDLINE database via Ovid, covering all records from database inception through May 3, 2024.

Expert Opinion Study

Experts in anatomy and related health sciences were recruited through personal invitations extended via the professional networks of the research team. We aimed to engage a total of 6 experts—3 male and 3 female individuals—to ensure balanced representation and to capture a diverse range of perspectives across relevant areas of expertise.

Survey

The anonymous survey was conducted on Prolific [13], with a recruitment goal of 300 participants—an approximate sample size considered adequate for robust descriptive analyses in survey research [14]. Eligible individuals from the Prolific participant pool were able to self-select into the study if they met the inclusion criteria. Prior to beginning the 5-minute survey, participants provided electronic informed consent through the platform. Each participant received £0.75 (US $1) as compensation for their time.

Assessments

Review

All identified citations were imported into EndNote (version 21.2; Clarivate Analytics), where duplicates were identified and removed. The unique records were then transferred to Rayyan [15] for study selection. The selection process involved full-text screening of all articles, including appendices, to detect images of PD body charts. Each record was independently assessed by one reviewer (CM or SS), with 10% of excluded articles cross-checked by a second reviewer (SS or CM) according to predefined eligibility criteria. Discrepancies were resolved through discussion between the two reviewers or, if needed, by consultation with a third reviewer (JL-A or CMW). Articles that mentioned the use of PD body charts but did not include images were only retained if the type of body chart used was explicitly referenced and the images could be located through the cited source.

Data were extracted from papers included in the scoping review using the data extraction tool listed in Multimedia Appendix 2. This tool was piloted with 8 articles to ensure its reliability and comprehensiveness. Two reviewers (SS and CM) independently extracted data from the first 10 articles to establish consistency. For the remaining articles, one reviewer (either CM or SS) extracted the data, while a second reviewer cross-verified 10% of the extracted data to maintain quality control. The extracted data included specific details about the populations, concepts, contexts, and study methods relevant to the scoping review's questions and objectives. Any disagreements between the reviewers were resolved through discussion or, when necessary, by consulting a third reviewer (JL-A or CMW).

Expert Opinion Study

Following data extraction, our experts (GC, BAL, SM, LN, GWK, and CJL) independently assessed the sex representation of the PD body charts identified in the scoping review. Images of the body charts were compiled in a Microsoft Excel file for review. Experts were asked to classify each body chart by selecting one of the following predefined categories from a drop-down menu: "Male," "Female," "Sex-neutral," "Male and

XSL•FO
RenderX

female (>1 template)," or "Unclear." As the original articles rarely provided detailed descriptions of the body charts, there were no predefined correct or incorrect answers; rather, the goal was to capture the experts' subjective assessments informed by their anatomical expertise. In cases where the same body chart appeared multiple times—occasionally in slightly different versions—experts were instructed to assess each version individually. When a body chart included multiple figures with different sex representations, the category "Male and female (>1 template)" was used, where applicable. If none of the predefined categories were suitable, experts had the option to elaborate in a designated comments field.

Survey

The survey aimed to examine participants' perceptions of body charts, focusing specifically on how they classified the chart designed by Lukic et al [10] (as female, male, or sex-neutral), their preferences for selecting a body chart to represent their pain (female, male, or sex-neutral), and the importance they placed on having the option to select from these versions. Additionally, we collected self-reported demographic information, including age, current and past experiences with back pain, country of residence, sex assigned at birth, gender identity, educational attainment, and race. The survey also included additional questions related to the acceptability and usability of the body chart; however, these were not related to the research questions addressed in this paper and were analyzed separately [10].

Analyses

Review

We conducted a descriptive analysis of the extracted data, focusing on the geographical location of the studies, whether the sex of the body chart used was reported, and whether single or multiple body charts were used. We also assessed whether the studies reported the sex of the participants and, based on this information, whether they included both male and female participants, or exclusively one sex.

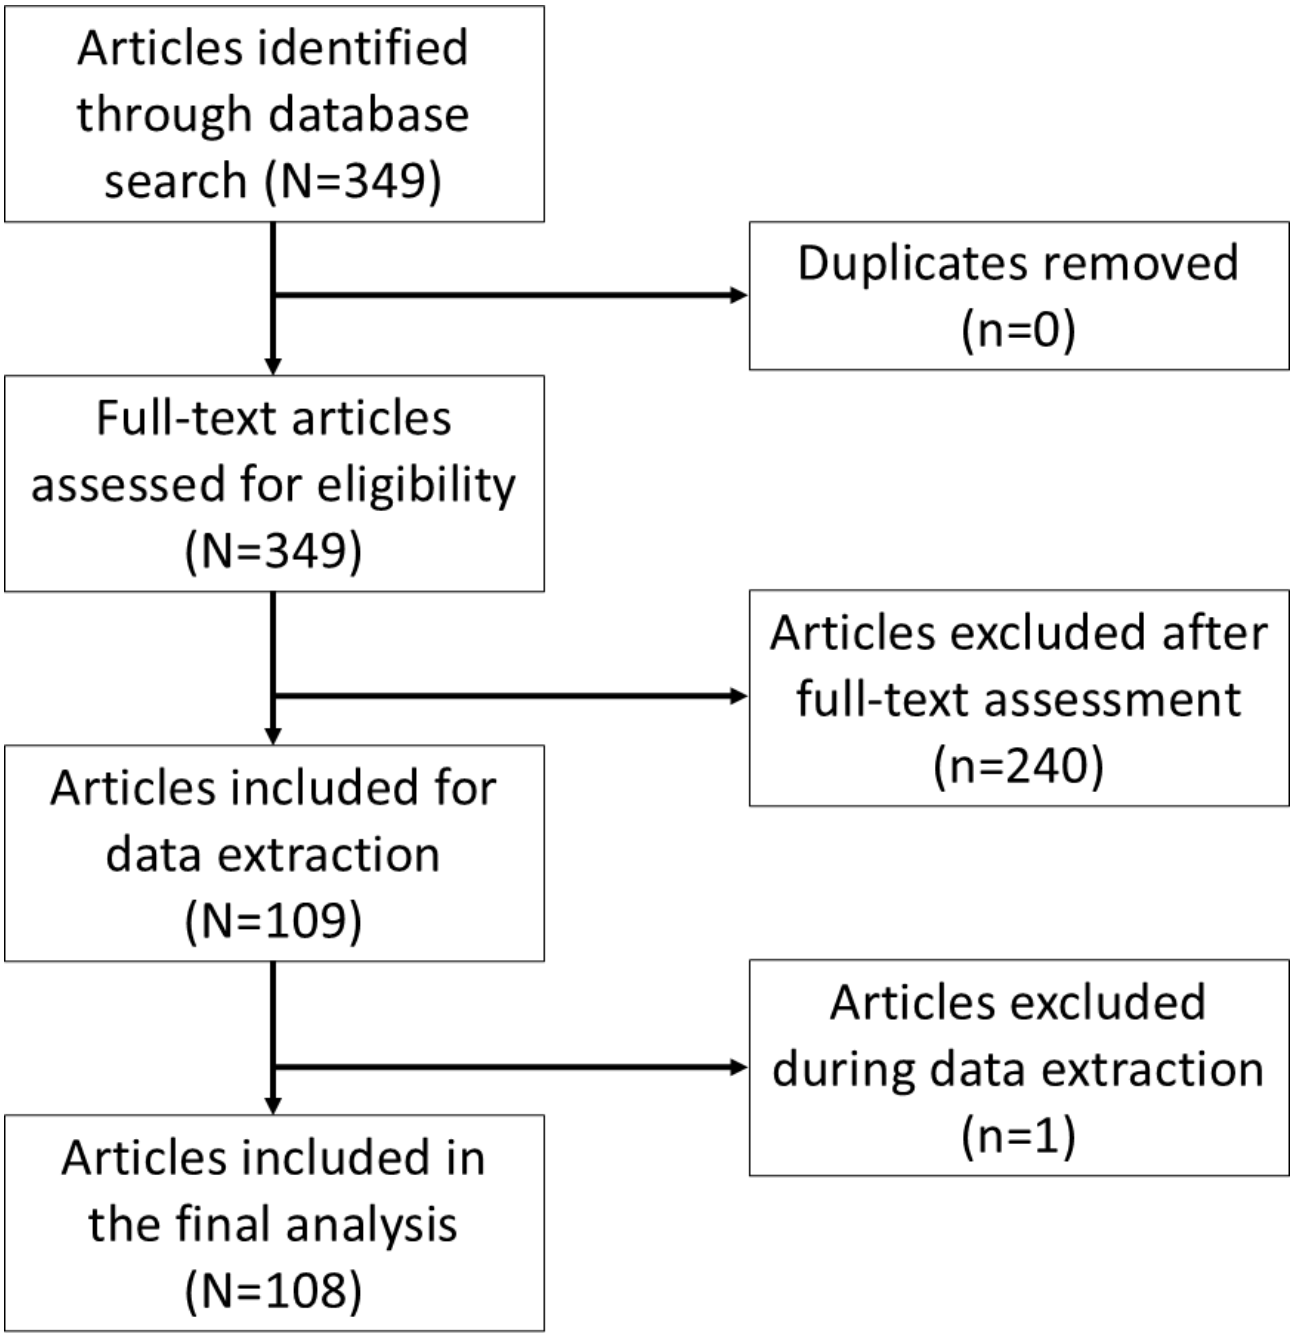
Expert Opinion Study

Due to the imbalanced distribution of ratings—51.2% of which fell into the "Male" category—both Fleiss κ and Gwet AC1 were calculated to assess inter-rater agreement. Fleiss κ provides a conservative estimate that accounts for prevalence effects, representing a "worst-case" scenario, while the Gwet AC1 offers a more robust measure in the presence of imbalanced data, reflecting a "best-case" scenario [16]. While Fleiss κ is a widely used standard metric, the Gwet AC1 is increasingly recommended for its reliability under uneven category distributions. Agreement levels for both statistics were interpreted using the guidelines established by Landis and Koch [17]. For additional context, raw percentage agreement was also calculated as a straightforward, unadjusted measure of observed consensus among raters. Analyses were performed using the *irr* (version 0.84.1), *irrCAC* (version 1.0), and *DescTools* (version 0.99.59) packages in R (R Foundation for Statistical Computing). Agreement was assessed across 5 categories reflecting experts' judgments of the body chart's sex: "Male," "Female," "Sex-neutral," "Male and female (>1 template)," and "Unclear." The analyses were performed for all raters collectively, as well as separately for female raters, male raters, and for all raters excluding one identified as a potential outlier based on preliminary rating patterns. Additionally, we analyzed majority ratings, defined as instances where at least 4 out of 6 raters assigned the same rating. We also evaluated the extent to which expert ratings aligned with explicit body chart descriptions reported in the literature. Finally, we investigated whether the sex classification assigned by experts corresponded with the sex of the study participants as reported in the articles, considering body charts rated as "sex-neutral" to be a match for participants of any sex.

Survey

Descriptive statistics were computed for the entire sample, followed by subgroup analyses to compare responses across sex, age groups, back pain experience (current or past), education level, and race. Chi-square tests were conducted to assess whether the distribution of responses differed significantly between subgroups. For the subgroup analyses, dichotomous groups were formed where appropriate: For age, participants were categorized into 2 groups based on the mean age: those aged older than 46 years (above the mean) and those aged 46 years or younger. Educational levels were categorized into "Non-tertiary education" (including "No formal qualification," "Lower secondary qualification," "Upper secondary qualification without university access," and "University entry qualification") and "Tertiary education" (including "Post-secondary below bachelor's level," "Bachelor's level," and "Master's level and above"). Race was grouped into "Largest racial group" (participants identifying as White) and "Other racial groups" (including those identifying as Asian, Black, Latino or Hispanic, Middle Eastern, Indigenous, Aboriginal or First Nations, or "Other," including multiracial participants). Participants who selected "I prefer not to answer" were excluded from race-based subgroup analyses. Due to the small number of participants with diverse gender identities, subgroup analyses by gender were not feasible. For descriptive purposes, free-text responses indicating "female" or "woman" were categorized as "woman," and those indicating "male" or "man" as "man." Responses unrelated to gender identity (eg, referring to sexual orientation) were classified as "other."

Results



Scoping Review

Our search yielded 349 articles, of which 109 were selected for further analysis after full-text screening. During data extraction, one article was excluded because it used actual participant photos instead of an illustrated body chart for PD, resulting in a final sample of 108 articles (see Figure 1 and full citations in Multimedia Appendix 3). The articles referred to studies predominantly conducted in Europe (n=60, 55.6%) and North America (n=31, 28.7%) and were published between 1988 and 2022. Notably, none of the articles explicitly stated an intention to use a sex-neutral body chart, and only 5 (4.6%) articles reported the sex of the body chart used. Among these, 4 articles [8,18-20] used 2 different body charts described as male and female, while 1 article [21] used a single body chart described

XSL•FO
RenderX

as male. Out of the 108 articles, 6 (5.6%) used 2 different body charts [3,8,18-20,22], while the remaining 102 (94.4%) used a single body chart. One of the studies using two charts included only female participants [22]. Among studies using a single body chart, 70.6% (72/102) included both male and female participants [4,21,23-92], 8.8% (9/102) included only female participants [93-101], and 2.0% (2/102) included only male participants [102,103]. In 18.6% (19/102) of studies, the sex or gender of participants was not clearly reported; these studies used general terms such as "patients," "subjects," or "employees," without further specification [104-122].

Figure 1. Flowchart of literature search and study selection

Expert Opinion Study

The expert panel consisted of 6 raters—3 female and 3 male raters—including 4 physicians (an orthopedic spine surgeon, a radiologist, a chiropractor, and an anatomy lecturer), an anatomical dissection specialist, and a neuroscientist. All experts self-identified as White. Each expert independently assessed the sex representation of body charts from 108 articles, resulting in a total of 648 individual ratings. The distribution of ratings was as follows: 332 (51.2%) ratings were classified as "male," 158 (24.4%) as "sex-neutral," 74 (11.4%) as "female," 27 (4.2%) as "male and female" (for charts depicting two different bodies), 57 (8.8%) as "unclear," and 0 (0%) as "other." Female experts classified 1.42 times more body charts as "male" (195 ratings, 60.2% of their total) compared to male experts (137 ratings, 42.3% of their total). Conversely, male experts assigned more than twice as many body charts as "sex-neutral" (108 ratings, 33.3% of their total) than the female experts (50 ratings, 15.4%

XSL•FO
RenderX

of their total). See Figure 2 for a visual representation of these findings.

Figure 2. Body chart ratings by category and expert sex. The categories represent experts' ratings of the perceived sex of the body charts. "Mixed" refers to body charts that included multiple figures perceived as both male and female. Each group of experts—female and male—contributed 324 ratings, for a total of 648 ratings.

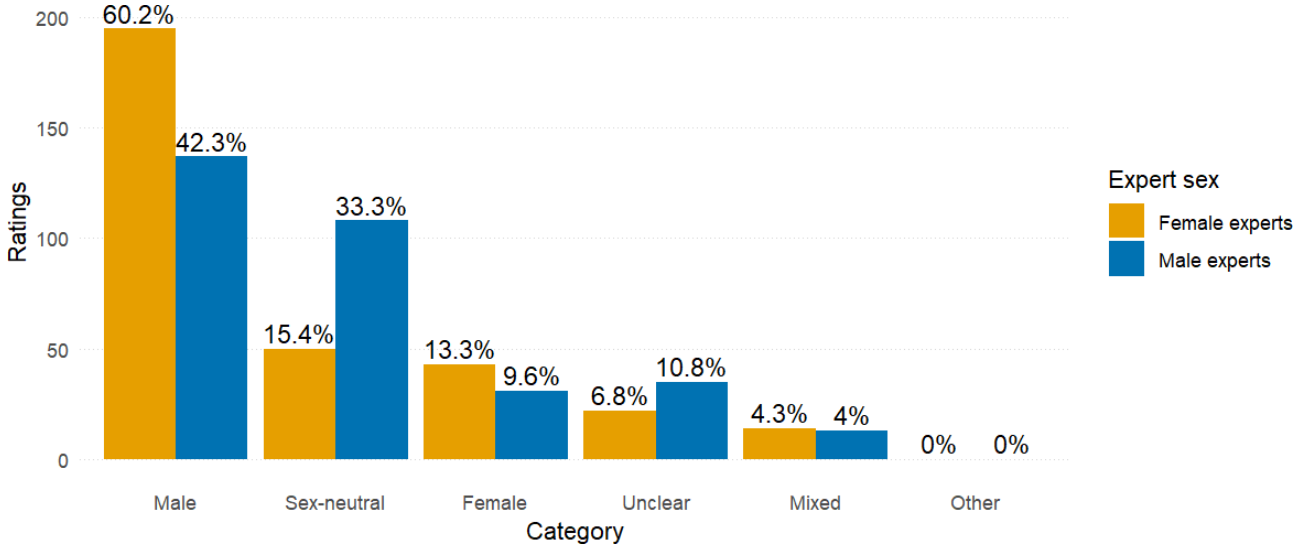


Table 1 presents the inter-rater agreement metrics for the overall sample and subgroups. Across all raters, the Fleiss κ indicated fair agreement, while the Gwet AC1 suggested moderate agreement. The simple percentage agreement was 10.2% (see Multimedia Appendix 4 for images that were rated identically). Subgroup analyses revealed the following patterns: for the 3 female raters, there was moderate agreement for both Fleiss κ and Gwet AC1, and the simple percentage agreement was 52.8%. The 3 male raters revealed slight agreement for Fleiss κ and fair agreement for Gwet AC1, with one suspected outlier; the simple percentage agreement was 13.9%. After excluding the suspected outlier, agreement among the remaining 5 raters increased to moderate agreement (Fleiss κ) and substantial (Gwet AC1), with a percentage agreement of 49.1%. All interpretations should be considered alongside the confidence intervals in Table 1, and percentage agreement values should be interpreted with caution due to the limited nuance.

Table . Inter-rater agreement metrics.

Group and metric	Metric value	95% CI	Interpretation
All raters (n=6)			
Fleiss κ	0.306	0.276 - 0.336	Fair agreement
Gwet AC1	0.456	0.401 - 0.511	Moderate agreement
Percentage agreement	10.2	N/A[a]	—[b]
Female raters (n=3)			
Fleiss κ	0.404	0.337 - 0.47	Moderate agreement
Gwet AC1	0.587	0.496 - 0.679	Moderate agreement
Percentage agreement	52.8	N/A	—
Male raters (n=3)			
Fleiss κ	0.098	0.031 - 0.165	Slight agreement
Gwet AC1	0.251	0.188 - 0.314	Fair agreement
Percentage agreement	13.9	N/A	—
Without male outlier (n=5)			
Fleiss κ	0.488	0.452 - 0.524	Moderate agreement
Gwet AC1	0.647	0.571 - 0.724	Substantial agreement
Percentage agreement	49.1	N/A	—

[a]N/A: not applicable.

[b]—: not available.

XSL•FO
RenderX

We also examined majority ratings, defined as at least 4 out of 6 raters assigning the same classification. Body charts were categorized as "male" in more than half of the articles (59/108, 54.6%), "female" in 10 (9.3%) articles, "sex-neutral" in 8 (7.4%) articles, "male and female" in 4 (3.7%) articles, and "unclear" in 1 (0.9%) article. In 26 articles (24.1%), ratings were too inconsistent to achieve a majority.

Of the 108 articles, only 5 explicitly described the body charts as male, female, or sex-neutral. Four of these articles included 2 body charts each, described as "male" and "female." In three of these articles, all raters classified the sex of the charts in line with the article descriptions. In the fourth, however, rater assessments diverged: four classified both charts as "female," and two as "sex-neutral." The fifth article included a single body chart described as male, which 5 experts identified as "male" and one as "unclear."

Finally, we assessed alignment between the expert-assigned sex of the body charts and the sex of study participants as reported in the articles. Of the 108 articles, 40 (37.0%) provided unclear descriptions of participants' sex or lacked a majority rating from the experts. In the remaining 68 articles, 22.1% (15/68) showed a match between the chart and participant sex. The majority, 67.7% (46/68), were male-biased (ie, male body charts used in studies not exclusively involving male participants), while 10.3% (7/68) were female-biased.

Survey

A total of 300 individuals participated in the survey; however, two were excluded due to technical issues, resulting in a final sample of 298 participants. Descriptive statistics for the sample are presented in Table 2, and subgroup comparisons, including chi-square test results, are shown in Table 3. The majority of respondents (204/298, 68.5%) perceived Lukic et al's [10] body chart as sex-neutral. In contrast, 20.1% (60/298) identified it as representing a male body, while 11.4% (34/298) perceived it as female. Chi-square tests revealed no significant differences in response distributions based on sex, age group, current or past back pain experience, or educational background. However, a significant association was observed for race: participants who identified as White were more likely to perceive the body chart as sex-neutral compared to those who identified as Asian; Black; Latino or Hispanic; Middle Eastern; Indigenous, Aboriginal, or First Nations; or "Other" (Table 3).

Table . Responses to the question: "Does this body chart represent a female, male, or sex-neutral body?" by participants' sex, age, back pain experience, education, and race.

Variable	Body chart, n (%)			Chi-square (*df*)	*P* value
	Sex-neutral	Male	Female		
Participants' sex				0.3 (2)	.92
Female (n=154)	104 (67.5)	31 (20.1)	19 (12.3)		
Male (n=144)	100 (69.4)	29 (20.1)	15 (10.4)		
Age groups (y)				4.3 (2)	.13
≤46 (n=139)	87 (62.6)	34 (24.5)	18 (13)		
>46 (n=159)	117 (73.6)	26 (16.4)	16 (10.1)		
Current back pain				0.9 (2)	.66
No (n=144)	97 (67.4)	32 (22.2)	15 (10.4)		
Yes (n=154)	107 (69.5)	28 (18.2)	19 (12.3)		
Past back pain				1.1 (2)	.57
No (n=59)	38 (64.4)	12 (20.3)	9 (15.3)		
Yes (n=239)	166 (69.5)	48 (20.1)	25 (10.5)		
Educational attainment				1.0 (2)	.61
Nontertiary (n=134)	93 (69.4)	24 (17.9)	17 (12.7)		
Tertiary (n=164)	111 (67.7)	36 (22)	17 (10.4)		
Race				15.9 (2)	.001
Other racial groups[a] (n=40)	17 (42.5)	13 (32.5)	10 (25)		
Largest racial group[b] (n=248)	181 (73)	44 (17.7)	23 (9.3)		

[a] "Other racial groups" includes participants who identified as Asian, Black, Middle Eastern, Latino or Hispanic, Indigenous, Aboriginal, First Nations, or "Other" (including multiracial).

[b] "Largest racial group" includes participants who identified as White.

Most participants (189/298, 63.4%) indicated that it was not important to them to be able to choose between female, male, or sex-neutral versions of the body chart. This included 53.3% (82/154) of female participants and 74.3% (107/144) of male participants. When given the option, over half of the female participants (85/154; 55.2%) said they would choose a female body chart, while 46.1% (71/154) preferred a sex-neutral body chart, and 2 (1.3%) selected a male body chart. In contrast, nearly two-thirds of male participants (88/144, 61.1%) preferred a sex-neutral body chart, 36.1% (52/144) chose a male body chart, 2.8% (4/144) opted for a female body chart. Two participants did not identify with the sex assigned to them at birth; both were assigned male and identified as women. One rated the body chart as male, preferred a female body chart, and expressed that having the option to choose is important. The other rated the chart as sex-neutral, preferred a sex-neutral chart, and reported that the option to choose is not important. Due to the small number of participants with diverse gender identities, no conclusions can be drawn regarding their perceptions and preferences.

Discussion

Principal Results

Our review revealed that the vast majority of articles in the back pain literature do not explicitly report the sex of the body chart used, nor do they indicate an intention of sex neutrality. Very few articles included both male and female versions of body charts. In our expert opinion study, over half of the body charts were classified as "male" and did not accurately reflect the sex of the study participants. Specifically, two-thirds were identified as male-biased—meaning male body charts were used in studies that did not exclusively involve male participants. Agreement among expert raters ranged from fair to moderate, with stronger agreement observed among female raters than male raters. This suggests that assessing the sex of body charts is inherently challenging. While many charts may have been designed to be sex-neutral, they are not consistently perceived as such. In contrast, Lukic et al's [10] body chart—explicitly designed as sex-neutral by an interdisciplinary team—was perceived as sex-neutral by two-thirds of male and female survey participants, regardless of age, back pain experience (current or past), or education level. However, a significant difference emerged by race: participants who identified as White were more likely to

XSL•FO
RenderX

perceive the chart as sex-neutral compared to those who did not identify as White. In terms of preference, female participants showed a slight inclination toward female body charts over sex-neutral ones, while male participants clearly preferred sex-neutral charts over male ones. Notably, both male and female participants generally considered the ability to choose among body chart versions to be of little importance. These findings suggest that a well-designed sex-neutral body chart is broadly accepted by both male and female users and holds the potential for promoting greater sex and gender inclusivity in PDs.

Comparison With Prior Work

Despite the introduction of sex-specific PD body charts in the late 1980 s [3], our findings show that most subsequent studies have continued to use a single body chart—typically perceived as male—to represent both male and female participants. This supports previous observations noting that most PD body charts used in the literature are male [1,7]. To more accurately reflect the diversity of study participants, future studies could either provide different versions of body charts that align with the sex or gender of participants [8,19,20] or offer a sex-neutral version that is broadly perceived as truly neutral [10].

The variability in expert ratings underscores the subjectivity involved in perceiving sex representations. What one expert identifies as male, female, or sex-neutral may differ from another's interpretation, even when both have similar anatomical training and expertise. This echoes earlier findings showing variability in how study participants perceive sex in body charts [7]. Such discrepancies may stem from individual experiences and implicit biases, as well as from the design of body charts that omit explicit sex-specific cues. While the absence of these cues is likely intended to enhance neutrality, it may also make interpretation difficult, leading to the fair to moderate agreement levels observed in our study. This suggests that many of the body charts found in the literature were likely intended to be sex-neutral but were not consistently interpreted as such—instead, they are most often interpreted as "male."

A male bias has been well-documented in human sex perception and anatomical illustrations. Research indicates that when faced with ambiguity or uncertainty, humans are more likely to perceive a figure as male [123,124]. This perceptual bias may have evolutionary roots: misidentifying a potentially dangerous individual (typically male) as female could have higher survival costs, aligning with instinctual self-preservation mechanisms [123]. Therefore, "male" often becomes the default in sex perception, while "female" is only assumed when explicit female sex cues are present [124]. This phenomenon aligns with our findings and may help explain why body charts with ambiguous or unclear sex cues were predominantly perceived as male. Additionally, the design of the body charts themselves—even when designed to be sex-neutral—may reflect a bias toward male figures. Such bias is not unique to PDs but mirrors a broader trend in anatomical illustrations, where male figures are overrepresented, reinforcing the male body as the normative standard [125-129].

Given this observed male bias and the imbalance in sex representation, it is essential to consider the needs and preferences of individuals currently underrepresented in PD tools. Our survey results suggest that a truly sex-neutral body chart is well-accepted by both male and female individuals. While female individuals showed a slight preference for a female-specific body chart, the option to choose between different body chart versions was generally not considered crucial. This nuance builds on the findings of Egsgaard et al [1], who reported a preference among female participants for female body charts. It is important to note, however, that participants in Egsgaard et al's study [1] were only presented with male and female options—without the inclusion of a sex-neutral alternative. Interestingly, while female participants in that study expressed a clear preference for female body charts over male ones, more than half indicated that the ability to choose was not particularly important. This aligns with our results, suggesting that although preferences exist, they may not be a crucial factor in pain reporting. The methodological difference in body chart options presented likely accounts for the partial discrepancy in findings between our study and the study by Egsgaard et al [1]. Together, these insights highlight the potential value of including truly sex-neutral body charts in PD tools, as they may offer a more inclusive and representative option for diverse patient populations while still accommodating those with a preference for sex-specific representations.

Limitations

Our scoping review aimed for comprehensiveness but was limited by language restrictions (English and German) and the exclusive use of the MEDLINE database. These constraints may have introduced selection bias, potentially excluding relevant literature and culturally specific body charts. Future research should expand language criteria and database inclusion to ensure a more comprehensive review. Another potential limitation is that some articles may have displayed only a single body chart, despite using multiple charts in their study. This could have led to misinterpretations and inaccurate conclusions in our review.

Regarding the expert assessment, an important limitation was the lack of cultural diversity among the experts, as all experts self-identified as White. Future studies should aim to include a more diverse panel to assess how cultural backgrounds might influence perceptions of the body charts.

Similarly, of the 298 survey participants, only 40 did not identify as White, which limits the generalizability of our findings to racially diverse populations. Despite this, the survey sample was broad in terms of age and educational background and approximately balanced in terms of sex. Future research should explore how the body chart designed by Lukic et al [10] is perceived by individuals from a broader range of racial and cultural backgrounds to better understand its cross-cultural applicability and inclusivity.

Clinical Implications

The observed acceptance of our sex-neutral body chart across sexes highlights the potential of sex-neutral PD tools to offer a more universally applicable approach to pain assessment. These tools may be particularly valuable in clinical settings where traditional sex-specific charts are impractical or where sex

XSL•FO
RenderX

information is unavailable or deemed nonessential—for example, in emergency care settings, large-scale epidemiological studies, or in the care of nonbinary and transgender individuals. This approach aligns with a growing shift toward inclusivity in medical tools, such as the development of non–sex-specific growth charts for transgender youth [125]. Moreover, sex-neutral PD tools could be particularly beneficial in digital health applications, where standardized, sex-neutral inputs would facilitate automated analysis and improve consistency across diverse populations.

Conclusions

Our scoping review and subsequent studies reveal important gaps and biases in the reporting and representation of sex in PD body charts used in back pain research. The majority of charts are perceived as male, often misrepresenting the study population they are intended to depict. Expert assessments showed fair to moderate agreement, suggesting the complexity of sex perception and indicating that many charts—despite possibly being intended as sex-neutral—are not consistently perceived as such. Our study offers a promising solution: a newly designed sex-neutral body chart, developed with expert input, was widely perceived as sex-neutral across diverse participant groups. However, variations in perception across racial groups highlight the importance of incorporating cultural considerations into design. These findings underscore the potential of a truly sex-neutral body chart to support greater sex and gender balance in pain assessment tools. Future research should prioritize the development and evaluation of culturally sensitive body chart designs to further promote inclusivity and equity in both back pain research and clinical practice.

Funding

This research was supported by the Digitalization Initiative of the Zurich Higher Education Institutions. Abstract

Background: To better understand the effects of media use on children, it is essential to examine the various factors influencing the media use of digital native children. In the situational context, parental media usage, parents' attitudes toward media, and parenting styles have all been identified as significant factors influencing children's media use. This study focuses on the key factors and examines these relationships in greater depth, drawing on existing research to understand their impact on the media usage patterns of digital native children.

Objective: This study examines parental influences related to young children's media use in Korea over a 3-year period (2022 - 2024) using independent, nationally representative cohorts.

Methods: Using multigroup structural equation modeling, we analyzed data from 3 independent parent–reported cohorts (for 2022, n=1058; for 2023, n=1020; for 2024, n=1020) to investigate how parental media habits, attitudes, and distinct parenting styles predict children's daytime and nighttime media consumption.

Results: The online survey results revealed that parental media time, particularly for mothers, consistently correlated with higher levels of children's daytime media use (β=.002-.003). Positive parental attitudes toward media increased children's daytime media use (β=.028-.102), whereas negative attitudes had a limited effect (β=−.069-.140). Among the 7 parenting styles, positive parenting consistently reduced children's daytime media use in 2022 and 2023 (β=−.228 for 2022, β=−.215 for 2023), but harsh punishment emerged as the strongest factor in daytime media use in 2024 (β=−.078 for 2022, β=−.090 for 2023, and β=−.072 for 2024). Notably, parenting styles showed no significant effect on children's nighttime media use throughout the study, suggesting that parental influence may be more effective during daytime hours.

Conclusions: This analysis extends existing research by differentiating media use patterns across time periods and highlights the evolving influence of parenting styles. These findings have implications for the development of targeted parental guidelines for managing young children's media exposure, especially as digital media continues to become a pervasive part of daily life.

Introduction

Parental Influences on Children's Media Use in South Korea

An increasing number of children access media at younger ages, with many actively consuming it. In the United States, 70% of children under the age of 1 year and 91% of children aged 2-3 years access media several times per week [1]. Similarly, in South Korea, approximately 60% of children aged 3-9 years are exposed to television before their first birthday, and 30% begin using smartphones before the age of 1 year [2]. This growing trend is in contrast with the recommendation by the American Academy of Pediatrics [3], which advises against media use for children under the age of 2 years [4]. Despite the recommendation, children's media consumption remains high. The typical 8- to 10-year-old children spend almost 8 hours daily across different media, and this number increases for older children and teenagers to more than 11 hours per day [1].

While media may not be a leading cause of major health concerns, previous research suggests that media exposure contributes to various risks and health problems [3]. For example, younger children's media use, as early as preschool

XSL•FO
RenderX

years, has been associated with developmental difficulties such as reduced physical fitness and psychosocial health [5,6]. Specifically, engagement in risky online social behaviors [7], poor academic performance [8], obesity [9,10], reduced quality of life [11], and impaired executive function [12] have been associated with increased children's media use. Additionally, previous studies have shown that excessive television viewing can lead to cognitive, language, and social-emotional delays [13-16]. Research has further shown that infants and toddlers gain more developmentally beneficial skills through play with physical objects rather than screen-based devices [17,18].

Numerous longitudinal [19] and cross-sectional studies [5,13,20] showed that children with greater screen time had a higher level of behavioral difficulties. A longitudinal study investigating children between the ages of 2 and 6 years showed an association between increased media use and poorer well-being outcomes, even though the results varied for boys and girls [13]. Additionally, each extra hour of television viewing per week between the ages of 2 and 4 years was associated with a 5% increase in body mass index at the age of 10 years, a 9% - 10% rise in the consumption of soda and snacks, and a 13% reduction in outdoor weekend activities [21]. A study from South Korea with survey data from mothers and teachers of 5- and 6-year-old children showed that increased use of smart devices was associated with increased levels of aggression [22]. Altogether, the findings suggest that children's excessive consumption of media may have adverse developmental and behavioral effects.

To better understand the effects of media use on children, it is essential to examine the various factors influencing the media use of digital native children (ie, children who have access to and utilize a wide range of media and platforms from birth) [23]. One key factor is the physical environment, or in other words, the advancements in digital media technology that enable children to use media freely without restrictions of time and space through traditional means such as television as well as portable devices like smartphones and tablet PCs. Another key factor is the situational context, such as the influence of parents, given that parents shape their children's behaviors and attitudes as primary role models [24-26]. Parental media usage [27-29], attitudes toward media [30,31], and parenting styles [26,32] have all been identified as significant factors influencing children's media use. In addition, the impact of these factors varies according to the developmental stage or age of the children [25,26,32]. This study seeks to focus on the second key factor and examine these relationships in greater depth, drawing on existing research to understand their impact on the media usage patterns of digital native children.

Although extensive research has examined children's overall media or screen time, much less is known about how parental factors influence media use across different times of day. This is a critical gap because daytime and nighttime media use may have distinct developmental implications (eg, school readiness, sleep quality, and behavioral regulation). Moreover, little evidence exists on how these influences shift across post-COVID years when children's reliance on screen-based media has been both normalized and expanded to include educational contexts [33,34]. This study addresses this problem by examining parental media use, attitudes, and parenting styles as predictors of children's daytime and nighttime media use in a large, national Korean sample drawn from three independent cohorts across 3 years (2022 - 2024). In this study, "media use" is defined operationally as children's screen-based engagement, including television, smartphones, tablets, and computers, as reported by parents in a 24-hour matrix of daily activities. Conceptually, we focus on electronic and online media rather than print or offline formats, as these account for the majority of children's daily exposure in contemporary contexts.

Parents' Media Use and Social Learning Theory

Children's screen time can be explained by Bandura's social learning theory [35], which posits that learning and behavior are shaped by observing others in one's environment. Young children learn by observing their parents, siblings, and others around them, picking up on daily habits, social interactions, and responses to various situations, including media use in the home. When parents model media behaviors, their children are likely to replicate those patterns. For instance, a national survey found that children often imitate their fathers or older siblings by playing with game controllers, even when they lack the skills to use them effectively [36].

Parents' prolonged or habitual consumption of media at home may serve as a role model for children's media use. Research indicates that parents' media use and habitual patterns of consumption are associated with increased media use time and habitual use among children [37]. Notably, children's media use was more closely related to their parents' habitual consumption of media than to parental restrictions on media use. Further, studies have shown that children's screen time tends to be higher when their mothers report substantial media use [38,39]. These findings suggest that parents' media use may significantly influence children's ability to regulate their own media consumption. Accordingly, we propose:

- H1: A parent's screen time will be positively related to a child's media use.

Parent Attitudes and Media

Parent attitudes are another important factor in children's screen time. Parents play a critical role in establishing rules within the household, with their influence on media consumption being particularly pronounced in younger children. Parent attitudes toward media, whether positive or negative, shape the rules governing media use, thereby directly influencing the amount of time children spend engaging with media [26]. Given their substantial influence on their children's behaviors [40], parents often modify their behaviors as a strategy to affect changes in their children's behaviors [41].

In the United States, a survey focused on electronic media use among children aged 6 months to 6 years indicated that parents had varied attitudes toward media use [36]. Some parents encouraged media use, finding it beneficial for children and useful for household management, such as keeping children occupied while doing chores. While similar proportions of parents felt that television had both positive (38%) and negative (31%) effects on learning, the majority supported computers as beneficial (70%) but video games as detrimental (49%) [29]. It is possible that parents aim to help their children maximize the

XSL•FO
RenderX

benefits of the rich resources offered by video media while simultaneously shielding them from harmful content [42].

In general, the children of parents who view media positively tend to have higher screen time. Among preschoolers, parent attitudes and beliefs about media were strong indicators of children's screen time [30]. For younger (0 - 2 y) and older (5 - 6 y) children, positive parent attitudes have been shown to significantly contribute to exceeding the recommended screen time limits set by the American Academy of Pediatrics [3,43], particularly in relation to television viewing [44]. Although parent attitudes significantly influenced the television and computer use of children, their influence on mobile devices was less pronounced [31].

Additionally, parental rules based on positive attitudes tend to support media use in the home, while negative attitudes encourage restrictions. The more critically parents evaluate media, the more likely they are to engage positively in parental mediation (active or restrictive) to mitigate the negative effects of their children's media exposure [41]. Parental mediation has been shown to effectively influence children's responses to media exposure [45], and experts have even advocated for increasing the level of parental mediation provided by parents [46]. Therefore, we hypothesize:

- H2: Parents with a positive attitude toward media will have children with higher levels of media use.
- H3: Parents with a negative attitude toward media will have children with lower levels of media use.

Parenting Style and Media Use

Finally, parents considerably contribute to children's media use, indicating that parents may mediate children's media use and, in turn, the overall developmental outcome. For example, while children with increased media use showed a decreased level of prosocial behavior, the level of parent-child interactions mediated the association between the children's media use and level of prosocial behavior [19]. Specifically, parenting style—or specific sets of parental mediation strategies and behaviors—may explain children's varying levels of media use. Previous studies have shown that parental control over children's access to smart media influences the amount of time younger children spend using such media [47]. Research in Korea has further indicated that among parental mediation strategies, supervisory control tends to be more pronounced before the age of 6 years but diminishes after the age of 7 years. In particular, for children aged 5-6 years, multiple factors—including media use patterns, self-regulatory abilities, and parental supervision—exert significant influence. This suggests that age-specific approaches to parents' mediation are necessary [48]. Research also indicates that mediation practices vary not only in form (eg, restrictive, active, or co-use) but also in effectiveness, depending on the child's age. For younger children, restrictive mediation (eg, setting time limits) has been shown to reduce overall screen exposure, whereas older children and adolescents benefit more from active mediation approaches that involve discussion, explanation, and joint engagement [25,32,49-51].

Baumrind [52] and Maccoby and Martin [53] identified four different parenting styles: authoritative, authoritarian, indulgent, and neglectful. Each parenting style varied in their levels of demandingness and responsiveness. Generally, studies showed that children with authoritative parents (ie, highly demanding and responsive) had the most positive developmental outcome, while children with authoritarian (ie, highly demanding but not responsive) and permissive (ie, not demanding but highly responsive) parents had more negative outcomes.

The Ghent Parental Behavior Scale, developed by Leeuwen and Vermulst [54], categorizes parenting strategies into 9 distinct domains: positive parenting, autonomy, rules, monitoring, discipline, harsh punishment, material reward, inconsistent discipline, and ignoring. A material reward is a tangible incentive, such as a toy, snack, small gift, or even cash, provided to a child in exchange for a specific behavior or compliance. Positive parenting styles, such as permissive and neglectful parenting, are characterized by strategies including autonomy, positive parenting, and rules. In contrast, negative parenting styles, such as authoritative or authoritarian approaches, are associated with parenting strategies including monitoring, harsh punishment, material rewards, and ignoring [54].

A recent study by Lee et al [26] showed that a child's daytime media use between the ages of 4 and 6 years significantly increased for parents who gave more autonomy to their children (ie, permissive and neglectful parenting style), and a child's nighttime media use decreased with the parenting style of discipline (ie, authoritative and authoritarian parenting style). Lee et al also found that parents' use of material rewards was the strongest predictor of the child's nighttime media use, as the child's nighttime media use significantly increased when parents practiced material reward. Similarly, other studies showed that children between the ages of 10 and 11 years exhibited higher levels of screen exposure when they had parents with lower levels of control over their children [27,32]. The parental behavior in this example aligns with a permissive and neglectful parenting style, where parents provide more autonomy to their children and incorporate positive parenting. On the contrary, studies showed that parents who exercise higher levels of control and support would engage in behaviors or strategies employing active and restrictive mediation [32,55]. Specific strategies would include monitoring and rules, discipline, harsh punishment, and material reward. Collectively, the literature suggests that children with permissive and neglectful parents would be more likely to have higher levels of media use, while children with authoritarian and authoritative parents would be more likely to have lower levels of media use [26].

Despite the clear implications of the parent's role in shaping children's media use, previous studies have focused on descriptive and correlational analyses. As Lee et al [26] suggested, further investigation on the relationship between parental determinants, such as parenting style and children's media use, is needed. The primary goal of the study is to determine the relationship between parenting style and children's media use across various age groups. The researcher distributed surveys to parents because young children cannot reliably self-report their daily media use, and parent reports are generally considered appropriate for estimating children's media use, such

XSL•FO
RenderX

as video and app games, computer use, and television viewing [56]. Based on previous findings that parenting style may potentially have important effects on children's media use, we hypothesize the following:

- H4: Specific parenting styles will be associated with children's level of media use.

The secondary goal of the study is to extend the findings of Lee et al [26] by replicating the previous findings. Therefore, we incorporated the 2 hypotheses related to parenting style used in Lee et al [26]:

- H5: Children who have parents with permissive and neglectful parenting styles (ie, exercise positive parenting and give autonomy to children) will have higher levels of media use.
- H6: Children who have parents with authoritative and authoritarian parenting styles (ie, monitoring, rules, discipline, harsh punishment, and material reward) will have lower levels of media use.

Previous findings support a clear relationship between parenting style and children's media use. To extend the existing literature, it is imperative to identify the parental determinant that explains children's media use, and the researcher of this study aims to answer the following research question:

- RQ1: Among parent's media use, media attitudes, and parenting styles, what is the most influential factor on children's media use?

Methods

Participants

A total of 1058 parents of children aged 5-7 years, 1020 parents of children aged 6-8 years, and 1020 parents of children aged 7-9 years completed questionnaires between April 26 and May 9, 2022; October 26 and November 9, 2023; and July 31 and August 21, 2024, respectively. All participants completed the questionnaire through an online survey conducted by a Korean survey company, Macromill Embrain, which recruited participants from its national panel pool. Each year's sample primarily consisted of an independent cross-sectional group, although approximately 5% - 10% of the participants may have overlapped across years due to the nature of the panel system. However, the study did not track individuals over time, and analyses were conducted separately for each dataset. The age and sex distribution of the children was balanced across each dataset. Detailed demographic characteristics for all three groups are presented in Table 1.

Ethical Considerations

The study received ethical approval from the Institutional Review Board of Ewha Womans University (Institutional Review Board approval number: EWHA-202103-0028-01). All data were anonymized prior to analysis, and no personally identifiable information was stored or retained. Informed consent was obtained from all participants involved in the study. As the participants were members of a registered survey company panel, an honorarium was provided based on the survey response time at a rate of 100 KRW (approximately US $0.67) per minute. Participants who discontinued the survey prior to completion were also compensated with a prorated stipend corresponding to their participation time.

Instrument and Measures

Overview

The questionnaire was initially developed in English and then translated into Korean, with translation equivalence verified by bilingual researchers. In addition to the main variables, media use (ie, time spent on media via television, personal device, smartphone) and demographic information of both children and their parents were collected. Tables 2, 3, and 4 present the reliabilities and descriptive statistics of the variables, along with their correlations. Composite variables were calculated once unidimensionality and acceptable reliability were confirmed. All variables were measured with 5-point Likert scales (1=“strongly disagree” to 5=“strongly agree”) unless otherwise noted.

Children's Age at First Media Use

Parents were asked about their child's age at first media exposure with the question, "How old was your child when he/she first started watching media content?" The response options included "less than 12 months," "1 year," "2 years," "3 years," "4 years," "5 years," "6 years," and "7 years."

Parents' Media Time

Each participant reported both their own and their spouse's media watching time. Two questions were used: "How many hours and minutes do you spend watching media on a typical weekday?" and "How many hours and minutes do you spend to watch media on a typical weekend?" Responses were averaged after weighing (ie, (weekday time × 5 days + weekend × 2 days)/7)) and converted to minutes.

Parents' Positive and Negative Attitudes Toward Media Use

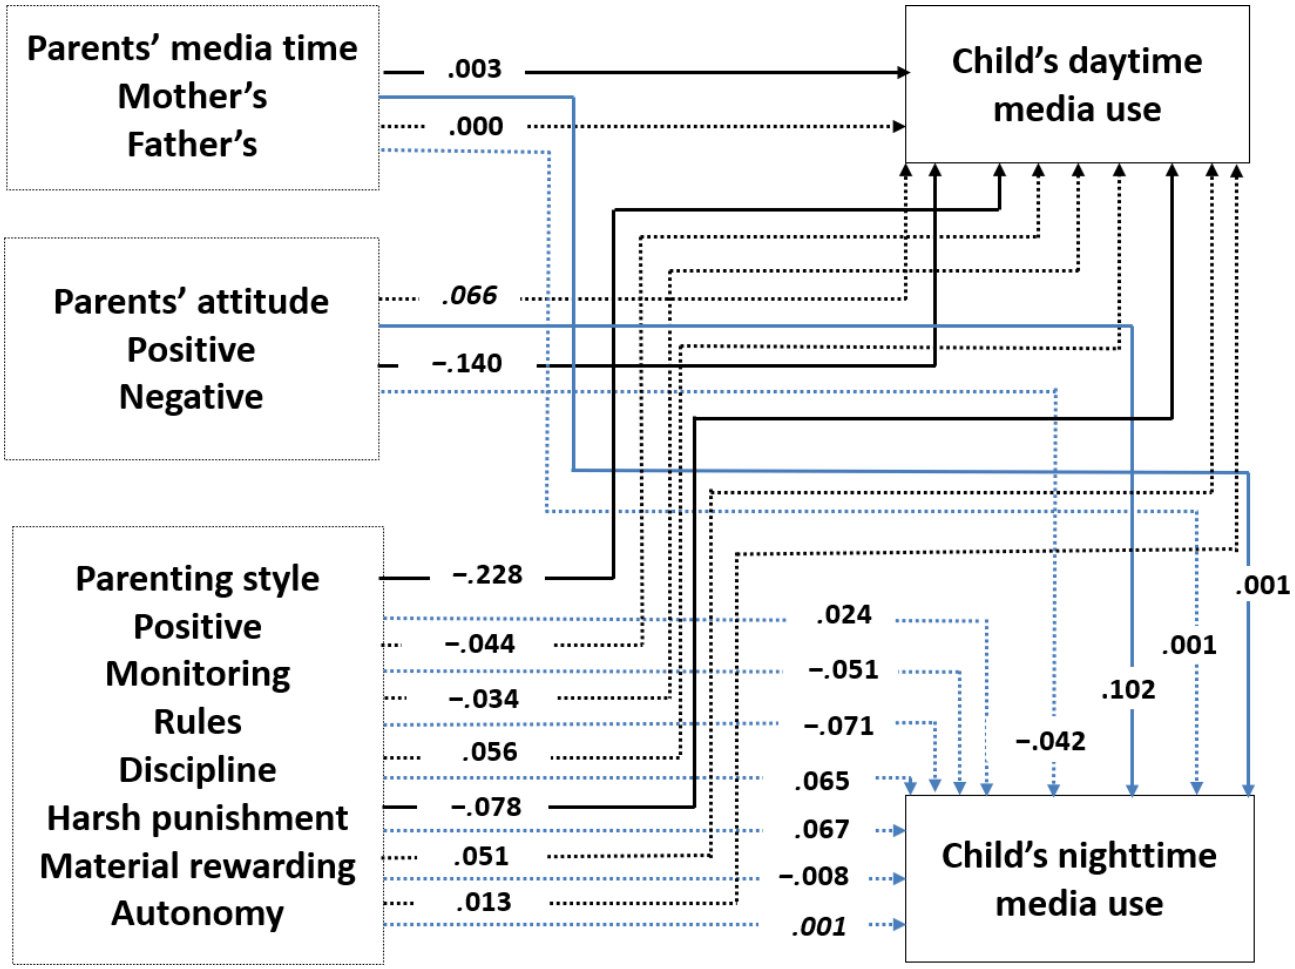
Based on scales by Elias and Sulkin [57] and Nikken and Jansz [58], 9 items measured positive attitudes (eg, "I think watching media will positively influence my child's behavioral development."). Negative attitudes were measured with 2 dimensions: intellectual and social. Each dimension included 4 items, such as "I think watching media will hurt my child's creativity." for the intellectual dimension and "I believe watching media will negatively affect my child's play with friends." for the social dimension.

Parenting Styles

The Ghent Parental Behavior Scale [54] was used to measure the parenting styles. This scale has demonstrated valid structure in diverse samples. Seven dimensions were included due to reliability concerns with 2 original dimensions (inconsistent discipline and ignoring). The included dimensions are positive parenting (11 items: eg, "I make time to listen to my child when he/she wants to tell me something."), monitoring (4 items: eg, "I keep track of the friends my child is seeing."), rules (6 items: eg, "I teach my child to obey rules."), discipline (4 items: eg, "When my child does something I don't approve of, I punish him/her."), harsh punishment (4 items: eg, "I spank my child when he/she is disobedient."), material reward (3 items: eg, "I reward my child with money or a small gift for good behavior."), and autonomy (3 items: eg, "I teach my child to solve problems independently."). Items excluded for reliabilities included 1 ("I teach my child respect for the authorities.") from the rules dimension and 2 items ("When my child has been misbehaving, I give him/her a chore for punishment." and "It happens that I don't punish my child after he/she has done something that is not allowed.") from harsh punishment dimension. All items and dimensions can be referenced in Leeuwen and Vermulst's measurement study [54].

Child's Media Time

Participants selected a cell in a 24-hour matrix to indicate when a child watched media during both weekdays and weekends. Daytime use was defined as viewing between 7:00 AM and 9:00 PM, while viewing before 7:00 AM or after 9:00 PM was classified as nighttime use. This classification was based on developmental sleep guidelines: given that elementary schools in Korea typically begin at 9:00 AM, and the American Academy of Sleep Medicine [59] recommends 10 - 13 hours of sleep for children aged 3 - 5 and 9 - 12 hours for children aged 6 - 12, we estimated that 10 - 11 hours of sleep starting from 9:00 PM would allow children to function healthily on a daily basis. In practical terms, a 9:00 PM bedtime enables children to sleep until approximately 7:00-8:00 AM, providing sufficient time to prepare for and arrive at school. In addition, "screen time" was measured during 2022 - 2024, when academic activities had resumed their normal patterns following the COVID-19 pandemic, thereby minimizing the potential impact of external variables. Media time was averaged and reported in hours. Due to the varied and skewed nature of the data, standardized *z* scores were used for analysis.



Results

Multigroup structural equation modeling was conducted to test the hypotheses and research question using Mplus 8.0 [60], which uses the maximum likelihood estimation method. To evaluate the model fit, confirmatory fit index (CFI), goodness-of-fit index (GFI), and normed fit index (NFI) were used.

Acceptable goodness-of-fit indices were obtained for the overall model [61]: $\chi^2_1=1.2$, $P=.27$, CFI=0.99, GFI=1.00, NFI=0.99 for 2022, $\chi^2_1=8.9$, $P<.01$, CFI=0.99, GFI=1.00, NFI=0.99 for 2023, and $\chi^2_1=44.7$, $P<.001$, CFI=0.98, GFI=0.99, NFI=0.98 for 2024. The estimated coefficients are presented in Figures 1-3.

In addition, paths leading to nighttime media use are shown in light blue, while paths leading to daytime media use are shown in black.

H1 predicted that parents with a higher level of screen time would have children who have a higher level of media use. The results partially supported this hypothesis. Regarding a child's daytime media use, mother's media time had a positive effect consistently in 2022, 2023, and 2024 (β=.002-.003), but father's media time showed a significant positive effect on child's daytime in 2023 only (β=.001). Regarding a child's nighttime media use, mother's media time showed a positive effect in 2022, 2023, and 2024 (β=.001).

H2 and H3 hypothesized that parents' positive and/or negative attitudes toward media use would affect child's media use. Parents' positive attitude toward media use increased a child's nighttime media use (β=.028-.102) and parents' negative attitude decreased a child's daytime media use (β=−.069-.140). H2 and H3 were supported.

Finally, H4 predicted that parents with permissive and neglectful parenting styles would be positively associated with children's media use, while parents with authoritative and authoritarian parenting styles would be negatively related to child's media use. Positive parenting style decreased a child's daytime media use (β=−.228 for 2022, β=−.215 for 2023), and harsh punishment (β=−.078 for 2022, β=−.090 for 2023, and β=−.072 for 2024) among the 7 parenting styles significantly decreased a child's daytime media use. Material reward was positively associated with child's nighttime media use (β=.072) in 2024.

RQ1 examined which factors were the most influential among parents' media use, attitude on media, and parenting styles. The results showed that parents' positive parenting style was the strongest predictor of a child's daytime media use in 2022 and 2023, but parents' harsh punishment was the strongest predictor in 2024. Parents' positive and negative attitudes on media use were the strongest predictor of a child's nighttime media use in 2022 only.

Discussion

This study investigated the connection between young children's media use and various parental influences, including media time, attitudes toward media, and parenting styles. The results across 2022, 2023, and 2024 consistently demonstrate the critical role parents play in shaping their children's media use habits. Similar to previous studies, it was observed that when parents—especially mothers—engage in higher media use, their children's media consumption during both daytime and nighttime increases, supporting the findings from past research [26,38,39]. This aligns with the idea that parental behavior directly influences children's media use habits.

XSL•FO
RenderX

Prior research has typically collapsed media consumption into a single metric, overlooking potential temporal differences. Our findings show that parental influences such as parent attitudes and parenting styles are differentially affected by the temporal contexts (ie, daytime vs nighttime). Specifically looking at parent attitudes, across the 3 years, a negative parent attitude toward media consistently correlated with decreased daytime media use, but a positive parent attitude toward media consistently correlated with increased nighttime media use. These consistent relationships across 3 years reflect the findings by Cingel and Krcmar [30] that emphasize the predictive power of parental attitudes on children's screen time.

Parenting style showed distinct influences on children's media use patterns over the 3-year period. In 2022 and 2023, positive parenting emerged as a significant factor in reducing children's daytime media use, highlighting that nurturing and supportive approaches were effective in moderating screen time during the day. By 2024, however, harsh punishment had become the strongest predictor of reduced daytime media use, suggesting a shift where more stringent disciplinary actions had a notable impact on limiting screen time. This change may reflect an evolving role of disciplinary measures in influencing children's media habits over time.

Contrary to expectations, none of the parenting styles showed a significant association with children's nighttime media use across the 3 years except 1. In 2024, material reward was positively associated with a child's nighttime media use. The findings indicated that parenting styles, while impactful on daytime media consumption, may have a limited role in controlling screen time during nighttime hours. Overall, the findings of daytime and nighttime media use suggest that while positive parenting consistently influences daytime media use, the emergence of harsh punishment and material reward as a stronger factor in 2024 points to potential shifts in the effectiveness of various parenting strategies over time.

The findings from a study focused on a younger age group (aged 3-6 y) than this study [26] demonstrated that children's daytime media use increased when parents provided more autonomy to their children. Conversely, nighttime media use decreased among children of parents who emphasized discipline. Children's nighttime media use was significantly increased when parents employed material rewards as a motivational tool. This study extended the findings of Lee et al [26] by investigating an older group of children (ie, aged 5-7 y). The findings from the 2 studies collectively suggest that as children grow older, the effectiveness of these parental interventions, particularly in reducing nighttime media use, diminishes significantly. These findings contribute to a broader understanding of the role of parental determinants in shaping children's media use and underscore the necessity for age-specific parental guidelines.

Previous results consistently highlighted the value of parental mediation in amplifying the positive effects and mitigating the adverse effects of children's media exposure [45,62]. These findings have encouraged scholars to highlight the critical role of parental engagement in managing children's media use [41]. However, a significant gap persists in the implementation of parental controls. For instance, most American adolescents report having no rules or restrictions from their parents regarding either the type of television content or the amount of time spent viewing [1].

Parents play a crucial role in ensuring safe and beneficial use of digital devices, particularly given that children's cognitive and functional abilities are still in developmental stages. Studies have shown that parents can actively promote children's growth and development through well-informed media management practices. Rather than relying on restrictive approaches, Wu et al [63] proposed integrating restrictive, instructive, and joint approach strategies to create a balanced and effective framework. This combined approach encourages collaboration and communication between parents and children, facilitating the establishment of developmentally appropriate media use habits that support overall growth.

Furthermore, these results extend previous research on parental determinants of children's media use and underscore the importance of establishing specific parental guidelines tailored to different times of day. The differentiation between daytime and nighttime media use is particularly relevant, as studies have shown that media use affects multiple developmental domains, including sleep quality, cognitive development, language, and socioemotional and physical health [13-16]. The variations observed over the years suggest that a longitudinal approach can provide a more comprehensive understanding of parental influences on media habits.

From a policy perspective, these findings support the creation of targeted recommendations that help parents foster healthy media use patterns at home. With children increasingly exposed to media, guidelines that encourage informed parental choices could mitigate the potential risks associated with excessive screen time. This evidence-based approach can empower parents to optimize on- and off-screen activities for their children's development.

However, this study is not without limitations. First, it is important to acknowledge that the data were collected during COVID-19 and post-COVID years (2022 - 2024), when screen time became both more prevalent and more socially normalized. In this period, children's daytime media use may not solely reflect leisure activities but may also encompass school-related or educational screen exposure. Second, parental self-reports remain susceptible to social desirability bias, especially given the awareness of recommended screen time limits [64]. Future research should incorporate observational methods to provide a more objective measure of media use. Additionally, distinguishing between types of media would allow for a more nuanced understanding of the effects of specific content on children's behavior and development, as different media types (eg, gaming vs educational content) may have distinct impacts. Similarly, a limitation of this study is the reliance on parent-reported 24-hour matrix data, which, while useful for distinguishing daytime and nighttime use, does not capture the content, context, or quality of children's media exposure. Prior work highlights that screen time measures often overlook these dimensions and that more comprehensive approaches are needed to assess family media environments [65,66]. Future studies

should integrate both time-based metrics and contextual measures to provide a fuller understanding of children's media use. Although the survey company's online panel is designed to mirror the Korean population in terms of key demographic characteristics (eg, sex, age, and family structure), the sampling method is not entirely random. Therefore, the findings should not be interpreted as being representative of the whole population. Rather, the results should be considered in the context of the study's sample, and caution should be exercised when generalizing these patterns to all Korean parents and children. Finally, the correlational nature of this study does not imply causation; thus, further research should explore potential genetic and environmental moderators that could influence the relationship between parental behavior and children's media habits.

In conclusion, the study across 3 years underscores those parental influences, including media time, attitudes, and specific parenting strategies, continue to shape children's media behaviors. By accounting for temporal patterns, researchers and policymakers can provide parents with tailored guidance to support balanced media use, enhancing children's overall well-being in the digital age.

Abstract

Background: Discrimination can greatly impact both physical and mental health due to frequent stressors. Younger individuals, particularly those under the age of 17 years, are more adversely affected by victimization. Within the European Union, Romania exhibits poor rankings concerning LGBTQ+ (lesbian, gay, bisexual, transgender/transsexual, queer, and other minority sexual orientations and gender identities) inclusion, with large numbers of LGBTQ+ teenagers experiencing bullying due to their sexual orientation. Given that much of this discrimination and harassment occurs within schools, teachers and counselors are vital in affecting institutional change.

Objective: This study aims to investigate the impact of an intervention on reducing prejudice against the LGBTQ+ community among Romanian teachers and counselors. Most prior interventions of this nature target Western, educated, industrialized, rich, and democratic populations.

Methods: In this randomized controlled trial, we recruited 175 Romanian teachers via a national closed online user group and assigned them to either the experimental or control condition. Participants in the experimental condition received the intervention first and then completed the web-based outcome measures, while those in the control condition completed the measures first and then received the intervention. The intervention, designed for internet-based delivery, consisted of a 1-hour video session led by a pair of researchers. It blended educational information with testimonials of LGBTQ+ people, perspective-taking tasks, and a self-efficacy exercise. We measured LGBTQ+ prejudice (using Attitudes Toward Lesbians and Gay Men Scale, Homophobia Scale, and Attitudes Toward Homosexuals Scale), behavioral intentions, self-efficacy, perspective taking, intergroup disgust sensitivity, intergroup anxiety, empathy, factual knowledge about LGBTQ+ issues, as well as participants' feelings toward lesbian, gay, and bisexual individuals.

Results: Participants in the experimental group (n=89) showed significant reductions in prejudice when using the Attitudes Toward Lesbians and Gay Men Scale ($F_{1,173}$=7.22; P=.008) when compared to the control group (n=86), but not when using the other 2 attitudinal scales. We also found that the experimental group had warmer feelings ($F_{1,173}$=4.40; P=.04; d=0.32), were more likely to engage in supportive behaviors ($F_{1,173}$=13.96; P<.001; d=0.56), displayed more self-efficacy ($F_{1,173}$=9.14; P=.001; d=0.33), had more factual knowledge ($F_{1,173}$=11.98; P=.001; d=0.52), and had a higher ability to take the LGBTQ+ perspective after controlling for contact ($F_{1,172}$=4.77; P=.03; d=0.28). We did not observe significant differences in terms of intergroup disgust sensitivity ($F_{1,173}$=0.816; P=.37), intergroup anxiety for either positive ($F_{1,173}$=.383; P=.54) or negative emotions ($F_{1,173}$=0.51; P=.48), or empathy ($F_{1,173}$=0.02; P=.89).

Conclusions: The intervention offers initial evidence for the effectiveness of a cost-effective and portable online resource for educators and high school counselors, particularly in regions where negative attitudes toward the LGBTQ+ community are prominent. The results show that integrating blended cognitive (information), affective (indirect contact and perspective taking), and behavioral (self-efficacy and empowerment) approaches is a promising avenue for intervention in producing positive outcomes related to LGBTQ+ issues within the school environment.

Introduction

Background

The LGBTQ+ (lesbian, gay, bisexual, transgender/transsexual, queer, and other minority sexual orientations and gender identities) community has historically faced great adversity, as centuries of prosecution have only recently begun to be overturned. The collapse of communism in Eastern Europe brought several changes in civil societies after they began shifting their focus to prioritizing human rights values and norms [1]. In Romania, homosexuality was officially decriminalized in 2001 because of external and international pressures [1]. Despite these changes, the consequences of the decades of oppression are seen even today, as attitudes toward LGBTQ+ individuals remain overall negative [2]. In fact, when it comes to LGBTQ+ inclusion, Romania tends to perform poorly compared to other EU countries. According to a recent survey [3,4], 45% of LGBTQ+ individuals in Romania reported experiencing discrimination in at least one aspect of their lives, but only 8% reported their experiences to an organization dealing with such issues. Additionally, 43% of the respondents said they faced harassment due to their sexual orientation or gender identity, the second-highest rate among all the EU countries.

The rates mentioned above are particularly concerning when viewed from the perspective of the minority stress model [5]. This model proposes that minorities face unique stressors because of stigmatization and discrimination, and that these can lead to detrimental effects on health. The stress caused by repeated experiences of discrimination can accumulate over time and negatively impact both physical and mental health in the long run.

Several studies have been conducted to test this model. In terms of physical health, a systematic review of 26 studies [6] found that minority stress impacted several physical health outcomes in sexual minorities, including cancer incidence, changes in cardiovascular function, and immune response. Additionally, a different systematic review [7] found that sexual minorities face significantly elevated risks for cardiovascular diseases. Similarly, mental health issues in LGBTQ+ individuals have been widely studied. A systematic review [8] revealed that sexual minorities had a higher risk for mental health issues, substance abuse, and suicide risk. In line with the minority stress model, evidence suggests that individuals who identify as LGBTQ+ also face several obstacles that negatively impact their mental health, such as discrimination, emotional distress, victimization, and barriers to accessing mental health services [9].

Moreover, although data suggest that minority stress affects all LGBTQ+ individuals, it seems that age impacts the stress felt by sexual minorities. Several studies have shown that younger individuals generally report more stress than older ones [10,11]. A meta-analysis revealed that victimization had more negative effects on LGBTQ+ individuals under the age of 17 years as compared to those aged more than 17 years [12]. These findings are corroborated by the impact on suicide risk. A meta-analysis of 35 studies [13] showed that suicide risk was higher for young LGBTQ+ individuals aged 12-20 years compared to cisgender straight young people. Furthermore, sexual minority youth are more likely to experience mental health issues such as anxiety, depression, and impaired academic performance [14]. This effect is especially prevalent within school environments, as supported by a systematic review showing significant negative effects of bias-based bullying for minorities, including LGBTQ+ students [15].

In fact, 44% of LGBTQ+ pupils aged 15 to 17 years in Romania have admitted to hiding their sexual orientation or gender identity in school, the third highest rate in the European Union after Croatia (51%) and Cyprus (47%), and significantly higher than in countries like the Netherlands (16%), France (20%), or Denmark (20%). Disturbingly, half of the respondents aged 15 to 17 years (50%) said that they were bullied at school because of their sexual orientation [3,4]. This finding is further supported by the United Nations Educational, Scientific and Cultural Organization report on school violence [16]. As such, given that discrimination and harassment against LGBTQ+ individuals are quite prevalent in Romanian schools and among students [3,4], it is therefore imperative to create programs that help reduce the stigma and prejudice that Romanian LGBTQ+ students face.

We decided to focus such efforts on teachers as they are perhaps the most significant group that can affect institutional change. Teachers can influence their students' experiences by creating inclusive classroom norms, making these interventions most effective. In fact, survey evidence suggests that supportive communities and schools buffer the negative effects of bias-based bullying for LGBTQ+ students in schools [17] . This finding is backed up by qualitative data, with interviews in schools showing the importance of teacher attitudes and education in creating safe and inclusive environments for LGBTQ+ students [18]. Overall, a recent rapid realist review of interventions to promote LGBTQ+ inclusivity in schools [19] showed that interventions work best when the staff in the school are trained, including education on sexuality, gender issues, as well as how to be an effective ally. Teacher training was related to LGBTQ+ students experiencing less victimization, increased safety, greater self-esteem, improved mental health, and

XSL•FO
RenderX

improved academic performance. Moreover, teacher training improved the effectiveness of teacher involvement in gay-straight alliances, which directly impacts LGBTQ+ youth's outcomes in schools [20].

In this paper, we aim to present the findings of a teacher-oriented intervention whose protocol has already been published [21]. The main objective of the intervention is to use a 1-hour online session that focuses on education and contact as primary training elements. The session is meant to help high school teachers cope with cases of witnessing bullying acts against LGBTQ+ students and to improve their knowledge and attitudes toward LGBTQ+ students.

To create a safe and inclusive learning environment for LGBTQ+ students, it is crucial to not only address teacher biases toward them, but also to equip teachers with the skills and knowledge needed to intervene in LGBTQ+-related victimization. This includes providing teachers with training on how to recognize and respond to instances of LGBTQ+ bullying or discrimination, as well as model appropriate behaviors and attitudes toward LGBTQ+ students. By taking a proactive and comprehensive approach to support LGBTQ+ students, we can help ensure that they feel valued, respected, and included in the classroom, thus reducing the risk of significant mental and physical health costs.

According to a meta-analysis [22], interventions can be effective in reducing sexual prejudice. The effect size of these interventions can range from one-third to one-half of an SD. Furthermore, the analysis highlights the most effective strategies for reducing different outcomes. These strategies include educational interventions, contact with LGBTQ+ individuals, and a combination of education and contact. It is worth noting that the majority of interventions aimed at reducing homophobia have been conducted among undergraduate students in Western countries, with none conducted in Eastern Europe or other regions that still harbor clear animosity and prejudice toward the LGBTQ+ community. While some recent research has tested interventions in other countries such as Jamaica [23] or Brazil [24], in Romania (or Eastern Europe), no such interventions have been tested, particularly on teachers.

However, equally important is how the effect of these interventions is measured. The term "homophobia" has garnered a lot of attention since its inception in the 1970s [25]. Several researchers [26,27] have argued the term should not be used because of its inaccuracy, as the inclusion of the word "phobia" would suggest an anxiety-related measure rather than an attitudinal one. Additionally, the misnomer would mainly focus on attitudes toward gay men and leave out lesbians and bisexuals. This conceptual confusion has seeped into the measurements used when measuring the impact of the interventions. Currently, several measures exist that claim to test sexual prejudice, but few interventions have used more than 1 instrument. It would be, therefore, beneficial to include several measures to see which, if any, would better capture the effects of the intervention. Besides prejudice, behavioral, cognitive, and emotional outcomes are also vital in predicting and ensuring significant changes in the classroom.

In order to ensure the success of interventions, it is crucial to consider the cultural and institutional context in which they are implemented. A recent qualitative analysis [28] has shown that participants frequently criticize interventions for their lack of alignment with the context in which they are conducted. This can be used as a justification for resisting change. To achieve better outcomes, interventions should be tailored to the community's unique characteristics, including their beliefs, values, traditions, and social norms.

Aims and Hypotheses

The main objective of this research is to test an intervention plan that aims to improve Romanian teachers' LGBTQ+ outcomes. Our intention is to consider particular cultural and institutional characteristics, rather than simply implementing previous intervention strategies. Our approach involves using education and contact as primary training elements, consistent with meta-analytic findings [22] on training effectiveness. However, we design the educational components according to the specific needs of our target group. For example, we incorporate information on the biological (rather than social) causes of homosexuality, as this is a common misbelief among Romanians. The protocol for this study is peer-reviewed and published in Research Protocols [21].

Additionally, we addressed potential feelings or perceptions of threat (such as the belief that exposure to LGBTQ+ individuals will "cause" children to become gay) as, according to intergroup threat theory [29], these are important predictors of anti-gay bias. We included several elements that had been found useful in other interventions, such as perspective-taking [30] and self-efficacy [31,32]. We also ensured that these elements were culturally appropriate. The trial protocol details were reported elsewhere [21], including a complete list of intervention components, subcomponents, and contents. Further details are given in Table 1 in a previous research paper [21].

Through a randomized controlled trial, we aim to measure the impact of the intervention on the attitudes, behavior, cognition, and emotions of teachers toward the LGBTQ+ individuals compared to those randomly assigned to the control condition. Additionally, we also measure the participants' factual knowledge about LGBTQ+ issues in the classroom, as well as their attitudes toward LGBTQ+ individuals.

Methods

Ethical Considerations

The ethical review committee of the West University of Timisoara, Romania, approved this study (notice 74505/10.11.2022) after reviewing the procedure, measures, and materials used. Each participant was informed of the data collected and the details of the intervention on 3 separate occasions: upon signing up for the intervention session, upon beginning the intervention, and when responding to the questionnaires. Participants provided informed consent by clicking a radio button on an online sign-up page containing written information about the study.

Upon finishing the online multimedia intervention, respondents received an automatic unique code that they had to submit in a

XSL•FO
RenderX

separate form to confirm their full participation in the intervention. Once participants confirmed their full participation, they were sent a certificate of participation that could be used to earn continuing education credits. They were also given the opportunity to enter a raffle to win a gift certificate worth 500 RON (equivalent to US $110 or €100).

All research data (outcome measures) were collected anonymously without recording any personal or identifiable information. However, to ensure that participants were indeed teachers, and to generate the participation certificates, the researchers collected personal information (email and name) that was stored in a separate database and never associated with the actual study results.

Participant Recruitment and Eligibility Criteria

By working with the local center for educational resources and assistance to distribute an online message to all their national members, we aimed to recruit teachers or counselors employed in Romanian schools. The interested teachers and school counselors had the opportunity to sign up for 1 of the 17 advertised sessions across 3 months (from December 2022 to February 2023), scheduled at different times during the day, depending on their availability. To ensure more participation, the teachers who signed up for a session were sent a reminder email 24 hours before the commencement of the session.

All participants had to be either teachers or school counselors and be fluent in Romanian, as the intervention was conducted in this language. Additionally, because the trial was advertised and conducted online, respondents had to have basic computer or internet literacy to access the recruitment form and the Zoom meeting links (Zoom Communications, Inc).

Study Design

The experimental design used in this intervention was a randomized controlled trial. We randomly assigned participants to either the experimental or control condition using a 2-group design. Those in the experimental condition received the intervention first and then completed the outcome measures, while those in the control condition completed the outcome measures first and then received the intervention. All participants had to fill out the outcome measures through the use of online questionnaires. This design was chosen for ethical reasons so that all participants would benefit from the intervention and associated resources by the end of their participation. Given the rigorous random assignment to the training and control conditions, we did not expect any baseline differences to influence the outcome measures. We did, however, conduct analyses with and without controlling for habitual contact with LGBT individuals. We chose this approach because discussions in the contact literature suggested that baseline levels of contact can potentially lead to a selection bias of participants to these studies [33,34] and as such, controlling those levels can help us isolate the intervention's specific effect beyond habitual exposure.

Participants were grouped into sessions of up to 30 individuals, depending on their availability. Cluster randomization was done at the session level by the lead researcher, with each session being randomly assigned to either the experimental or control condition. The randomization was done with the use of an online number generator. Individual randomization within the session was not possible given that the intervention was presented to all participants at the same time.

Sessions were scheduled outside of typical working hours on different days and times to ensure there were no systematic biases due to participants' session choice.

This study did not involve any risk to the participants' physical or mental integrity, and no unintended harms were observed during implementation.

In addition to being published in an academic journal [21], the study protocol was also registered in an international clinical study registry (ISRCTN84290049) [35]. The study is reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines as per the completed checklist (Checklist 1).

Intervention

To ensure a standardized experience for all participants, regardless of the session they attended, each session was led by a pair of researchers who were tasked with delivering scripted instructions, answering participant queries, and ensuring that the study was completed at a consistent pace with minimal distractions.

The stand-alone intervention was designed for internet-based delivery and was multimedia in nature. It contained a recorded animated presentation that contained information on terms, threat reduction, and effects of stigma, behavioral tools, testimonials of LGBTQ+ people, a perspective-taking task, and a self-efficacy exercise. In total, the intervention lasted 50 minutes. The full details on all the components of the intervention are presented in Table 1 in a previous research paper describing the protocol in detail [21].

Sample Size Estimation

In order to determine the appropriate sample size for our study, we undertook a power analysis. Drawing on an average effect size of d=0.66 from a meta-analysis by Bartos et al [22], we aimed to achieve a statistical power of 0.80 as per the Cohen [36] recommendation that type II error should be limited to a probability of 0.20. Our analysis indicated a required sample size of 122 participants, although we elected to over-recruit in order to account for multiple outcomes. There was no pre-established stopping rule, and recruitment continued until all interested participants had been given the opportunity to participate in 1 of the 17 scheduled sessions.

All participants who completed their participation in the study were included in the data analysis, with no exclusions.

Outcomes

Overview

In order to ensure the reliability of the final scores for each outcome, we verified that the Cronbach α coefficient passed the 0.7 threshold. Additionally, to ensure the accuracy of the

XSL•FO
RenderX

results in our research, we used 3 different scales in measuring sexual prejudice and antigay bias.

Attitudes Toward Lesbians and Gay Men Scale: Measure of Sexual Orientation Prejudice

This 10-item scale measured beliefs and attitudes toward gay men and lesbians ("I think male homosexuals are disgusting" and "Sex between two women is just plain wrong.") [37]. Items were rated on a Likert scale from 1 (strongly disagree) to 5 (strongly agree). After reverse coding 4 items, scores were averaged into a final score with higher values denoting more negative attitudes. Reliability for this measure was very good (Cronbach α=0.88).

Homophobia Scale (HS): Attitudes Toward Gay Individuals

This scale was composed of 25 items that assessed attitudes toward gay individuals, as well as social avoidance and aggression toward them [38]. Examples of items from the scale included, "Gay people make me nervous" and "I make derogatory remarks about gay people." Participants rated each item on a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). After reverse coding 9 items, the scores were averaged to obtain a final score. Higher scores indicate more negative attitudes toward gay people. The scale has shown excellent reliability with a Cronbach α of 0.93.

Attitudes Toward Homosexuals Scale: Assessment of Negative Beliefs

We used an additional scale to measure the attitudes toward and avoidance of gay people [39]. The 12 items included statements such as "Homosexuality is disgusting in the eyes of God," and "If I can, I prefer to not be in the company of homosexuals." Participants rated the statements on a Likert scale from 1 (strongly disagree) to 5 (strongly agree). Out of all, 5 items were reverse scored, and the statements were averaged into a final score with higher values denoting more negative attitudes. Reliability for this measure was excellent (Cronbach α=0.91).

Self-Efficacy

The original 10-item scale [40] was adapted for working with LGBTQ+ students in a school setting. The scale measured self-efficacy in dealing with issues related to LGBTQ+ students. Sample items included "If I try hard, I can solve difficult issues related to LGBTQ+ students" and "I can deal with unexpected situations that arise with LGBTQ+ students." Ratings ranged from 1 ("Not at all true for me") to 4 ("Perfectly true for me"), and higher scores indicating more self-efficacy in dealing with LGBTQ+–related behaviors in the classroom. The scale showed an excellent reliability with a Cronbach α of 0.92.

Behavioral Intentions

We used a 16-item scale to evaluate the propensity of teachers to exhibit supportive professional conduct in the classroom pertaining to LGBTQ+ issues [39,40], including discussing queries regarding sexual orientation with students or having books about gay and lesbian issues in the classroom. Each item was rated on a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). A final score was obtained by averaging the responses, with higher scores indicating a greater willingness to engage in LGBTQ+ supportive behaviors in the classroom. The measure showed excellent reliability (Cronbach α=0.95).

Factual Knowledge About LGBTQ+ Issues

We designed a questionnaire consisting of 7 questions to evaluate the level of understanding of the participants on LGBTQ+ topics. The questions were carefully crafted based on the training content and covered a range of topics such as the biological basis of gender and the elevated risk of suicide among LGBTQ+ youth. The items were rated as either true or false, and the final score was calculated by adding up the number of correct responses. Participants with higher scores demonstrated a greater knowledge of and familiarity with LGBTQ+ issues.

Feeling Thermometer

We assessed the teachers' attitudes toward gay, lesbian, and bisexual individuals using a feeling thermometer [41]. We asked them to rate their feelings toward each group using a sliding thermometer scale that ranged from 0 (indicating very negative feelings) to 100 (indicating very positive feelings). We then averaged the ratings for the 3 groups into an overall lesbian, gay, and bisexual (LGB) feelings thermometer. The scale showed excellent reliability (Cronbach α=0.98).

Intergroup Disgust Sensitivity

We used a 7-item scale to evaluate the repulsion toward LGBTQ+ groups [42]. The scale included statements such as "After shaking hands with someone who has a different sexual orientation, even if their hands were clean, I would want to wash my hands." Participants rated items on a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). One of the items was reverse-scored. The final score was calculated by averaging all the scores, with higher values indicating more disgust toward the LGBTQ+ community. Reliability for this measure was very good (Cronbach α=0.83).

Intergroup Anxiety

This scale consisted of 10 items that were designed to measure anxiety when interacting with people of another sexual orientation [43]. Participants were asked to rate the likelihood of feeling several emotions such as embarrassed, unsure, happy, or accepted, on a scale of 1 (not at all) to 10 (extremely). We calculated 2 scores, one for positive emotions and another for negative emotions. The reliability for both positive (Cronbach α=0.82) and negative emotions (Cronbach α=0.88) the reliability of the scale was very good.

Perspective Taking

This measure consisted of 5 items that assessed how well individuals can empathize with LGBTQ+ people [44]. Participants were asked to rate their ability to understand the issues that are important to LGBTQ+ people. The overall reliability of the scale was very good, with a Cronbach α score of 0.88.

Toronto Empathy Questionnaire

This scale consisted of 16 items that evaluated participants' level of empathy toward others [45]. Examples of statements

XSL•FO
RenderX

in the scale included "I feel upset when someone is treated disrespectfully." Participants were asked to rate the statements on a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Among all, 7 items were reverse coded, and the final score was computed by averaging all items. Higher scores indicated higher levels of empathy. Reliability for this measure was very good (Cronbach α=0.80).

Control Variables

Demographics

We asked respondents to indicate their age, gender, and sexual orientation. As all respondents were either teachers or counselors, they are required to have at least a bachelor's degree in their respective field. Therefore, respondents were not asked to provide their education level.

Contact With LGBT People

We inquired about the frequency of contact (eg, speaking) with individuals who identify as gay, lesbian, bisexual, and transgender on a scale of 1 (almost daily) to 6 (never).

The Duke University Religion Index was used to measure religiosity [46]. The scale included 5 items that assessed religious involvement, organizational and nonorganizational religious activity, as well as subjective religiosity or intrinsic religiosity. The responses to each item were averaged to obtain a single score, which indicated the level of religiosity. Higher scores suggested greater religiosity. Cronbach α for this scale was 0.81, suggesting a very good reliability.

We also asked participants to indicate their political ideology on a 100-point scale from very conservative to very liberal or progressive.

Statistical Analysis

Quantitative data from the surveys were analyzed using SPSS (version 24; IBM Corp) [47]. To examine our hypotheses, a series of one-way between-participants ANOVAs were performed. The objective of this analysis was to compare outcomes between the participants in the experimental and control groups. We also conducted the analyses while controlling for contact with LGBTQ+ individuals (ANCOVA), given that people's different experiences may influence their response to training, particularly when it comes to affective outcomes. The results were presented as *F* test and *P* values, along with descriptive statistics such as n, mean, and SD. In order to estimate the effect size using means and SDs, we calculated Cohen *d*.

There was no deviation in the analysis from the registered protocol [21]. However, we decided to include a post hoc analysis in Multimedia Appendix 1, to explain some inconsistent results in the case of one outcome—the HS. We also controlled the analyses using the Benjamini-Hochberg false discovery rate (FDR) method to correct for any type I errors that could occur when testing for multiple hypotheses [48]. These analyses were conducted using the R programming language (version 4.5.1; R Foundation for Statistical Computing) [49]. The results are presented with both the corrected (noted as P_{FDR}) and uncorrected *P* values.

Results

Descriptive Statistics

A total of 382 individuals signed up to attend one of the advertised sessions. Further examination revealed that 6 of the submissions were duplicated, rendering 376 unique individuals that signed up. Of these, 175 out of 382 (45.81%) participants actually participated and finished the intervention, and 201 individuals did not attend despite repeated reminders. A CONSORT (Consolidated Standards of Reporting Trials) flowchart of the phases of the intervention is provided in Figure 1. A full summary of the descriptive statistics, for the full sample (N=175), as well as for the experimental group (n=89) and control group (n=86), is presented in Table 1. Also included in the table are the statistical analyses made to check whether there were any significant differences between the 2 groups. As can be seen, no significant differences were found between the experimental group and the control group in terms of age, gender, sexual orientation, religiosity, ideology, or LGBT contact. This confirms successful randomization across the 2 experimental conditions.

Outcomes

Significant differences were observed for the Attitudes Toward Lesbians and Gay Men Scale ($F_{1,173}$=7.22; P=.008; P_{FDR}=.02), where teachers in the control group had more negative attitudes (mean 2.70, SD 0.93) than those in the experimental group (mean 2.36, SD 0.77). The effect size, as indicated by Cohen *d*, was small to medium (d=0.41). Teachers who completed the intervention reported less negative attitudes toward lesbians and gays compared to teachers who did not complete the intervention. When controlling for the effect of contact, the experimental condition remained significant ($F_{1,172}$=9.16; P=.003; P_{FDR}=.009; d=0.46).

Interestingly, for the HS, while we did see lower scores for the experimental group (mean 1.95, SD 0.64) than the control group (mean 2.08, SD 0.76), these differences were not statistically significant ($F_{1,173}$=1.58; P=.21; P_{FDR}=.32). This effect remained nonsignificant when controlling for contact ($F_{1,172}$=2.36; P=.13; P_{FDR}=.20). The same can be observed for the Attitudes Toward Homosexuals Scale, where no statistically significant differences ($F_{1,173}$=1.67; P=.20; P_{FDR}=.32) were observed between the experimental group (mean 2.14, SD 0.65) and the control group (mean 2.31, SD 0.88). This effect also remained nonsignificant when controlling for contact ($F_{1,172}$=2.40; P=.12; P_{FDR}=.20).

Initially, significant differences were seen for the LGB feelings thermometer, in that respondents in the experimental group had higher (therefore warmer) feelings toward LGB community members (mean 71.80, SD 27.35) when compared to respondents in the control group (mean 62.64, SD 30.35; $F_{1,173}$=4.40; P=.04; P_{FDR}=.09; d=0.32), though the effect size was small, but after applying the LGB FDR correction, the main result failed to reach significance. When controlling for the effect of contact, the experimental condition remained significant even after applying the FDR correction ($F_{1,172}$=5.82; P=.02; P_{FDR}=.048).

We did not find significant differences between the 2 groups in terms of intergroup disgust sensitivity ($F_{1,173}$=0.82; P=.37; P_{FDR}=.49), intergroup anxiety for either positive ($F_{1,173}$=0.38; P=.54; P_{FDR}=.59) or negative emotions ($F_{1,173}$=0.42; P=.52; P_{FDR}=.59), or empathy ($F_{1,173}$=0.02; P=.89; P_{FDR}=.89). Even when controlling for the effects of contact with LGBTQ+ individuals, we did not see any significant results for intergroup disgust sensitivity ($F_{1,172}$=1.11; P=.29; P_{FDR}=.39), intergroup anxiety for either positive ($F_{1,172}$=0.500; P=.48; P_{FDR}=.52) or negative emotions ($F_{1,172}$=0.51; P=.48; P_{FDR}=.52), or empathy ($F_{1,172}$=0.04; P=.84; P_{FDR}=.84).

However, we did see significant differences in terms of behavioral intentions, in that respondents in the experimental group were more willing to engage in helping behaviors (mean 4.19, SD 0.68) than those in the control group (mean 3.75, SD 0.89; $F_{1,173}$=13.96; P<.001; P_{FDR}=.006; d=0.56), even after controlling for contact ($F_{1,172}$=19.54; P<.001; P_{FDR}=.004).

We also saw that factual knowledge was significantly higher in respondents from the experimental group (mean 5.04, SD 1.24) than those in the control group (mean 4.37, SD 1.32; $F_{1,173}$=11.98; P=.001; P_{FDR}=.006; d=0.52), even when controlling for contact ($F_{1,172}$=12.03; P=.001; P_{FDR}=.004). Furthermore, respondents in the experimental group (mean 3.18, SD 0.42) had significantly higher levels of self-efficacy than those in the control group (mean 2.94; SD 0.93; $F_{1,173}$=9.14; P=.003; P_{FDR}=.01; d=0.33), even after looking at the effects of contact ($F_{1,172}$=11.82; P=.001; P_{FDR}=.004).

Finally, the difference between the experimental and control conditions in terms of perspective taking was just shy of reaching significance ($F_{1,173}$=3.27; P=.07; P_{FDR}=.14; d=0.28), such that respondents in the experimental group had a slightly higher ability to take the LGBTQ+ perspective (mean 3.87, SD 0.69) than those in the control group (mean 3.66, SD 0.80). This analysis only reached significance after controlling for contact ($F_{1,172}$=4.77; P=.03; P_{FDR}=.06), although we note that the effect was small, and after applying the FDR correction, the results were again insignificant.

We conducted the above analyses in line with the preregistered research protocol published in a study by Latu et al [21].

Discussion

Principal Results

Our intervention suggests that even a 1-hour online session that combines informative materials (education, factual knowledge, and behavioral tools to address bullying and support LGBTQ+ students) and testimonials (vicarious contact) produces small to average positive effects on various LGBTQ+ outcomes. The intervention decreased teachers' negative attitude toward LGBTQ+ topics, increased their self-efficacy in dealing with LGBTQ+ issues in the classroom, and led to a higher level of behavioral intentions to engage in supportive behaviors for LGBTQ+ students facing bullying in school contexts. It should be noted that the cognitive and behavioral outcomes were most stable, with the attitudinal outcome being relatively inconsistent across measures and types of analysis. Our inconsistent results across several scales of homophobia or antigay attitudes, together with our supplementary analyses, suggest that latent variables may be at play and that future research should systematically investigate the attitudinal components of homophobia or antigay bias for appropriate measurement.

The online intervention, however, did not lead to significant differences between the experimental and the control groups in terms of intergroup disgust or intergroup anxiety, nor on more general and nonspecific measures such as their empathy level toward other people. This may be because such emotional responses, compared to behavioral and cognitive components, are less malleable especially in the context of LGBTQ+ biases which are deeply ingrained in the Romanian mainstream culture. Our findings may also suggest that it was the educational and behavioral components of our intervention that were most effective. Improved affective outcomes, on the other hand, may result from the contact component of interventions [50]. Although vicarious contact was used in our intervention via recorded video testimonials, more direct and prolonged forms

XSL•FO
RenderX

of contact with LGBTQ+ individuals may have the power to change affective responses.

The small to average effect sizes obtained for various outcomes align with an existing meta-analysis [22], in which interventions meant to reduce sexual prejudices obtained similar effect sizes, namely from one-third to one-half of an SD. As already explained elsewhere [21], most of these interventions have been implemented on undergraduate students from Western countries, and none has been implemented in Eastern Europe.

Likewise, our results suggest the opportunity to implement a multipurpose intervention, as suggested in prior studies [24]. Despite its shortness, the intervention showed multiple benefits at the attitudinal, cognitive, affective, and behavioral intention levels.

Taking together, our results are encouraging and a promising starting point for addressing LGBTQ+ biases in teachers. The findings show that an online intervention that is relatively low-cost in terms of personnel and resources could be implemented at a larger scale. Likewise, the session could represent a valuable resource to be added to a more complex intervention. The resource we developed could be an excellent tool for teachers in their professional development training when it comes to topics such as accepting sexual and gender diversity or when required to tackle LGBTQ+–related bullying in school contexts.

Another strength of this work is that the intervention was implemented in a country (Romania) which maintains strong negative attitudes toward LGBTQ+ individuals in the public sphere, with roots in conservative and religious beliefs. Such an educational resource turns away the attention from the moral or religious to psychological aspects such as perspective-taking and diversity acceptance, including vicarious contact with LGBTQ+ people and the problems they face in school settings. The emphasis on the humanistic view in teachers, backed up by education, seems to work even in less tolerant environments concerning LGBTQ+ issues. Therefore, the program behind the current intervention can be seen as a useful and more portable resource for guidance counselors in high schools as well as for other specialists who are interested in upscaling the positive results obtained in various high schools. When evaluating our findings, we believe that the intervention is especially useful given that it led teachers to perceive themselves as more equipped to intervene when LGBTQ+ students experience bullying acts.

Limitations

A significant limitation of this study is the absence of long-term follow-up measurement of outcomes, with measurement being conducted in the same session as the intervention. Although these findings do not allow for inferences about long-term effects, we know that the outcomes of such interventions generally tend to be short-term. For example, a contact intervention [50] showed reduced LGBTQ+ negativity in the short term, but levels returned to baseline 7 days after. In contrast, those in the control condition who were not exposed to the intervention showed even more increased LGBTQ+ negativity 7 days later. Such findings suggest that our intervention, although short-term, can potentially lead to longer-term prevention of worsening of biases. We also suggest that, to secure long-term effects and change inclusivity norms in schools, our intervention could be part of a long-term curriculum of development for teachers.

Another limitation is that there may have occurred biases related to self-selection. Participants were included in the trial based on their voluntary consent and without any certain financial benefit (except for their inclusion in a raffle with a small chance of winning some financial benefits). Although their effort was minimal (attending an online 1-h session excluding the time required for the completion of the outcome questionnaires), it still could have led to the selection of a biased sample from the teachers' population, as most likely teachers with strong negative attitudes toward LGBTQ+ people were more reluctant to attend our study. However, due to random assignment to conditions and the presence of significant effects, we believe there is sufficient evidence about the efficacy of the training.

Another limitation of the study is related to the lack of blinding to the experimental conditions. Because of the nature of the intervention and how it was organized, we could not effectively blind respondents and experimenters to the nature of how the trial worked, thus increasing the risk of a type I error. Future intervention could use artificial intelligence or other automated methods to deliver the intervention in a standardized way, to avoid any demand characteristics or experimenter effects.

A final issue is around the gender composition of our sample, which predominantly consists of women. This gender composition is in line with worldwide trends [51] but also national trends in the Romanian education system [52]. However, theoretically, future studies could investigate the effects of gender on the efficiency of such training tools and adapt them accordingly.

Conclusions

This intervention is a promising resource that can serve as a valuable and relatively low-cost resource (no specialized human intervention is needed) for teachers and high school counselors, particularly in countries where negative attitudes toward LGBTQ+ people prevail. Our study also offers suggestions as to how such interventions could be improved and embedded in a longer-term program to increase classroom inclusiveness for LGBTQ+ students.

Acknowledgments

The authors thank Sebastian E Barto , Lavinia Chirică, and Andre Rădulescu for their advice and assistance in developing the intervention.

Abstract

Background: The rising number of refugees and migrants has created growing mental health needs that health care systems struggle to address. Providing assessment and treatment for mental health problems in a digital format could help increase access to care and facilitate the provision of adapted interventions. Psychologists are key stakeholders in the delivery and influence of clinical services within routine care settings, but there are limited data on their perspectives regarding the use of digital solutions to assess and treat common mental health problems in refugees and migrants.

Objective: This study aimed to examine psychologists' usage, knowledge, and attitudes toward digital mental health solutions for assessing and treating common mental health problems in refugees and migrants within the Swedish health care system.

Methods: A cross-sectional online survey was conducted among psychologists in Sweden between December 2023 and February 2024. Responses included Likert-scale items and categorical variables, which were analyzed using descriptive statistics, independent samples *t* tests, and Fisher exact test to explore differences between subgroups.

Results: A total of 81 psychologists responded to the survey. Among them, 58 (72%) were women, and nearly half (40/81, 49%) worked in a public health care region. Respondents showed the highest acceptance for guided internet-based cognitive behavioral therapy (ICBT), blended treatment, and videoconferencing therapy. Only 20% (16/81) reported using digital solutions for refugees or migrants with mental health problems. Most respondents had low or very low knowledge of digital assessment and screening (61/81, 75%) and digital treatment (58/81, 72%) for these groups. Those using digital formats for refugees and migrants, or working in a setting that did so, had significantly higher ratings on all 5 knowledge items compared to those that did not ($P<.001$ to $P=.01$). Respondents emphasized the importance of digital solutions being provided in refugees' and migrants' native languages (70/81, 86%) and being culturally adapted (56/81, 69%). Those using digital formats for refugees and migrants considered cultural adaptation less necessary ($P=.05$). The preferred implementation approach was through specialized or decentralized units in primary care (66/81, 81%).

Conclusions: While psychologists recognize the potential of digital mental health solutions, significant barriers remain, including limited knowledge and experience with using digital formats for refugees and migrants. Psychologists prefer digital solutions in the native language of refugees and migrants that are implemented at the primary care level. The need for cultural adaptation should be further explored. Addressing psychologists' preferences could facilitate the future integration and implementation of digital formats for refugees and migrants in routine care settings.

Introduction

The world is experiencing an unprecedented rise in the number of forcibly displaced people. By the end of 2024, over 123 million people across the globe were displaced or stateless, having left their homes due to war and conflict, natural disasters, consequences of climate change, or political changes, including 31 million refugees [1]. Refugees often endure pre-, peri-, and postmigration challenges that increase the risk of developing mental health problems [2] and complicate integration in the new host country [3]. Research in Swedish and international contexts shows that refugees and certain migrant groups experience elevated symptoms of depression, anxiety, and posttraumatic stress [4-6] and that these problems are also prevalent among children and adolescents [7]. Although effective treatment options exist for these conditions [8], the use of health care services among refugees and migrants differs from that of the native-born population. Refugees and migrants tend to underuse available resources and experience barriers to care due to cultural differences such as language difficulties, lack of awareness, and mental health stigma [9-12], leading to untreated mental health problems and further societal marginalization and exclusion from health care systems.

One way of increasing the reach of mental health interventions and overcoming the lack of access and availability of mental health professionals [13] is by providing digital psychological treatment. This format of delivery has expanded considerably during the last 2 decades [14,15] and was further accelerated during the COVID-19 pandemic [16,17]. Internet-based treatment and videoconferencing therapy have been found effective for common mental health problems, including social phobia, generalized anxiety, panic disorder, posttraumatic stress disorder, and depression [18,19], yielding similar results as face-to-face treatment [20,21]. Other digital formats, such as chat, email therapy, and smartphone apps, are being provided by mental health care professionals and have shown promising results [22-25]. Also, the use of digital material together with face-to-face sessions in a blended format, a combination often preferred by providers [26], has been shown to be effective for common mental health problems [27]. Modern information technology is also used for the assessment of mental health status. Providing questionnaires and screening measures online has been shown to be equivalent to paper and pencil provision [28] and can be used to screen for refugee mental health problems [29]. Digital mental health interventions have been shown to be less effective for culturally and linguistically diverse groups such as ethnic minorities, indigenous communities, migrants, and refugees [30,31]. Few studies so far have examined digital solutions tailored to the specific needs of refugees and migrants [32-34], even though there exist specific frameworks for the cultural adaptation process [35], studies describing the adaptation process [36], and research suggesting that culturally adapting psychological treatment can increase both compliance and effect [37]. There is also a need to learn more on how digital interventions can be scaled and integrated into health care systems in different settings, including factors related to acceptability, practice, and structure [38].

When introducing and implementing a new method, the influence of health care professionals as stakeholders is crucial and considered an important determinant in implementation frameworks [39]. As implementation is essentially a social process, the views of health care professionals also exert a strong influence on dissemination efforts [40,41] and they have been shown to be gatekeepers that strongly influence the implementation of internet-delivered treatment in routine mental health care settings [42]. Concerning mental health services, psychologists constitute an important health care profession often engaged in implementing and providing new services [43]. In Sweden, the term “Psychologist” is a protected title, and psychologists are key stakeholders, as they play an important role in the health care system, assessing and treating common mental health problems in primary care and providing interventions for more severe problems in specialized settings specifically targeting refugee health problems. The psychology profession has undergone a digital transition within the Swedish health care system in private and public settings, both before [44] and during the COVID-19 pandemic [45], with many already using digital modalities for assessment and treatment in their everyday work [15,46]. The opinions of therapists, including psychologists, in this transition have generally been positive [44,47]. However, far less is known about psychologists’ knowledge and attitudes toward the use of digital mental health solutions for refugees and migrants. Sweden experienced a significant increase in the number of refugees and asylum seekers during the 2010s, peaking in 2015, primarily from Arabic-, Farsi-, and Dari-speaking countries such as Syria, Iraq, Iran, and Afghanistan [48], Today, Arabic is the second most commonly spoken language in Sweden [49], and migrants and refugees with insufficient Swedish proficiency often cannot access mental health treatment without interpreter support or the use of translated material. Therefore, there is a specific need to learn more about psychologists’ perspectives of providing digital interventions for refugees and migrants not fluent in the Swedish language.

The objective of the survey was to explore psychologists’ use, knowledge, and attitudes toward digital solutions for the assessment and treatment of common mental health problems in refugees and migrants with limited proficiency in Swedish.

Methods

Study Context

The survey was conducted as part of the “SAHA” (“health” in Arabic) project, an academic collaboration aimed at developing

XSL•FO
RenderX

and evaluating digital assessments and interventions for refugees and migrants speaking Arabic, Dari, or Farsi [50].

Study Procedure and Participants

The Checklist for Reporting Results of Internet E-Surveys (CHERRIES) was used to guide the reporting of the survey [51]. A filled-out version of the checklist can be found in Multimedia Appendix 1. An online self-report survey was distributed between December 2023 and February 2024. A convenience sampling method was used to collect the data. Survey respondents were licensed psychologists working mainly in private, public, or nongovernmental settings in Sweden. The survey intentionally targeted both psychologists working with refugees and migrants and those without such experience but working with interventions for common mental health problems to explore potential differences in responses based on workplace and experience with the target groups. Study information and an invitation to participate in the survey were distributed using a variety of digital channels of communication available for the research group. This included emails to selected individual representatives from a private psychology consultant company, a private health care provider, 7 public health care settings, 2 nongovernmental organizations (NGOs), and 2 professional interest groups for psychologists. Selected representatives received information about the study to distribute within their organizations. Recruitment also included distributing information about the study through mailing lists for employees at 2 public research and clinical centers, one mailing list for cognitive behavioral therapy therapists, and social media posts in 6 closed professional Facebook (Meta Platforms) groups for psychologists (≈200-10,000 members). Data on actual reach through these different distribution channels are not available. Posts and emails described the study as a survey for psychologists about their perspectives on using digital solutions for mental health problems in refugees and migrants and included a link to the online survey. Reminders were sent once or twice through the above-mentioned distribution channels. Invitations included a brief description of the study, the intended respondents, and a link to the survey (see Multimedia Appendix 2).

Survey Development

The authors KV and AG developed the initial version of the survey, drawing on a previous study by the research group at Linköping University that examined knowledge, attitudes, acceptability, and near-future expectations regarding digital treatment formats for depression [26]. Questions considering the provision of care were added to further address implementation perspectives. The new survey was reviewed by all researchers within the SAHA project who had expertise in digital assessment and treatment, refugee and migrant groups, and cultural adaptations. Based on the team review, changes were made concerning terminology, comprehensibility, the inclusion of topics related to the research project, themes regarding refugees and digital mental health, and alignment with overarching analytic entities such as knowledge and attitudes. A beta version of the survey was distributed again to the SAHA research group, as well as 3 psychologists representing the public, private, and nongovernmental (NGO) sectors, to test for contextual fit. Based on this feedback, the survey was again modified, including adjustments of important terminology, grammatical errors, and clarification of how questions were related to the purpose of the study, until a final version of the survey named SAHA-Stakeholder was decided upon. The terms “migrant” and “refugee” were defined at the beginning of the survey for respondents and were used consistently throughout. As phrased, these terms included individuals with no or limited proficiency in Swedish and did not specify current residence status (eg, individuals with no residence permit, asylum seekers, or holders of temporary or permanent permits).

The final version of the survey included 26 closed questions and 5 open-ended free text questions. It was distributed through the Iterapi platform (Linköping University, Sweden), a secure and widely used solution for providing online surveys, questionnaires, and internet-based interventions [52], and took approximately 15-20 minutes to complete. Two of the open-ended questions, addressing specific barriers and facilitators to implementation, were analyzed separately using conventional content analysis and will be reported in a separate manuscript. Closed questions were conveyed as binary questions (yes or no), nominal scale alternatives (eg, children, youth and adolescents, adults, and older adults), or multiple-choice selections. All knowledge questions used 5-point Likert scale answers, ranging from 1 (very low) to 5 (very high). Three of the closed questions included an option for the respondent to provide a free-text answer if the available answers did not apply to the respondent. Data on ethnicity were not collected due to restrictions on this type of data collection in Sweden. The survey was developed and distributed in Swedish. For a translated English version of the survey and a detailed description of the Iterapi platform, see Multimedia Appendices 3 and 4.

Data Analysis

All quantitative data were processed and analyzed using descriptive and inferential statistical procedures in IBM SPSS Statistics (version 29.0; IBM Corp). All inferential statistics were considered exploratory due to the limited sample size and the absence of an a priori power analysis. Responses to the survey questions on respondent characteristics from the survey questions (items 1-8, 12, and 13) were recoded into binary variables to ensure adequate cell sizes in correlational analyses and *t* tests, thereby supporting valid statistical comparisons and improving the interpretability of results. Details of the recategorization are provided in Multimedia Appendix 5.

Due to the low expected frequencies in some cells, Fisher exact test was used as an alternative to the chi-square test for analyzing nominal and ordinal data. Moreover, adjusted standardized residuals were examined to assess the impact of each cell in analyses exceeding the 2x2 table format, with a value of 1.96 indicating significant deviations from expected frequencies. Since this analysis provides descriptive indicators of cell contributions rather than effect size measures, and most tables exceeded the 2x2 format, odds ratios and confidence intervals were not calculated.

Two-tailed *t* tests were used to analyze Likert-scale responses to the 5 knowledge questions and compare groups using the

XSL•FO
RenderX

binary categories. The data were treated as continuous variables, in line with the common use of parametric tests for Likert-type scales in social science research [53-55]. The Shapiro-Wilk test results indicated that the data were not normally distributed. However, *t* tests are generally considered robust to such violations, based on the central limit theorem, when sample sizes are well above 30, such as in this study. To assess the robustness of the findings given these deviations, a nonparametric alternative—the Mann-Whitney *U* test—was conducted as a sensitivity analysis. The results were consistent with those of the independent samples *t* test, with one exception. Free-text responses from the 3 open-ended questions on currently used digital tools, preferred digital tools, and gatekeepers, as well as from the 3 "Other" response options, were grouped into categories but not formally analyzed. They are included in the discussion section only to provide contextual understanding.

Ethical Considerations

Ethical approval was obtained from the Swedish Ethical Review Authority (2022-04274-02). All participants provided informed consent digitally before accessing the survey. Participation was voluntary, and respondents could not proceed to the questionnaire without providing consent (see Multimedia Appendix 6). Participants were informed about the purpose of the study, the voluntary nature of participation, their right to withdraw at any time prior to submission, and how their data would be used. Data were collected anonymously through the online survey platform and stored securely in accordance with applicable data protection regulations. Only the research team had access to the data. The results are reported in aggregate form to prevent identification of individual participants. No financial or other incentives were provided for participation.

Results

Sample Characteristics

The study website received 501 unique visitors, of whom 122 provided informed consent. Among these, 111 respondents started the survey, and 81 (73%) completed it. Only completers were included in the analysis. Sample characteristics of the respondents can be found in Table 1. The most common free-text answer in the "Other" category for "Level of care" was working in a private practice (n=3), while 10 respondents did not provide an explanation.

Experience of Refugee and Migrant Mental Health Interventions

Of respondents, 28 out of 81 (35%) reported that they worked in a setting that provided interventions for mental health problems that were specifically targeting refugees or migrants. A large proportion of respondents, 60 out of 81 (74%), reported having experience working with Arabic-, Dari-, or Farsi-speaking refugees or migrants. Most respondents did not speak Arabic, Dari, or Farsi, apart from 3 who reported being fluent in Dari or Farsi and 2 who had a limited understanding of Arabic. In terms of first-hand personal experience working with mental health problems in refugees, respondents stated that they had experience of psychotherapeutic or psychological treatments (48/81, 59%), assessment or diagnosis (41/81, 51%), psychosocial support (30/81, 37%), referrals (20/81, 25%), prevention (8/81, 10%), and medical or pharmacological treatment (2/81, 2%). A total of 15 respondents (18%) had no firsthand experience working with refugees or migrants.

XSL•FO
RenderX

Use of Digital Solutions for Migrants and Refugees

Respondents reported limited availability of digital solutions at their workplace for addressing mental health problems among refugees and migrants (15/81, 19%). A large proportion of the sample responded that they were not using digital solutions for these groups, or they were using them only for other target groups (see Table 2).

Table 2. Psychologists reported use of digital assessment and treatment for refugees and migrants with mental health problems (N=81).

Reported use of solutions for refugees and migrants	Values, n (%)
Assessment or screening, and treatment	11 (14)
Assessment or screening	3 (4)
Treatment	2 (2)
No, but for other target groups	27 (33)
No use of digital tools	38 (47)

Knowledge

The knowledge of digital interventions for refugees was limited in the sample, with 75% (61/81) rating their knowledge of digital screening and assessment as low or very low, and 72% (58/81) rating their knowledge of digital treatment formats similarly (see Table 3). More than half of the respondents (42/81, 52%) stated a lack of knowledge about the organization of care for refugees and migrants.

Explorative *t* tests indicated that those working in settings that provided interventions for refugees or migrants had significantly more knowledge of mental health assessment and treatment for refugees and migrants (t_{79}=3.920; *P*<.001), guidelines and organization of care (t_{79}=4.371; *P*<.001), and cultural considerations and adaptations (t_{79}=2.269; *P*=.03). Similar results were found for those with personal experience of working with refugees or migrants (t_{79}=3.446; *P*<.001; t_{79}=3.079; *P*=.003; t_{79}=2.925; *P*=.004) and those with specific experience of working with Dari-, Farsi-, and Arabic-speaking refugees or migrants (t_{79}=3.892; *P*<.001; t_{79}=2.189; *P*=.03; t_{79}=2.722; *P*=.008). Respondents in workplace settings that provided interventions for refugees or migrants also had significantly higher knowledge of digital treatment formats (t_{79}=2.978; *P*=.005). Those working in settings that provided digital formats for mental health problems for refugees or migrants and were themselves using digital formats for refugees or migrants had significantly higher scores on all 5 knowledge questions (t_{79}=2.699 to 3.717; *P*<.001 to *P*=.01). Additionally, respondents employed at a health care region rated their knowledge of guidelines and organization of care for refugees significantly lower (t_{79}=–2.419; *P*=.02), and the sensitivity analysis indicated that psychologists working in specialist care settings reported greater knowledge of digital screening and assessment tools (*U*=228; Z=–2.113; *P*=.04).

Table 3. Knowledge about the provision, organization, and cultural adaptation of mental health interventions for refugees and migrants (N=81).

Knowledge about	Frequency[a]	Mean (SD)
Assessment and/or treatment	1=6; 2=20; 3=30; 4=17; 5=8	3.08 (1.08)
Guidelines and organization of care for assessment and/or treatment	1=24; 2=18; 3=24; 4=8; 5=7	2.46 (1.26)
Digital assessment or screening tools	1=41; 2=20; 3=13; 4=4; 5=3	1.86 (1.09)
Digital treatment	1=33; 2=25; 3=13; 4=7; 5=3	2.04 (1.12)
Cultural adaptations of assessment and/or treatment	1=8; 2=21; 3=29; 4=14; 5=9	2.94 (1.13)

[a]Responses were measured on a 5-point Likert scale ranging from 1 (very low) to 5 (very high).

Acceptability and Cultural Adaptation

Most respondents indicated a need to provide assessment and treatment in a digital format for refugees and migrants within the Swedish health care system (56/81, 69%). One in four selected the “Do not know” alternative (21/81, 26%). A significant proportion of respondents stated that digital solutions should be provided in the mother tongue of refugees and migrants (70/81, 86%) and that digital assessment and treatment should be culturally adapted (56/81, 69%). Those currently using, or having personal experience of, digital formats for refugees or migrants had significantly more “No” answers on the question if digital interventions should be culturally adapted than those without experience (*P*=.48; residual 2.3).

The respondents considered it most acceptable to provide digital treatment for refugees and migrants in the form of guided internet-based cognitive behavioral therapy (ICBT), by video, or in a blended treatment format (see Table 4). Respondents in specialist settings were significantly more positive about the use of video for refugees and migrants (*P*=.007) than those working in primary care, and women were more positive than men about self-help apps (*P*=.004).

No digital treatment is suitable	2 (3)	79 (97)

[a]ICBT: internet-based cognitive behavioral therapy.

[b]CBT: cognitive behavioral therapy.

For most diagnoses and common mental health problems in refugees and migrants, a moderate level of severity was considered the highest level that could be treated using digital interventions (see Table 5). Fisher exact test showed that participants employed outside of a public health care region were more likely to report that moderate and severe depression could be treated with digital formats (*P*=.02). In the residual analysis, the "Moderate" response contributed 1.9, and the "Severe" response contributed 2.5. Respondents from public health care regions were more likely to report that posttraumatic stress disorder (PTSD) treatment for refugees and migrants was not suitable for digital formats (*P*=.04), with the "Not at all" response contributing 2.8 in the residual analysis. Those working in settings that had no digital formats for refugee or migrant mental health problems considered mild PTSD to be a more suitable option for digital treatment (*P*=.02).

Table 5. Highest level of severity that can be treated with digital interventions (N=81). Percentages may not total 100% due to rounding.

Diagnose	Not at all, n (%)	Mild, n (%)	Moderate, n (%)	Severe, n (%)	Do not know, n (%)
Depression	2 (2)	16 (20)	44 (54)	6 (7)	13 (16)
Social anxiety disorder	2 (2)	12 (15)	36 (44)	17 (21)	14 (17)
Panic disorder	1 (1)	17 (21)	33 (41)	15 (18)	15 (18)
Generalized anxiety disorder	7 (9)	21 (26)	28 (35)	11 (14)	14 (17)

Insomnia	2 (2)	10 (12)	31 (38)	24 (30)	14 (17)
Complicated grief	3 (4)	17 (21)	25 (31)	15 (18)	21 (26)

[a]PTSD: posttraumatic stress disorder.

Preferred Provision of Care and Access to Digital Tools

Most respondents answered "No" to the question of whether refugees and migrants receive the care they need through Sweden's health care system (58/81, 72%). Only 4 said "Yes" (5%), and 19 (23%) chose to answer, "Do not know." Respondents in workplace settings that provided interventions for refugees or migrants had a higher proportion indicating that refugees and migrants do not receive the mental health care they need in the current health care system (*P*=.04; residual=2.6). Those in settings that did not provide such interventions had a higher proportion of "Do not know" responses (*P*=.04; residual=2.0).

Eighteen (22%) respondents worked in settings where digital treatment was already provided, and the other respondents were divided on whether such interventions should be implemented at their workplace (31/81, 38%) or not (32/81, 40%). Those working in settings that did not provide digital formats for refugee or migrant mental health had a significantly higher number of "Does not, but should" responses than those working in settings that did (*P*<.001; residual=2.2). Respondents preferred interventions for refugees and migrants to be provided through specialized units in primary care (38/81, 47%), followed by decentralized dissemination in primary care (28/81, 35%) and secondary or specialized care (6/81, 7%). Significantly more respondents working at the primary care level at the time of this writing believed that digital formats should be provided through specialist settings than those already working in such settings (*P*=.03; residual 2.6). In contrast, respondents working in specialist care settings were more likely to believe that dissemination should occur in nonspecialized settings in primary care compared to psychologists working there (*P*=.03; residual 1.9).

XSL•FO

Discussion

Principal Findings

In this survey, 81 psychologists working primarily in public, private, and NGO health care settings provided their perspectives on the use of digital formats for the assessment and treatment of common mental health problems in refugees and migrants. Results from the survey showed that guided ICBT, blended treatment, and videoconferencing therapy were the most accepted digital formats for treating refugee and migrant mental health problems, although respondents had limited experience and low knowledge of using these or other digital solutions for refugees and migrants. There was a strong consensus in favor of providing digital solutions in refugees' native language. Although a majority believed that interventions should also be culturally adapted for better fit, explorative analyses showed that those currently working with digital formats for refugees or migrants considered cultural adaptations to be less necessary. Psychologists preferred digital solutions to be delivered at the primary care level, either through centralized units or a decentralized approach.

Role of Knowledge and Personal Experience

The lack of knowledge and use of digital formats for refugees and migrants among respondents highlights the current landscape in digital mental health, where interventions and assessment procedures are mainly targeting (and being created for) Western, native-speaking populations [56]. This lack of personal experience and knowledge among psychologists could act as a barrier to the use of digital formats, as seen in other studies [57].

Since increasing knowledge about digital solutions has been shown to increase perceived advantages and reduce perceived disadvantages of digital mental health interventions [58], awareness- and knowledge-raising activities for psychologists could serve as an important first step in health care settings where implementation of digital formats is being discussed or planned. The use of digital formats among psychologists in Sweden may facilitate the transition to similar alternatives for refugees and migrants, as therapists' experience in delivering online mental health interventions during COVID-19 was associated with higher acceptance of these formats [59]. For those not using digital formats at the time of this writing, there is a need to examine how such a transition is perceived [44], recognizing that those transitioning may perceive both negative and mixed views on using new technologies for the provision of care [60].

Positive Attitudes and Preferred Digital Solutions

The preference for ICBT, videoconferencing, and blended treatment among respondents may not be surprising, as these are the most commonly used digital delivery formats in the Swedish health care system by psychologists and have been widely studied by researchers [19,27,61]. An interesting finding was that guided ICBT received more positive ratings than blended treatment, which contrasts with earlier surveys showing the opposite [26,57,62]. This could be due to the fact that ICBT programs have been available for 8 years through the public national online platform for internet-delivered treatment and support [63] and are frequently delivered by psychologists. Additionally, it may be preferred because it can facilitate the provision of evidence-based treatment in Arabic, Dari, or Farsi, without requiring the psychologist to be fluent in these languages, thus overcoming the barrier of using an interpreter [64]. The positive attitudes toward the use of video in specialist settings may be explained by the fact that it was the preferred digital solution in the transition to digital formats in psychiatric care during the COVID-19 pandemic [45]. Another perspective is that videoconferencing therapy has been used for diagnoses often treated in specialist settings (eg, PTSD) and can be perceived as more easily adapted for more severe conditions than other digital formats [21]. This and the generally positive attitudes toward digital interventions expressed by psychologists, including the use of smartphone apps among women, could facilitate the transition to digital alternatives, as acceptability has an impact on implementation and scalability [65].

Need for Translated and Culturally Adapted Solutions

Even though most respondents had at least some experience working with refugees or migrants, including working with Arabic-, Dari-, or Farsi-speaking patients, no psychologists in this survey could speak Arabic fluently. Since Arabic is the second most widely spoken mother tongue in Sweden [49], and a significant proportion of refugees originate in countries where Arabic, Dari, or Farsi is spoken [48], there is an obvious gap between the need for linguistically adapted solutions and the language skills of psychologists providing interventions. Increasing the workforce by employing psychologists who speak Arabic, Dari, or Farsi as their mother tongue or educating culture brokers to facilitate understanding between patients and health care providers [10] are viable options but will take time and not be sufficient. Instead, using translated assessment and treatment materials or facilitating the use of interpreters in digital formats, such as video, could swiftly increase access by adapting existing technology and content. The preference for culturally adapted digital solutions seen in this study has been confirmed by other studies, for example, in a survey of New Zealand mental health clinicians, where three-quarters expressed a need to tailor solutions for specific populations, including immigrants and refugees [62]. As existing frameworks simplify the process of cultural adaptation [35,66,67], and culturally adapted interventions have been found to lead to better outcomes [37], adapting digital interventions could increase the possibility of dissemination in routine care settings. An interesting finding in our exploratory analysis was that those already working with digital interventions for refugees or migrants considered cultural adaptations less necessary. It could be that these psychologists had prior experience with nonadapted versions being sufficient, which led them to answer "No" to the question of whether cultural adaptations were necessary. This finding can be seen in the light of a recent meta-analysis that found no added effects for culturally adapted digital interventions in low-income settings [68], making the question of cultural adaptations a complex issue that requires further examination [69].

XSL•FO
RenderX

Appropriate Level of Severity for Digital Interventions

Given that there are few studies on digital interventions specifically targeting refugees [70] and migrants [71,72] at the time of writing, the acceptability among respondents of digital interventions for conditions such as depression and panic disorder could be influenced by research on internet-delivered interventions in general, which supports the efficacy for mild to moderate common mental health problems [73]. An increase in digital mental health research targeting refugees and migrants could help inform key stakeholders, making their opinions more based on evidence and less dependent on personal preferences and attitudes toward digital formats. The acceptability of using digital solutions for more severe mental health problems, such as for severe levels of insomnia, social anxiety, and depression in this study, confirms findings from other surveys [26,74]. This suggests that using digital interventions for more difficult psychiatric conditions should be examined further, both from an effectiveness and provider perspective. On the other hand, respondents working in a public health care region and those working in settings where digital solutions for refugees and migrants were not available responded more cautiously about using digital formats for PTSD. Since PTSD is more common among refugees [4] and often treated in specialized settings in Sweden, the lower degree of acceptability could be attributed to it being considered a more difficult diagnosis to treat, contributing to it being viewed as unsuitable for digital formats or only preferable for milder forms of mental health problems. New innovative digital interventions for PTSD could also have the potential to increase acceptability, being more adapted to refugee needs and degree of complexity [75].

Provision of Care and the Perceived Treatment Gap

The already recognized gap in both high- and low-income settings between the mental health burden of refugees and migrants and their access to care [76,77] was confirmed by respondents in this survey. If digital interventions are to help close this gap, it is essential to understand how they should be provided in routine care settings [78], including through broad dissemination that extends beyond trauma-focused treatment in specialized settings [64]. An interesting finding was that respondents in specialized settings preferred implementation in primary care settings, and vice versa, which highlights the difficulty of organizing care for refugees in the existing health care systems. ICBT has been organized in both a centralized (specialized) and decentralized fashion in Sweden [15]. When comparing 2 organizational models in Swedish primary care, a decentralized and a more concentrated model, both models had specific advantages that could make them viable options also from a refugee perspective [79]. A centralized model could increase therapist and organizational competence of refugee mental health and provision of adapted digital interventions, but a decentralized model could make digital treatment more accessible to refugees as they receive their care in the same setting as others enduring mild to moderate mental health problems. When views of outpatient mental health care deliverers (psychotherapists and psychiatrists) were investigated in a large survey study in Switzerland, almost half of the respondents reported having treated refugees and asylum seekers within the last 12 months with a median waiting time of only 3 weeks [64]. This result indicates that a more decentralized model of provision, which could include digital interventions, has the possibility of increasing access to care for refugees compared to more selective and highly specialized services.

As implementation research highlights the importance of decisions and involvement in outer and inner contexts, along with the influence of individual stakeholders, in successful implementation efforts [80], it is crucial to ensure psychologists feel involved in the setup and implementation of digital solutions. Free text responses on potential gatekeepers showed that respondents were unsure of which individuals or organizations were the most important for the facilitation of successful implementation and stated that gatekeepers were politicians and leaders in health care settings, not health care staff. This finding, along with other data from this study showing generally low knowledge about the organization of care for refugees, may also highlight a knowledge and perceived influence gap, not only in the provision of care but also in understanding the organization of care and the role of one's own profession. One way forward could therefore be to increase the interest of professional psychology societies in helping to establish clinical guidelines and influence the organization and provision of digital mental health in health care contexts [81].

Limitations

The sample size was very small for a national survey and restricts the generalizability of the findings and increases the risk of overinterpretation. As such, all findings should be interpreted cautiously. Also, the use of convenience sampling may introduce self-selection bias into the sample and does not permit an accurate estimation of the number of potential respondents who received information about the survey. To contextualize the sample characteristics, we compared the demographic distribution of respondents with national data on licensed psychologists in Sweden. The sample showed a similar distribution with respect to age and gender [82,83]. However, due to the convenience-based recruitment strategy, the findings cannot be considered representative of all psychologists in Sweden. The survey may also have attracted individuals with an existing interest in digital solutions, and results could reflect a more positive view of digital interventions than what is typical among psychologists. Although the survey aimed to include clinical psychologists in health care settings, 9 (11%) respondents reported that the question about level of care (eg, primary or specialized) was not applicable to their work. These respondents may therefore not fully represent a health care context, which should be considered when interpreting the results.

There are several commonly used terms that overlap in their definition and are closely related, such as "migrant," "immigrant," "refugee," "asylum seeker," and "forcibly displaced individuals." The term "asylum seeker," as well as distinctions within refugees and migrants based on residence status (no permit, temporary permit, and permanent permit), was not included in the survey. This omission may have reduced internal validity, as respondents might have answered differently had the survey differentiated between individuals in the asylum process and those with temporary or permanent residence

RenderX

permits, given the legal differences in access to health care and exposure to mental health stressors across these groups. Our definitions of refugees, migrants, and digital solutions were included in the introduction to the survey (see Multimedia Appendix 7) and were based on established terminology and a consensus process within the research group. We received no feedback from the participants indicating that further clarification was needed regarding the terms used in the survey.

The inferential analyses were exploratory in nature, as no a priori power analysis was conducted, and the sample size was relatively small. To facilitate statistical analysis and increase the number of data points in each cell, survey responses were combined into binary categories. This categorization may limit the conclusions drawn from the inferential statistics used in the study. The survey included 3 open-ended questions on the used digital tools, preferred digital tools, and gatekeepers for dissemination. Responses were not subjected to formal content analysis procedures due to the design of the questions and the nature of the material provided by participants, which primarily consisted of short answers or simple descriptions.

Future Directions

Psychologists can strongly influence the provision of care and the implementation of new methods, including digital mental health interventions. It is therefore important to examine further how they and other mental health professionals perceive how and if digital interventions for refugees and migrants should be implemented in a health care context [42]. Understanding the perspectives of psychologists who have yet to use digital formats is vital to address potential resistance and ensure successful implementation. There is a need for further stakeholder surveys, in-depth qualitative interviews, continuous monitoring of psychologists' knowledge and skills, and increased use of specific implementation frameworks to guide further analysis and dissemination efforts. Strategies to enhance learning and acceptance of digital formats among health care professionals are crucial, as awareness-raising activities and targeted training programs could help reduce barriers and lead to greater adoption and inclusion of marginalized groups such as refugees and migrants.

Conclusions

This survey represents an important first step in understanding psychologists' perspectives on using digital mental health solutions for refugees and migrants in Sweden. While knowledge and experience were limited, attitudes were generally positive, with guided ICBT, blended treatment, and videoconferencing therapy being the most accepted formats. The emphasis on linguistic accessibility underscores the need for adapted solutions in mental health care provision for refugees and migrants. However, the need for cultural adaptation is more complex and requires further exploration. Despite limitations, such as potential self-selection bias and exploratory statistical analyses, the findings provide valuable insights that can inform future research and implementation efforts. Addressing knowledge gaps, fostering acceptance of digital solutions, and developing scalable, adapted interventions are crucial steps toward alleviating the mental health burden for refugees and migrants in Sweden and beyond.

Acknowledgments

All authors made substantial contributions to the study. KV and AG conceptualized and designed the study. The survey was created by KV and AG with significant input from GA, NT, and SS. All authors contributed to the acquisition of data. KV conducted the statistical analyses. KV wrote the first draft of the manuscript, and all other authors contributed with crucial input on all parts of the manuscript. We want to acknowledge all the researchers in the SAHA research group for their input at various stages of the survey development, as well as the webmaster George Vlaescu for his support with the survey platform. We also extend our thanks to all the respondents who participated in the survey.

Funding

The study was supported by a grant from the Swedish Research Council, "Development and evaluation of internet-supported treatment for recently arrived children and adolescents with psychiatric problems."

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author for noncommercial purposes on reasonable request.

Abstract

Background: In mobile health care, text messages play an important role in improving physical activity. Recent studies have developed message banks based on theories, including the behavior change technique (BCT) taxonomy. However, little evidence is available for individual differences (ie, who responds to which BCTs presented in messages), which is crucial for optimizing message delivery.

Objective: We investigated how individuals perceive messages supporting physical activity and what clusters of individuals are identified by their responses.

Methods: Japanese-speaking adults (n=2859; mean age 54.5, SD 17.5 years; 1486 women) were presented with messages conveying different BCTs and rated how motivational each message was. The motivation ratings were subjected to latent class analysis to identify clusters of individuals per motivation rating.

Results: A total of 7 clusters were identified. Two clusters gave consistently high ratings across BCT types; one showed a general receptivity to all messages, while the other showed a clearer preference for information-based BCTs. Two clusters showed moderate ratings, both preferring information about consequences but differing in their additional preferences for goal setting vs rewards. Two clusters gave overall low ratings and typically included less active individuals in the preaction stages, both showing a preference for information-based BCTs. The remaining cluster showed the greatest variability in BCT preferences, with the strongest preference for salience of consequences.

Conclusions: These results highlight individual differences in perceived motivations across BCTs, informing what BCTs should be prioritized in delivery. The practical implications for message tailoring are also discussed.

Introduction

Background

The rapid growth of mobile technology enables remote, interactive, and timely access to relevant health information, expanding the applicability of health behavior change interventions to promote physical activity (PA) [1]. A popular intervention modality is the use of SMS text messages to deliver educational materials, health care tips, individual goals and achievements, and other motivational information. Text message interventions (TMIs) are considered a promising form of mobile health (mHealth) intervention for PA [2] because smartphone ownership is very high and the implementation cost is relatively low (eg, an estimated average cost per message is US $0.10)

XSL•FO
RenderX

[3]. Furthermore, messages allow for quick and easy access to necessary information and require little or no effort for information search, which helps message recipients maintain their interest in and commitment to health behavior goals [4]. Another important advantage is that messages can be tailored to recipients' demographic characteristics and psychosocial attributes, or even personalized for individual recipients (eg, to include their names in message headers) to enhance message acceptability and the efficacy of an intervention [5]. TMIs can also be scaled up as ecological momentary or just-in-time adaptive interventions [6] if messages are designed to target a particular moment, such as when a recipient is most likely to accept and respond to messages.

A literature review [7] identified 6 TMI trials targeting PA, of which 3 reported statistically significant effects of TMIs. A meta-analysis [8] synthesized the results of 10 trials, most of which assessed self-reported PA as an outcome, and estimated an effect size of Cohen *d*=0.50. Another meta-analysis [2] of 13 trials targeting objectively measured PA concluded that TMIs lead to significantly greater postintervention steps (*d*=0.38), whereas the effect on moderate to vigorous PA was smaller and marginal (*d*=0.31). Notably, both meta-analyses documented moderate to high heterogeneity in efficacy [2,8], which can be at least partly attributed to the variability in TMI delivery and implementation. Therefore, exploring how TMIs can be optimized is important, particularly to clarify to whom and what messages should be delivered.

Researchers have developed message banks to address this challenge. Several different messages are registered in a bank, from which practitioners and app-implemented algorithms can select the appropriate ones to deliver to their client users. Text messages take various forms in terms of content and tone, depending on the purpose of the TMI (eg, providing education, enhancing motivation, delivering feedback related to goals, and sending reminders for participants' PA plans) [2]. The development of messages is also based on various sources, such as feedback from experts and patients [9], clinical guidelines [10], and reviews of previous studies [11].

Messages are typically tailored to a target population based on their demographic and psychosocial characteristics. Pathak et al. [12] developed messages for low-income minority individuals with comorbid diabetes and depression by lowering the reading level (below the sixth-grade level) and ensuring cultural and linguistic appropriateness. Feedback from message recipients is also an important source for tailoring messages, which has been suggested to improve the ease of understanding and acceptability of the delivered messages (eg, for patients with chronic obstructive pulmonary disease [9] and coronary heart disease [13]). Moreover, message content and tone can vary across individuals at different stages of behavior change, particularly when integrated into a treatment or intervention. Prior studies have used tailoring focused on recipients' gender and PA levels [14], lifestyle habits among adults with type 2 diabetes (eg, individuals' dietary behavior, PA, and medication) [15], and goal progress among older adults at risk of cardiovascular disease [11]. However, researchers have noted the lack of theoretical underpinnings for several message banks and argued that the design and validation processes are not always transparent [16]. These circumstances critically limit the opportunities for replicating and reproducing TMIs and prevent fair evaluations of message quality [17,18]. Furthermore, having a link to theories appears to directly affect the efficacy of digital interventions. For example, 1 meta-analysis showed larger effects of theory-based interventions than those not based on a specific theory ([19]; however, see also [5,20]). An exceptional study is MacPherson et al [18], who developed messages to deliver in a diabetes prevention program using the behavior change wheel (BCW) [21]. The BCW is an integrative framework used to guide the development of behavior change interventions [22] and can be a theoretical basis for researchers and practitioners to select the intervention approaches or behavior change techniques (BCTs) that are most suitable for addressing individuals' specific barriers and facilitators [18]. BCTs have been structured and numbered in the form of a taxonomy [21] to which 93 different types of BCTs (classified into 16 categories) are registered, such as goal setting—behavior (1.1) and problem-solving/coping planning (1.2). In their message-development process, MacPherson et al [23] identified 43 BCTs relevant for PA (and dietary) behavior change adherence, encompassing barriers and facilitators to engage in target behaviors. For the identified BCTs, messages were developed and refined based on feedback from program coaches and participants. Therefore, each message is tagged with a specific BCT-taxonomy label while maintaining clarity and acceptability for recipients [18]. Example messages include "Think about what exercise goal you want to make today, if any," tagged with the BCT labels of goal setting—behavior (1.1) and outcome (1.3), and "Sometimes we need the support of others to help us stick to our goals. Think about who in your life can help you stick to your exercise plan," labeled as social support—emotional (3.3) and unspecified (3.1). The message bank comprises BCTs that are most frequently implemented in PA intervention, including goal setting, social support, self-monitoring of behavior, and instruction on how to perform the behavior, which have been commonly identified in systematic reviews and meta-analyses on mHealth interventions for various populations (eg, adults, children, and patients with a specific disease [24-31]).

However, as MacPherson et al [18] acknowledged, which specific messages (or BCTs offered in messages) are more effective than others remains unclear. As noted above, although the BCW serves as a foundation for interventions using BCTs, it does not clearly specify which BCTs work best, for whom, in which contexts, and delivered by what means [32]. Although common BCTs, such as goal setting and self-monitoring of behavior, are frequently used in interventions, they are not necessarily perceived as helpful or motivational by all recipients. Thus, an important evidence gap is that individual differences in terms of who finds which messages helpful remain understudied. These issues are of practical importance when tailoring message delivery because knowing which messages should be delivered to whom is an important step toward achieving precision health [33]. To address these individual differences, the Behavior Change Resource Model (BCRM) may be a useful framework [34]. BCRM assumes that BCTs work by acting on individuals' resources and proposes a behavior change framework based on these resources. It

XSL•FO
RenderX

distinguishes three types of resources: facilitating (providing external resources), boosting (building and strengthening internal reflective resources), and nudging (activating affective resources). These 3 resources partly correspond to the capability, opportunity, motivation-behavior (COM-B) model, which is central to the BCW [35], but the 2 frameworks have different roles. COM-B classifies the conditions necessary for behavior. In contrast, BCRM explains how resources are generated and activated in the brain's motivational and reward systems and describes how BCTs act on these resources, based on neurobiological mechanisms. In this way, because BCRM classifies BCTs according to the resources they target, differences in BCT preferences across clusters may reflect differences in the resources each cluster needs or prioritizes. Michaelsen and Esch [34] also suggest identifying the resources needed to move to the next stage of behavior change and selecting BCTs accordingly. For example, individuals in the early stages of behavior change may lack motivation and may prefer BCTs categorized as nudging, which do not require deliberate effort. In contrast, individuals who are already performing the behavior may prefer BCTs categorized as boosting, which involve intentional effort.

Objectives

This study investigated how individuals perceive BCT-tagged messages for improving PA. We focused on individual differences in participants' responses to different BCTs recommended in the messages. Specifically, we assumed that different individuals would find different BCTs to be motivational. Therefore, we used a clustering approach to identify groups of people who showed similar responses to presented messages. Through this analysis, we aimed to determine how many response patterns (ie, clusters) should be assumed in a sample and which messages can be delivered together to a particular group of recipients. Moreover, we explored how frequently implemented BCTs [24-31] would manifest in these clusters. We expected that while most clusters would perceive goal setting and other common BCTs as motivational, some clusters might not prefer them. The analysis was conducted using cross-sectional survey data, in which participants rated how motivational each BCT message was in enhancing PA. Messages were adapted from the bank of MacPherson et al [18], to which we added (1) messages localized for the target population of this study (Japanese-speaking adults) to indicate the exact information source such as a health guideline of the country, and (2) messages framed with gain and loss focuses ([36]: *gain framing*, focusing on benefits of a behavioral alternative, and *loss framing*, emphasizing the associated costs of a behavior) [36-38]. Although framing is not a dimension well integrated into the BCW or BCT taxonomy, it has been applied to behavior change based on prospect theory, which suggests that individuals respond differently depending on whether information is presented from a cost (loss framing) or benefit (gain framing) perspective [36]. However, in the context of PA, it remains unclear which type of framing is more effective [39]. Therefore, examining which individuals are more likely to prefer each type of framing, in combination with BCT preferences, may help inform more precise message delivery design. We exploratorily examined how it appeared across clusters of message response types (eg, a cluster might find loss framing and goal setting more motivational than other message types).

Methods

Participants

Participants (N=2862) were recruited from a database of a survey firm, in which >1.3 million individuals (all residents in Japan) had been registered as potential participants. This study was part of longitudinal surveys started in 2022, and the sampling for this study was conducted in November 2024. The overarching project had multiple purposes, for example, to investigate motivational and environmental factors that influence PA [40] and the prevalence of mHealth tool use among Japanese-speaking adults [41,42]. For this study, invitations were sent to the participants who completed the initial, main survey of the overarching project (n=20,611 [43]). Quota sampling was used to ensure that the data covered each age group and gender. The sample size was determined arbitrarily—we aimed to sample around 100 participants for each age group of 5-years interval for each gender. No missing values were recorded as the survey platform required participants to respond to each item to complete the survey. Participants were allowed to stop responding in the middle of the survey, but in that case, no record was created in the database. Data from 3 participants were deemed unreliable and excluded from analysis (2 reported a height of <100 cm and 1 reported a weight of <10 kg). The final data included 2859 participants. We adhered to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement [44] in conducting and reporting this study.

Ethical Considerations

The study protocol was approved by the Ethics Committee of the National Institute of Advanced Industrial Science and Technology (approval ID: 2022-1279). Participants provided informed consent prior to responding to the survey. Participants were compensated with a voucher for online shopping after the completion of the survey. All data were collected via an online survey company and provided to the research team in anonymized form, such that individual participants could not be identified. The dataset was stored on a password-protected computer accessible only to the research team.

Measures

Message and Motivation Rating

Each participant rated 83 messages, 72 of which were adapted and translated from the bank of MacPherson et al [18], which was originally developed for a type 2 diabetes prevention program conducted in Canada. Messages that included program-specific references or mentions of specific service names were excluded (eg, "Remember the exercise you did at the YMCA with your coach? Try to reach those same target heart rate zones on your own!"). After translation, the content validity of the messages was confirmed by the second and third authors. For the remaining messages, 3 were gain-framed, 3 were loss-framed, and 5 were localized with explicit mentions of the health guidelines and authorities in Japan (as credible

XSL•FO
RenderX

sources; for the specific messages, see Table S1 in Multimedia Appendix 1). Messages were contextualized in terms of digital health, with the instructions indicating that messages were intended to be delivered via AI or a chatbot implemented through a smartphone app supporting PA and exercise. The instructions are as follows:

Below are messages designed to support and motivate exercise and PA. These messages are intended for a broad audience, including those who do not have exercise habits yet and those who already maintain an exercise routine. Please read these messages and rate how motivated you would feel if you received them. The intended context is that individuals seek to change their lifestyle habits to maintain or improve their health, and they received these messages in their daily lives. Please assume that the sender of the messages is a chatbot or AI implemented in an exercise or training app.

Each message was rated on a 5-point scale (1=not at all; 5=very much). The number of BCT labels that appeared in the message bank was not balanced (Table 1). The most frequent label was information about health consequences (5.1), tagged for 14 messages, followed by credible source (9.1), for 11 messages.

[a]Some messages had multiple BCT labels.

PA Measure

Subjective PA was assessed using the International Physical Activity Questionnaire-Short Form (IPAQ-SF) [45,46]. The IPAQ-SF asks respondents to report the number of days and duration spent on each of the following three PA dimensions over an average week: (1) walking, (2) moderate-intensity activity, and (3) vigorous-intensity activity. Weekly minutes of PA were calculated and transformed into metabolic equivalents (METs; METs-hour/week) to represent total PA levels. The IPAQ-SF originally included items on sedentary time, which were not used in this study.

Stage-of-Change for PA

Stages of change (SoC) for PA were assessed using the SoC questionnaire [47-50]. Each participant indicated the most applicable statement from the following five statements: “I currently do not exercise and do not intend to start exercising in the future” (Precontemplation); “I currently do not exercise but I am thinking about starting to exercise in the next six months” (Contemplation); “I currently exercise some, but not regularly” (Preparation); “I currently exercise regularly, but have only begun doing so within the last six months” (action); and “I currently exercise regularly and have done so for longer than six months” (Maintenance). The instructions explicitly defined regular exercise as exercising twice or more per week for 20 minutes or longer on each occasion.

Statistical Analysis

Latent class analysis (LCA) was used to identify groups of individuals (ie, clusters) who gave similar ratings to the presented messages [51]. LCA is a type of finite mixture modeling that represents clusters in the form of categorical latent variables estimated from categorical observed variables. We performed LCA on dichotomized motivation ratings (with values coded based on whether they were above or below the overall mean) using maximum likelihood estimation. LCA computes the probabilities for each observation to belong to each cluster; therefore, we attributed each participant to the cluster to which they were most likely to belong [52]. To determine the optimal number of clusters, models were estimated with 2-14 clusters, and model fit was evaluated using the Bayesian Information Criterion (BIC). The characteristics of each identified cluster were inspected based on the (1) mean motivation ratings for each message in each cluster, (2) mean motivation ratings per BCT label in each cluster, and (3) standardized mean ratings per BCT label within each cluster. Within-cluster standardization helped interpret which BCTs each cluster perceived as more (or less) motivational.

Results

Demographic Characteristics and Descriptive Statistics

Table 2 summarizes the participants’ demographic characteristics. More than half of the participants were married and had at least 1 child. Most had graduated from high school, and household income was distributed around JPY 2-6 million (US $12,600-US $37,900), which is comparable to the population distribution in Japan (average JPY 5.45 million [US $34,400]). On average, participants were more active than the recommended level (23 METs-hours/week) by the authorities, and approximately one-third reported being in the maintenance stage. Table 1 presents the mean motivation ratings for each BCT label. Information about social and environmental consequences (5.3) was rated as the most motivational, followed

XSL•FO
RenderX

by salience of consequences (5.2). The least motivational messages were prompts/cues (7.1), self-monitoring of behavior (2.3), and behavioral experiments (4.4).

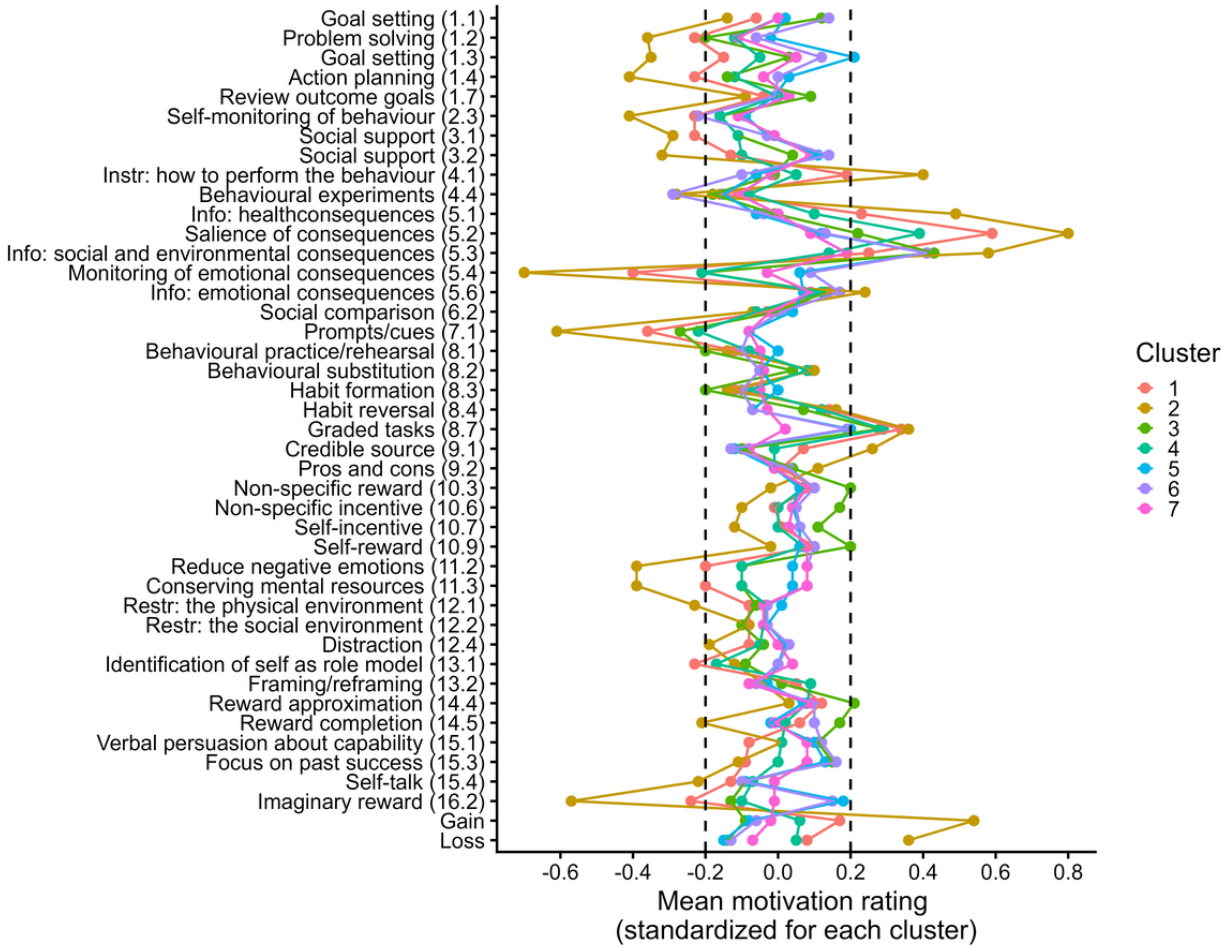
Latent Class Analysis

The LCA identified 7 clusters as the best solution that achieved the minimum BIC (5 clusters=198,459, 6 clusters=197,399, 7 clusters=197,350, 8 clusters=197,413, and higher for the larger number of clusters). The entropy for the 7-cluster solution was 0.943, indicating that the classification accuracy was sufficient.

Among the identified 7 clusters, cluster 7 had the highest motivation ratings for each message, whereas cluster 4 had the lowest ratings (Figure 1). The other clusters fell between clusters 7 and 4, although cluster 2 showed the largest variance across messages, suggesting that it had the most selective preference for different messages.

XSL•FO
RenderX

Figure 1. Mean motivation ratings per behavior change technique and cluster.



Cluster Characteristics

We calculated the mean motivation ratings per BCT (Figure 1) and standardized them within each cluster to visualize the rating patterns across clusters (Figure 2). Statistical tests did not help interpret between- and within-cluster differences because of the enormous number of possible paired comparisons between BCTs and clusters. Therefore, we focused on (1) the BCTs with the highest and lowest standardized mean motivation ratings within each cluster, (2) the BCTs whose within-cluster standardized mean exceeded the reference threshold in that cluster but not in any other cluster. A within-cluster standardized mean of 0.20 was used as a reference threshold to identify BCTs with meaningful differences in ratings, corresponding to a small effect size based on Cohen's (1988) benchmarks (small: d=0.20; medium: d=0.50; large: d=0.80) [53].

XSL•FO
RenderX

Figure 2. Mean motivation ratings standardized within each cluster.

Cluster 7 gave the highest ratings to any BCTs, with almost no preference for a particular BCT. No BCTs had within-cluster standardized mean values greater than 0.20 or less than –0.20. Cluster 6 also showed high ratings for most BCTs, with most mean motivation ratings above 3.0, but exhibited a clearer preference pattern than cluster 7. Specifically, it showed the highest ratings for information about social and environmental consequences (5.3: within-cluster standardized mean 0.41) and the lowest for behavioral experiments (4.4: within-cluster standardized mean –0.29). Clusters 5 and 3 showed overall moderate ratings for BCTs, with most mean motivation ratings between 2.0 and 3.0. Cluster 5 showed the highest rating for information about social and environmental consequences (5.3: within-cluster standardized mean 0.41), and no BCTs were rated low enough to exceed the reference threshold (no BCTs with a within-cluster standardized mean below –0.20). Goal setting (1.3: within-cluster standardized mean 0.21) exceeded the reference threshold only in this cluster. Similarly, cluster 3 showed the highest ratings for information about social and environmental consequences (5.3: within-cluster standardized mean 0.43) and the lowest for prompts/cues (7.1: within-cluster standardized mean –0.27). Nonspecific rewards (10.3: within-cluster standardized mean 0.20), self-reward (10.9: within-cluster standardized mean 0.20), and reward approximation (14.4: within-cluster standardized mean 0.21) exceeded the reference threshold only in this cluster. Clusters 4 and 1 showed overall low ratings for BCTs, with most mean motivation ratings between 1.0 and 2.0. Cluster 4 showed the highest ratings for salience of consequences (5.2: within-cluster standardized mean 0.39) and the lowest for prompts/cues (7.1: within-cluster standardized mean –0.22). Cluster 1 showed the highest ratings for salience of consequences (5.2: within-cluster standardized mean 0.59) and the lowest for monitoring of emotional consequences (5.4: within-cluster standardized mean –0.40). Identification of self as role model (13.1: within-cluster standardized mean –0.23) exceeded the negative reference threshold only in this cluster. Finally, cluster 2 showed the strongest differentiation in preferences for BCTs. It showed the highest ratings for salience of consequences (5.2: within-cluster standardized mean 0.80) and the lowest for monitoring of emotional consequences (5.4: within-cluster standardized mean –0.70). BCT groups related to goals and planning, feedback and monitoring, and social support did not exceed the positive reference threshold in this cluster, whereas instruction on how to perform the behavior (4.1: within-cluster standardized mean 0.40) exceeded it. High ratings for both gain- and loss-framed messages were also observed (gain: within-cluster standardized mean 0.54; loss: within-cluster standardized mean 0.36).

Among the BCTs commonly used in interventions (ie, goal setting, social support, self-monitoring of behavior, and instruction on how to perform the behavior), goal setting (1.3) exceeded the positive reference threshold only in cluster 5 (within-cluster standardized mean 0.21), whereas it exceeded the negative reference threshold only in cluster 2 (within-cluster

XSL•FO
RenderX

standardized mean –0.35). Instruction on how to perform the behavior (4.1) exceeded the positive reference threshold only in cluster 2 (within-cluster standardized mean 0.40). Self-monitoring of behavior (2.3) exceeded the negative reference threshold in clusters 1, 2, and 6, as did social support (3.1) in clusters 1 and 2, and social support (3.2) in cluster 2.

Table 3 presents the demographic characteristics, self-reported PA levels, and SoC for each cluster. Clusters 7 and 6 were the most male-dominant (191/364, 52% and 288/514, 56%), whereas cluster 2 was the oldest (mean age 63.8 years) among the 7 clusters. BMI showed no significant between-cluster differences. Clusters differed significantly in PA level ($F_{6,\ 2852}$=11.39; P<.001); however, the omnibus effect size was small (ηp^2=.02), indicating that the practical magnitude of between-cluster differences in PA was limited despite statistical significance arising from the large sample. Pairwise comparisons were therefore interpreted with this small overall effect in mind, using the same benchmarks as reference points for effect size interpretation (small: d=0.20; medium: d=0.50; large: d=0.80). Descriptively, cluster 7 showed the highest PA level, followed by cluster 2; this difference was negligible in magnitude (d=0.152). Cluster 6 and cluster 7 differed by a similarly small margin (d=0.200), while cluster 6 and cluster 2 showed almost no difference (d=0.048). Cluster 4 showed the lowest PA level, and the remaining clusters (1, 3, and 5) fell in between, with negligible differences among them (ds<0.05). Approximately half (43%-53%) of clusters 7, 6, and 2 were in the maintenance stage. The least active cluster was cluster 4, in which >80% of the individuals were in the preaction (precontemplation-preparation) stages. In other clusters (1, 3, and 5), the proportions were similar across stages, except for the action stage. Although pairwise comparisons did not detect any significant differences in PA levels between adjacent clusters (eg, cluster 7 vs 2, see Tables S2 and S3 in Multimedia Appendix 1), the high-rating clusters (clusters 7, 6, 5, and 2) had significantly higher PA levels than the low-rating clusters (clusters 1, 3, and 4); t_{2857}=6.062; P<.001; d=0.227). Similarly, the proportion of individuals in the maintenance stage was higher in high-rating clusters than in low-rating ones (odds ratio 2.089, 95% CI 1.78-2.45; P<.001).

Discussion

Principal Findings

This study investigated how individuals perceive BCTs offered in health messages to support PA. Specifically, we explored which clusters would be identified by individuals' motivation ratings for messages extracted from the extended message bank of MacPherson et al [18]. LCA identified 7 clusters as the optimal solution. Overall, clusters 7 and 6 showed higher ratings across messages, clusters 5 and 3 showed moderate ratings, and clusters 1 and 4 showed lower ratings. Cluster 2 showed the most variable ratings across messages. However, within each broad rating level, clusters differed in their preferences for specific BCTs. The observed heterogeneity in BCT preferences across clusters may be partly explained by differences in the psychological resources individuals require at different stages of behavior change, as proposed by the BCRM framework.

Clusters 7 and 6 showed generally high ratings across different message types. Cluster 7 was labeled "General receptivity" based on its uniformly high ratings across all BCT types, with no particular preference or aversion (no BCTs exceeding a within-cluster standardized mean of ±0.20). Individuals in this cluster had the highest PA levels and approximately half were in the maintenance stage, suggesting the establishment of stable PA habits. Cluster 6 was labeled "Preference for low-effort boosting" based on its highest rating within the cluster for information about social and environmental consequences (5.3) and its lowest rating within the cluster for behavioral experiments (4.4). This cluster showed generally high ratings across BCT types, but with a clearer preference pattern than cluster 7. Both BCTs fall under boosting in the BCRM framework, but they may differ in the degree of active engagement required. In the BCRM, reflective resources refer to internal cognitive capacities that support behavior change, such as beliefs about consequences, intentions, and decision-making processes. While behavioral experiments (4.4) may require active self-engagement, information about consequences (5.3) may allow individuals to build reflective resources, such as beliefs about consequences and decision-making processes, more passively. This suggests that individuals in cluster 6 preferred less effortful forms of boosting. Approximately half of the individuals were in the maintenance stage, where behavior tends to become habitual and automatic, and the need for further change is often reduced [35]. Therefore, individuals in this cluster may have preferred approaches that build reflective resources, such as beliefs about consequences, through passive receipt of information, rather than those requiring active cognitive engagement, such as deliberate self-monitoring or behavioral experimentation.

Clusters 5 and 3 showed overall moderate ratings across BCT types. Cluster 5 was labeled "Preference for outcome information and goal setting" based on its highest rating for information about social and environmental consequences (5.3) within the cluster, and goal setting (1.3), which exceeded the reference threshold only in this cluster, with no BCTs rated notably low (no BCTs below a within-cluster standardized mean of –0.20). Cluster 3 was labeled "Preference for outcome information and rewards over prompts" based on its highest rating within the cluster for information about social and environmental consequences (5.3), rewards such as reward approximation (14.4), which exceeded the positive reference threshold only in this cluster, and its lowest rating within the cluster for prompts/cues (7.1). In both clusters, more than half of individuals were in the preaction stages (precontemplation to preparation; ≥65%), in which knowledge and insight are considered necessary to motivate behavior change [35]. Furthermore, nudging BCTs (reward approximation and prompts/cues), which activate affective resources without requiring conscious deliberation [34], were responded to differently between the 2 clusters. Therefore, even within the same stage, cluster 5 was characterized by a preference for building reflective resources through outcome information, whereas cluster 3 showed a greater emphasis on activating affective resources in addition to such information.

Clusters 4 and 1 showed overall low ratings across BCT types. Cluster 4 was labeled "Low receptivity with preference for outcome information" based on its highest rating within the cluster for salience of consequences (5.2) and its lowest rating within the cluster for prompts/cues (7.1). This cluster had the highest proportion of individuals in the precontemplation stage and the lowest PA levels among all clusters. At a stage where motivation was low and the benefits of PA were not well recognized, prompts/cues that encourage PA may be less acceptable (eg, "Reminders can be super helpful when we are trying to form new habits. Put a reminder in your phone, a note on your fridge, or get creative!"). Instead, BCTs that can enhance intrinsic motivation toward behavior change, such as providing information about outcomes, may be more effective for this group. Cluster 1 was labeled "Preference for external outcome information without self-engagement" based on its highest rating within the cluster for information about social and environmental consequences (5.3), its lowest rating within the cluster for monitoring of emotional consequences (5.4), and identification of self as role model (13.1), which exceeded the negative reference threshold only in this cluster. A large proportion of individuals in this cluster were in the preaction stage. In this preaction stage, where knowledge and insight are considered necessary to motivate behavior change, individuals in this cluster may have preferred approaches that provide external information about outcomes, rather than those requiring active self-reflection or role-based engagement.

Finally, cluster 2 was labeled "Selective preference for concrete guidance with framing sensitivity" based on its greatest variability in BCT preferences among all clusters. Specifically, this cluster showed the highest rating within the cluster for salience of consequences (5.2) and the lowest rating within the cluster for monitoring of emotional consequences (5.4). With the exception of instruction on how to perform the behavior (4.1), commonly used BCT groups (ie, goals and planning, feedback and monitoring, and social support) did not exceed the positive within-cluster standardized mean reference threshold in this cluster. In addition, both gain- and loss-framed messages exceeded the positive reference threshold only in this cluster, with a slightly stronger preference for gain framing. Approximately half of the individuals were in the maintenance

XSL•FO
RenderX

stage, with PA levels similar to cluster 7. From the perspective of prospect theory, gain framing is generally more effective for low-risk preventive behaviors, whereas loss framing is considered more effective for high-risk detection behaviors [54]. Given that many individuals in cluster 2 were already engaging in PA, gain framing may have been slightly more preferred in the context of preventive action. Moreover, cluster 2 had the highest mean age among the clusters, and the messages explicitly referred to conditions more commonly associated with older adults, such as hypertension and diabetes (eg, "Eat more leafy greens and less sugar, and exercise more! These simple actions have been shown to decrease the risk of type 2 diabetes"). Therefore, the self-relevance of the messages may have contributed to the preference for gain-framed messages in cluster 2, although the interaction between age and message framing was not directly tested in this study. Future research should further examine the role of age, including whether the inclusion of age-relevant diseases in messages influences framing effects.

Previous systematic reviews have suggested that behavior change interventions for PA frequently implement the following BCTs: goal setting, social support, self-monitoring of behavior, and instruction on how to perform the behavior [24-31]. Our findings revealed between-cluster differences in the motivation ratings for these common BCTs. For example, goal setting (1.3) exceeded the positive within-cluster standardized mean reference threshold only in cluster 5, whereas it fell below the negative reference threshold only in cluster 2. Instruction on how to perform the behavior (4.1) exceeded the positive reference threshold only in cluster 2. In contrast, self-monitoring of behavior (2.3) fell below the negative reference threshold in clusters 1, 2, and 6, as did social support (3.1) in clusters 1 and 2, and social support (3.2) in cluster 2. These results align with previous findings that frequently used BCTs are not necessarily perceived as helpful or motivational [55,56]. Furthermore, self-monitoring attracts different viewpoints from intervention recipients [57]. Some individuals found diary (manual) recordings of PA repetitive and time-consuming, whereas others found it useful to visualize progress and detect barriers to PA. The effect of self-monitoring on PA is also somewhat mixed, and self-monitoring is suggested to work only when delivered with objective monitoring tools (eg, accelerometers) [58]. Future research must disentangle the discrepancies between the perceived and actual efficacy of self-monitoring considering individual differences because some individuals may perceive it as boring but benefit from it by changing their PA habits.

The findings of this study have several practical implications. When designing a TMI with tailored message delivery, the first decision should be whether the target recipients are open to the TMI. Our results suggest that several clusters rate any message as not motivational. These clusters included a higher proportion of individuals in the preaction stages, suggesting that selecting BCTs that target the resources required at this stage may be effective. The preaction stage is characterized by low motivation for behavior change, with a need for knowledge and insight. Therefore, presenting information about outcomes may be beneficial for building reflective resources for behavior change. In contrast, approaches requiring active self-engagement or providing concrete instructions for action may be less acceptable. Additionally, given the limited reflective resources at this stage, the use of rewards may also be somewhat effective as a supplementary approach. Similarly, practitioners could refer to demographic information when tailoring messages to send. Cluster 2 typically included older people, and this cluster showed relatively higher ratings for both gain- and loss-framed messages, suggesting that age may be a relevant factor in framing preferences, although this was not directly tested in this study. Tailoring variables do not have to be limited to demographic and trait-like characteristics, such as PA and SoC. Fu et al [59] suggested that the key to further facilitating personalization would be for an intervention to assess what BCTs have and have not worked for each individual at an early stage of the intervention. This would clarify the additional support that should be offered to meet individuals' changing needs over the progress of an intervention, considering that different BCTs would be needed at different stages of intervention.

Limitations

This study had several limitations. First, we exclusively recruited Japanese-speaking adults with Internet access. Caution should be exercised when interpreting these results in terms of cultural differences and generalizability. Cluster 2 included several older people who showed unique preferences for framed messages. However, these individuals may not be representative of the older population, which is the generation typically facing the digital divide [60]. Furthermore, the potential influence of selection bias should be considered. Because the participants had previously taken part in surveys conducted by our research group [43], the sample might be more motivated, health-aware, and digitally literate than the general population. This may have generally increased positive responses to mHealth interventions and may also have contributed to the relatively high baseline PA levels, as well as the presence of clusters characterized by high responsiveness to messages (eg, cluster 7). Second, motivation was rated cross-sectionally. Therefore, whether each message triggers actual behavior, and not only motivation or intention, remains unclear. While the association between intention and PA is well established, substantial discrepancies have been observed in experimental studies [61]. Therefore, a high level of motivation in response to messages may not necessarily translate directly into increased PA. Additional constructs that strengthen intention (eg, self-regulation and automaticity) have been proposed. Future research should examine, through experimental and longitudinal designs, whether higher motivation leads to engagement in PA or whether it operates through interactions with other factors. Third, standardizing each message for the tone used and resources referred to (eg, national guidelines) was difficult, mainly because we relied on an established message bank. We focused on the BCTs offered in each message as the key dimension of the analysis; however, motivation ratings could be affected by other factors. Our intention was to analyze an existing message bank to leverage individual differences in motivation ratings for tailoring message delivery. However, a future study could use a factorial design to rigorously control for other factors to clarify what (combinations of) factors determine motivation.

XSL•FO
RenderX

Furthermore, fatigue and reduced concentration associated with evaluating 83 messages may have influenced participants' ratings. Fourth, we specified message delivery in the mHealth context, and the participants were instructed to assume that each message was sent by an AI chatbot implemented in a health care app. This was because this study was intended to be the basis for future mHealth TMIs. However, different senders (eg, human health care professionals) may cause the messages to be perceived differently. Beyond the specific delivery context, the text message format itself has inherent limitations. TMIs remain a valuable component of mHealth due to their cost-effectiveness, ease of personalization, and potential to be scaled up as ecological momentary or just-in-time adaptive interventions. However, not all BCTs may be equally suited to this format. For example, self-monitoring typically assumes a bidirectional process in which individuals record behavior and receive feedback accordingly. The messages used in this study merely prompted recording without reproducing this interactive process, which may have contributed to the relatively low motivation ratings for self-monitoring. Future research should therefore examine how BCTs can be effectively combined with interactive and multimodal features of mHealth tools, such as apps with feedback loops and wearable integration, to clarify which BCTs are most suitable for text message-based delivery and which require more dynamic formats. Fifth, the possibility of cluster solutions other than the 7-cluster solution remains. When conducting a latent profile analysis using continuous variables, models with 9 or more clusters failed to converge, preventing a full comparison across solutions. Although the BIC was lowest among the converged solutions for the 8-cluster solution, we were unable to demonstrate the adequacy of the 8-cluster solution. Therefore, the 7-cluster solution was selected based on the BIC and entropy obtained from the LCA. Nevertheless, the identified clusters should be interpreted as a pragmatic summary of response patterns rather than definitive latent subgroups, as more complex solutions may also exist with continuous variables. Further investigation is needed to determine whether the 7-cluster solution can be replicated in other datasets. Sixth, the number of messages per BCT included in the data bank was unbalanced. As the LCA was conducted using dichotomized motivation ratings for each of the 83 individual messages as input variables, BCTs represented by a greater number of messages may have had a greater influence on the cluster patterns. No weighting or adjustment was applied to account for this imbalance, as it reflects the composition of the original message bank. Its potential impact on the clustering results should therefore be considered when interpreting the findings.

Conclusion

Despite the limitations, we believe that our findings will pave the way for data-driven approaches to tailored health message delivery for enhancing PA. Our analysis identified clusters of individuals who were generally open to any BCTs, and these individuals had typically been active and maintained PA habits. The clusters that did not find the messages to be motivational were generally less active and in the preaction stages. However, they appeared to appreciate information about the consequences of health behaviors, with some also showing a preference for rewards, which may serve as a good starting point should TMIs be offered for inactive individuals. The BCTs that have commonly been used in interventions were not necessarily perceived as motivational. Although we found some individual (or between-cluster) differences, self-monitoring was not consistently rated as motivational across all clusters. This does not mean that self-monitoring and other common BCTs are not effective in promoting PA, but that some care would be appropriate to reduce message recipients' resistance when introducing these BCTs. To further increase message acceptability, it is important to consider the mechanisms of action [34,62] to address individual needs, which can be communicated more explicitly in each message. In this study, BCRM was used as one perspective on mechanisms of action to interpret the psychological resources underlying preferences for different messages. The mechanisms of action serve as another tailoring dimension along with the BCT taxonomy, while identifying what proximate outcomes (eg, knowledge and skills) should be targeted for individual message recipients. Furthermore, drawing on classification systems grounded in self-determination theory, such as that proposed by Ahmadi et al [63], may help clarify the links between these outcomes and underlying motivational processes. Future research should expand the focus to how BCTs could be contextualized in interventions (eg, specifying proximate outcomes and resolving how they could be achieved) to make TMIs more personalized, cover the taxonomy, and achieve dynamic and process-oriented tailoring.

Abstract

Background: Digital health technologies have become integral to modern health care, yet consumer adoption remains uneven. These technologies span a range of consumer-facing tools, including remote care services, mobile apps, wearable devices, conversational agents, and digital medication services, with uptake varying considerably across tool types and by gender. An earlier analysis of this dataset revealed a gender paradox: women reported higher digital literacy compared to men yet demonstrated lower adoption and curiosity toward digital health tools. The Capability, Opportunity, Motivation – Behavior (COM-B) model proposes that behavior occurs when individuals have the capability (skills and confidence), opportunity (access, affordability, and contextual support), and motivation (trust, perceived usefulness, and willingness) to act.

Objective: This study aimed to examine associations between digital literacy, self-reported COM-B domains, gender, and adoption across digital health technologies and to explore whether these associations differ by gender.

Methods: This cross-sectional quantitative study with an integrated qualitative component enrolled 416 adults and used multivariable logistic regression to examine associations between COM-B domains and adoption across five consumer-facing digital health technologies. Exploratory gender-by-predictor interaction and gender-stratified analyses examined potential gender-specific patterns, while self-reported reasons for nonuse were mapped to COM-B domains using directed content analysis.

Results: Women had lower odds of chatbot/virtual assistant use (adjusted odds ratio [aOR] 0.32, 95% CI 0.18-0.59), marginally lower odds of e-pharmacy use (aOR 0.48, 95% CI 0.22-1.01), and higher odds of mobile health (mHealth) app use (aOR 2.59, 95% CI 1.28-5.25). Of 20 exploratory interaction tests, chatbot digital literacy-by-gender (P=.021) and capability-by-gender (P=.044) interactions were nominally significant. In directed barrier analysis, the gender distribution differed significantly for mHealth apps (P=.009), whereas the wearable result showed a trend (P=.079); motivation-related barriers were most frequent for most technologies.

Conclusions: Behavioral determinants of digital health technology adoption varied by technology type. Women used several technologies less often than men despite reporting higher digital literacy, capability, and motivation, and opportunity emerged as the most consistent factor across the models examined. Exploratory analyses suggested these patterns may differ by gender for selected technologies but did not support a single gender-differentiated pathway. These findings are exploratory and require confirmation in larger studies.

Introduction

Background

Health systems worldwide are under escalating pressure from aging populations, rising chronic disease prevalence, and persistent workforce shortages [1,2]. In response, many countries are accelerating digital transformation to support more sustainable, person-centered models of care. As digital health technologies become embedded in routine health care delivery, attention has increasingly shifted to digital health readiness, including the data, technology, analytic, workforce, and human factors required to realize the benefits of digital health, while minimizing harms [2].

Internationally, a broad range of digital health technologies, such as telehealth, mobile health (mHealth) apps, wearable devices, conversational agents, and e-pharmacies, are being integrated into health care systems. However, adoption remains uneven and is shaped by stakeholder needs, implementation context, trust, infrastructure, and alignment with health care workflows [3,4]. Evidence from Australia reflects a similar pattern: although telehealth use surged during the COVID-19 pandemic, adoption of newer or more autonomous tools has been slower, particularly among older adults, people with lower educational attainment or income, those living in rural or remote areas, and individuals with limited digital or health literacy [5,6]. Accordingly, Australian digital health policy identifies inclusive, person-centered engagement as central to realizing the benefits of digital transformation across the population [7].

Prior Digital Health Technology Adoption/Implementation Research

Research examining digital health technology adoption has expanded rapidly in recent years; however, important limitations remain. Much of the existing literature focuses on single technologies, applies narrow or technology-specific behavioral models, or targets specific subpopulations, such as older adults or individuals with chronic disease [8-10]. In addition, although behavioral determinants are increasingly recognized as important to digital health technology adoption and implementation, they are not always examined using structured behavioral frameworks, and limited attention has been given to how these determinants vary across gender groups or across different types of digital health technologies [8,10,11].

Australian research shows that digital health technology adoption is strongly patterned by socioeconomic status, education, broadband availability, and digital health literacy, which together predict engagement, particularly with national personal health records [12,13]. Consistent with this, implementation reviews continue to identify persistent adoption gaps in rural and underserved populations and note the limited use of behavioral theory in digital health technology adoption research [14]. More broadly, this literature often emphasizes individual digital literacy, while giving less attention to the structural and contextual conditions that shape engagement with digital technologies [4]. The World Health Organization (WHO) Global Strategy on Digital Health similarly notes that literacy alone is insufficient for equitable participation without inclusive design, supportive infrastructure, and equitable access [15].

Together, these gaps mean the evidence base provides an incomplete account of why adoption varies across population groups. In particular, gender is often reported descriptively rather than examined as a factor that may shape how individuals experience, interpret, and engage with digital health technologies. This study analysed behavioral drivers across multiple digital health technologies and examined gender differences in adoption using a structured behavioral framework.

Gendered Patterns of Digital Engagement

A preliminary conference paper using this dataset reported high-level descriptive findings on digital literacy, the current use of digital health technologies, and curiosity toward emerging technologies. The analysis observed that women report higher digital literacy but lower use of some digital health technologies; however, it did not formally examine the behavioral mechanisms underlying these differences using multivariable or Capability, Opportunity, Motivation – Behavior (COM-B)–based analyses [16]. Digital literacy refers to the skills and confidence required to access, understand, and use digital technologies effectively [13,17]. Curiosity, defined as an intrinsic motivation to seek information and explore technologies, is conceptually distinct from digital literacy or confidence [18,19]. This study applied the COM-B framework to examine behavioral determinants of adoption through multivariable regression, gender-by-predictor interaction analyses, gender-stratified models, exploratory nested modeling, and COM-B-guided analysis of reported reasons for nonuse. In this way, the current study moved beyond describing gender differences in literacy and technology use to investigate whether capability, opportunity, and motivation are associated with the observed gender-specific patterns of adoption.

Global analyses highlight persistent gender inequalities in digital participation. Even where women attain high levels of education and digital skills, engagement with digital technologies remains constrained by affordability, safety concerns, time poverty, and structural inequalities in science, technology, engineering, and mathematics (STEM) education [20-23]. Time poverty, limited discretionary time arising from disproportionate domestic and caregiving responsibilities, further restricts opportunities for digital engagement [24].

Consistent with these broader patterns, Australian and international studies have documented a gender gap in digital health engagement. Women, particularly in their roles as patients and carers, may be more likely to experience inequitable or suboptimal digital health interactions [25,26]. Scholars also caution that digital health tools may insufficiently reflect women's needs and that design choices, data governance practices, or algorithms can embed gender bias, while limited integration of gender-responsive and intersectional perspectives

XSL•FO
RenderX

in digital health research may reinforce existing inequalities [25,27].

These dynamics are particularly significant, given women's central roles within health systems. In Australia, women make up a large proportion of the formal health workforce, and primary informal carers are also predominantly female [28,29]. Qualitative evidence from Australia also shows that many women use digital health information, not only as patients, but also to provide advice and support to family members and friends [30]. Consequently, women's engagement with digital health technologies is consequential in its own right and may shape broader patterns of adoption, trust, and diffusion within families and communities [23,30].

Overall, this evidence points to a potential capability-opportunity mismatch in digital health technology adoption: women's digital skills and familiarity with health care settings may coexist with structural, temporal, and contextual barriers that constrain opportunities to use digital technologies [24,25,31]. Addressing these dynamics is essential to ensure that digital transformation does not widen existing inequalities and to support the design and development of technologies that are responsive to the needs, preferences, and contexts of diverse populations [25,32].

Theoretical Framework: COM-B and the Behavior Change Wheel

To examine these dynamics, this study applied the COM-B model, which conceptualizes behavior as the product of interaction between capability, opportunity, and motivation [33]. Capability refers to the psychological and physical capacity to perform a behavior (including relevant knowledge and skills). Opportunity captures external factors, both physical and social, that enable or prompt the behavior. Motivation encompasses reflective and automatic processes, including goals, beliefs, emotions, and habits, that energize and direct behavior [33].

COM-B forms the hub of the Behavior Change Wheel (BCW), a widely used framework for diagnosing behavioral barriers and mapping them to potential intervention strategies and policy levers [33]. Relative to technology adoption models, such as the Technology Acceptance Model and the Unified Theory of Acceptance and Use of Technology, which emphasize constructs such as perceived usefulness, ease of use, performance expectancy, and facilitating conditions [34,35], COM-B provides a broader behavioral lens by incorporating psychological, social, and environmental determinants of behavior. In this study, however, the COM-B constructs were operationalized through self-reported composite indices and should be interpreted as perceived behavioral domains rather than objective measures of physical or psychological capability.

Study Aim

This study aimed to examine gender differences in digital health technology adoption and to explore how self-reported behavioral determinants within the COM-B model are associated with those patterns. The analyses were exploratory and association based; they were not designed to establish causal pathways or mediation.

Using a survey dataset, this study examined technology-specific associations with capability, opportunity, and motivation and evaluated exploratory gender-by-predictor interactions. It addressed gaps in multitechnology behavioral research, while explicitly distinguishing overall pooled predictors from evidence of gender moderation. To translate behavioral insights into practical implications, findings were mapped to the BCW, which linked COM-B determinants to intervention functions and policy strategies that may support more equitable digital health technology adoption. As this was a self-reported study, results reflect perceived rather than objectively measured behaviors; nonetheless, they provide theory-informed insights into gendered determinants of digital health engagement that can inform equitable digital health policy, design, and implementation.

Methods

Overview

A cross-sectional online survey (Research Electronic Data Capture [REDCap]) was conducted to examine Australian adults' digital literacy, engagement with digital health technologies, and preferences for future services. Eligible participants were aged ≥18 years and residing in Australia. As an exploratory pilot examining behavioral pathways and gender differences, no a priori sample size calculation was performed. The achieved sample (N=416) supported multivariable and interaction analyses but may have been underpowered to detect small effects.

The survey was developed collaboratively by academic investigators, Medibank Private Limited, and consumer organizations to ensure relevance and accessibility. It included demographic items and open- and closed-ended questions on digital health experiences and behaviors.

Participants were recruited using convenience sampling through social media, consumer advocacy networks, Medibank communication channels, and research team networks. The sample was not designed to be nationally representative. Data were collected between July 21 and August 24, 2023. Participants could enter a prize draw for an AU $50 (US $36) voucher funded by Medibank Private Limited.

Survey design was informed by the COM-B model and the Australian Digital Capability Framework, with items adapted to the digital health context (Multimedia Appendix 1) [36]. A review by the Consumer Health Forum of Australia and state-based organizations was conducted to optimize accessibility.

Measurement

Predictors

Digital literacy was measured using a 22-item scale covering information/data literacy, communication/collaboration, content creation, safety, and problem solving. Items were averaged, with higher scores indicating greater self-reported digital competence (α=0.81).

Capability, opportunity, and motivation were operationalized as theory-informed composite indices based on

XSL•FO
RenderX

COM-B-informed survey sections. Capability reflected perceived functional readiness, knowledge, skills, and confidence; opportunity reflected perceived access, affordability, availability, infrastructure, and social/professional support; and motivation reflected trust, perceived usefulness and benefits, preferences, interest, intentions, and emotional responses to digital technology. Digital literacy was treated as a related but distinct measure of self-reported digital competence. All measures were self-reported and therefore reflected perceived rather than objectively assessed capability or digital skills.

The Capability index comprised 15 items (α=0.83), the Opportunity index 5 items (α=0.76), and the Motivation index 13 items (α=0.61). These indices were developed for this exploratory study and were not intended as validated psychometric COM-B scales. Items were coded so that higher scores represented greater capability, opportunity, or motivation, with negatively worded items reverse-coded, as appropriate. Item scores were averaged within each domain and standardized (*z*-scores), such that odds ratios represented a 1-SD increase. Exploratory factor analyses indicated that the Opportunity index showed the clearest evidence of unidimensionality, consistent with its internal consistency estimate. The Capability and Motivation indices showed evidence of multidimensionality, suggesting they each capture related but heterogeneous constructs within their respective domains; this is reflected in the lower internal consistency of the Motivation index in particular and should be considered when interpreting findings associated with these composites. Intercorrelations between digital literacy and the three COM-B indices were modest to moderate (r=0.39-0.57), providing preliminary evidence that the constructs were related but distinct.

Complete item-to-domain and subdomain mapping, scoring rules, reverse-coded items, handling of "do not know" responses, item-level missingness, and exploratory measurement analyses are provided in Tables S2-S4 in Multimedia Appendix 2.

Outcomes (Behavior)

Adoption of each technology (telehealth, mHealth apps, wearable devices, chatbots/virtual assistants, and e-pharmacy) was operationalized as self-reported current use and coded as a binary outcome (current user vs nonuser). This measure captured current user status rather than the frequency, duration, or intensity of technology use.

Effect Modifier

Gender (female vs male) was examined as an effect modifier. Interaction terms between gender and each of the four predictors (digital literacy, capability, opportunity, and motivation) were included in separate exploratory models (Table S1 in Multimedia Appendix 2), resulting in 20 interaction tests across five technology outcomes. These analyses were hypothesis generating rather than confirmatory.

Covariates

Participants were grouped by age (≤34, 35-54, and ≥55 years) to reduce sparse cells and maintain adequate group sizes. The exact age in years was not collected; therefore, age could not be modeled as a continuous variable. Models adjusted for age group, education (low/intermediate, bachelor/advanced diploma, postgraduate), occupation (white collar, blue collar/service, other/not in labor force), region (Eastern, Central/Western, Southern/Territory), and residence (metropolitan vs rural/remote). Occupation and region were collapsed from the original survey categories to maintain model parsimony. These groupings were defined during data preparation, and covariates were selected a priori as structural determinants of digital access.

Statistical Analysis

Overview

Quantitative responses, including Likert-scale items, were summarized using descriptive statistics. Qualitative free-text responses were analyzed using directed content analysis guided by the COM-B framework. Cross-tabulations by key demographic variables, including age, gender, education level, and geographic location, were performed using IBM SPSS Statistics, whereas all inferential and multivariable analyses were conducted in Stata version 19.5 [37].

Quantitative Analysis

Participant characteristics were summarized by gender. Categorical variables were compared using χ^2 tests. Continuous or ordinal variables were summarized as median (IQR) and compared using Mann-Whitney *U* tests. Differences in adoption rates by gender were compared using χ^2 tests.

Logistic regression models were used to examine associations between digital health technology adoption and gender, digital literacy, COM-B domains, and sociodemographic covariates. The primary fully adjusted models included gender, digital literacy, capability, opportunity, motivation, age, education, occupation, region, and rural/remote residence. Adjusted odds ratios (aORs) with 95% CIs were reported. Digital literacy, capability, opportunity, and motivation were standardized (*z*-scores), such that their aORs represented a 1-SD increase.

To descriptively examine changes in the gender coefficient after inclusion of the COM-B domains, pre-COM-B-reduced models included gender, digital literacy, and the same sociodemographic covariates as the primary models, but excluded capability, opportunity, and motivation. Covariate definitions and coding were identical between these models and the primary fully adjusted models. These comparisons were descriptive and were not interpreted as evidence of mediation or mechanisms.

Effect moderation by gender was explored by including gender-by-predictor interaction terms for digital literacy, capability, opportunity, and motivation across each of the five technology outcomes, resulting in 20 interaction tests. These analyses were exploratory and hypothesis generating. For nominally significant interactions, adjusted predicted probabilities of technology adoption were estimated at −1 SD, the mean, and +1 SD of the relevant predictor, holding other covariates at their observed values using Stata's *margins* command. Gender-stratified logistic regression models were additionally estimated to characterize within-gender patterns (Table S1 in Multimedia Appendix 2).

Multicollinearity was assessed using variance inflation factors (<2). Model fit was evaluated using likelihood-ratio χ^2 and

XSL•FO
RenderX

pseudo-R^2 statistics. Robust (Huber-White) SEs were used for the primary models. There were no missing data for variables included in the primary multivariable models; consequently, all models included the full analytic sample (N=416).

Given the relatively small number of nonevents for some outcomes, model complexity and robustness were additionally assessed. For each primary model, we examined the number of complete cases, events/nonevents, and estimated parameters. Simplified sensitivity models retained gender, digital literacy, capability, opportunity, motivation, and age, while excluding the remaining sociodemographic covariates. These were fitted for both the primary models and the 20 gender-by-predictor interaction models and compared with the primary fully adjusted models to assess sensitivity to model complexity. A further sensitivity analysis excluding participants in the "other/not in labor force" occupation category was directionally consistent with the primary models (results not shown).

Given the lower internal consistency of the Motivation index (α=0.61), additional sensitivity analyses examined alternative motivation specifications, including exclusion of the e-pharmacy-specific preference item and a reduced composite excluding the three items with the lowest corrected item-rest correlations (Table S5 in Multimedia Appendix 2). Given the exploratory nature of this pilot study and multiple behavioral predictors across technology-specific models, estimates were interpreted cautiously, with emphasis on the magnitude, direction, consistency, and uncertainty of associations.

Qualitative Analysis

For participants who had not adopted specific technologies, reasons for nonuse were captured through open-ended responses and analyzed using directed content analysis guided by the COM-B framework. Responses were imported into Stata version 19.5 and preprocessed prior to coding. Initial categorization was conducted using lexical pattern matching (*regexm* functions) to flag responses corresponding to capability, opportunity, and motivation domains (eg, "no access," "prefer in-person," "not confident"). Lexical matching was used as an initial screening and organizational step rather than as the basis for final classification. The technology-specific coding framework, operational definitions, and illustrative lexical triggers are provided in Table S6 in Multimedia Appendix 2.

Two PhD-qualified researchers independently reviewed all flagged responses against the complete response text and validated or revised the initial classifications based on contextual meaning. Where responses reflected more than one COM-B construct, a primary barrier was assigned according to the predominant reason for nonuse identified from the complete response. Discrepancies between researchers were resolved through iterative discussion and consensus. Because the two researchers' independent judgments were not retained as separate ratings, an interrater agreement statistic was not calculated. Coding rigor was instead supported by the technology-specific framework with documented operational definitions (Table S6 in Multimedia Appendix 2). Coding was blinded to participant gender; gender was linked to the final COM-B classifications only after coding for the gender-stratified descriptive analyses.

Within-gender frequencies of capability, opportunity, and motivation barriers were summarized for each technology and integrated descriptively with the quantitative findings. Because open-ended responses were obtained from a predefined survey sample rather than through iterative qualitative sampling, saturation was not used as a stopping criterion. Given small cell counts in the gender-stratified barrier analyses, Fisher's exact test was used for comparisons.

Ethical Considerations

Ethics approval was obtained from the La Trobe University Low-Risk Human Research Ethics Committee (HREC #23100). Participation was voluntary, with informed consent obtained prior to survey completion. Data were collected anonymously using REDCap, a secure, web-based platform designed to support data collection and management for research. De-identified data were exported and stored securely on a password-protected research drive, with access restricted to the research team.

Results

Participant Profile

Of 416 respondents, 61.1% (n=254) were male and 38.9% (n=162) female. The age distribution differed by gender (P=.019), with women more often aged ≥35 years (n=84, 51.8%) and more likely to hold postgraduate qualifications (n=73, 45.1%) compared to men (P=.001). Occupational distribution differed significantly between genders, with approximately three-quarters (n=123, 75.9%) of women working in white-collar roles compared to 42.9% (n=109) of men (P<0.001), whereas men were more commonly employed in blue-collar or service occupations. Residence area was broadly similar between genders, although regional distribution differed significantly.

Across COM-B domains, women reported higher digital literacy, capability, and motivation, whereas opportunity scores were similar between genders (Table 1). These differences supported examining gender-specific pathways in subsequent analyses.

The Adoption Paradox: Technology-Specific Gender Gaps

Overall, nearly all participants (n=413, 99.3%) reported using at least one digital health technology. Adoption was highest for clinician-mediated modalities, including telehealth and mobile apps.

Gender differences were observed for newer or more autonomous technologies. Women were less likely to use wearable devices, chatbots/virtual assistants, and e-pharmacies (Table 2). After full adjustment, women remained significantly less likely to use chatbots/virtual assistants, whereas the association with e-pharmacy use was marginal and the association with wearable device use was attenuated (Table 3). These findings indicate that gender differences are technology-specific, particularly for tools requiring greater autonomy or trust.

Behavioral Determinants of Digital Health Technology Adoption (COM-B Domains and Gender)

Before inclusion of the COM-B domains, pre-COM-B-reduced models, including gender, digital literacy, and sociodemographic covariates, showed significantly lower odds of wearable-device (aOR 0.47, 95% CI 0.26-0.85; *P*=.012), chatbot/virtual assistant (aOR 0.30, 95% CI 0.16-0.54; *P*<.001), and e-pharmacy (aOR 0.41, 95% CI 0.20-0.86; *P*=.018) use among women. Gender was not associated with telehealth (aOR 1.01, 95% CI 0.42-2.44;

XSL•FO
RenderX

P=.981) or mHealth app (aOR 1.36, 95% CI 0.72-2.56; *P*=.342) use. After inclusion of capability, opportunity, and motivation in the primary fully adjusted models (Table 3), the magnitude of these gender associations changed to varying degrees.

Opportunity emerged as the most consistent and influential determinant of digital health technology adoption across technologies. A 1-SD increase in opportunity was associated with higher odds of telehealth, mHealth app, and wearable device use, highlighting the central role of access, affordability, availability, and contextual support in enabling engagement.

Motivation showed a nominally significant positive association with e-pharmacy adoption in the primary model; however, this association should be interpreted cautiously, as it was attenuated and the CI included the null when model complexity was reduced in sensitivity analyses. This pattern may potentially reflect the role of trust and perceived safety in medication-related digital transactions but requires confirmation in larger studies. In contrast, digital literacy showed an inverse association with telehealth use and was not independently associated with other technologies after adjustment, suggesting that technical competence alone is insufficient to drive adoption.

Capability was negatively associated with chatbot/virtual assistant use, indicating that individuals with higher perceived capability were less likely to engage with conversational agents. This may reflect a preference among more capable users for alternative sources of information or care.

After full adjustment, women remained significantly less likely to use chatbots and marginally less likely to use e-pharmacies, while being 2.6 times more likely to use mHealth apps. Collectively, these results indicate that structural and contextual opportunity is the most consistent determinant of engagement across digital health technologies, with patterns of adoption varying by technology type and gender (Table 3).

The primary pooled models examined overall associations between behavioral determinants and technology adoption across the full sample, adjusted for gender and sociodemographic covariates. These overall associations should be distinguished from the exploratory gender moderation analyses presented in the *Gender Moderation and Stratified Behavioral Pathways* section. All primary models included 416 complete cases and 14 predictor parameters. The numbers of events/nonevents were 385/31 for telehealth, 323/93 for mHealth app use, 329/87 for wearable device use, 308/108 for chatbot use, and 357/59 for e-pharmacy use. Simplified-model sensitivity analyses showed that the principal COM-B findings were generally directionally consistent, particularly the opportunity associations with telehealth, mHealth app, and wearable-device use and the capability association with chatbot use. For e-pharmacy use, the motivation association remained positive but was attenuated in the simplified model (aOR 1.35, 95% CI 0.98-1.87; *P*=.070) compared to the primary model (aOR 1.50, 95% CI 1.05-2.15; *P*=.026).

Gender Moderation and Stratified Behavioral Pathways

Exploratory interaction analyses suggested potential gender differences in behavioral associations, most notably for chatbot/virtual assistant use. Nominal interactions were observed for digital literacy (interaction aOR 2.10, 95% CI 1.12-3.96; *P*=.021) and capability (interaction aOR 1.83, 95% CI 1.02-3.29; *P*=.044), as shown in Table S1 in Multimedia Appendix 2. Adjusted predicted probabilities further illustrated these patterns. For capability, the adjusted predicted probability of chatbot use decreased from 92.1% at −1 SD to 70.7% at +1 SD among men and from 67.5% to 55.5% among women, suggesting a steeper decline among men. For digital literacy, the adjusted predicted probability of chatbot use decreased from 89.0% to 76.4% among men but increased from 55.8% to 64.8% among women across the same range.

Interaction estimates were directionally consistent across specifications. In simplified models retaining only the primary predictors and age, chatbot interactions were similar but more precise (digital literacy aOR 2.29, 95% CI 1.28-4.07; capability aOR 1.99, 95% CI 1.17-3.39), and the wearable capability interaction reached nominal significance (aOR 1.82, 95% CI 1.05-3.18) having been nonsignificant under full adjustment (aOR 1.63, 95% CI 0.89-2.99). These models omit education, occupation, region, and rural/remote residence and are reported only as a check on model complexity. The interaction findings are hypothesis generating.

Gender-stratified analyses provided additional descriptive evidence of potentially differing behavioral patterns. Opportunity was positively associated with mHealth app adoption in both genders. For wearable devices, opportunity was positively associated with adoption among both women and men, while higher capability was associated with lower adoption among men. For chatbot use, higher capability was associated with lower adoption among men, whereas no statistically significant association was observed among women. These stratified findings were interpreted descriptively and not as independent evidence of gender differences.

Gendered Barriers to Digital Health Technology Adoption (COM-B Mapping)

Reported barriers were consistent with the COM-B framework (Table 4). A detailed summary of self-reported barriers to digital health technology adoption by COM-B domain is provided in Multimedia Appendix 3, whereas Table 4 provides a brief overview. Motivation-related barriers, such as preference for in-person care or low perceived need, were the most commonly reported category overall, accounting for 41.5% (34/82; mHealth apps) to 69.6% (32/46; e-pharmacy) of nonuse reasons across technologies, and were the leading barriers for telehealth, chatbots/virtual assistants, and e-pharmacy. For wearable devices, opportunity-related barriers were the most frequent (n=36, 46.2%), and for mHealth apps, motivation- and capability-related barriers were equally common (n=34, 41.5% each). Capability-related barriers were otherwise less frequent, ranging from 6.5% (3/46; e-pharmacy) to 21.0% (21/100; chatbots/virtual assistants), whereas opportunity-related constraints, such as limited access, cost, and lack of availability, varied by gender and technology.

Table 4. Self-reported reasons for nonuse of digital health technologies by gender, mapped to COM-B[a] domains.

Technology	Nonusers with a codable reason, n (%)	Opportunity, n/N (%)[b]	Motivation, n/N (%)[b]	Capability, n/N (%)[b]	*P* value[c]
Telehealth	30 (96.8)	M[d]: 4/14 (28.6); F[d]: 6/16 (37.5)	M: 8/14 (57.1); F: 10/16 (62.5)	M: 2/14 (14.3); F: 0	.460
mHealth[e] app	82 (88.2)	M: 5/55 (9.1); F: 9/27 (33.3)	M: 22/55 (40.0); F: 12/27 (44.4)	M: 28/55 (50.9); F: 6/27 (22.2)	.009
Wearable device	78 (89.7)	M: 8/25 (32.0); F: 28/53 (52.8)	M: 12/25 (48.0); F: 22/53 (41.5)	M: 5/25 (20.0); F: 3/53 (5.7)	.079[f]
Chatbot/virtual assistant	100 (92.6)	M: 7/28 (25.0); F: 16/72 (22.2)	M: 14/28 (50.0); F: 42/72 (58.3)	M: 7/28 (25.0); F: 14/72 (19.4)	.755
e-Pharmacy	46 (78.0)	M: 5/16 (31.3); F: 6/30 (20.0)	M: 11/16 (68.8); F: 21/30 (70.0)	M: 0; F: 3/30 (10.0)	.464

[a]COM-B: Capability, Opportunity, Motivation – Behavior.

[b]Percentages are within-gender column percentages.

[c]Fisher's exact test.

[d]M: male; F: female.

[e]mHealth: mobile health.

[f]*P*=.05-.10 (trend). *P*<.05 indicates a statistically significant gender difference. Totals differ from nonuser counts in Table 2 because barrier analyses included only nonusers who provided a codable reason for nonuse.

Women more frequently reported opportunity-related barriers for mHealth apps, including issues of access, affordability ("too expensive"), and contextual support (eg, "never been offered"), whereas men more commonly cited capability-related barriers, including uncertainty and technical skill limitations ("not sure how to use it"). Similar, but nonsignificant, patterns were observed for wearable devices, with women emphasizing access and affordability (n=28, 52.8%), including cost ("too expensive") and lack of device ownership ("don't have a smartwatch"), and men citing technical skill limitations (20%). For telehealth, chatbots, and e-pharmacies, motivational barriers such as low perceived usefulness ("no need") and preference for in person care ("prefer human") predominated for both genders, although opportunity related constraints were also evident, particularly for chatbots ("haven't come across any") and e-pharmacies ("not offered," "haven't had the chance").

These findings suggest that structural barriers, such as cost, limited access, and lack of availability, were more prominent among women for selected technologies, most clearly mHealth apps, where the gender difference in the barrier profile was statistically significant. For mHealth apps, men more frequently reported capability-related barriers, including uncertainty and technical skill limitations. These qualitative findings complemented, but did not fully mirror, the quantitative results. In the quantitative models, higher capability was sometimes associated with a lower likelihood of use among men, particularly for chatbots and wearable devices. This divergence may reflect selective nonadoption among more confident users who perceive limited value in specific technologies. Meanwhile, the pooled quantitative models identified opportunity as an important overall correlate of adoption across several technologies. Taken together, these findings suggest technology-specific opportunity constraints rather than a consistently female-specific opportunity effect across all technologies.

Discussion

Principal Findings

This study applied the COM-B framework to examine gender differences in digital health technology adoption [33]. Although women reported higher digital literacy, capability, and motivation than men, they demonstrated lower unadjusted adoption of several technologies, particularly wearables, chatbots, and e-pharmacies. After adjustment, the most robust gender difference remained for chatbot/virtual assistant use, with a marginal difference observed for e-pharmacy use. These findings contribute to understanding the digital health gender paradox and suggest that lower engagement among women is unlikely to reflect a simple deficit in digital literacy, capability, or willingness to use these technologies. Rather, they are consistent with evidence that gendered digital health inequities may arise through system design, access, governance, and service contexts, rather than individual skill deficits alone [25,38].

The principal contribution of these findings is not simply that opportunity was an important overall predictor of adoption but also that the relationships between behavioral determinants and adoption appeared to vary according to both gender and technology type. Women's lower unadjusted use of several technologies occurred despite their higher reported digital literacy, capability, and motivation, indicating that greater perceived capacity or readiness to use digital technologies does not necessarily translate into greater engagement. Exploratory interaction and gender-stratified analyses further suggested gender-differentiated associations for selected technologies, particularly chatbot/virtual assistant use. These findings extend the digital health gender paradox by suggesting that the behavioral conditions associated with adoption may differ across gender groups, although these patterns were not uniform across

technologies and should be regarded as hypothesis generating rather than evidence of a single gender-specific mechanism.
