An important distinction arising from these findings is between the capacity to use a digital health technology and actual engagement with that technology. Digital literacy and perceived capability reflect whether an individual has, or perceives themselves to have, the skills and confidence required to engage, whereas adoption also depends on whether appropriate opportunities for use are available and whether the technology is perceived as relevant or worthwhile. In this study, higher reported digital literacy among women did not consistently translate into greater technology use. This finding aligns with emerging evidence that, although necessary, digital literacy alone is insufficient to drive adoption in the absence of supportive structural conditions [12,13,15,39]. Effective digital health technology use requires not only skills and confidence but also access to technologies, integration into care pathways, and trust in how technologies are designed and delivered. Interventions focused solely on improving digital literacy are therefore likely to have limited impact unless accompanied by strategies that address opportunity-related barriers. It is important to note though that digital literacy and perceived capability are conceptually distinct from actual engagement. Having the capacity or confidence to use a technology does not necessarily mean that it is accessible, affordable, relevant, trusted, integrated into care, or ultimately used. Infodemiological research using Baidu search data similarly illustrates how observable population-level health information-seeking behavior can reveal patterns of digital engagement that are not equivalent to self-reported knowledge, capability, or intentions [40,41]. Although these studies do not directly examine the gender paradox investigated here, they provide a complementary example of the distinction between perceived capacity and observable digital behavior.

Opportunity emerged as one of the most consistent determinants of adoption across several technologies, particularly telehealth, mHealth apps, and wearable devices, reinforcing the importance of structural and contextual factors in enabling digital health engagement. However, the gender-specific pattern was more nuanced. In the self-reported barrier data, women more frequently identified opportunity-related constraints for some technologies, most clearly for mHealth apps, including barriers relating to access, affordability, and whether digital options were available or offered. A similar pattern was observed for wearable devices, although the evidence was less certain. Men, in contrast, more frequently reported capability-related barriers for some technologies. Together with the interaction and stratified analyses, these findings suggest potentially different behavioral patterns across gender groups, while also demonstrating that these patterns depend on the specific technology being considered. The opportunity-telehealth association should be interpreted with particular caution, given the small number of telehealth nonusers (n=31) relative to model parameters, which may contribute to imprecision in this estimate.

Alternative explanations should also be considered. The technologies examined differ substantially in purpose, cost, availability, required device ownership, integration with health care services, and the degree of autonomy required from users. Gender differences in health needs, prior exposure to particular technologies, device ownership, age distribution, occupation, or patterns of health care use may therefore also contribute to the observed adoption differences. In particular, the substantial difference in occupational composition between genders, with approximately three-quarters of women in white-collar roles compared with 43% of men, may have contributed to observed adoption patterns, given that white-collar occupations may involve greater prior exposure to digital technologies; although occupation was included as a covariate in all models, residual confounding from unmeasured aspects of occupational digital exposure cannot be excluded. Although the multivariable analyses adjusted for several sociodemographic characteristics, residual confounding and unmeasured contextual factors cannot be excluded.

Unexpected Findings

After adjusting for COM-B domains, women were more likely than men to adopt mHealth apps. This pattern may indicate that women's engagement with mHealth apps becomes more evident once structural and contextual factors are considered. Given that opportunity was the strongest determinant of mHealth app adoption, the result is consistent with mobile app engagement being associated not only with individual literacy or motivation but also with contextual conditions, such as access, availability, affordability, and service integration. However, because the study was cross-sectional, changes in gender coefficients across adjusted models should not be interpreted as evidence that these factors causally explain the gender difference. This interpretation aligns with prior research showing that digital health engagement is influenced by structural, service, access, and support-related conditions, even when digital literacy is present [13,25,39].

An inverse association between capability and chatbot adoption was observed among men. This may reflect selective nonuse among digitally confident individuals who perceive limited value, reliability, or usefulness in automated health agents. Emerging evidence highlights the role of trust, perceived usefulness, and user concerns in the adoption of artificial intelligence (AI)–enabled health chatbots, including concerns about accuracy, cybersecurity, empathy, and preference for human interaction [42-44].

Motivation showed a positive association with e-pharmacy adoption in the primary model; however, this association was attenuated and the CI included the null in the simplified sensitivity model. This finding should therefore be interpreted with caution and regarded as hypothesis generating. It may potentially reflect the role of trust and perceived safety when technologies involve medication management or financial transactions, consistent with prior research showing that perceived risk, trust, privacy, price, availability, and product-related concerns influence consumers' willingness to purchase medicines online [45,46]; however, confirmation in larger, adequately powered studies is needed.

Addressing Opportunity Barriers in Digital Health Technology Adoption

The distinction between capacity and engagement has practical implications for intervention design. Where opportunity-related barriers were observed in this study, particularly barriers concerning access, affordability, availability, and the offering of digital options, strategies directed solely at increasing digital skills are unlikely to address the full range of conditions associated with nonuse. Instead, implementation approaches may also need to modify the environments in which digital health technologies are made available and offered to consumers. The BCW proposes that opportunity-related barriers can be addressed through intervention functions, such as environmental restructuring and enablement, which modify the context in which behaviors occur [33,47]. Interventions most directly aligned with barriers reported in this study could therefore include improving access to appropriate technologies, reducing financial or device-related barriers, and ensuring that suitable digital options are consistently offered within health care encounters. In the context of digital health, this may include integrating digital services into clinical workflows; proactively offering digital options during health care encounters; and reducing financial, technological, or service access barriers that limit engagement, as suggested by broader implementation literature [7,15,48]. Communication strategies may further support adoption by increasing awareness, improving acceptability, and normalizing digital health services. Patient portal implementation provides a directly relevant example. In a multi-institutional patient portal implementation, uptake was shaped not only by patient interest or capability but also by provider engagement, change management support, leadership endorsement, broad rollout and marketing strategies, technology infrastructure, and policy alignment [49]. Similarly, a systematic review of patient portal adoption found that adoption rates were substantially higher in actively recruited controlled studies than in real-world deployments, suggesting that availability alone is insufficient unless implementation creates practical opportunities for use [50]. These examples illustrate how service design and implementation can influence the practical opportunity to engage with digital services, even among individuals who may already possess the skills required to use them. These findings should also be interpreted within broader gender inequalities in digital participation. Although women increasingly achieve high levels of education and digital skills, structural disparities persist in areas such as access to technology, participation in the digital workforce, and representation in technology development. These factors may influence how digital technologies are designed, implemented, and experienced by users [21,24,51]. Evidence from Australia similarly highlights the importance of gender diversity and inclusion in the digital health workforce, particularly for ensuring that digital health innovation reflects diverse perspectives and needs [38].

Taken together, these findings suggest that digital health technology adoption should not be conceptualized solely as an issue of individual digital literacy. Rather, adoption is shaped by structural opportunity, including access to services, integration into health care pathways, and the broader social context in which digital technologies are developed and deployed. Without interventions that expand opportunity and embed digital services within routine care, digital health initiatives risk reinforcing existing gender inequities despite high levels of individual capability and motivation.

Strengths and Implications

The integration of quantitative modeling with self-reported barrier data strengthened interpretation by allowing behavioral associations identified quantitatively to be considered alongside participants' reported reasons for nonuse. The inclusion of five different digital health technologies was also valuable because it demonstrated that adoption determinants were not uniform across technology types. Digital literacy levels were relatively high within the sample, providing a useful context in which to examine why comparatively high self-reported literacy and capability did not consistently correspond with adoption. Future research should examine longitudinal adoption patterns and evaluate interventions targeting opportunity-related barriers.

Limitations

The cross-sectional study design limits causal inference and does not capture longitudinal changes in digital health technology adoption. Measures of digital literacy and technology use were self-reported and may therefore be subject to recall or social desirability bias. The study used convenience sampling through social media, consumer advocacy networks, Medibank communication channels, and research team networks; therefore, the sample may be subject to selection bias and should not be considered nationally representative of Australian adults. The binary adoption measure did not capture the frequency, duration, or intensity of technology use and may therefore represent different levels of engagement across the five technologies.

The sample was moderately skewed toward men (61.1% male), which may reflect the recruitment channels used and may limit generalizability. The high uptake observed, with 99.3% of respondents reporting use of at least one digital health technology, suggests that the sample may have included individuals with relatively high baseline engagement in digital health. This may limit the extent to which findings apply to populations with lower digital access, lower digital literacy, or less prior exposure to digital health technologies. Although this imbalance may have reduced statistical power to detect smaller gender-by-COM-B interaction effects, analyses were adjusted for key sociodemographic variables and supplemented with exploratory gender-stratified models.

Conclusion

This study provided behavioral evidence on the digital health technology adoption gender paradox, showing that women's lower unadjusted engagement with several digital health technologies occurs despite higher reported digital literacy, capability, and motivation. Using the COM-B framework, the findings suggest that behavioral determinants of adoption may vary by gender and technology type, with opportunity-related barriers, including access, affordability, and inconsistent offering of digital services, appearing particularly relevant to women's nonuse for some technologies. Some findings also suggested that men's nonuse may be more closely linked to capability-related concerns, including confidence and perceived

XSL•FO
RenderX

ease of use. These gendered behavioral patterns suggest that digital transformation initiatives focused primarily on improving digital literacy may not achieve equitable adoption. Addressing structural opportunity barriers through gender-responsive, theory-informed implementation strategies may therefore be important for supporting equitable digital health technology adoption.

Acknowledgments

The authors acknowledge the Consumer Health Forum of Australia and participating consumer organizations for their contributions to survey review and accessibility feedback during survey development. The authors also acknowledge Medibank Private Limited for supporting participant recruitment and funding the participant prize draw voucher. The authors thank all participants who took part in the survey and shared their experiences and perspectives regarding digital health technologies.

Funding Statement

This study received no external competitive funding. Medibank Private Limited provided support for participant recruitment and funded the participant prize draw.

Generative AI Use Disclosure

ChatGPT (OpenAI) was used for language editing and manuscript refinement, including improving grammar, clarity, concision, and wording during manuscript development. All artificial intelligence–assisted content was reviewed and verified by the authors, who take full responsibility for the final manuscript.

Data Availability

The datasets generated and analyzed during the study are not publicly available due to ethics and privacy restrictions associated with participant consent and de-identified survey data but are available from the corresponding author upon reasonable request and subject to ethics approval requirements. For enquiries relating to the research presented in this manuscript, please contact URK.

Conflicts of Interest

Medibank Private Limited contributed to survey development, supported participant recruitment through its communication channels, and funded the AU $50 (US $36) participant prize-draw voucher, as described in the Funding Statement section. This involvement is disclosed because of the potential for a perceived conflict of interest arising from the participation of a private health insurer in the study. Medibank's involvement was intended to facilitate recruitment and broaden the reach of this consumer-focused digital health survey through its established communication channels. Beyond these activities, Medibank Private Limited played no role in data analysis, interpretation of the findings, manuscript preparation, or the decision to submit the manuscript for publication. The authors declare no other conflicts of interest.

Abstract

Background: Older people who receive aged care services at home experience high rates of depression, anxiety, and loneliness, yet have poor access to services to support their well-being. Digital interventions are widely available, but research is required to determine whether they are acceptable to the in-home aged care population.

Objective: This study aimed to explore the perspectives of in-home aged care recipients on the use of digital technologies to support their emotional well-being.

Methods: Eleven older people (aged 70-87 years) who received in-home aged care from a national provider participated in a semistructured interview. The interview aimed to understand care recipients' experiences of using technology, as well as their current access to emotional support and attitudes toward using digital technologies to support their well-being.

Results: Participants reported high access to technology (mean 5, SD 1.6 devices) but varied usage. Most required support to use technology, typically provided by family members, and reported a range of concerns related to technology use. Participants received a variety of informal supports for their emotional well-being, typically from family members and their communities, but only one accessed professional support. Most were open to using technology to support their emotional well-being, and some were willing to receive such support from their aged care provider.

Conclusions: The willingness of older people who receive in-home aged care to use digital technologies to supplement existing informal emotional support is encouraging. Aged care providers are well placed to implement digital well-being programs and can leverage older people's existing access to digital devices but should consider their requirements for technical support. Technologies and implementation strategies should be purpose-designed for this population and address identified barriers.

Introduction

Globally, population aging has resulted in increased demand for health care and aged care services, with growing numbers of older people requiring assistance to manage increasingly complex needs [1]. Older people typically prefer to remain at home for as long as possible [2], and many countries have observed significant increases in the number accessing in-home aged care (also known as social care). For example, in Australia, the number of older people who received a government-funded Home Care Package to enable them to remain at home nearly quadrupled over the past 10 years [3].

Symptoms of depression and anxiety, and other indicators of poor emotional well-being, such as loneliness, social isolation, grief, and adjustment difficulties, affect more than half of older people who receive aged care at home [4,5] and appear to be increasing alongside other chronic health conditions, frailty, and multimorbidity [6]. Aged care providers commonly provide social support to lonely or socially isolated clients (eg, drive clients to social events or provide company in the home) and may escalate to the older person's medical practitioner for follow-up if they suspect a mental health problem. However, aged care recipients have limited access to specialist services, with recent research indicating that only 2.5% of home care recipients in Australia use government-funded mental health support [7].

With shortages in both aged care and mental health workforces [8,9], alternative approaches are required to address the growing mental health and well-being needs of aged care recipients. Older adults experience significant barriers to accessing outpatient services, especially those with impaired mobility and who live in regions where services are sparse [10]. Digital technologies offer an opportunity to deliver interventions and support at scale to reach large numbers of older people with depression, anxiety, and other aspects of poor emotional well-being who currently have poor access to support and address the current scarcity of mental health in-reach programs in the community [11].

There has been enormous growth in the development of digital mental health and well-being interventions in recent years. These interventions use a variety of technologies and can be grouped into several overlapping categories based on existing taxonomies [12]: (1) synchronous provider-delivered support, such as counseling or psychotherapy delivered by videoconference; (2) guided digital interventions, including web-based or app-based programs supported by a clinician, coach, or facilitator; (3) self-guided tools, such as mobile apps or websites for mood monitoring, psychoeducation, mindfulness, relaxation, or activity planning; (4) social connection technologies, including video calling, online peer-support groups, forums, and social media platforms; and (5) supportive or assistive technologies, such as smart speakers, reminders, and conversational agents. This typology highlights that digital support for emotional well-being extends beyond formal treatment of depression or anxiety to include technologies that foster social connectedness, meaningful activity, and day-to-day self-management in the home environment. The paper uses "emotional well-being" as an umbrella term to encompass mental health symptoms and conditions, as well as related aspects of well-being, including distress, grief, sense of purpose, and social connection. This usage is consistent with recent conceptualizations of emotional well-being as encompassing affective experience, meaning and purpose, and social connection [13].

While most technologies to support emotional well-being have been designed for younger people [14], there is promising evidence that some digital interventions (eg, online cognitive behavior therapy) are effective in reducing symptoms of depression in older people when designed specifically for this population [15], although reviewers have noted that more research is needed [16]. Digital interventions may also be effective in improving loneliness and social connection in older people [17,18]. However, there is little work exploring their use in older people who receive aged care at home.

Older people are generally open to learning to use digital devices [19], and there is an established literature on the use of digital technologies to facilitate health care by older people [20]. Research is also emerging about the views and experiences of older people in using digital technologies to support their emotional well-being, which has been synthesized in recent literature reviews [11,19]. While digital technologies offer convenience and anonymity [19], identified barriers for older people include doubts about the usefulness of digital approaches for emotional well-being, poor access to technology and low digital literacy, as well as physical, cognitive, or sensory impairments, and concerns related to privacy and security [11,19]. Older people with mental health disorders such as depression [19] appear more hesitant to use digital interventions and overall, older people may prioritize the management of other aspects of their health, such as chronic illness, pain, and medications, over mental health and emotional well-being [11]. These findings indicate it is important to consider attitudes toward the use of digital interventions within the broader context of older people's willingness to attend to mental health issues and access emotional support more generally.

There is a particular gap in research examining the use of technology to support emotional well-being among older people who require aged care services to remain at home. Aged care recipients are significantly older than the "older people" recruited to most research studies (eg, in Australia, the median age at commencement of home care services is 81 years [3]) and this population experiences high rates of multimorbidity and frailty [6], as well as other indicators of complexity, such as cognitive decline [21]. While there is growing adoption of

XSL•FO
RenderX

technology by older people generally, the oldest old and those in poor health are more likely to experience a digital divide [22]. Thus, research on use, facilitators, and barriers in relation to digital interventions for emotional well-being derived from general older adult community samples may not generalize to this group. There are indications from interviews with aged care providers that some care recipients are willing to use technology to maintain their social connections, with providers reporting strong uptake of digital communication technologies among their clients during the COVID-19 pandemic [10]. However, there is a lack of published literature on the perspectives of in-home aged care recipients themselves regarding the use of technology to support their emotional well-being.

This study had 3 aims. First, we aimed to gather information from older adults accessing in-home aged care about their experience in using digital technologies in general. Second, we aimed to explore their current access to emotional support and their views on using technology to support their emotional well-being. Finally, we aimed to understand care recipients' willingness to take up such programs when offered by the organization providing their aged care services.

Methods

Study Design and Setting

An interview study was conducted with older people receiving aged care services at home from a single provider. The service provider offers a range of aged care services, including domestic support, personal care, social support, home modifications, nursing, allied health, and transport.

Participants

Study participants were in-home aged care clients who resided in metropolitan Victoria, Australia. Clients were approached by their aged care provider if they were considered to have poor emotional well-being, such as depression or low mood, based on their professional judgment, and were potentially interested in participating in a study on how technology can improve older people's mood and emotional well-being. Participants were not required to have a diagnosis of a mental health disorder, and no mental health or well-being screening was conducted for this study. Eligibility criteria included age of 65 years or older and current receipt of a government-funded aged care service. Participants were not required to have any level of expertise in technology or digital literacy. Exclusion criteria included a diagnosis of dementia or presence of significant cognitive impairment, an acute health-related issue that could interfere with research participation, and difficulty engaging in an interview conducted in English.

Procedure

After an initial conversation with the aged care provider, if the client indicated an interest in taking part in the research, a researcher called them on the telephone, confirmed their willingness to participate, and set up a time to visit their home for the interview. The participant information sheet and consent form were mailed or emailed to all participants prior to the interview. A researcher visited the client's home, obtained written consent, and conducted the audio-recorded interview, using a semistructured interview format. Participants were given the opportunity to have a family carer present during the interview.

Materials

Demographic variables included client age, sex, living arrangement, and geographical location, which were obtained from the participant's care record prior to the home visit. Additional data were collected during the visit: level of education, marital status, and a single item on the presence or absence of a health problem that prevents the participant from doing things people their age can normally do, which was answered "Yes," "No," "Don't Know," or "Prefer Not to Disclose." A full list of demographic questions is available in Multimedia Appendix 1.

A semistructured interview was developed for the study, with interview questions exploring care recipients' existing access to and use of technology, current access to support for their emotional well-being, and their views on the use of digital technologies to improve their mood or emotional well-being, such as web-based platforms, mobile apps, or videoconferences. Questions also explored their views of emotional support being offered by their aged care provider (refer to Multimedia Appendix 1 for interview schedule).

Analysis

Demographic data were analyzed using descriptives (eg, mean, range, and frequency). Qualitative data were transcribed and coded using thematic analysis: a "method for identifying, analyzing and reporting patterns (themes) within data" to find "repeated patterns of meaning" [23]. The 6 phases of thematic analysis described by Braun and Clarke [23], namely, familiarization, generation of initial codes, searching for themes, reviewing themes, and naming themes, followed by report production, were used. No formal codebook was developed. Instead, an inductive strategy was used, which allowed the themes to arise from the data, and the phases of analysis were treated in a reciprocal manner, allowing movement back and forth between the phases. All transcripts were coded by 3 team members (DC, TDD, and HD) using Microsoft Excel. Any discrepancies were resolved through consensus during discussions. Regular discussions were held within the multidisciplinary research team to provide further insight into the themes arising from the analysis. Quotes were selected based on their ability to capture the theme accurately and articulately, ensuring that perspectives were drawn from across the participants.

Ethical Considerations

Ethical approval was granted by the Swinburne University of Technology Human Research Ethics Committee, and data were collected between October and December 2023.

Results

Participant Characteristics

Fifteen clients were nominated for the study by the aged care provider. Two did not meet eligibility criteria (one due to dementia and one due to language issues), 1 could not be

XSL•FO
RenderX

contacted, and 1 declined to participate. The final client sample included 11 aged care recipients (7 female participants and 4 male participants), who were all retired and ranged in age from 70 to 87 (mean 79, SD 5.2) years (Table 1). The sample size of 11 was determined to be sufficient as interviewers identified that saturation had been reached, with no new themes arising in the final interview, and data collection was ceased. Seven participants lived alone, while 4 lived with family members, and 7 were born in Australia. There was a range of formal education: most did not finish secondary school (n=7), but 1 participant had completed secondary schooling, 2 had completed technical or vocational training, and 1 had completed an undergraduate degree. Participants were either married (n=5), widowed (n=4), or divorced or separated (n=2). The majority were living with a health problem that prevented them from doing things people their age can normally do (n=7), but 2 answered “no” to this question, and 2 either were not sure or elected not to answer. Three clients were accompanied by a family carer in the interview, typically their spouse; however, in order to focus on the perspectives of clients themselves, only comments from the clients were included in this analysis.

XSL•FO

Table 1. Participant characteristics and technology ownership and usage.

Participant	Sex	Age (years)	Education status	Technology owned	Technology usage
1	Female	78	2 years of secondary school	Smartphone, tablet, computer, smartwatch, and internet access	• Communication (calls, SMS, WhatsApp, and Messenger), entertainment (YouTube), and social media (faith groups on Facebook)
2	Female	79	3 years of secondary school	Smartphone, tablet, computer, smart TV, and internet access	• Communication (calls and SMS), entertainment (puzzles such as Sudoku), information and tasks (plans holidays using Google), and social media (Facebook: reads only, does not post) • Limited use of smartphone
3	Male	83	Technical college	Smartphone, tablet, computer, smart TV, internet access, and electronic book (e-book) reader	• Communication (calls, SMS, email, FaceTime, and Zoom), entertainment (YouTube, Netflix, Amazon Prime, news, and reading books), and information and tasks (internet banking, postal services, maps, monitoring electricity usage, booking appointments with doctors, and managing pension)
4	Male	78	4 years of secondary school	Smartphone, tablet, smart TV, and internet access	• Communication (calls and email [can only read, not respond], video calls, and unable to use SMS), entertainment (Netflix and YouTube), information and tasks (booking appointments with doctors), and social media (Facebook but rarely posts)
5	Female	83	Vocational training	Smartphone, tablet, computer, smart TV, and internet access	• Communication (calls and FaceTime), entertainment (Foxtel, Netflix, Disney+, ABC, and Solitaire, news), and information and tasks (Google)
6	Male	73	University degree	Smartphone, tablet, computers (1 running macOS and 1 running Windows), smart TV, and internet access	• Communication (calls, SMS, WhatsApp, and email, video calls), information and tasks (online courses, Google, Calendar, and Photoshop), entertainment (YouTube, Netflix, news), and social media (Facebook and Twitter: reads only, does not post) • Has difficulty using smartphone given size of text
7	Female	70	2 years of secondary school	Smartphone, computer, smart TV, smartwatch, and internet access	• Communication (calls and SMS), entertainment (games), information and tasks (weather, calendar, Google, monitors steps and heart rate on watch, taking photos, and asks questions using Alexa or Siri), and social media (Facebook) • Unable to use laptop, email, or phone banking
8	Male	86	4 years of secondary school	Smartphone, tablet, smart TV, and internet access	• Communication (calls only), information and tasks (Google), and entertainment (Netflix and YouTube) • Has an email account but managed by daughter • Has access to social media (Facebook) but does not use it • Does not use tablet
9	Female	75	Did not complete primary school	Smartphone, tablet, computer, smart TV, and internet access	• Communication (calls, learning to use SMS, WhatsApp, and email [view only]), information and tasks (takes photos), and social media (Facebook but is limited in what she can do) • Does not use the computer in the house, and limited use of tablet
10	Female	79	2 years of secondary school	Smartphone, computer, no internet at home, and no tablet or smart TV	• Communication (calls and SMS) and information and tasks (taking and sharing photos) • Does not use laptop
11	Female	87	Finished secondary school	Smartphone, tablet, computer, smart TV, smartwatch, internet access, and smart speakers	• Communication (calls, SMS, and email), entertainment (Netflix, Disney+, listening to music on smart speakers, and news), and information and tasks (Google for health information)

XSL•FO
RenderX

Technology Ownership and Use

Results are summarized in Multimedia Appendix 2, including illustrative participant quotes.

Technology Ownership

Participants reported owning 5 different types of technology (range 2-7) on average. Eleven participants owned a smartphone, 9 owned a tablet, 9 owned a laptop or desktop computer, 9 had a smart TV, 3 had a smartwatch, 1 had a smart speaker, and 1 had an electronic book (e-book) reader. Levels of internet access were also high (91%); only 1 participant reported no internet access at home (Table 1).

Technology Use

Collectively, participants reported using technology for a range of reasons, including to access general media, such as news or current affairs programs (n=4); social media (n=7); video entertainment, such as television shows, movies, or YouTube videos (n=7); online games (n=3); and for communication purposes, for example, sending and receiving emails (n=5, though with varying capabilities), SMS text messaging (n=8), and video calls (n=5; Table 1).

Participants commonly streamed television and movies on their smart TV (n=7), but typically only after being set up by family members:

> *My daughter and son bought me a smart TV and they organized for it all to be hooked up. I wouldn't have a clue that they did, but I've watched a lot of Netflix.* [Participant 4, male, 78 years]

The social media platform Facebook (Meta Platforms, Inc) was also commonly viewed (n=7) but participants typically did not post themselves or provide comments:

> *I look at Facebook. I don't know how to get it, to get in to put anything on it...but I do look at it. Yeah, you know, what everybody's saying or looking at, you know.* [Participant 9, female, 75 years]

While 6 care recipients reported using technology to seek information from the internet, only 4 reported using technology to manage physical health issues. One person used a smartwatch to monitor steps taken and heart rate, 1 participant described searching for health advice online, and 2 reported using technologies to manage clinician appointments via app or SMS text messages.

The use of devices varied markedly between participants. Some (n=3) accessed a broad range of digital functionality across multiple devices to support their daily activities, including managing email, calendars and banking, and engaging in online forums. Within this group, 2 participants operated digital devices using a voice-activated digital assistant such as Alexa or Siri, and 1 participant used a smartwatch to take calls and messages:

> *[Smartwatch] has got everything. Yeah, it's got the lot, and you can receive messages, and I can also talk on it too. If I'm out mowing or something, you know?* [Participant 11, female, 87 years]

Remaining participants (n=8) made more limited use of the potential functionality offered by their devices. Many only used their smartphone for calls and/or SMS text messaging (n=6), and in some cases, to play simple games (n=3) or take photographs (n=3):

> *I only ring my family, my husband. He rings me. And well, I send messages to the family. That's all I use it [mobile phone] for. And if I get a photo of it, take a photo of the garden, I'll send it to them and stuff, but that's it.* [Participant 10, female, 79 years]

Several participants (n=5) described difficulty using core functions, such as email and SMS text messaging:

> *If I get an email, I don't know how to respond to it...I don't know how to send a text message, but yeah, I just, I would rather speak to somebody* [Participant 4, male, 78 years]

In addition, a small number of participants (n=4) reported they did not use at least one of the devices (smartphone, tablet, or computer) in their home at all, which in some cases (n=3) had been provided by their family members:

> *I don't even want to know how to use things on my phone. Not interested... I just say I'm just too old to start learning things.* [Participant 2, female, 79 years]

Support in Using Technology

While participants described a wide range of technology use, most participants (n=8) reported receiving at least some support to use technology, typically from a close family member. In some cases (n=3), adult children appeared to routinely take charge of tasks managed through technology. This often involved sharing sensitive or personal information, such as passwords or banking information:

> *The daughter has [my banking information] on her computer because, um, like I got...a message I guess it was saying that the registration was due on the car and so I took it around and she said "there you are, done and paid for" because she can have access to my bank account.* [Participant 4, male, 78 years]

However, one participant indicated that they only turned to family members if they could not resolve the issue themselves:

> *Oh, I'd try to [do it myself], if it was something I absolutely couldn't do...So yes, I did go to [my son-in-law] because I couldn't work out what was going on.* [Participant 11, female, 87 years]

While adult children were often seen as a primary source of information and training in using technology, in some cases (n=2), participants' continued use of technologies required ongoing support that did not eventuate, limiting participants' ability to make full use of the technologies:

> *I need to be shown more than once, that's my problem...I really just want to be able to say, "Yes, I can use the computer," yeah. And you know, years ago, the kids taught me, and I was doing bits and pieces, but now it's just got photos on it.* [Participant 7, female, 70 years]

No participants reported accessing technology support available from technology companies (eg, Apple and Microsoft) or

XSL•FO
RenderX

independent organizations that provide technology support. One participant reported receiving support available in their local community to use technology:

> *When we first moved into the village here, they had a woman come to show us different things. That lasted for about four weeks. Once a week she would come in and show us how to use our laptop, so that's good.* [Participant 5, female, 83 years]

There were, however, some participants (n=4) who were confident in using a range of devices, and described positive attitudes towards learning new technologies, and detailed technological knowledge:

> *Yes, I'm using two computers. One is Macintosh, one is Windows...because Apple doesn't have all the programs.* [Participant 6, male, 73 years]

> *It's just interesting, it's a new challenge. Something nice, new to learn, yeah.* [Participant 11, female, 87 years]

Barriers to Technology Use

Despite technology being common in their homes, participants reported a range of barriers to technology use. Approximately half the participants (n=5) expressed concerns around privacy and scams. For example, this participant discussed low trust in using their smartphone and the high volume of spam calls they were experiencing:

> *Trusting...no! It's no secret anyone can get our data...at least this is the nuisance from our telephone, coming about at least six or seven calls coming or spam, that is a headache.* [Participant 6, male, 73 years]

Cost was identified as a barrier to use of some technologies for 2 participants. One participant on an aged pension described having to choose between having internet access at home and other priorities, leaving them without core technological infrastructure:

> *I can't afford to live and save up a bit of money to go on a holiday and have those sort of things [internet access], as well on an age pension.* [Participant 10, female, 79 years]

Other participants (n=2) raised concerns about breaking the technology or engaging with it in a way that could cause a negative outcome, which limited the technologies they chose to use and how they used them:

> *I will never do phone banking [on an app], okay? Because I'm worried that I might press the wrong button.* [Participant 7, female, 70 years]

> *If I have to learn something new...I just panic if I'm gonna do the wrong thing, you know? And I think and then I'm going to be in big trouble...And that's my fear of it, you know.* [Participant 9, female, 75 years]

Several participants (n=3) reported the need to make minor modifications to their devices, such as increasing font size, to reduce usability barriers:

> *Yes (I use it) but I don't like the phone because it's too small. I can't read and every, every time I have to make [the font] bigger, bigger and read, so it's big.* [Participant 6, male, 73 years]

Support for Emotional Well-Being

Results are summarized in Multimedia Appendix 2, including illustrative participant quotes.

Current Sources of Support

Participants were asked to describe any sources of support they engaged in for their emotional well-being. Only 1 participant reported not receiving emotional support from any source. Seven of the 11 participants reported they received emotional support from family members (in particular, their daughter), which was most commonly provided in person or over the phone:

> *My daughter rings every day. She's just rung about half an hour ago.* [Participant 5, female, 83 years]

> *You just get lonely by yourself. And we just sort of support each other that way, you know...I've got 4 kids. I know I've always got them. But if I've got something on my mind, I'll sort of talk it over with [my daughter], you know?* [Participant 2, female, 79 years]

Six participants reported receiving emotional support from their broader community, although the nature of this support differed, including informal support from friends and neighbors and formal support from a community center. For example, this participant described receiving support from others in their retirement village who had experience with grief:

> *A lot of people in the village here have all that [grief]...all gone through it, and we talk a lot to people there, about [grief and loss]* [Participant 3, male, 83 years]

In contrast, only 1 participant reported receiving current professional support for their emotional well-being, which was organized by her general practitioner (GP). Another participant had also accessed a counselor but several years ago:

> *I've got another 4 visits, but it's up to the doctor, I think to ask for more if I need it. As soon as I mentioned it, he was straight on [organized a referral]. I had [a phone call] the next day.* [Participant 7, female, 70 years]

> *I used to [be depressed], but not anymore...oh, going back how many years? 1995. So, it's been a lot of years and I, I spoke to a counselor and that and yeah, I'm fine.* [Participant 10, female, 79 years]

Barriers to Seeking Support

Remaining participants gave reasons for not seeking professional help. This was commonly expressed in terms of not wanting "to be a burden on anybody" (Participant 4, male, 78 years) or preferring to discuss personal details with their family:

> *I like to talk about myself with my family members, not others.* [Participant 6, male, 73 years]

XSL•FO
RenderX

One participant described difficulty accessing the support he wanted, citing issues with waiting times as a critical reason for discontinuing his search for support:

> *I must admit everything seems to just take so long, and, and you get to the point where you just say "Oh, forget it!" And you don't carry on with it.* [Participant 8, male, 86 years]

Willingness to Engage in Support

Participants were asked if they would be willing to engage in professional help to support their well-being in the future, if available. The majority (n=10) indicated they were open to receiving support for their emotional well-being. However, participants commonly expressed initial reticence before identifying circumstances in which support could be useful:

> *No, I say no...But you never know because a friend of mine committed suicide. So, I say, you know, at the moment, no, I wouldn't use it, but you never know, I mean, probably it's a shame that he didn't speak to somebody...Well, maybe, yeah, maybe in time. Yeah, I would say maybe probably once I give up driving. I think then yes maybe.* [Participant 4, male, 78 years]

> *There are times when you feel that you would probably like to talk to someone else, other than family...It's never struck me as being absolutely necessary, but I think there are times when it'd be nice if it was there.* [Participant 8, male, 86 years]

While the majority (n=10) spoke about support in terms of speaking with a professional, 1 participant noted a preference for peer support for their emotional well-being:

> *I think it'd be the fact that I can talk to somebody else, a stranger who doesn't know the history, but has maybe gone through something like that themselves, or knows of somebody. Umm, but just to get some feedback.* [Participant 7, female, 70 years]

Only 1 participant stated they would not consider engaging in professional emotional support:

> *No, no. Strangers. They'd be strangers. People I didn't know that would be talking, probably from rote. No, no, it wouldn't, wouldn't mean a thing to me.* [Participant 11, female, 87 years]

Use of Digital Technologies to Support Emotional Well-Being

Results are summarized in Multimedia Appendix 2, including illustrative participant quotes.

Current Use of Technology to Support Emotional Well-Being

Participants were asked to share their current experiences using technology to support or enhance their well-being. Seven participants reported diverse experiences, including engaging with music, hobbies such as games, quizzes, or reading, and remote religious support:

> *[I] read a lot, I've got a little Kindle [eReader], and I sit at the computer for half an hour and just see what's happening in the world.* [Participant 3, male, 83 years]

> *On my phone, I have apps that I can go to and bring up a message from [church group].* [Participant 1, female, 78 years]

Barriers to Accessing Digital Emotional Well-Being Support

Participants identified several barriers to use of emotional support delivered online, including barriers to using technology in general, such as poor motivation to engage online and difficulties with hearing, vision, or compromised physical ability:

> *If you ask me if I want online or face to face, I will definitely say face to face ... online, it will be there in my computer, I may not open it...it is easy to put things off if they are online.* [Participant 6, male, 73 years]

> *...with the arthritis, now I don't have the strength in my hand...I use the left hand just to press the buttons.* [Participant 4, male, 78 years]

Two participants shared a perspective that they would require training and assistance to successfully access online emotional support:

> *If there was an app that I could put on my phone, then I probably would use it, as long as I knew how to use it. And if I can take it in, but then I need to be shown more than once. That's my problem. Yeah, it's learning how to use the damn thing.* [Participant 7, female, 70 years]

> *It would need a lot of teaching. I would need a lot of support from my son and my daughter.* [Participant 4, male, 78 years]

Factors such as relevance, trust, and credibility were also identified by participants as being important for uptake in this cohort:

> *It has to have a purpose that can be seen and understood.* [Participant 4, male, age 78]

> *Yeah, has to be trust around it. So I don't. I don't know whether the government can do that ... evaluate those things [digital tools] and give a tick* [Participant 6, male, 73 years]

Support Preferences

Participants were also asked their views on receiving online emotional support. The majority (n=7) of participants expressed a preference for face-to-face support, which was seen as "more personal" (Participant 6, male, 73 years). Despite this, many (n=6) were open to videoconferencing and other digital approaches. Participants expressed that digital approaches could make it easier to access someone to talk to when needed and could also help by providing them with guidance in managing their well-being:

> *Actually, it's very good, very good, because patients like us need some help...I can walk and I can do some things, but there are some people that can't do*

XSL•FO
RenderX

> *anything, so it's better. It's better to have [digital] services...Definitely convenient to people.* [Participant 6, male, 73 years]
>
> *...To get some ideas of what I can do... to use it and talk to someone, I suppose.* [Participant 5, female, 83 years]
>
> *Well, I guess for people, if they're feeling a bit down and that...yeah, that they can, you know, look at or to support them. I mean there must be a lot of lonely people out in the world.* [Participant 4, male, 78 years]

Online emotional support was also seen as potentially appealing to people who were uncomfortable with face-to-face support, as some "don't like face-to-face" [Participant 3, male, 83 years]. Perceived benefits of digital approaches included providing a sense of anonymity and making it easier to establish rapport or access relevant lived or professional experience:

> *Maybe if it was online and I don't see who it is, maybe you could express yourself better. Sometimes I can see people I don't like. I don't feel comfortable with them... you're not going to express yourself if you don't feel comfortable with somebody.* [Participant 2, female, 79 years]

There were mixed views on accessing virtual emotional support provided through their aged care provider, whether using online programs or apps or support via telehealth. Four participants responded they would welcome this, while 5 reported they might be open to receiving this support from their provider:

> *Yeah, definitely. I will use it if I get some service from [aged care provider] or from somebody else I will use it...definitely, I will use it.* [Participant 6, male, 73 years]
>
> *If you can just say "I feel depressed," I can log into [service provider] and say, "I'm a bit down. Can I talk to somebody about something?"* [Participant 3, male, 83 years]

In contrast, 2 care recipients responded negatively to this proposal, with one person perceiving their care provider as providing physical support only, while the other did not welcome emotional support that was provided outside of their family.

Discussion

Principal Findings

This study extends existing literature on the use of digital technologies in later life by focusing on a clinically complex population that has been largely overlooked by researchers but is growing rapidly. Aged in their 70s and 80s, this in-home aged care sample was considerably older than participants in much of the research previously published on this topic, with many researchers defining "older adults" as young as aged 50 or 55 years plus [19,24-26]. Participants in this study generally had limited postschool education, and most reported they were unable to do things others their age could do. Previous research has demonstrated that advanced older age [27-30], poorer health [29,30], and physical disability [28]—all of which are ubiquitous in the home care setting—have a negative impact on use of technology in daily life.

Our findings indicated that while participants generally had good access to digital devices and internet at home, access did not equate to independent or confident use. Technology use varied considerably: some participants used multiple devices for a broad range of activities and functions throughout their daily lives, while others used devices only for basic communication or were unable to use available devices or functions without support. Aged care providers should routinely assess not only device access, but also digital confidence, skills, support needs, and the availability of informal assistance, before introducing digital tools into care.

Most participants used their devices for communication, entertainment, social media, or to access information, while only a minority described using technology to manage their physical health, for example, to monitor their health or to seek health-related information. Participants did not use purpose-designed digital mental health or well-being tools and appeared largely unaware of them, despite their widespread availability in the general population [31]. However, many used technology for hobbies, social connection, music, reading, games, and religious content, which may indirectly support well-being [24]. This suggests that digital well-being tools may be more acceptable if embedded into familiar activities and existing care interactions, rather than presented as stand-alone programs. Aged care providers could address the gap in awareness by recommending apps aligned with their clients' interests that have a strong evidence base, and by incorporating brief digital check-ins via telehealth.

Despite being identified by their aged care provider as likely experiencing poor emotional well-being, only 1 participant was receiving current professional support, although another had previously received counseling, and a further participant had attempted to access support. Most participants were open to receiving professional support, particularly when framed around having someone to talk to, rather than as mental health treatment. This aligns with previous research describing the reticence of in-home aged care recipients to seek mental health care [32] while also suggesting that many accept formal support at key points in their lives if presented in a nonstigmatizing and personally relevant way. Service providers should frame supportive services in terms of helping the person maintain their well-being, engage in valued activities and interests, or implement lifestyle changes.

Most participants expressed a preference for face-to-face or hybrid emotional support rather than fully online, consistent with previous research [19,32]. However, several were open to using telehealth to access mental health specialists, counselors, or people with lived experience, and identified convenience and anonymity, which are important enablers for digital mental health interventions [19]. Participants also recognized the potential for telehealth approaches to address barriers to accessing care, such as limited mobility. Their perceptions may have been shaped by strong current reliance on informal sources of emotional support. Ready access to family or community support may reduce perceived need for digital alternatives and

XSL•FO
RenderX

reinforce preferences for personal, face-to-face interactions. This may help explain participants' preference for in-person support, alongside their openness to digital tools when positioned as complementary to, rather than replacing, existing support networks.

Digital emotional well-being approaches must account for both general barriers to accessing mental health support, such as negative attitudes, low awareness, availability, and accessibility of services [21], as well as digital-specific barriers. In this study, participants identified challenges related to sensory impairments, reduced physical dexterity, low confidence, privacy and scam concerns, and the need for repeated practical instruction. These findings are consistent with previous research showing that older people may require accessible, reliable, and easy-to-use technologies, supported by clear instructions [11,19]. The current findings indicate that training for home care recipients should be ongoing, rather than one-off, with opportunities for repetition and practical demonstration. Approaches such as in-home coaching, simple step-by-step guides, and embedding support within routine care interactions may help to build confidence and sustain engagement over time.

Trusted health care providers may be well placed to introduce suitable digital well-being tools, either by sharing information about available options or embedding selected tools into service delivery [19,26]. Some participants were enthusiastic about the potential to receive emotional support from their aged care provider, while the majority indicated they might be willing to consider this approach, consistent with other recent research [32]. Future research should identify which types of digital supports are most acceptable and feasible in home-based aged care. While many digital mental health offerings focus on managing symptoms of depression and anxiety, in these interviews, care recipients described a broad range of activities that they saw as helpful for their emotional well-being, which offers the possibility of extending the types of interventions for greater engagement and uptake.

Implementation should address older people's concerns about making a mistake or damaging technology, privacy, scams, and the credibility of digital tools, all of which may impact their willingness to engage [10,11,20,26]. Most participants in this study required at least some support in using digital technologies at home, typically provided by their adult children. While some only sought assistance after attempting to resolve technology problems independently, family members routinely completed digital tasks on behalf of other older people. Although family support may often be appropriate during implementation [11,33], reliance on family alone may reinforce dependence and limit autonomy. Encouragingly, even among care recipients who reported poor skills in using technology, many were willing to learn, consistent with previous research [33]. Proactive, no-cost support is likely important for successful implementation, given this sample's poor uptake of existing technological support services available in the community and previous reports of limited use of technology helpdesks [34]. Roles such as digital navigators, technology mediation workers or facilitators within aged care services could support older people's adoption and use of technology [25,26]. Policymakers should ensure that aged care funding enables older people to access not only apps, devices, and internet services where required, but also the practical support needed to use them. Greater coordination between aged care providers, health services, and community organizations (eg, community-based digital literacy programs) may also help ensure older adults can access consistent and trusted sources of assistance.

The findings can be understood through the lens of the Unified Theory of Acceptance and Use of Technology (UTAUT) [35], which proposes that uptake is shaped by performance expectancy (perceived usefulness), effort expectancy (perceived ease of use), social influence, and facilitating conditions. Participants' emphasis on technologies needing a clear and meaningful purpose aligns with performance expectancy, with care recipients being more open to using digital tools when they could see how these would support their daily lives or well-being, or help them engage in valued activities. However, low confidence, fear of making mistakes, and the need for repeated instruction reflect low effort expectancy, highlighting perceived complexity as a key barrier.

Social influence played a central role in shaping technology use, with family members, particularly adult children, playing a central role in introducing and supporting technology use, although in some cases they completed digital tasks on behalf of participants. Technology adoption in this population is not solely an individual process but is strongly embedded within social relationships, which may both facilitate and inadvertently limit independent use. Facilitating conditions were often limited, with most participants relying primarily on informal support networks and reporting limited engagement with structured sources of technological assistance for training and ongoing assistance.

Collectively, applying UTAUT highlights that limited uptake of digital technologies to support emotional well-being in home-based aged care is not primarily driven by lack of interest, but by a combination of modifiable factors related to usability, support, and perceived value, as well as lack of awareness of relevant tools. Technology adoption in this population is strongly shaped by reliance on informal carers and the need for ongoing, hands-on support, rather than access alone. Even when interest is high, low effort expectancy and limited support can constrain engagement. Together, this suggests that improving uptake of digital well-being interventions in this population will require not only demonstrating value but also reducing complexity and embedding sustained support within service models. This study extends existing literature on UTAUT by demonstrating how these constructs operate in a clinically complex, home-based aged care population, where reliance on informal carers and physical limitations may amplify effort expectations and limited access to resources.

Limitations

While this is the first in-depth exploration of the views of in-home aged care recipients in using technology to support their emotional well-being, there are several limitations of this study, most notably the small size of the sample and the potential for sampling bias; those with very low interest in using technology and those uncomfortable discussing emotional well-being may have chosen not to participate in the study. In

XSL•FO
RenderX

addition, the study recruited participants considered by their care workers to have poor emotional well-being, given the broad focus of the research. Some of the participants may have experienced symptoms of depression, anxiety, or other mental health conditions, but their mental health status was not formally assessed, and different results may have been obtained with a sample with confirmed mental health conditions. It is also possible, given the absence of formal criteria provided to referring staff, that some participants did not experience poor emotional well-being at the time of the interview; however, all participants referred to either current or previous periods where they struggled with low mood or aspects of poor well-being during interviews. Aged care recipients from regional or rural areas, those who were non–English-speaking, and those with significant cognitive impairment were not included in this study; additional research is required to understand the perspectives of these populations. Similarly, the research was conducted with recipients of a single aged care provider, and the results may not generalize to the broader population of older people who receive aged care at home. Three participants had a family carer present during their interview, which may have influenced how they responded to interview questions. Finally, the interviews were conducted from October to December 2023 and explored technologies readily available at that time. Novel AI-based tools to support emotional well-being, such as chatbots, were not discussed in interviews. With technology evolving rapidly, research findings should be updated regularly.

Conclusions

Despite the limitations, this study highlights an openness to both formal and informal support for well-being among in-home aged care recipients. Digital technologies could play an important role in supporting a population facing increasing mental health rates [36] and poor access to professional mental health services [7]. As well as increasing access to support, digital technologies have the potential to allow older people to self-manage their well-being. However, our findings suggest that access to everyday digital devices does not necessarily translate into awareness or use of purpose-designed digital well-being tools among frail and clinically complex older people living at home. Aged care providers could play a valuable role in introducing suitable programs to older people, leveraging established trusting relationships and should consider integrating digital tools into existing service delivery to support their clients' well-being [11].

When considering digital initiatives, aged care providers should prioritize those that can be delivered using the devices older people already access in their homes, particularly smartphones, tablets, and smart TVs. Importantly, many care recipients will require significant and ongoing technology training and support in using new technologies, even those accessed via their existing devices, which requires appropriate resourcing [11]. This study identified several barriers that should be addressed throughout implementation and highlighted the need for a highly tailored implementation approach, given the heterogeneity in care recipients' digital literacy and experience using technology—one size will not fit all. The routine use of brief assessments of care recipients' technological readiness has been proposed previously for the aged setting [10]. It may also be beneficial to provide education to aged care workers [10], some of whom may hold negative perceptions about the use of technology in aged care [11,25] and may themselves have low digital readiness [10,11,37], which could impact their willingness to offer these solutions.

Acknowledgments

The authors would like to thank those who participated in this research and the aged care workers who assisted with recruitment.

Funding

This research was funded by Aged Care Research and Industry Innovation Australia (ARIIA). The funder did not take part in planning, conducting, or reporting this research.

Data Availability

The qualitative data generated and analyzed during this study are not publicly available because participants did not consent to the sharing of their interview data. Relevant supporting information is provided within the article and multimedia appendices.

Generative AI Use

The original version of the manuscript was written without the use of AI. During manuscript revision, the authors used Microsoft Copilot to assist with language editing and improve clarity. The authors reviewed and approved all suggested changes and take full responsibility for the accuracy, originality, and integrity of all content in the manuscript.

Abstract

Background: Administrative workload in general practice limits time for direct patient care. AI-assisted documentation has been proposed as a way to reduce the documentation burden, but evidence from routine primary care settings remains limited.

Objective: This study aimed to evaluate general practitioners' (GPs) acceptance of AI-assisted documentation and its association with documentation time and clinical note quality in routine Danish general practice.

Methods: We conducted a quantitative pragmatic pre-post quality improvement evaluation in Danish general practice. A total of 20 GPs documented 239 consultations before and 236 consultations after implementation of an AI-assisted documentation system. Documentation quality, structure, clinical clarity, and documentation time categories were self-assessed using standardized audit forms completed immediately after each consultation. Technology acceptance and usability were assessed using the technology acceptance model (TAM) and the System Usability Scale (SUS).

Results: Self-assessed documentation structure increased from 3.99 to 4.45, while self-reported documentation time categories decreased from 2.85 to 2.29. Technology acceptance and usability were high (TAM domain means 3.76-4.19; SUS mean 77.5). GP-level paired analyses showed moderate improvements in structure and clarity and a reduction in documentation time. Combined blinded external assessments showed higher postimplementation scores for quality, structure, and clinical clarity, although reviewer-specific ratings diverged, and interrater reliability was low. The association between documentation time and perceived quality was negligible. TAM and SUS indicated high clinician acceptance.

Conclusions: AI-assisted documentation was associated with lower self-reported documentation time categories while maintaining or modestly improving perceived clinical note quality. These findings support the feasibility of AI-assisted documentation in primary care, while highlighting the need for controlled studies with objective time measurement and longer follow-up.

Introduction

Administrative workload in general practice has increasingly constrained the time available for direct patient care and continuity of clinical interaction [1,2]. A substantial proportion of this burden relates to documentation and maintenance of electronic health records (EHRs), which often compete with patient-facing time and contribute to clinician workload and dissatisfaction [3]. In response, digital health innovations aimed at supporting documentation processes have received growing attention.

Recent advances in AI have enabled the development of so-called "ambient" or AI-assisted documentation systems that capture clinician-patient dialogue, generate real-time transcripts, and produce draft clinical notes for clinician review and approval [4-6]. These systems are designed to support clinical documentation by generating draft clinical notes for clinician review and approval rather than functioning as autonomous documentation systems. The clinician retains full responsibility

XSL•FO
RenderX

for reviewing, editing, and approving the final clinical note. International studies suggest that AI-assisted documentation may reduce perceived documentation burden and support workflow efficiency without compromising documentation quality [1,4,5,7]. However, the existing evidence base is heterogeneous, and many studies are conducted in selected settings or under experimental conditions.

Implementation of AI-based documentation in general practice raises specific considerations related to trust, usability, data protection, and professional accountability. In European primary care settings, compliance with the General Data Protection Regulation (GDPR), transparency of data handling, and clinician control over documentation are central prerequisites for adoption [8,9]. Qualitative studies indicate that general practitioners (GPs) perceive both opportunities and reservations regarding AI-supported documentation, emphasizing the importance of usability, reliability, and a clear "human-in-the-loop" workflow [9,10].

Despite growing interest, evidence from routine primary care workflows remains limited, particularly from Scandinavian general practice. Moreover, few studies have examined whether clinicians' self-assessments of AI-assisted documentation quality correspond with independent professional evaluations. External blinded assessment of documentation quality is rarely included in implementation studies, yet such evaluation is relevant to address concerns regarding potential bias in self-reported outcomes.

The aim of the present study was therefore to evaluate the feasibility of implementing an AI-assisted documentation system in routine Danish general practice. Specifically, we aimed to assess (1) GPs' acceptance and perceived usability of the system; (2) perceived changes in documentation time; and (3) changes in clinical note quality, structure, and clinical clarity. To strengthen the evaluation beyond self-assessment alone, we additionally compared GPs' ratings of documentation quality with blinded assessments performed by independent physicians. By combining clinician-reported outcomes with external evaluation under real-world conditions, this study aimed to contribute pragmatic evidence on the role of AI-assisted documentation in everyday primary care practice.

Methods

Study Design and Setting

We conducted a quantitative pragmatic pre-post quality improvement evaluation of the implementation of an AI-assisted clinical documentation system in routine Danish general practice. The primary objective was to evaluate clinician acceptance, perceived usability, and integration of the system into routine clinical workflows rather than patient-level clinical outcomes. The study was carried out within a regional primary care quality cluster ("klynge" in Danish) comprising 7 GP clinics and 20 participating GPs. The cluster had been an established structure for several years before the study and was not formed specifically for this project. It was based on administrative and geographic criteria and was not established based on interest in digital health or information technology, thereby reflecting a routine primary care setting. Participation was voluntary and offered to all GPs within the quality cluster. The participating practices included both solo and partnership practices, but formal measures of practice characteristics, patient population, and digital maturity were not collected. Data collection was conducted between October 2025 and November 2025.

Selection of the AI-Assisted Documentation System

Prior to study initiation, several AI-assisted documentation systems available for Danish general practice were informally explored by the project group with regard to usability and fit with routine clinical workflows. This was a pragmatic local assessment rather than a formal comparative evaluation or procurement process. Noteless (Noteless AS) was selected pragmatically by the project group based on perceived suitability for implementation in routine Danish general practice and its availability for use within the participating quality improvement initiative. The selection was not based on a formal comparative evaluation of available AI-assisted documentation systems. Consequently, the findings should be interpreted as specific to this system, version, and implementation context and may not be directly transferable to other AI-assisted documentation systems.

Participants and Consultations

Participating GPs were instructed to document up to 12 consecutive in-person consultations before implementation of the AI-assisted documentation system. Following system installation, a 2-week familiarization period was allowed to enable integration into routine clinical workflows. After this period, GPs documented up to 12 consecutive in-person consultations using the AI-assisted system.

During both periods, GPs aimed to document 12 consecutive in-person consultations in each period; consultations could be excluded at the GP's discretion if deemed unsuitable, and inclusion continued until 12 eligible consultations were reached when feasible. Documentation time categories and note quality ratings were completed by the participating GP immediately after each documented consultation. No restrictions were placed on patient characteristics or consultation type within these in-person consultations, and participating GPs were encouraged to use the AI-assisted documentation system whenever they considered it appropriate within routine clinical practice. Due to pragmatic clinical conditions, incomplete registrations, and missing ratings, the number of evaluable notes varied between GPs. Only notes with complete outcome ratings were included. GP-level analyses were therefore based on the mean of available preimplementation and postimplementation notes for each GP. This pragmatic approach was chosen to minimize disruption to routine clinical workflows and reduce the additional documentation burden associated with study participation. Consequently, participating GPs were not required to document reasons for excluding individual consultations.

Intervention: AI-Assisted Documentation Workflow

The intervention consisted of using the AI-assisted documentation system Noteless during routine in-person consultations. Immediately before each eligible consultation, the GP initiated a secure personal web browser session and

XSL•FO
RenderX

activated real-time transcription. The system captured clinician-patient dialogue to generate a draft clinical note at the end of the consultation. The GP then reviewed and edited the AI-generated draft before final approval and storage in the EHR. The AI-assisted documentation system operated as a web-based application and was not directly integrated with the participating practices' EHR systems. After reviewing and editing the AI-generated draft, the GP manually transferred the final note into the local EHR by copying and pasting. The specific EHR systems used by the participating practices were not recorded.

Audio capture was used solely to enable real-time transcription and draft note generation. Complete audio recordings were not retained. According to the implemented workflow, audio data were deleted immediately, while transcription outputs and generated draft notes were temporarily retained within a European Union (EU)–based cloud environment for up to 24 hours to allow clinician review and editing, after which they were deleted. These transcription outputs and draft notes were not accessible to the vendor after deletion and were not used for AI model training. Evaluation data were not made accessible to the vendor, and clinical notes used for external assessment were deidentified before sharing.

Data Collection and Outcomes

Data were collected using structured audit forms completed by participating GPs, along with the technology acceptance model (TAM) questionnaire and the System Usability Scale (SUS).

Primary Outcomes (Pre-Post)

The following 4 outcomes were assessed both before and after implementation using structured audit forms: overall satisfaction with the quality of the clinical note, whether the clinical note was well structured, whether another health care provider could understand the patient's clinical course based on the note, and documentation time. The first 3 outcomes were rated on 5-point Likert scales, with higher scores indicating more favorable assessments. Documentation time was recorded using 5 ordinal categories (<1 minute, 1 minute, 2-3 minutes, 4-5 minutes, and >5 minutes) and coded from 1 to 5, with lower values indicating shorter documentation time.

All primary outcomes were self-assessed by participating GPs for each documented consultation.

Postimplementation Additional Outcome

After implementation, GPs additionally rated the perceived impact on time available for direct patient care using a 5-point Likert scale. As no corresponding preimplementation measure was available, this outcome was analyzed descriptively only.

Technology Acceptance and Usability

Technology acceptance was assessed using a modified TAM questionnaire comprising 12 items covering 4 domains: perceived usefulness (4 items), perceived ease of use (4 items), attitude toward use (2 items), and behavioral intention to use (2 items). All TAM items were rated on a 5-point Likert scale ranging from strongly disagree to strongly agree. The TAM questionnaire was translated into Danish by 1 of the investigators for use in this quality improvement project and did not constitute a formally validated Danish version. System usability was assessed using the standard 10-item SUS, also using a 5-point Likert response scale. Participants completed the original English SUS questionnaire, while a Danish translation was provided solely as a reference to support comprehension if needed. The questionnaire explicitly instructed participants to answer the original English items and to consult the Danish translation only if they were uncertain about the meaning of the English wording. SUS responses were converted to a total score ranging from 0 to 100, with higher scores indicating better perceived usability.

Blinded External Assessment of Clinical Notes

To reduce potential self-assessment bias, all preimplementation and postimplementation clinical notes were deidentified and randomly ordered. Patient-identifying information was manually removed before the notes were assigned unique study ID numbers. The deidentified notes were then randomly ordered and compiled into PDF documents for independent review. The reviewers did not access the Noteless system or the EHR. Following completion of the assessments, the study ID numbers were used to restore the original allocation for analysis. Two independent physicians (1 GP and 1 hospital-based rheumatologist), not involved in the project and without prior experience using the AI system, independently evaluated each note while blinded to implementation status. The hospital-based rheumatologist was selected because of extensive clinical experience with referrals from general practice to both hospital and rehabilitation services, providing substantial familiarity with documentation from primary care despite not working in general practice.

External reviewers rated the final clinical notes after GP review, editing, and approval, corresponding to the version stored in the EHR rather than the initial AI-generated draft. Clinical note quality, structure, and clinical clarity were rated using the same 5-point Likert scales as those used by the participating GPs. Each note was evaluated independently by both reviewers. The extent of GP editing of the AI-generated drafts was not quantified.

Statistical Analysis

Analyses were conducted at the GP level to avoid inflation of precision due to multiple notes per clinician. For each GP, mean scores were calculated across all available preimplementation notes and all postimplementation notes for each outcome.

The primary analyses used 2-tailed paired *t* tests on GP-level mean differences. Although the underlying variables were measured on ordinal Likert scales, averaging approximately 12 observations per GP resulted in approximately continuous GP-level outcomes. Inspection of the paired differences showed no evidence of marked skewness or influential outliers. Therefore, 2-tailed paired *t* tests were considered appropriate. Wilcoxon signed-rank tests were additionally performed as sensitivity analyses and yielded consistent conclusions.

Given the exploratory nature of the evaluation, *P* values were interpreted descriptively and presented alongside mean differences, 95% CIs, and paired-samples Cohen d_z, calculated as the mean paired change divided by the SD of the paired changes.

XSL•FO
RenderX

For blinded external assessment, mean preimplementation and postimplementation scores were calculated by averaging ratings across both reviewers prior to GP-level aggregation. Interrater reliability between the 2 blinded reviewers was assessed using intraclass correlation coefficients (ICCs; using a 2-way random-effects model with absolute agreement).

Ethical Considerations

The project was conducted as a pragmatic pre-post quality improvement evaluation within routine clinical practice. According to Danish regulation, the project was classified as a quality improvement initiative and therefore did not require approval from a regional research ethics committee. A data protection impact assessment (DPIA) and a data processing agreement were completed before implementation. All data were handled in accordance with Danish data protection regulations and the GDPR.

Prior to participation, patients received information about the AI-assisted documentation system through information screens in the waiting area, written information available in the consultation room, and verbal information provided by the GP. Patients were given the opportunity to ask questions and decline the use of Noteless before the consultation. Patients verbally consented to participation prior to the consultation. Participation could be declined without any consequences for care. Consultation data were contractually prohibited from being used for AI model training. No identifiable patient information was stored in the study dataset or shared for external assessment.

Results

Study Sample and Data Completeness

A total of 20 GPs from 7 general practice clinics participated in the study. Due to incomplete registrations or inconclusive outcome ratings, not all GPs contributed the intended 12 notes in both periods. In total, 475 clinical notes were included in the analysis (preimplementation notes: n=239; postimplementation notes: n=236). One preimplementation note and 2 postimplementation notes were missing because 2 GPs did not reach 12 documented consultations, and 2 postimplementation notes were excluded due to incomplete or inconclusive ratings. The median number of evaluable notes per GP was 12 (IQR 12-12) both before and after the implementation. Analyses were therefore conducted at the GP level using available data.

All participating GPs contributed to the self-assessment analyses. All included notes were available for blinded external assessment by 2 independent physicians.

Self-Assessed Documentation Quality and Time Use

Descriptive self-assessed documentation scores before and after implementation of AI-assisted documentation are summarized in Table 1.

Table . Mean self-assessed and blinded documentation scores before and after implementation of AI-assisted documentation[a].

Outcomes	Self-assessed documentation, mean (SD)		Blinded documentation, mean (SD)	
	Preintervention score	Postintervention score	Preintervention score	Postintervention score
Quality	4.02 (0.44)	4.05 (0.59)	4.29 (0.40)	4.53 (0.20)
Structure	3.99 (0.49)	4.45 (0.57)	4.30 (0.37)	4.60 (0.18)
Clinical clarity	4.10 (0.46)	4.42 (0.57)	4.42 (0.39)	4.73 (0.19)
Documentation time category	2.85 (0.46)	2.29 (0.68)	—[b]	—

[a]Values are presented as mean (SD) based on general practitioner (GP)–level mean scores from 20 participating GPs. Quality, structure, and clinical clarity were rated on 5-point Likert scales (1="lowest" to 5="highest"). Documentation time was recorded using 5 ordinal categories (1="<1 minute" to 5=">5 minutes"). Self-assessments were completed by participating GPs; blinded assessments were performed by 2 independent physicians.

[b]Em dashes indicate that documentation time category was not assessed in the blinded external assessment.

At a descriptive level, mean self-assessed overall documentation quality showed minimal change after implementation, whereas structural quality and clinical clarity increased. The documentation time category decreased, indicating shorter self-reported documentation time following AI-assisted note generation.

GP-level paired analyses are presented in Table 2. Structural quality was higher after implementation, with a mean increase of 0.45 points (95% CI 0.05-0.84; Cohen d_z=0.50). Clinical clarity also appeared higher after implementation, with a mean increase of 0.31 points (95% CI −0.01 to 0.62; Cohen d_z=0.45). No statistically significant change was observed for overall self-assessed quality.

Self-assessed documentation time category was lower after implementation at the GP level (mean change −0.55; 95% CI −0.94 to −0.16; Cohen d_z=−0.61). A mean change of −0.55 categories corresponded approximately to a shift of half a category toward shorter documentation times at the GP level.

Sensitivity analyses using the Wilcoxon signed-rank test yielded results consistent with the primary 2-tailed paired *t* test analyses. Improvements in documentation structure (*P*=.03) and documentation time category (*P*=.02) remained statistically significant, whereas overall documentation quality (*P*=.60) and clinical clarity (*P*=.08) remained nonsignificant, supporting the robustness of the primary analyses.

XSL•FO
RenderX

Table . General practitioner (GP)–level paired pre-post analyses of self-assessed documentation outcomes[a].

Outcomes	Mean change (SD)	95% CI	Cohen d_z	*P* value[b]
Quality	+0.02 (0.80)	–0.33 to 0.37	0.03	.91
Structure	+0.45 (0.90)	0.05 to 0.84	0.50	.04
Clinical clarity	+0.31 (0.69)	–0.01 to 0.62	0.45	.06
Documentation time category	–0.55 (0.89)	–0.94 to –0.16	–0.61	.01

[a]Analyses were conducted at the GP level (N=20) using 2-tailed paired *t* tests, with each GP's mean score across available consultations. Mean change is reported with 95% CIs. Paired-samples Cohen d_z is reported as the standardized effect size.

[b]*P* values are reported for exploratory purposes only.

Associations Between Documentation Time and Perceived Quality

Exploratory analyses showed a negligible association between documentation time category and self-assessed note quality (GP-level scatter plots; R^2=0.01-0.05), suggesting that longer documentation time was not associated with higher perceived quality.

Blinded External Assessment of Documentation Quality

Blinded external assessments are summarized in Table 1.

For external reviewer 1, mean scores increased across all domains following implementation: overall quality from 4.00 to 4.63, structural quality from 4.00 to 4.66, and clinical clarity from 4.26 to 4.75.

For external reviewer 2, mean overall quality changed from 4.58 before implementation to 4.44 after implementation, while structural quality changed from 4.60 to 4.52. Clinical clarity increased from 4.58 to 4.70. Thus, reviewer-specific ratings were not fully concordant: reviewer 1 rated all 3 domains higher after implementation, whereas reviewer 2 rated clinical clarity higher but overall quality and structure slightly lower after implementation. Accordingly, the blinded external assessment should be regarded as supportive rather than confirmatory evidence.

When combining ratings from both blinded reviewers (Table 3), mean overall quality increased from 4.29 before implementation to 4.53 after implementation (mean change +0.24). Structural quality increased from 4.30 to 4.60 (+0.30), and clinical clarity increased from 4.42 to 4.73 (+0.31).

Table . Blinded external assessment of documentation quality and interrater reliability[a].

Outcomes	Pre-post score change, mean (SD)	95% CI	Cohen d_z	Intraclass correlation coefficient (95% CI)
Quality	0.24 (0.33)	0.08-0.37	0.68	0.19 (0.10-0.28)
Structure	0.30 (0.31)	0.17-0.44	0.98	0.24 (0.15-0.32)
Clinical clarity	0.31 (0.30)	0.18-0.44	1.04	0.34 (0.25-0.42)

[a]Interrater reliability between 2 blinded reviewers was assessed using intraclass correlation coefficients (2-way random effects, absolute agreement). Higher values indicate greater agreement. Analyses were performed at the general practitioner (GP) level (N=20), using each GP's mean score across available consultations.

Interrater Reliability

Overview

Interrater reliability between the 2 blinded external reviewers is presented in Table 3. Interrater reliability was low (ICC 0.19-0.34 across domains), indicating substantial between-rater variability in absolute ratings. Despite this variability, the combined reviewer scores were higher after implementation across all assessed domains. However, reviewer-specific ratings were not fully concordant, and the blinded external assessment should therefore be interpreted cautiously.

Perceived Impact on Time Available for Patient Care

In the postimplementation audit, GPs reported a mean score of 3.86 (SD 1.08) for perceived increased time available for direct patient care. As no corresponding preimplementation measure was available, this outcome is reported descriptively only.

Technology Acceptance and Usability

Technology acceptance was high across all TAM domains. Mean perceived usefulness was 3.76 (SD 0.99), and perceived ease of use was 4.19 (SD 0.78). Attitude toward use was similarly positive, with a mean score of 3.97 (SD 0.97), while behavioral intention to use the system was 3.76 (SD 1.10).

SUS scores indicated good overall usability, with a mean score of 77.5 (SD 14.6), corresponding to high perceived ease of use and learnability.

Discussion

Overview

This study evaluated the implementation of an AI-assisted documentation system in routine Danish general practice, combining self-assessment by participating GPs with blinded

XSL•FO
RenderX

external evaluation. Overall, the findings suggest that AI-assisted documentation appeared feasible to integrate into everyday clinical work and was associated with high clinician acceptance, lower self-reported documentation time categories, and maintained or modestly improved perceived documentation quality. Blinded external assessment provided limited supportive evidence for these findings but should be interpreted cautiously given the low interrater reliability and reviewer-level differences. These findings should be interpreted within the context of an exploratory pragmatic pre-post evaluation and an evidence base that is still evolving for large language model–based ambient documentation systems.

Although the study was designed as a pragmatic quality improvement evaluation, we included GP-level paired pre-post analyses to provide transparent quantitative support for the observed changes. By defining the GP as the primary analytic unit and summarizing each clinician's documentation across multiple consultations, we aimed to balance methodological rigor with the exploratory and practice-oriented nature of the study, in line with recommendations for real-world digital health evaluations.

Principal Findings

Self-assessed documentation quality, structure, and clinical clarity appeared higher following implementation of AI-assisted documentation, while the self-reported documentation time category decreased from 2.85 to 2.29, corresponding to a shift toward shorter documentation time. The largest observed differences were found for structural quality and clinical clarity, whereas overall perceived quality showed minimal change. Importantly, these patterns were also observed by blinded external reviewers, who reported similar directional improvements in overall quality, structure, and clinical clarity.

The overall pattern observed in the blinded assessments was broadly consistent with the GPs' self-assessments, but reviewer-specific results were not fully concordant. One reviewer rated all domains higher after implementation, whereas the second reviewer rated overall quality and structure slightly lower and clinical clarity higher. Together with the low interrater reliability, this indicates that the external assessment should not be interpreted as confirmatory evidence of improved documentation quality. Rather, it provides limited supportive evidence that implementation was not associated with a clear deterioration in clinical clarity or overall documentation quality, while highlighting the subjective nature of evaluating narrative clinical notes.

Documentation Time and Quality

The observed reduction in self-reported documentation time categories without a corresponding decline in perceived quality is clinically relevant. Exploratory analyses demonstrated a negligible association between documentation time and perceived documentation quality, indicating that longer documentation time did not translate into higher-quality notes. This challenges the implicit assumption that perceived documentation quality necessarily depends on time investment and suggests that AI-assisted drafting may support more efficient documentation workflows without sacrificing clinical clarity.

These findings align with emerging international evidence showing that AI-assisted documentation systems, including ambient AI and AI-powered voice-to-text solutions, have been associated with reductions in perceived administrative burden while maintaining or improving documentation quality and clinician workflow [1,4-7,11]. Prior studies have reported reduced perceived workload, improved efficiency, and stable documentation quality in primary care and outpatient settings, although most have relied primarily on self-reported outcomes. By incorporating blinded external evaluation, the present study extends the literature with a more robust assessment of documentation quality under routine clinical conditions.

Our findings are also consistent with a recent longitudinal mixed methods implementation study from Dutch general practice, which similarly reported reduced perceived documentation burden and improved workflow following implementation of an ambient AI scribe. However, the authors also identified unintended consequences, including occasional inaccuracies in AI-generated summaries, challenges during sensitive consultations, and potential interference with clinicians' clinical reasoning [12]. Likewise, the recent *EBioMedicine* systematic review concluded that AI-assisted documentation systems show considerable potential to improve efficiency and patient-centered care while emphasizing persistent concerns regarding transcription errors, safety, and the limited generalizability of the current evidence base [6]. This distinction is also reflected in the recent *The Lancet Primary Care* review, which concluded that clinician satisfaction and perceived reductions in documentation burden have been reported more consistently than objectively measured improvements in efficiency. The present findings are consistent with this pattern, as documentation time was assessed using self-reported documentation time categories rather than objective time measurements [13]. Taken together, these findings suggest that AI-assisted documentation is promising, but that continued evaluation in routine clinical practice remains essential as these technologies evolve.

Acceptance, Usability, and Implementation Considerations

TAM and SUS results indicated high acceptance and perceived usability of the AI-assisted documentation system. High scores for perceived usefulness and ease of use are consistent with established determinants of digital health adoption and suggest that clinicians experienced the system as supportive rather than disruptive to clinical practice [9,10]. Behavioral intention to use also remained high, indicating potential for sustained use beyond the study period.

Implementation of AI-assisted documentation in general practice raises important considerations related to trust, transparency, and data governance. Previous qualitative research has shown that clinicians' willingness to adopt generative AI tools depends on perceived control, reliability, and clarity regarding data handling [9]. Similarly, a recent qualitative study of AI scribes in Norwegian general practice found that clinicians generally perceived ambient documentation systems as supportive of clinical workflows, while also highlighting concerns regarding accuracy, sensitive consultations, and maintaining clinician

XSL•FO
RenderX

oversight. These findings are consistent with the implementation considerations identified in the present study [14]. Similarly, patient perspectives emphasize the importance of transparency and appropriate data governance in the use of AI-based solutions in primary care [15]. The explicit deletion of audio data and short retention period of generated notes in the present implementation may therefore have contributed to both clinician and patient acceptance.

Strengths and Limitations

A key strength of this study is the combination of a pre-post design with blinded external assessment, reducing reliance on self-reported outcomes alone. The use of validated instruments (TAM and SUS) further supports the reliability and interpretability of the findings. Additionally, the study was conducted under routine clinical conditions within a nontechnology-selected group of GPs, enhancing ecological validity. However, formal measures of practice characteristics, including digital maturity, were not collected, limiting the assessment of transferability to other primary care settings.

Several limitations should be considered. The exploratory pre-post design limits causal inference and observed changes may partly reflect learning effects or increased familiarity with documentation practices over time. Because reasons for excluding consultations were not recorded, we were unable to assess whether the case mix differed between the preimplementation and postimplementation periods. The 2-week familiarization period may have been insufficient for all clinicians to fully integrate the system into their workflows, and longer exposure could yield different assessments of usability and efficiency. Documentation time was assessed using self-reported ordinal time categories rather than objectively recorded time measurements. The extent of GP editing of AI-generated drafts was not quantified, and we did not assess lexical characteristics such as note length, number of unique words, or documentation complexity. These measures may provide important complementary information in future evaluations of AI-assisted documentation systems. Consequently, the observed reduction should be interpreted as reflecting clinicians' perceived documentation burden rather than precise time savings in minutes. This distinction is particularly important given that a recent comprehensive review suggests that perceived improvements in documentation burden have been reported more consistently than objectively measured gains in efficiency for AI-assisted documentation systems [13]. Interrater reliability between the 2 blinded external reviewers was low, indicating substantial variability in absolute ratings. In addition, reviewer-specific ratings were not fully concordant, as 1 reviewer rated all domains higher after implementation, whereas the other rated overall quality and structure slightly lower and clinical clarity higher. The blinded external assessment should therefore be interpreted as limited supportive evidence rather than confirmatory evidence of improved documentation quality. We did not formally assess the success of reviewer blinding and therefore cannot exclude the possibility of partial unblinding.

This variability may partly reflect the inherently subjective nature of assessing narrative clinical documentation, even among experienced clinicians. In addition, the 2 reviewers represented different clinical contexts, with 1 working in hospital-based care and the other in general practice. Conceptions of high-quality documentation may therefore differ due to distinct workflows and informational needs rather than differences in documentation quality per se. Hospital-based documentation often emphasizes completeness and detailed clinical information, whereas general practice documentation typically prioritizes concise, structured notes that support rapid overview, continuity of care, and efficient clinical decision-making. Finally, although AI-assisted documentation systems show considerable promise, robust longitudinal real-world evidence for newer large language model–based systems remains limited. Future studies should therefore evaluate not only documentation quality and efficiency but also potential unintended consequences, including effects on clinical reasoning, patient communication, equity, and documentation accuracy as these technologies continue to evolve [13].

Implications and Future Research

Beginning January 1, 2027, Danish patients are expected to have online access to general practice clinical notes in a manner comparable to current access to hospital records. In this context, the quality, structure, and clinical clarity of documentation become increasingly important not only for interprofessional communication but also for patient understanding. The consistently high scores for structure and clinical clarity observed in this study suggest that AI-assisted documentation may support the production of more transparent and patient-readable clinical notes, extending potential benefits beyond efficiency gains alone.

Future research should include controlled study designs, longer follow-up periods, and assessment of patient perspectives, consultation-level characteristics, and clinical outcomes. Future studies should also incorporate objectively measured documentation time alongside clinician-reported outcomes to better distinguish perceived from actual workflow improvements. Further work is needed to evaluate how AI-assisted documentation influences continuity of care, medico-legal documentation quality, interprofessional communication, documentation accuracy, clinical reasoning, and equity across patient populations.

Conclusions

Implementation of AI-assisted clinical documentation in Danish general practice was associated with lower self-reported documentation time categories and no clear deterioration in documentation quality. Clinician acceptance and perceived usability were high. Blinded external assessment provided limited supportive evidence, but low interrater reliability and reviewer-level divergence warrant cautious interpretation. Larger controlled studies with objective time measurement, patient-level and consultation-level data, and longer follow-up are needed to evaluate effectiveness, safety, documentation accuracy, and potential unintended consequences in routine primary care.

Acknowledgments

The authors thank the general practitioners participating in the Aarhus primary care quality cluster for their voluntary participation and engagement in this study. The authors also acknowledge Noteless (Noteless AS) for providing access to the AI-assisted documentation system during the study period and for delivering an introductory online training session at a single cluster meeting. Noteless had no role in study design, selection of outcomes, questionnaire development, data collection, data analysis, interpretation of results, manuscript preparation, or the decision to submit the manuscript for publication. The authors retained full editorial independence. The vendor did not review or approve the manuscript prior to submission and had no access to the study dataset, evaluation data, statistical analyses, or individual-level use data used for the evaluation.

During the preparation of this manuscript, the authors used ChatGPT (OpenAI) for language editing and assistance with manuscript wording. The authors reviewed and revised all AI-assisted content and take full responsibility for the final content of the manuscript.

ChatGPT (OpenAI) was also used to assist in creating the graphical image for the article.

Funding

The authors declare that this study received no external funding.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to privacy and confidentiality considerations related to patient clinical data, but are available from the corresponding author on reasonable request, subject to applicable data protection requirements.

Authors' Contributions

All authors met the criteria for authorship as recommended by the International Committee of Medical Journal Editors (ICMJE) and approved the final manuscript. LNO was responsible for data collection and all communication with participating general practitioners, conducted the data analysis, drafted the manuscript, and approved the final version for publication. PH contributed to the conception and development of the research project, developed the questionnaires administered to the general practitioners, and critically revised the manuscript. ABL contributed to data collection and curation, participated in aspects of the data analysis, and contributed to drafting and critical revision of the manuscript. JL contributed to data collection in clinical practice, interpretation of the results, and drafting and critical revision of the manuscript. MHC conceived and initiated the research project and contributed to study design, interpretation of results, and critical revision of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Digital therapeutics (DTx) are evidence-based software interventions with the potential to treat health conditions. However, uptake remains limited by low public awareness and overly complex patient education materials that exceed recommended readability levels. Large language models (LLMs) may simplify such content; however, their effects on users' understanding have not been empirically demonstrated.

Objective: This study aimed to examine whether LLM-based simplification of DTx explanatory materials enhances perceived understanding and subjective evaluations of readability, clarity, and comprehensibility compared with manufacturer-provided documents.

Methods: We developed a simplification tool using the GPT-4o application programming interface (API), configured for deterministic outputs and guided by structured readability instructions. Original DTx explanatory materials about insomnia and nicotine dependence were obtained from manufacturers and transformed into simplified versions. Two randomized, between-subject online experiments were conducted (n=1000, with 500 participants in each experiment). Participants were stratified by age and sex and screened for relevance (Insomnia Severity Index ≥8 for the insomnia experiment and smoking ≥5 cigarettes per day for the nicotine dependence experiment). Within each experiment, participants were randomly assigned to review either the original or the LLM-simplified explanatory material. Perceived understanding was assessed before and after exposure. Postexposure evaluations of ease, clarity, and comprehensibility were also collected.

Results: Repeated measures ANOVA revealed significant group×time interaction effects on perceived understanding in both experiments: insomnia ($F_{1,498}$=24.8; P<.001) and nicotine dependence ($F_{1,498}$=14.1; P<.001), with greater improvements observed in the LLM-simplified groups. Mann-Whitney U tests further showed that LLM-simplified explanations were rated as easier, clearer, and more comprehensible than the original versions in both experiments (all P<.05), with small to moderate effect sizes (r=0.11-0.24).

Conclusions: Compared with manufacturer-provided original materials, LLM-simplified DTx explanations led to greater improvements in perceived understanding and subjective evaluations of readability among lay audiences, even after a single exposure. This finding highlights the potential scalability of LLM-based simplification as a strategy to improve the perceived accessibility of health information for lay audiences. Integrating such tools into patient education may enhance how lay audiences perceive and engage with DTx, although further research using objective comprehension measures is needed to confirm these benefits.

Introduction

Background

Digital therapeutics (DTx) represent a significant advancement in health care and are defined as high-quality software programs delivering evidence-based therapeutic interventions for a wide range of physical, mental, and behavioral conditions [1-3]. Unlike traditional pharmaceuticals and devices, DTx are often cost-effective and designed to encourage sustained user engagement, making them a promising avenue for modern health care [4,5]. DTx have been applied to various conditions, including chronic pain, cardiometabolic diseases (eg, diabetes and hypertension), heart failure, and mental health disorders. They demonstrate potential to complement pharmacotherapy; improve adherence; enable remote monitoring; and expand therapeutic options through emerging technologies, such as virtual reality and wearable sensors [6-10]. In this study, we focused on 2 DTx use cases, insomnia and nicotine dependence, as accessible and representative examples to evaluate the effects of large language model (LLM)–based simplification.

Prior Work

Despite promising applications, the adoption of DTx remains limited [11,12]. Public awareness is low, and many individuals outside the medical community are unfamiliar with DTx or do not fully understand their purpose [13]. For new health technologies to achieve broader societal diffusion, individuals must develop a clear understanding of their value [14-16].

A significant barrier is the inherent complexity of medical information. Research indicates that the average health literacy level of US adults corresponds to that of 13- to 14-year-olds, and medical education materials are recommended to be written at the level of 10- to 11-year-olds [17]. However, over 95% of existing patient education materials require a reading level of at least high school, making them inaccessible to a significant portion of the general population [18]. Producing simplified yet accurate resources remains a resource-intensive and time-consuming process that requires substantial expertise [19-21].

LLMs offer a promising solution. Trained on vast amounts of text data, LLMs can perform natural language tasks, such as summarization, translation, and simplification [22]. Their ability to adapt content to different comprehension levels has been shown to improve the readability of health information, often quantified through automated metrics, such as Flesch-Kincaid grade levels [23-25]. However, these evaluations have rarely examined whether improved readability translates to greater comprehension or more positive user perceptions among lay audiences. This gap highlights the need for empirical studies that directly assess how individuals experience and interpret simplified LLM-generated health information.

Study Objectives

This study aimed to address these gaps by empirically testing whether LLM-based simplification of DTx explanatory materials for insomnia and nicotine dependence enhances perceived understanding and subjective evaluations. Two outcome categories were assessed. The first was the cognitive outcome, which examined whether exposure to LLM-simplified explanations yields greater perceived understanding than exposure to the original explanations. The second was the subjective outcome, which examined whether LLM-based simplification improves evaluations of explanatory materials regarding ease, clarity, and overall comprehensibility.

Specifically, we aimed to determine whether LLM-simplified DTx explanations, compared with the original manufacturer-provided materials, lead to (1) greater improvements in perceived understanding and (2) higher subjective ratings of ease, clarity, and comprehensibility, across 2 independent randomized online experiments.

Methods

Study Design

This study used a randomized, between-subjects online experimental design to evaluate the effectiveness of LLM-simplified DTx explanations. Two independent experiments were conducted, each focusing on a different therapeutic area: insomnia or nicotine dependence.

In both experiments, participants were randomly assigned to one of two groups:

1. Control group—received the original manufacturer-provided DTx explanatory materials
2. Experimental group—received LLM-simplified versions of the same materials

This design allowed direct comparison of the effects of the original versus simplified explanations on participants' perceived understanding and subjective evaluations.

Development of the LLM-based Simplification Tool

To address the challenge of making DTx information more comprehensible to the public while maintaining clinical accuracy, we developed a lightweight text simplification tool. The tool used the GPT-4o (OpenAI) application programming interface (API), a state-of-the-art LLM, for its advanced natural language processing capabilities. The primary goal was to generate simplified text that would be understandable to lay audiences while ensuring fidelity to the original medical content.

In alignment with recommendations for health education materials that suggest a readability level suitable for 10- to 11-year-olds [17], the tool was specifically designed to simplify complex DTx explanations to this level, ensuring accessibility across diverse populations regardless of health literacy.

The simplification process was guided by structured instructions covering content preservation, logical coherence, terminology adaptation, clarity enhancement, tone and style, emphasis, length management, and readability. The full prompt text provided to the LLM is available in Multimedia Appendix 1.

For model configuration, the temperature parameter was set to 0 to minimize randomness and maximize reproducibility, and the top p parameter was fixed at 1 to ensure comprehensive consideration of relevant tokens. This deterministic setup was critical for maintaining precision and consistency in the medical information. These design choices enabled the creation of a tool

XSL•FO
RenderX

that converts complex DTx documents into simplified, patient-friendly explanations without compromising medical accuracy.

DTx Explanatory Materials

To evaluate the generalizability of the proposed text simplification approach, we selected 2 DTx that addressed distinct health conditions: insomnia and nicotine dependence. This design enabled the assessment of the applicability of the LLM-based simplification tool across different therapeutic domains, rather than within a single disease context.

For each DTx, original patient education and explanatory documents were obtained directly from the respective manufacturers. These materials, characterized by high complexity and technical terminology, served as baseline texts for the simplification process. Using the LLM-based tool described above, simplified versions of each document were generated, resulting in two parallel sets of materials for each DTx product: (1) the original manufacturer-provided version and (2) the LLM-simplified version.

The LLM-simplified versions incorporated several modifications, including vocabulary simplification, tone adjustment, and formatting improvements, such as clearer paragraph structuring and emphasis of key points. In contrast, the original manufacturer-provided materials were presented in their original plain-text format without any modification.

To ensure medical accuracy and logical coherence, all LLM-generated materials were independently reviewed by a panel of 3 board-certified psychiatrists who regularly treat conditions such as insomnia and nicotine dependence. This expert validation confirmed that the simplified content faithfully preserved the original medical meaning, avoided factual errors or misinterpretations, and presented information in a logically coherent manner. This review process was essential to maintaining the clinical integrity and trustworthiness of the materials used in this study. The full texts of the original and LLM-simplified explanatory materials are provided in Multimedia Appendix 2.

Participants and Recruitment

In total, 1000 participants were recruited through an online panel service (Macromill Embrain Co, Ltd) [26], with 500 participants allocated to each experiment (n=500, 50% to insomnia DTx and n=500, 50% to nicotine dependence DTx). Stratified assignment was applied during recruitment to ensure comparable sex and age distributions between the control and experimental groups.

The general inclusion criteria were (1) age between 19 and 64 years, (2) access to a smartphone or computer with internet connectivity, and (3) provision of informed consent before participation. Condition-specific screening thresholds were established in consultation with 3 board-certified psychiatrists to enhance contextual relevance while recruiting participants from the general population rather than from patient groups. For the insomnia DTx experiment, only participants with an Insomnia Severity Index score of ≥8 were included, corresponding to at least mild insomnia symptoms [27]. The Insomnia Severity Index is a 7-item self-report scale assessing insomnia symptom severity, with total scores ranging from 0 to 28. For the nicotine dependence DTx experiment, only participants who reported smoking at least 5 cigarettes per day were eligible. These criteria were selected to ensure that participants, although not recruited as patients, shared health-related characteristics that made the DTx materials meaningful and relevant to their personal contexts.

Procedure

This study used an online, randomized, between-subjects experimental design. Participants were recruited through an online panel service and screened according to the general and condition-specific inclusion criteria described above. Only individuals who met eligibility requirements were invited to participate.

After confirming eligibility, participants provided digital informed consent. In each experiment, participants were recruited from an online panel service [26] that collected demographic information (age and sex) during the screening process. To ensure balance across conditions, stratified randomization was applied, assigning participants to either the control group (original materials) or the experimental group (LLM-simplified materials) within each demographic stratum. This approach minimized allocation bias and maintained between-group comparability.

Following the group assignment, participants completed a structured online questionnaire in the following sequence:

- Pre-exposure assessment of perceived understanding of the respective DTx
- Exposure to the assigned explanatory materials (original vs LLM-simplified) with a minimum enforced viewing time of 30 seconds
- Postexposure assessment of perceived understanding of the respective DTx
- Evaluation of explanations, where participants rated the difficulty, clarity, and overall comprehensibility of the materials

All responses were anonymized to ensure the strict protection of participant privacy. After completing the survey, participants received compensation according to the agreement established by the online panel service.

Measures

Perceived Understanding

Participants' perceived understanding of the 2 DTx was assessed both before and after exposure to the explanatory materials. This construct was measured using 5 items adapted from Flynn and Goldsmith subjective knowledge scale [28], modified to capture how much participants believed they understood each DTx. Responses were recorded on a 5-point Likert scale ranging from 0 (not at all) to 4 (very much). The exact wording of the 5 adapted items is provided in the Multimedia Appendix 3. The scale demonstrated good internal consistency, with Cronbach α=0.80 for the insomnia DTx experiment and α=0.82 for the nicotine dependence DTx experiment.

XSL•FO
RenderX

Evaluation of Explanations

Participants' evaluation of the explanatory materials was measured after exposure using single-item ratings on a 0 to 4 scale, where 0 indicated "not at all" and 4 indicated "very much." Three aspects were assessed: (1) ease (how easy or difficult the explanation was to read and follow), (2) clarity (how clear the explanation was perceived overall), and (3) comprehensibility (the extent to which participants felt they could understand the explanation).

All questionnaires were administered in Korean. No objective knowledge tests (eg, recall or factual questions) were included; thus, all outcome measures relied on participants' subjective self-reports.

Ethical Considerations

This study was approved by the Institutional Review Board of the Catholic Medical Center (approval MC25QNSI0039) and was conducted in accordance with the principles of the Declaration of Helsinki [29]. All participants provided informed consent before participation. All participant data were anonymized and kept strictly confidential; no personally identifiable information was collected or retained. Participants received compensation for their participation in accordance with the terms established by the online panel service [26]. This study is reported in accordance with the Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (CONSORT-EHEALTH) guidelines; the completed checklist is provided in Checklist 1.

Statistical Analysis

All statistical analyses were conducted using Jamovi (version 2.6.26). A significance threshold of α=.05 was applied to all tests. To examine the effect of explanation type on perceived DTx understanding, repeated measures ANOVA was conducted. Each model tested the group (LLM-simplified vs control)×time (before vs after exposure) interaction to determine whether changes in perceived understanding over time significantly differed between groups. The assumptions of normality, homoscedasticity, and sphericity were satisfied.

Participants' postexposure ratings of ease, clarity, and comprehensibility of the DTx explanations were compared between groups using the Mann-Whitney *U* test. This nonparametric approach was selected because of the ordinal nature of the single-item Likert-scale ratings. These analyses evaluated whether LLM-based simplification had a significant influence on participants' subjective evaluations of the materials.

Results

Sample Characteristics

A total of 1000 participants completed the study, with 500 (50%) allocated to the insomnia DTx experiment and 500 (50%) to the nicotine dependence DTx experiment. Stratified assignment ensured comparable sex and age distributions between the control and experimental groups. Demographic information used for stratification was limited to sex and age. Participant demographic characteristics are presented in Table 1.

Table . Participant demographic characteristics by group (insomnia and nicotine dependence experiments).

Characteristic	Insomnia control (n=250)	Insomnia test (n=250)	Nicotine control (n=250)	Nicotine test (n=250)
Sex, n (%)				
Male	125 (50)	125 (50)	125 (50)	125 (50)
Female	125 (50)	125 (50)	125 (50)	125 (50)
Age (years), n (%)				
20	63 (25.2)	63 (25.2)	63 (25.2)	63 (25.2)
30	63 (25.2)	63 (25.2)	63 (25.2)	63 (25.2)
40	62 (24.8)	62 (24.8)	62 (24.8)	62 (24.8)
50-65	62 (24.8)	62 (24.8)	62 (24.8)	62 (24.8)

Effect on Perceived Understanding

No significant main effect of group was observed in either the insomnia experiment ($F_{1,498}$=3.32; P=.07; partial η^2=0.007) or the nicotine dependence experiment ($F_{1,498}$=2.88; P=.09; partial η^2=0.006; Table 2).

XSL•FO
RenderX

Table . Repeated measures ANOVA results for perceived understanding across insomnia and nicotine dependence digital therapeutics (DTx) experiments.

Experiment and effect	*F* test (*df*)	*P* value	Partial η^2
Insomnia DTx			
Group	3.32 (1, 498)	.07	0.007
Time	38.5 (1, 498)	<.001	0.072
Group×time	24.8 (1, 498)	<.001	0.048
Nicotine DTx			
Group	2.88 (1, 498)	.09	0.006
Time	21.5 (1, 498)	<.001	0.041
Group×time	14.1 (1, 498)	<.001	0.028

A significant main effect of time was observed in both the insomnia experiment ($F_{1,498}$=38.5; *P*<.001; partial η^2=0.072) and the nicotine dependence experiment ($F_{1,498}$=21.5, *P*<.001; partial η^2=0.041), with postexposure assessment scores higher than pre-exposure assessment scores across groups.

A significant group×time interaction was observed in both experiments. In the insomnia experiment, the interaction effect was $F_{1, 498}$=24.8; *P*<.001; partial η^2=0.048; and in the nicotine dependence experiment, it was $F_{1, 498}$=14.1; *P*<.001; partial η^2=0.028 (Table 2).

Descriptive statistics for each group and time point are presented in Table 3. As shown in Figure 1, the LLM-simplified group demonstrated greater increases in perceived understanding than the control group in both experiments.

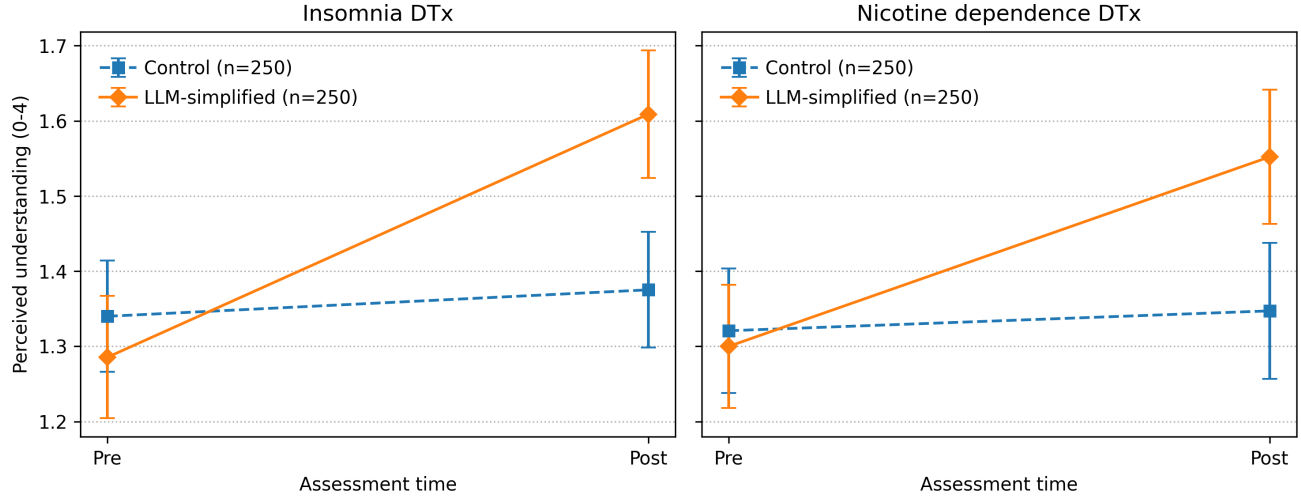

Table . Perceived understanding scores by group and time point (n=250).

Experiment and group	Pretest, mean (SD; 95% CI)	Posttest, mean (SD; 95% CI)
Insomnia DTx[a]		
LLM[b]-simplified	1.29 (0.65; 1.20-1.37)	1.61 (0.68; 1.52-1.69)
Control	1.34 (0.59; 1.27-1.41)	1.38 (0.62; 1.30-1.45)
Nicotine DTx		
LLM-simplified	1.30 (0.66; 1.22-1.38)	1.55 (0.72; 1.46-1.64)
Control	1.32 (0.66; 1.24-1.40)	1.35 (0.73; 1.26-1.44)

Evaluation of Explanations

In the insomnia experiment, the LLM-simplified explanations were rated significantly higher for ease (U=27,281; P=.008; r=0.127), clarity (U=27,803; P=.02; r=0.110), and comprehensibility (U=25,125; P<.001; r=0.196). Similarly, in the nicotine dependence experiment, significant group differences were observed for ease (U=23,727; P<.001; r=0.240), clarity (U=27,697; P=.02; r=0.114), and comprehensibility (U=24,738; P<.001; r=0.208). The distribution of ratings across response categories is illustrated in Figure 2.

Figure 2. Group distribution of postexposure ratings (0 - 4) for ease, clarity, and comprehensibility in both experiments. Bars represent 100% stacked proportions. The neutral category (2) is split and plotted on both sides of the center, such that lower ratings (0 - 1) extend to the left of 0 and higher ratings (3-4) extend to the right. This split-neutral presentation allows the direction of responses (negative vs positive) to be visually compared while preserving the full distribution of ratings. Group labels indicate sample sizes (control vs large language model [LLM]–simplified). Between-group differences were tested using 2-sided Mann-Whitney U tests with Holm correction across measures; rank-biserial effect sizes (r) are reported in Table 4. DTx: digital therapeutics.

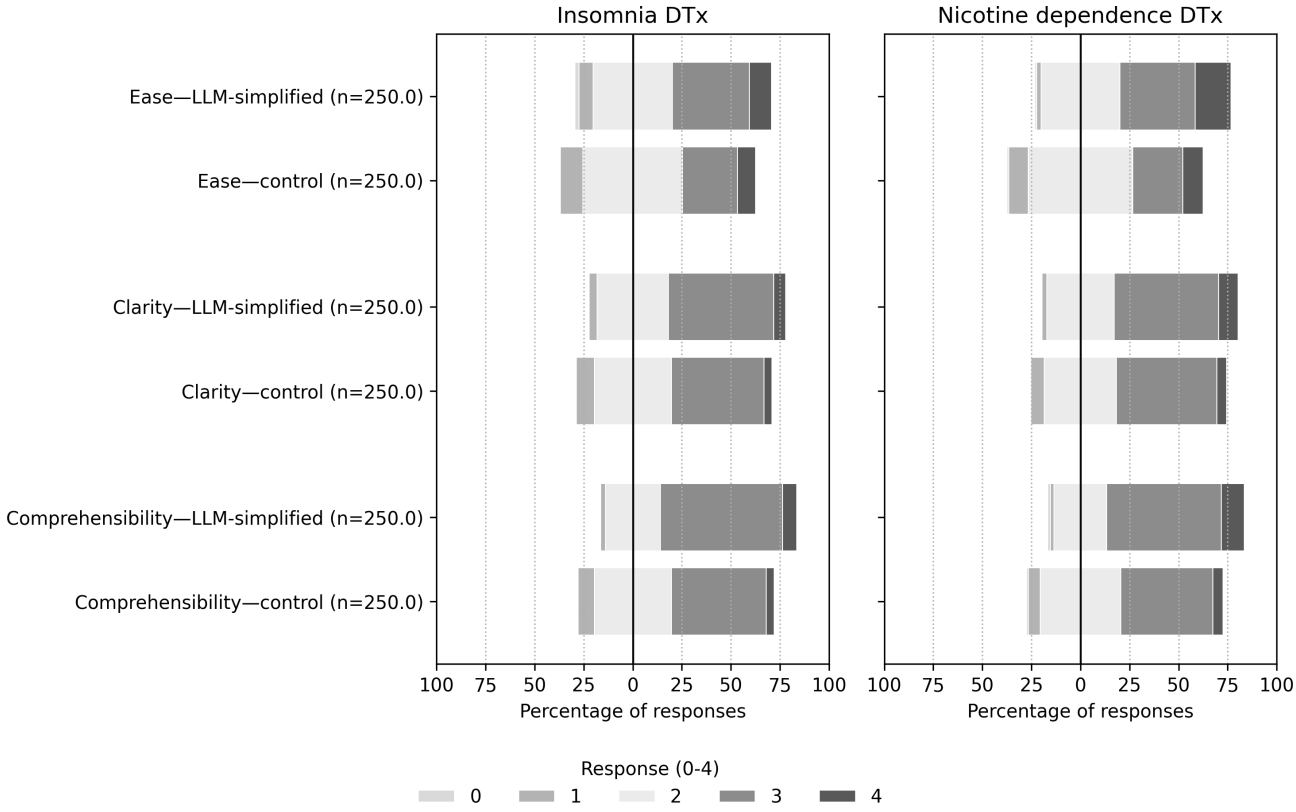

Table . Mann-Whitney U test results comparing subjective evaluation of explanations between groups.

Experiment and measure	U	P value	Adjusted P value[a]	r

Discussion

This study evaluated whether LLM-based simplification of DTx explanatory materials improves perceived understanding and subjective evaluations among lay audiences through 2 independent randomized online experiments targeting insomnia (500/1000, 50%) and nicotine dependence (500/1000, 50%).

XSL•FO
RenderX

Principal Results

Our findings indicated that LLM-based simplification of DTx explanatory materials improves perceived comprehensibility and subjective evaluations of accessibility. In 2 independent experiments on insomnia and nicotine dependence, participants who received LLM-simplified explanations reported significantly greater gains in perceived understanding than those who received the original manufacturer-provided explanations. In addition, the simplified versions were consistently rated as easier, clearer, and more comprehensible, indicating improved subjective evaluations. These findings suggest that LLM-based simplification may improve perceived understanding and subjective evaluations across multiple therapeutic contexts. However, further research using objective comprehension measures and more diverse populations is needed to confirm the robustness and generalizability of these findings.

Although these findings demonstrate improvements in perceived understanding, these improvements do not necessarily indicate accurate or complete comprehension of medical information. Feeling confident about understanding health information may differ from actually understanding the details and appropriate use of a medical intervention. Therefore, future research should incorporate objective knowledge measures to determine whether LLM-based simplification improves actual comprehension in addition to perceived understanding.

The observed differences in subjective evaluations were statistically significant, but the effect sizes were generally small to moderate (r=0.11 - 0.24). These magnitudes suggest modest but consistent improvements in participants' evaluations following a single brief exposure. Given the minimal intervention required, such improvements may still be meaningful in real-world settings where scalable approaches to improving the perceived accessibility of health information are needed.

These findings emphasize the potential for safe and practical applications of LLMs in health care communication. Although concerns about hallucinations highlight the risks of using LLMs to generate new clinical content or make medical decisions [30], their role in transforming clinically validated information into more accessible formats carries considerably lower risk [31]. Prior research has demonstrated that readability can be improved while maintaining factual accuracy [23-25]. This study extends that evidence by incorporating independent reviews from 3 board-certified psychiatrists who confirmed the medical accuracy and logical coherence of the simplified texts. Collectively, these results demonstrate that LLM-based simplification represents a scalable and trustworthy strategy for improving the perceived accessibility and comprehensibility of DTx information among lay audiences.

Comparison With Prior Work

The findings of this study align with a substantial body of research that highlights the challenges of health literacy and the frequent mismatch between the readability of medical information and patients' comprehension skills [17]. Previous studies have consistently shown that most patient education materials are written at a level above the recommended reading level, limiting accessibility for the general population [18]. Recent advances in natural language processing and LLMs suggest that automated text simplification can serve as a promising solution, with evidence demonstrating improvements in readability across a range of health-related documents [22]. However, much of this prior work relied on computational readability metrics (such as Flesch-Kincaid scores) rather than empirical evaluations with end users [23-25].

This study extends this line of research by providing experimental evidence that LLM-simplified explanations not only achieve higher readability but also enhance perceived understanding among lay audiences. Notably, the results demonstrate that accuracy can be preserved, consistent with prior findings that LLM-based simplification improves accessibility without compromising factual correctness [23-25]. Unlike earlier studies, this study combines expert clinical validation by board-certified psychiatrists with large-scale user experiments across 2 therapeutic contexts, thereby offering novel empirical evidence of both accuracy and effectiveness. These findings reinforce the growing recognition that LLM-based simplification may help improve the perceived accessibility of DTx information and support users' perceived understanding of complex health technologies.

Limitations

This study has some limitations. First, participants were recruited from an online panel and allocated through stratified randomization based on sex and age, which may have reduced natural variability and limited the generalizability of the results [32]. Because participation required internet access and familiarity with digital environments, the study sample may have had higher digital literacy than typical patient populations. Therefore, the findings may not fully generalize to individuals with limited digital literacy. In addition, because demographic information was limited to sex and age, other potentially relevant characteristics (such as education, income, health literacy, and prior DTx exposure) were not collected, further limiting the interpretability of the results. In particular, differences in education level and baseline health literacy may influence how individuals respond to simplified health information and should be considered when interpreting the generalizability of the findings. Second, comprehension was assessed only through self-reported perceived understanding rather than objective knowledge tests [33], which limits conclusions about actual comprehension. Third, ease, clarity, and comprehensibility were evaluated using single-item measures, restricting measurement reliability. Fourth, the short-term exposure with a minimum enforced viewing time of 30 seconds leaves the durability and behavioral relevance of the effects uncertain. Fifth, although participants were screened for relevance (eg, minimum insomnia symptoms or daily smoking frequency), they were not clinically diagnosed; thus, caution is warranted when extrapolating these findings to treatment populations. Sixth, the intervention relied on a single LLM (GPT-4o) and specific prompt configurations, underscoring the need for replication using alternative models and implementation conditions to establish robustness. Finally, the intervention involved multiple simultaneous modifications, including vocabulary simplification, tone adjustment, and formatting improvements, such as paragraph structuring and

XSL•FO
RenderX

emphasis of key points. Notably, the original manufacturer-provided materials were presented in plain text without visual enhancements, whereas the LLM-simplified versions incorporated formatting elements, such as bolding, structured paragraph breaks, and emphasis of key terms, as part of the simplification process. Therefore, the comparison was not purely linguistic; differences in visual presentation may have independently contributed to the observed improvements in perceived comprehensibility and subjective evaluations. This constitutes a bundled intervention, and the present design does not allow for disentangling the effects of linguistic simplification from those of visual formatting. Future studies should isolate these components—for example, through factorial designs that independently vary linguistic complexity and visual formatting—to better understand their individual and combined effects.

Conclusions

This study demonstrates that LLM-based simplification of DTx explanatory materials significantly improves perceived understanding and subjective evaluations of readability, clarity, and comprehensibility among lay audiences. By focusing on the transformation of clinically validated content, LLMs can provide a safe and scalable approach to improving the perceived accessibility of digital health information.

Beyond DTx, these findings have broader implications: many types of medical documents, including patient education materials, informed consent forms, and clinical instructions, can be made to feel more accessible through LLM-based simplification. Importantly, by helping patients feel more confident in engaging with health information, LLM-based tools may have the potential to reduce passive compliance and instead promote active engagement, adherence, and shared decision-making.

Future studies should extend these results in several ways. Research involving clinically diagnosed patient populations is necessary to confirm the applicability of this approach in real-world treatment settings. Additionally, objective knowledge assessments and longitudinal designs are needed to determine whether improvements in perceived understanding translate into sustained learning and behavioral change. Finally, evaluations across diverse health conditions, populations, and languages are essential to establish the robustness and generalizability of LLM-based simplification strategies.

Acknowledgments

The authors thank Aimnext Co, Ltd and Innerwave Co, Ltd for their cooperation in providing the original explanatory materials for the digital therapeutics evaluated in this study.

Funding

This work was supported by the Bio-Industrial Technology Development Program (RS-2022-KT217960; Development of an online platform for DTx full-cycle clinical trial support using metaverse technology) funded by the Ministry of Trade, Industry and Resources (MOTIR, Korea). This funding covered both the research process and the article processing charge. The funder had no role in the design of the study, data collection, analysis, interpretation, or manuscript preparation.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available due to participant privacy considerations but are available from the corresponding author on reasonable request, subject to renewed institutional review board approval.

Abstract

Background: The 5-Star Quality Rating System for nursing homes plays a central role in evaluating quality of care, although it has both strengths and limitations. This system relies heavily on the Minimum Data Set and derives several quality measures (QMs) from it. In this study, we validated the effectiveness of the 5-Star Quality Rating System for nursing homes and its underlying QMs in estimating quality of care. We constructed a panel dataset of US nursing homes (n=15,416) active from May 2020 to June 2023, retrieving data from three major sources: (1) COVID-19 nursing home data, (2) Payroll-Based Journal data, and (3) nursing home QM snapshots. The outcome variables included (1) resident infection, (2) staff infection, or (3) resident and staff deaths. The predictor variables were the 5-Star Quality Rating System for nursing homes and its underlying QMs classified as structure, process, or outcome (SPO) QMs.

Objective: This study aims to evaluate the effectiveness of nursing home QMs by regressing nursing home COVID-19 outcomes on nursing home QMs, classified using the Donabedian SPO framework. We hypothesized that nursing homes with better structural quality (eg, greater staff availability, better skill mix, and so on), better process quality (eg, lower restraint use and higher vaccination rates), and better outcome quality (eg, lower number of residents with pressure ulcers and a lower number of resident falls) experienced better COVID-19 performance in terms of resident and staff infections and deaths.

Methods: To examine the association between the COVID-19 outcomes and SPO QMs, we imputed missing values in the dataset using random forest. Subsequently, we modeled the imputed dataset using hurdled zero-inflated negative binomial mixed effects models. The zero inflation model included factors influencing initial susceptibility to COVID-19 or factors influencing the possibility of death after COVID-19 had been contracted. The model estimates were conditioned on zero inflation and random effects.

Results: Staffing measures (P<.001 for all variables in all models), health deficiency scores (P<.001 for all variables in at least 1 model), COVID-19 hospitalization rates (P<.001 for all variables in at least 2 models), and vaccinations (P<.001 for all variables in at least 2 models) exhibited meaningful relationships with the COVID-19 outcomes, while the 5-star components, Medicaid dependency, and ownership showed no clear relationships.

Conclusions: Although widely used, the 5-Star Quality Rating System for nursing homes is an unreliable performance measure. Concerted efforts from lawmakers, policy makers, and lobbyists are needed to refine and enhance the measure, thereby ensuring its reliability and effectiveness.

Introduction

In the United States, nursing homes are essential care providers for more than 1.3 million residents across 15,600 facilities [1,2]. As the third-largest sector in the health care industry, nursing homes employ more than 1.7 million dedicated staff members [2] who cater to the complex needs of the older adults, who are often frail and affected by multimorbidity [3-6]. With projections indicating consistent increases in the older adult population [7] and average life expectancy [8,9], the demand for nursing home care is expected to rise sharply [8,10,11]. This makes it crucial for nursing homes to optimize their resource allocation while providing excellent care. Embracing the concept of quality of care (QoC) is not just a strategic necessity for survival in a competitive market but also a moral obligation to ensure the well-being of older adults.

The United States recorded 649,611 excess deaths more than expected in the first year of the COVID-19 pandemic, a 23% increase over the previous year. The largest share of excess deaths occurred among older adults [12]. In the nursing home setting, older adults were disproportionately affected [2] because of a combination of individual factors, such as advanced age [13,14] and comorbidities [14,15], and organizational factors, such as understaffing, crowding [2], limited supply of personal protective equipment [16], and inadequate infection prevention and control readiness [2,17,18]. While the Centers for Disease Control and Prevention proposed rigorous COVID-19 control measures, including maintaining personal hygiene practices, mask use, self-isolation, mobility restrictions, and physical distancing [19,20], they could not compensate for the chronic noncompliance of infection prevention and control practices. A May 2020 United States Government Accountability Office report found that 82% of Centers for Medicare and Medicaid Services (CMS)–certified nursing homes had at least one infection-related deficiency between 2013 and 2017, with nearly half receiving citations over multiple years [17,21].

Aimed at deterring noncompliance and promoting accountability, CMS launched the Nursing Home Care (NHC) website in 2002 to improve transparency by expanding public access to quality information [22]. However, despite CMS's efforts, this website is not well known and is considered difficult to comprehend. When consulting NHC, consumers are unable to discern meaningful differences between nursing homes to make informed decisions about their well-being and that of their loved ones. To address this problem, the CMS introduced the 5-Star Quality Rating System for nursing homes in 2008, summarizing the detailed information provided on NHC [23].

The 5-Star Nursing Homes Quality Rating System for Nursing Homes is based on data from the Minimum Data Set (MDS) and includes several quality measures (QMs) derived from it. Concerns have been raised about the effectiveness of the 5-Star Quality Rating System for nursing homes because of its reliance on the MDS. The MDS has several limitations, including inconsistent reporting due to ambiguous instructions and subjective items [24]. In addition, comparing across facilities proves difficult when the QMs emphasize rare events. Such events usually lead to large SEs and large CIs, making it challenging to assess true quality differences [24]. The QMs are assumed to be linear; however, surprisingly, they are sometimes nonlinear [24,25]. The MDS QMs are also presumed to use the complete spectrum of possible values even in situations that deviate from medical norms, such as pressure ulcer rates below 2% [24,26]. Furthermore, ascertainment bias, a type of detection bias caused by inadequate recording of relevant QMs, and substantial interrater variability often impact the reliability of MDS data [24].

Additionally, nursing home studies face other challenges beyond those associated with the sector's reliance on the MDS. One problem is the absence of resident-level data, which impedes the establishment of causality. Moreover, endogeneity is inadequately controlled due to the nonindependence of dependent variables and error terms, which leads to biased results [27-29]. Additionally, the omission of risk adjustment for relevant confounders may make it impossible to capture any associations between a confounder and the other variables [27,30]. In this study, we used a panel dataset to evaluate the effectiveness of several nursing home QMs in explaining nursing home QoC in terms of COVID-19 health outcomes. We achieved this by regressing COVID-19 outcomes measured in the US nursing homes during the period May 2020 to June 2023 on nursing home QMs, classified using the Donabedian structure-process-outcome (SPO) framework, which are used in constructing the 5-Star Quality Rating System for nursing homes. Our research contributes to the literature in several ways. First, most scholars who used COVID-19 health outcomes have so far considered only a limited number of nursing home QMs. Moreover, they have relied on small sample sizes or used cross-sectional data over longitudinal data. We addressed these limitations by using a panel dataset of COVID-19 data for the nursing homes in the United States collected during the period May 2020 to July 2023. Second, to tackle the challenge of large SEs associated with rare events, we opted for a larger sample size, thus enhancing statistical power and refining our estimates. Third, to mitigate the concern of inadequate control of endogeneity, we used hierarchical generalized linear mixed effects modeling.

We hypothesized that nursing homes with better structural quality (eg, greater staff availability and better skill mix), better process quality (eg, lower restraint use and higher vaccination rates), and better outcome quality (eg, lower number of residents with pressure ulcers and lower number of resident falls) experienced better COVID-19 performance in terms of resident and staff infections and deaths. An empirical analysis of this issue offers fresh perspectives that were previously unavailable from existing research.

Methods

Data Sources

To test the study's hypotheses, we used a panel dataset created using 3 major publicly available data sources: COVID-19 nursing home data, Payroll-Based Journal data, and nursing home QM snapshots.

XSL•FO
RenderX

COVID-19 health outcomes for the period May 2020 to June 2023 were obtained from COVID-19 nursing home data. The latter were obtained as a single dataset containing weekly summaries of resident and staff infections and deaths. Payroll-Based Journal data are collected quarterly and offer daily summaries of employee weekly hours for different staff, including nursing, non-nursing, employee, and contract staff. Nursing home QM snapshots include monthly summaries of QMs obtained from multiple data sources, such as the MDS, claims, penalties, provider information, survey summaries, and vaccination data.

The data were aggregated to create a unified dataset. Data aggregation was performed using 2 unique identifiers: one identified the facility (ie, the federal provider number), whereas the other identified the period (ie, week, month, or quarter). All statistical analyses were performed using R version 4.0.0 or higher (R Foundation for Statistical Computing) [31], and a 2-sided *P* less than .05 was considered statistically significant.

Dependent Variables

The measures "residents weekly confirmed COVID-19," "residents weekly COVID-19 deaths," "staff weekly confirmed COVID-19," and "staff weekly COVID-19 deaths" monitored the number of residents or staff who tested positive for COVID-19 and those who died due to COVID-19 in a particular week. These figures were reported by providers weekly from May 24, 2020, to June 6, 2023, with the data for the week ending May 25, 2020, potentially including reporting from January 1, 2020, to May 24, 2020.

In the analysis, we combined "residents weekly COVID-19 deaths" and "staff weekly COVID-19 deaths" into a single value representing "total (resident and staff) weekly COVID-19 deaths." We adopted this approach because both variables were characterized by sparsity and a high number of zeros, and combining them in this manner increased statistical power and, subsequently, the variance for modeling of zero-inflated outcome variables [32].

Independent Variables

The set of independent variables was categorized based on the Donabedian SPO framework. According to this framework, the quality of health care, including nursing home care, can be assessed at a facility based on 3 quality components: structure, process, and outcome. *Structure* refers to the settings where health care is provided (eg, buildings and technology infrastructure) and accessibility features. *Process* encompasses the actions taken in giving and receiving care, such as pain management, error prevention, and care follow-ups. *Outcome* indicates the consequences of the provided health care, including mortality rates, readmission rates, and functional status. The quality of health care is contingent upon the interplay of these categories, as Donabedian eloquently stated, "A good structure increases the likelihood of good process, and good process increases the likelihood of good outcomes" [27,33].

Structural QMs

For our analysis, we used a comprehensive array of structural QMs encompassing various nursing home attributes (Textbox 1). To gauge the workforce dynamics, we factored in staffing hours, which were calculated separately for employees and contract staff and for nursing and non-nursing staff; we also examined turnover rates for nursing personnel, registered nurses, and non-nursing staff. Furthermore, we considered characteristics tied to the 5-Star Quality Rating System for nursing homes, including facility fines, penalties, and health and fire safety deficiencies, alongside organizational attributes, such as ownership type, provider category, special focus status, and the presence of resident and family councils, all of which contributed to our assessment of overall performance and stability.

XSL•FO

Textbox 1. Structural quality measures (count model predictors). "N" denotes a numeric variable, whereas "C" denotes a categorical variable. The number preceding "C" represents the number of levels in the categorical variable.

Provider information model variables

- Percentage of occupied beds (N)
- Provider type (4C)
- Provider resides in hospital (2C)
- Days since approval to provide Medicare and Medicaid services (N)
- Continuing care retirement community (2C)
- Special focus status (2C)
- Abuse icon (2C)
- Most recent health inspection more than 2 years (2C)
- Provider changed owner in previous 12 months (2C)
- With a resident and family council (4C)

Penalties and staffing model variables

- Employee nursing total weekly hours (N)
- Employee non-nursing total weekly hours (N)
- Contract nursing total weekly hours (N)
- Contract non-nursing total weekly hours (N)

Process QMs

An ample set of process QMs was considered (Textbox 2). Among these were factors pertinent to COVID-19, such as the number of residents hospitalized with confirmed cases and their vaccination status, along with weekly admissions of residents previously treated for the virus. The health care aspects included measures such as the percentage of long-stay residents appropriately receiving pneumococcal and influenza vaccines, the percentage of long-stay residents receiving antianxiety or hypnotic medications, those subjected to physical restraints, and those experiencing adverse effects of in-dwelling catheters. For short-stay residents, the metrics focused on appropriate pneumococcal and influenza vaccination rates and the percentage of residents receiving newly prescribed antipsychotic medications.

Textbox 2. Process quality measures (count model predictors). "N" denotes a numeric variable.

Process model variables

- Residents' weekly COVID-19 admissions (N)
- Residents hospitalized with confirmed COVID-19 (N)
- Residents hospitalized with confirmed COVID-19 and up to date with vaccines (N)
- Percentage of current residents up to date with COVID-19 vaccines (N)
- Percentage of current health care personnel up to date with COVID-19 vaccines (N)
- Percentage of long-stay residents assessed and appropriately given the pneumococcal vaccine (N)
- Percentage of long-stay residents assessed and appropriately given the seasonal influenza vaccine (N)
- Percentage of long-stay residents who have received an antianxiety or hypnotic medication (N)
- Percentage of long-stay residents who have received an antipsychotic medication (N)
- Percentage of long-stay residents who are physically restrained (N)
- Percentage of long-stay residents with catheters inserted and left in their bladders (N)
- Percentage of short-stay residents assessed and appropriately given the pneumococcal vaccine (N)
- Percentage of short-stay residents who have received a newly prescribed antipsychotic medication (N)
- Percentage of short-stay residents assessed and appropriately given the seasonal influenza vaccine (N)

XSL•FO
RenderX

Outcome QMs

The outcome QMs used for the analysis encompassed various measures of resident care and well-being (Textbox 3). Long-stay measures focusing on depressive symptoms, weight loss, deteriorating mobility, increased need for assistance with daily activities, urinary tract infections (UTIs), and loss of bowel or bladder control were included. Short-stay measures evaluated functional improvements in mobility, outpatient emergency department visits, and rehospitalizations within 30 days of admission.

Textbox 3. Outcome quality measures (count model predictors). "N" denotes a numeric variable.

Outcome model variables

- Number of residents with a new positive COVID-19 test result (N)
- Number of staff and personnel with a new positive COVID-19 test result (N)
- Percentage of SNF residents with new or worsened pressure ulcers (N)
- Percentage of high-risk long-stay residents with pressure ulcers (N)
- Percentage of long-stay residents who have experienced one or more falls with major injury (N)
- Percentage of long-stay residents who have depressive symptoms (N)
- Percentage of long-stay residents who have lost too much weight (N)
- Percentage of long-stay residents whose ability to move independently has worsened (N)
- Percentage of long-stay residents whose need for help with daily activities has increased (N)
- Percentage of long-stay residents with urinary tract infections (N)
- Percentage of low-risk long-stay residents who lose control of their bowels or bladders (N)
- Percentage of short-stay residents who have made improvements in function (N)
- Percentage of short-stay residents who have had an outpatient emergency department visit (N)
- Percentage of short-stay residents who have been rehospitalized after a nursing home admission (N)

Penalties and staffing model variables

- Total fines (N)
- Total amount (N)
- Total penalties (N)
- Total days (N)
- Number of facility-reported incidents (N)
- Total nursing staff turnover (N)
- Registered nurse turnover (N)
- Number of administrators who have left the nursing home (N)

Surveys model variables

- Total health deficiencies inspection cycle 1 (N)
- Total health deficiencies inspection cycle 2 (N)
- Total health deficiencies inspection cycle 3 (N)
- Total fire safety deficiencies inspection cycle 1 (N)
- Total fire safety deficiencies inspection cycle 2 (N)
- Total fire safety deficiencies inspection cycle 3 (N)
- Total weighted health survey score (N)

Data Cleaning

Prior to analysis, we removed all the observations in the dataset that contained a flag for either incorrect data or substandard data. This flagging was part of the Centers for Disease Control and Prevention's quality assurance check, conducted by CMS on 8 data fields to ensure they did not contain implausible or erroneous values. Our decision to exclude flagged observations mirrors those made in prior research in the field [34]. Removing flagged observations eliminated 77,684 observations, resulting in a dataset containing 2,429,283 observations. The latter were used in the analysis after imputing with random forest. The

XSL•FO

missing value profiles of the variables are shown below (Figures 1-5).

Figure 5. Missing value profile of the outcome quality measures.

Missing Value Imputation

When addressing the presence of missing values in our dataset, we made the deliberate choice to impute rather than exclude them, which aligned with the research goals and the nature of the missing data. In our study, we assumed that the missing data were missing at random (MAR). The MAR mechanism assumes that the probability of missingness depends on the observed data but not on the missing data [35]. As the nursing home data are aggregated at the institution level and include all institutions nationwide, missingness is likely related to differences in administrative or operational factors, such as staffing levels, documentation practices, reporting systems, or governance policies at the state, county, or local levels. We opted for random forest imputation, as it handles various data types seamlessly; it also excels in managing complex interactions and multicollinearity while efficiently scaling to accommodate large datasets. The implementation of random forest in the R package *missranger* [36] resulted in a reduction of up to 50% of imputation errors, and the average proportional deviation in out-of-bag imputation errors remained within the 10% to 15% range. All the variables (except the outcome variables) were imputed using the random forest algorithm. Although the best method to address MAR missingness is to perform multiple imputation [37], we were unable to adopt this approach due to time and resource constraints. The specifications used for random forest imputation are presented in Table 1.

Table . Specifications used for random forest imputation.

Parameter	Value
Predictive mean matching	5
Maximum iterations	20
Number of trees	20
Maximum depth	8

Data Modeling

Data Modeling

Using the imputed dataset, the variable called “percentage of occupied beds” was created using “total number of occupied beds” and “number of all beds.” A total of 10 observations from the calculation resulted in a not-a-number error and were excluded. All the numeric variables were standardized to have a mean of 0 and an SD of 1. All the unordered categorical variables or nominal variables were specified using sum contrasts. For ordered categorical variables or ordinal variables, we used orthogonal polynomial contrasts, and we standardized them onto a uniform scale. Consequently, each contrast column had a mean of 0 and an SD of 1. This approach allowed us to fit the regression models within a standardized framework and easily compare different model coefficients.

Furthermore, all unordered categorical variables containing more than 2 levels were binary encoded before being specified

XSL•FO
RenderX

using sum contrasts. Binary encoding is a machine learning technique that combines hash encoding and one-hot encoding. First, all levels of an unordered categorical variable are expressed using a unique numeric value. Then, the numbers are transformed into a unique combination of zeros and ones, making it efficient to store data that exhibit high cardinality.

The outcome variables were characteristic of count data and exhibited properties such as nonnegativity, integer values, positive skewness, and a greater prevalence of lower count values. Equidispersion assessment revealed significant overdispersion, which rendered the use of a traditional Poisson regression model unsuitable. Therefore, we used a negative binomial regression model. Unlike the Poisson model, the negative binomial model accounts for overdispersion with quadratic parameterization. The presence of excess zeros led to the implementation of a zero-inflated negative binomial (ZINB) model, and the panel structure of the dataset resulted in the specification of a mixed effects model. However, specifying a ZINB model requires the presence of zero inflation at all levels of the grouping variables (ie, states, counties, and facilities). Some of the levels did not have zero inflation; they had zero deflation. On the basis of recommendations in the literature [38], the final model we specified was a truncated ZINB mixed effects model.

We estimated multiple truncated ZINB models, specifying different outcome variables. To model the outcomes "residents weekly confirmed COVID-19" and "staff weekly confirmed COVID-19," the zero inflation (ZI) component of the model included factors influencing initial susceptibility to COVID-19 [39]. These included facility-level characteristics, such as bed size, as well as social determinants of health attributes, including urbanicity, political affiliation of the geographic location, median household income, and local COVID-19 vaccination coverage. To model the outcome "total weekly COVID-19 deaths," the ZI component of the model included factors influencing the possibility of death after COVID-19 had been contracted, such as lagged weekly resident confirmed COVID-19 cases per 1000 residents and lagged county confirmed COVID-19 cases per 1000 people. We assumed that newly infected residents (ie, infected at 1 time point before) had a higher likelihood of death compared to those who were not newly infected (ie, infected more than one time point before). Our assumption was informed by prior research, indicating that individuals who test positive for COVID-19 typically do not begin to develop detectable antibodies until approximately 1 week after the onset of symptoms [40]. Both lagged variables were calculated for a lag of 1. An overview of the outcome variables and their associated ZI model predictors is presented in (Textbox 4).

Textbox 4. Model outcomes and ZI model predictors. Letter "N" denotes a numeric variable, whereas "C" denotes a categorical variable. The number preceding "C" represents the number of levels in the categorical variable.

Residents weekly confirmed COVID-19

- Bed size (3C)
- Urban binary (2C)
- Democrat or Republican (2C)
- Median household income dollars inflation adjusted to data file year ACS (American Community Survey) 2016-2020 (N)
- Partially or fully vaccinated percent (N)

Staff weekly confirmed COVID-19

- Bed size (3C)
- Urban binary (2C)
- Democrat or Republican (2C)
- Median household income dollars inflation adjusted to data file year ACS 2016-2020 (N)
- Partially or fully vaccinated percent (N)

Total weekly COVID-19 deaths

- Lagged weekly resident confirmed COVID-19 cases per 1000 residents (N)
- Lagged county confirmed cases USA Facts new (N)

The model included random slopes and random intercepts for 3 levels of nesting, that is, nursing home facilities nested within counties nested within states. An autoregressive process of order-1 covariance structure was selected to model the correlations among time points for the same individual. The truncated negative binomial distribution with quadratic parameterization implemented in the R package *glmmTMB* [41] under the family "truncated_nbinom2" was used.

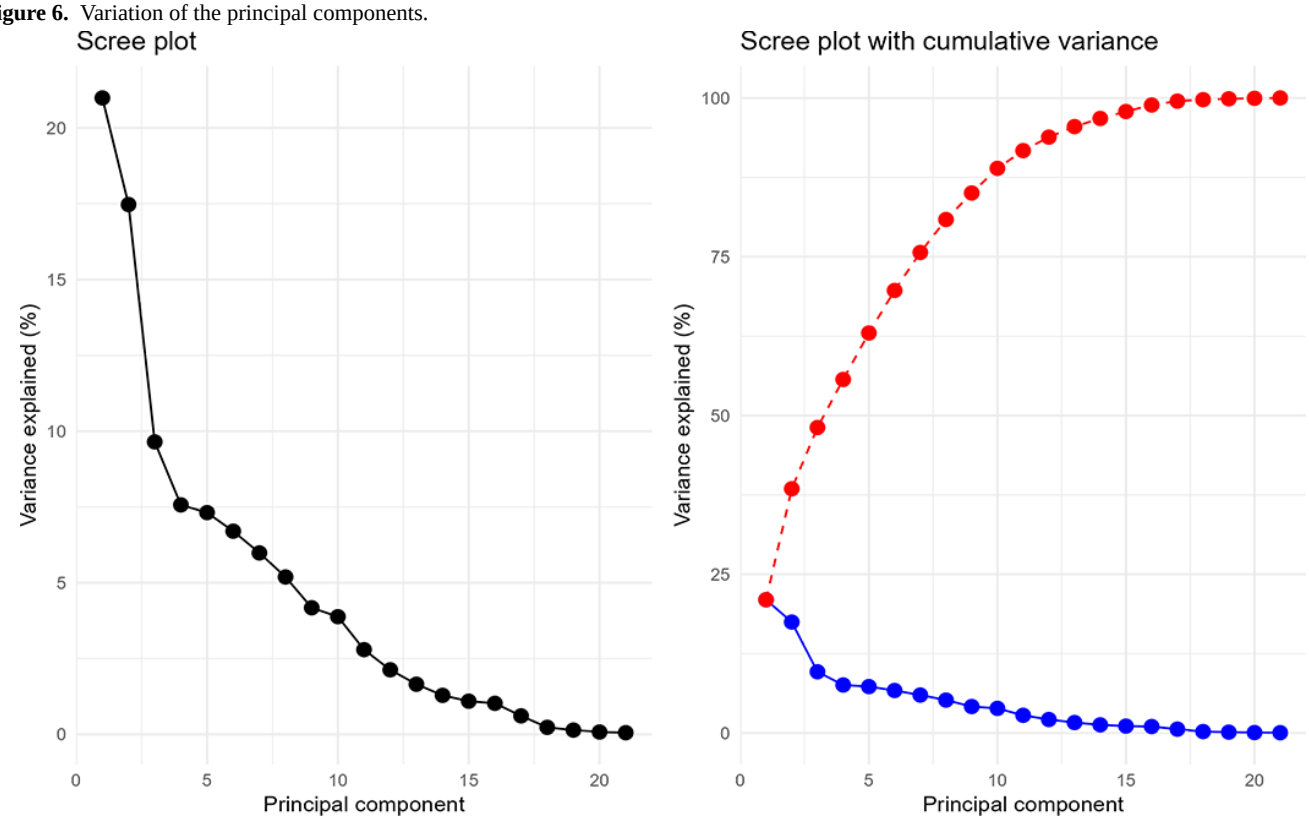
Mathematically, the model can be expressed as follows:

$$\mu=E(\text{count} \mid u,NSZ)=\exp(\beta 0+\beta ixi+u) \forall \text{ count}>0$$

$$u\sim N(0,\sigma u2)$$

$$\sigma 2=\text{Var}(\text{count}|u, NSZ)= \mu(1+\mu\theta)\forall \text{ count}>0$$

$$\text{logitp}=\text{logp}1-p=\beta 0(zi)+\beta i(zi)xi$$



where subscript I denotes the time point, u denotes the random effects terms in the model, NSZ denotes the event "nonstructural

XSL•FO
RenderX

zeros," P=1−Pr(NSZ) is the ZI probability, and θ is the dispersion parameter specific to the family "nbinom2."

For each outcome variable, we created 5 base models. Each model contained a different subset of nursing home QMs, namely, outcome QMs, process QMs, and structural QMs (surveys, provider information, and penalties and staffing). Using a subset of significant predictors (30/58) from the 5 base models, we performed principal component analysis (PCA) for dimensionality reduction on the mean-aggregated dataset, where data were averaged across repeated measures for each entity. Using the loadings (eigenvectors) from this PCA, we calculated principal component scores for the complete dataset, including all the repeated measures. Using the PCA scores as predictors, we created 2 predictive models for the states and the components of the 5-Star Quality Rating System of nursing homes. The first 8 principal components explained 80.86% of the variation present in 30 significant predictors (Figure 6).

Figure 6. Variation of the principal components.

Model Diagnostics

We performed model fit assessment through a combination of graphical diagnostics, goodness-of-fit statistics, and residual analysis. First, observed versus predicted count distributions were compared using histograms to visually assess the model's ability to accurately predict both zero and nonzero values. Second, goodness-of-fit statistics were computed, including the log-likelihood, Akaike Information Criterion, Bayesian Information Criterion, and deviance to evaluate and compare across statistical models. We selected several goodness-of-fit measures to achieve a more robust evaluation of model performance. Third, the Vuong test was applied to compare the ZINB model against standard negative binomial and Poisson models to determine whether the inclusion of a ZI component was statistically justified. Finally, residual diagnostics were performed using the R package *DHARMa* [42], and goodness-of-fit was evaluated through nonparametric, simulation-driven methods. *DHARMa* provided an assessment of outliers, over- or underdispersion, ZI, and the independence of observations by simulating new response data, computing empirical cumulative density functions, and defining residuals based on observed versus simulated values, ensuring a robust model adequacy assessment.

Ethical Considerations

This study is exempt from the institutional review board, as it involved only the use of publicly available data and did not involve human participants, in accordance with 45 CFR 46.102(e). No private, identifiable information was collected or analyzed.

Results

For the models involving outcome QMs as predictors, the number of new COVID-19 cases among residents (β=0.46, SE 0.002; β=0.02, SE 0. 001; and β=0.02, SE 0.003) and staff (β=0.01, SE 0.001; β=0.51, SE 0.002; and β=0.05, SE 0.004) were highly significant, with all the outcomes at the significance levels of P<.001 and P<.001 respectively. The percentage of long-stay residents with UTIs was significant, with staff infections as the outcome (β=−0.004, SE 0.002) at the significance level of P<.10 (P=0.06), resident infections as the outcome (β=−0.01, SE 0.003) at the significance level of P<.001, and total deaths as the outcome (β=−0.03, SE 0.009) at the significance level of P<.01 (P=.001).

XSL•FO
RenderX

For the models involving process QMs as predictors, the indicator concerning residents' weekly COVID-19 admissions (β=0.05, SE 0.003; β=0.04, SE 0.001; and β=0.048, SE 0.002) was significant, with all the outcomes at the significance level of *P*<.001.

Residents' hospitalizations with confirmed COVID-19 (β=0.03, SE 0.002 and β=0.02, SE 0.001), the percentage of current residents up to date with COVID-19 vaccines (β=0.06, SE 0.007 and β=0.02, SE 0.005), and the percentage of long-stay residents assessed and appropriately given the seasonal influenza vaccine (β=0.02, SE 0.005 and β=0.04, SE 0.01) were significant, with at least two of the outcomes at the significance levels of *P*<.001, *P*<.001, and *P*<.001, respectively.

Residents hospitalized with confirmed COVID-19 and up to date with vaccines (β=0.03, SE 0.005 and β=0.05, SE 0.02) and the percentage of long-stay residents with catheters inserted and left in their bladders (β=−0.05, SE 0.005; β=−0.01, SE 0.003; and β=−0.02, SE 0.009) were significant, with at least two of the outcomes at the significance level of *P*<.001 and *P*<.05, respectively.

For the models involving structural QMs (surveys) as predictors, total health deficiencies inspection cycle 2 (β=0.05, SE 0.005 and β=0.01, SE 0.004) was significant, with at least two outcomes at the *P*<.001 significance level.

Total health deficiencies inspection cycle 1 (β=0.04, SE 0.01 and β=0.01, SE 0.004), total health deficiencies inspection cycle 3 (β=0.04, SE 0.01 and β=0.01, SE 0.004), and total fire safety deficiencies inspection cycle 3 (β=0.02, SE 0.01 and β=0.01, SE 0.004) were significant, with at least one of the outcomes at the significance level of *P*<.001, *P*<.05, and *P*<.05, respectively.

For the models involving structural QM (provider information) as predictors, percentage of occupied beds (β=0.04, SE 0.005; β=−0.06, SE 0.004; and β=−0.25, SE 0.01), provider resides in hospital (β=0.19, SE 0.02; β=0.07, SE 0.01; and β=0.13, SE 0.03), and days since approval to provide Medicare and Medicaid services (β=0.08, SE 0.005; β=0.02, SE 0.005; and β=0.04, SE 0.01) were significant, with all outcomes at the *P*<.001, *P*<.001, and *P*<.001 significance levels, respectively.

Continuing care retirement community (β=0.08, SE 0.009 and β=0.06, SE 0.02) and at least one of the 2 binary components of provider type (component 1: β=0.26, SE 0.03; β=0.08, SE 0.03; and β=0.25, SE 0.06), with a resident and family council (component 1: β=0.02, SE 0.005; β=0.05, SE 0.01 and component 2: β=0.08, SE 0.01; β=0.03, SE 0.01; and β=0.16, SE 0.03), and new ownership type (component 2: β=0.05, SE 0.01 and β=−0.07, SE 0.01) were significant, with at least two of the outcomes at the *P*<.001, *P*<.001, *P*<.001, *P*<.001, and *P*<.001 significance level.

For the models involving structural QMs (penalties and staffing) as predictors, all the staffing variables, namely employee nurse total weekly hours (β=0.12, SE 0.006; β=0.09, SE 0.005; and β=0.06, SE 0.01), employee nonnursing total weekly hours (β=−1.06, SE 0.006; β=−0.09, SE 0.005; and β=−0.05, SE 0.01), contract nurse total weekly hours (β=0.1, SE 0.004; β=0.08, SE 0.003; and β=0.10, SE 0.008), and contract nonnursing total weekly hours (β=−0.1, SE 0.01; β=−0.1, SE 0.004; and β=−0.04, SE 0.01) were significant, with all the outcomes at the *P*<.001 significance level, respectively.

Component 3 of provider state (component 3: β=−0.23, SE 0.05; β=−0.23, SE 0.05; and β=−0.20, SE 0.06) was significant at the *P*<.001 significance level. None of the components of the provider county achieved a high level of significance.

The linear (β=0.08, SE 0.008 and β=0.05, SE 0.006), quadratic (β=0.02, SE 0.005 and β=0.02, SE 0.004), and cubic (β=0.03, SE 0.005 and β=0.02, SE 0.003) components of the health inspection rating were significant, with resident infections and staff infections as outcomes at the *P*<.001, *P*<.001, and *P*<.001 significance levels, respectively. However, only the quartic (β=−0.0156, SE 0.0079) component of the health inspection rating was significant, with total deaths as the outcome at the *P*<.05 (*P*=.048) significance level.

The QM rating had significant linear (β=−0.02, SE 0.01) and cubic components (β=−0.01, SE 0.005) in the model, with resident infections as the outcome at the *P*<.05 (*P*=.002) and *P*<.05 (*P*=.045) significance levels, respectively. In addition to the linear (β=0.0164, SE 0.0055) and cubic (β=−0.009, SE 0.003) components, the quartic (β=−0.006, SE 0.003) component was significant at the *P*<.05 (*P*=.003), *P*<.05 (*P*=.01), and *P*<.05 (*P*=.04) significance levels, respectively, in the model with staff infections as the outcome. The quadratic (β=−0.02, SE 0.01) and cubic (β=0.02, SE 0.01) components were significant at the *P*<.05 (*P*=.04) and *P*<.05 (*P*=.045) significance levels, respectively, in the model with total deaths as the outcome.

Staffing rating had a significant linear (β=0.02, SE 0.005) component in the models with staff infections and total deaths as the outcomes at the *P*<.001 significance level. The model with resident infections as the outcome only showed a significant cubic (β=−0.008, SE 0.004) trend at the *P*<.1 (*P*=.06) significance level. In the model with total deaths as the outcome, both the linear (β=0.12, SE 0.01) and quadratic (β=−0.05, SE 0.01) components were significant at the *P*<.001 and *P*<.001 significance levels, respectively, and the quartic (β=−0.01, SE 0.007) component was significant at the *P*<.1 (*P*=.05) significance level.

The discussed results are summarized in Tables 2 and 3. Multimedia Appendix 1, containing the complete model results in the original (log) scale, and Multimedia Appendix 2, containing the visualization of their 95% CIs in the response (exponent) scale, are provided for further reference.

Discussion

Principal Findings

In this study, we used a panel dataset to evaluate the effectiveness of several nursing home QMs in explaining nursing home QoC in terms of COVID-19 outcomes. Staffing measures (*P*<.001 for all variables in all models), health deficiency scores (*P*<.001 for all variables in at least 1 model), COVID-19 hospitalizations (*P*<.001 for all variables in at least 2 models), and vaccinations (*P*<.001 for all variables in at least 2 models) exhibited meaningful relationships with the COVID-19 outcomes. The 5-Star Quality Rating System for nursing homes, Medicaid dependency, and ownership showed no clear relationships with the COVID-19 outcomes.

We found a significant association with the percentage of long-stay residents with UTIs. In a retrospective study, the authors evaluated UTI diagnoses and antibiotic prescriptions in 622 COVID-19 hospital ward patients, and they found that 61% of cases had probably been overdiagnosed [43]. Several researchers studying long-term care facilities have also found evidence of overdiagnosis in the form of inappropriate initiation of antimicrobial treatment in 37% to 61% of patients [43-49].

We also identified significant associations with the percentages of long-stay and short-stay residents assessed and appropriately given the seasonal influenza vaccine. A study compared COVID-19 and seasonal influenza patient groups and suggested that preexisting chronic respiratory conditions more strongly impacted the severity of seasonal influenza than that of COVID-19 [50]. It has also been reported that chronic lower respiratory tract diseases claim the third highest number of lives among adults aged >65 years [51-55]. Therefore, older individuals with comorbidities for both respiratory infections may exhibit stronger symptoms of seasonal influenza than COVID-19, demanding management through the administration of seasonal influenza vaccines.

A significant association was uncovered for the percentage of long-stay residents with catheters inserted and left in their bladders. In a recent systematic review of 67 studies, scholars found that catheter prevalence among nursing home residents varied between 2.2% and 36.4%, with a typical rate of 7.3% [56,57]. Catheter-associated UTIs comprise 32% of all health care–associated infections [57,58]. The fact that catheter use is frequently reported in long-term care residents and is a leading cause of UTI helps explain our results, which show significant associations with COVID-19 outcomes for both the percentage of long-stay residents with UTIs and the percentage of long-stay residents with catheters inserted and left in their bladders.

Our findings indicate a significant association between health deficiency variables and resident and staff COVID-19 cases. During the period 2013 to 2017, more than four-fifths of nursing homes in the United States engaged in deficient infection prevention and control practices, including those that substantially reduced the spread of COVID-19, such as proper hand washing and isolation procedures [21,59]. It is possible that these poor practices continued during the pandemic, making nursing home residents and staff more susceptible to COVID-19 infections.

Several scholars have reported that lower resident density, measured by the proxy variable of the percentage of occupied beds, is associated with a lower prevalence of COVID-19 [59-65]. Our study showed a similar association with resident infections but an inverse association with staff infections and total deaths. We found that hospital-based nursing homes reported fewer COVID-19 cases and deaths than nonhospital-based nursing homes, which is consistent with the results of a study by Tarteret et al [66]. Gorges and Konetzka [67] demonstrated facility-level differences in QoC based on the proportion of residents with Medicaid coverage at the facility. Compared to nursing homes accepting Medicaid only, nursing homes accepting Medicare showed clearly better COVID-19 outcomes in only 2 of 3 models. In 1 model, the difference was less clear due to overlapping 95% CIs.

Evidence from various studies suggests that for-profit nursing homes are more prone to COVID-19 outbreaks compared to nonprofit and government nursing homes [59,61,65,68]. However, some scholars have found no statistically significant link in this regard [34,60,66]. We did not notice a clear difference between for-profit, nonprofit, and government nursing homes. Furthermore, no clear difference in outcomes was observed between nursing homes with or without continuing care retirement communities, resident councils, family councils, or resident and family councils. While not a key characteristic,

XSL•FO
RenderX

nursing homes newly approved to provide Medicare and Medicaid services had better COVID-19 outcomes compared to long-standing nursing homes. This could be because newer nursing homes underwent inspections more recently than previously approved homes as part of their approval process.

Inadequate nursing staff have been linked to a higher likelihood of COVID-19 outbreaks in some studies [59,62,64,65,68-70], but others indicate no significant connection [61,65,69,71]. Our findings show that increased staffing hours for nursing staff resulted in worse COVID-19 outcomes, whereas increased staffing hours for non-nursing staff resulted in better COVID-19 outcomes. We did not explore these associations further based on the types of nursing and nonnursing staff.

Most researchers have found no meaningful connection between nursing home overall quality rating and COVID-19 outcomes [34,60-62,69,72-79]. Similarly, most scholars have found no clear relationships between COVID-19 outcomes and 2 components of the 5-Star Quality Rating System for Nursing Homes, namely staffing rating and health inspection rating [61,64,70,73,78]. Our analysis did not reveal a clear relationship between the components of the 5-Star Quality Rating System for nursing homes and COVID-19 outcomes.

Limitations

This study has some limitations. It only considered temporal autocorrelation, without addressing spatial autocorrelation, thus ignoring potential interdependencies across spatial units. Temporal autocorrelation assumes that changes over time are isolated within units, which is rarely the case in interconnected systems, such as health care networks. We also did not perform multiple dataset imputations, which could have resulted in less robust statistical analyses, as a single imputation set may not adequately reflect the variability inherent in missing data. By generating a range of plausible datasets, MIs allow for more accurate and reliable parameter estimates by accounting for the uncertainty around the imputed values. Future scholars should consider modeling both spatial and temporal autocorrelations, as well as performing MIs, to increase the validity and reliability of their findings.

Conclusions

The evolution of quality in the nursing home industry is truly remarkable. However, sustained progress is essential to meet the needs of the growing older adult population. Although widely used in the nursing home industry, the 5-Star Quality Rating System for nursing homes is an unreliable performance measure. As demonstrated through the results of the study, it is hard to delineate nursing homes' performance based on the star ratings, after accounting for the underlying QMs. Concerted efforts from lawmakers, policy makers, and lobbyists will be required to refine and enhance the measure, thereby ensuring its reliability and effectiveness.

Funding

The authors did not receive support from any funding agency in the public, commercial, or not-for-profit sectors for the submitted work.

Data Availability

The datasets used in this study are available from the author's figshare repositories and are listed in the references.

Abstract

Background: Artificial intelligence (AI) detection tools for intracranial hemorrhage (ICH) are increasingly integrated into radiology workflows. In real-world practice, perceived utility depends not only on diagnostic performance but also on workflow fit, false positive burden, and how clinicians interpret and act on AI outputs.

Objective: This study aimed to characterize radiologists' perceptions of a Food and Drug Administration (FDA)–cleared ICH AI detection tool in a national teleradiology network, including perceived reliability, false positive burden, workflow impact, medicolegal concerns, and self-reported behaviors during routine use.

Methods: We conducted an anonymous cross-sectional survey of radiologists in a national teleradiology practice who had access to an FDA-cleared ICH AI overlay during noncontrast head computed tomography interpretation. Survey items used a 5-point Likert scale. Results are summarized as agreement proportions ("agree" or "strongly agree") with 95% CIs. We compared neuroradiologists with non-neuroradiologists using Fisher exact tests. One primary end point was prespecified: agreement that time spent reviewing examinations with false positive AI alerts outweighed the benefits. Remaining subgroup comparisons were treated as exploratory, with false discovery rate control using the Benjamini-Hochberg procedure.

Results: A total of 65 radiologists responded, including 23 (35.4%) neuroradiologists and 42 (64.6%) non-neuroradiologists. Only 18.5% (12/65; 95% CI 10.9%-29.6%) agreed that false-positive alerts were infrequent enough to be acceptable. Agreement that the AI correctly identified most ICH cases was 32.3% (21/65; 95% CI 22.2%-44.4%), and agreement that the AI rarely missed clinically important hemorrhages was 43.1% (28/65; 95% CI 31.8%-55.2%). Trust in AI output was conditional: 50.8% (33/65; 95% CI 38.9%-62.5%) reported trusting the AI when it agreed with their interpretation, whereas 3.1% (2/65; 95% CI 0.8%-10.5%) reported trusting it when it conflicted with their interpretation. Only 10.8% (7/65; 95% CI 5.3%-20.6%) reported reduced overall interpretation time, whereas 33.8% (22/65; 95% CI 23.5%-46.0%) agreed that time spent reviewing false-positive alerts outweighed the benefits. Self-reported reduced scrutiny after an AI-negative result was uncommon (4/65, 6.2%; 95% CI 2.4%-14.8%). In subgroup analysis, neuroradiologists more often endorsed the primary end point than non-neuroradiologists (12/23, 52.2% vs 10/42, 23.8%; unadjusted P=.03), but no exploratory subgroup differences remained statistically significant after false discovery rate correction. Free-text responses emphasized artifact- and calcification-driven false positives, delayed or inconsistent AI availability, consultation burden, and medicolegal concerns.

Conclusions: In this national teleradiology setting, radiologists reported substantial false positive burden, limited perceived time savings, and strongly conditional trust in an FDA-cleared ICH AI detection tool. Self-reported reduced scrutiny after negative AI outputs was uncommon but present in a minority of cases. These findings support the importance of specificity, interpretability, latency, and workflow-aware implementation when deploying radiology AI tools in practice.

Introduction

Intracranial hemorrhage (ICH) on noncontrast head computed tomography (CT) is a high-stakes diagnosis in emergency and inpatient care requiring timely identification and communication. Artificial intelligence (AI) systems intended to detect ICH are increasingly incorporated into radiology workflows, including as diagnostic assistive tools during radiologist interpretation and, in some implementations, as tools to support prioritization of urgent cases [1-4]. However, the real-world value of these systems depends not only on discriminative performance but also on how they interact with clinical workflow, how often they generate disruptive false-positive alerts, and how clinicians interpret their outputs in routine practice [2-5].

Post-deployment evaluation is increasingly recognized as essential for clinical AI. DECIDE-AI (Developmental and Exploratory Clinical Investigations of Decision Support Systems Driven by Artificial Intelligence) and related implementation literature emphasize that early live clinical evaluation should address workflow integration, human factors, and unintended burdens rather than focusing on accuracy alone [5]. Real-world studies of radiology AI have similarly shown that local prevalence, operational context, and implementation strategy can substantially shape perceived utility and clinician acceptance [2,3,6]. For example, deployment experience with an AI algorithm in clinical practice has highlighted how false discovery burden can create an "accuracy paradox" in which an apparently high-performing system is experienced as inaccurate because positive alerts are frequently false in a low-prevalence setting [6].

Human factors theory suggests that false alarms, workflow interruptions, and opaque outputs can alter clinician reliance on automation [7-10]. In health care more broadly, high alert burden and repeated alerts can contribute to alert fatigue and reduced responsiveness to clinical decision support alerts [8]. In radiology, incorrect AI outputs may affect reader confidence and performance, particularly when the AI appears authoritative or visually salient [9]. At the same time, survey data alone cannot establish whether AI changes diagnostic behavior; they are better suited to characterizing clinician perceptions, attitudes, and self-reported experiences.

We previously evaluated a Food and Drug Administration (FDA)–cleared ICH AI tool in a national teleradiology network and reported operational observations, including false positives and radiologist-reported effects on interpretation time [1]. The study reported in this paper extends that work by focusing on radiologists' perceptions during routine exposure to the tool. Specifically, we sought to characterize perceived reliability, false positive burden, workflow impact, medicolegal concerns, and self-reported behaviors during AI-assisted interpretation and explore whether these perceptions differed by neuroradiology subspecialty training.

Methods

Study Design

This was an anonymous cross-sectional survey study conducted within a national teleradiology practice. This study was designed as a real-world implementation evaluation aligned with early-stage clinical AI assessment principles, with emphasis on workflow context and user experience [5].

Ethical Considerations

This evaluation met the US Department of Veterans Affairs criteria for quality assessment and nonresearch and received a determination of nonresearch from the Stanford University Institutional Review Board (protocol 73642). Participation was voluntary and anonymous.

Participants

Eligible participants were practicing radiologists within the teleradiology group who had access to the ICH AI output during routine noncontrast head CT interpretation. Respondents self-reported whether they had neuroradiology fellowship training or primarily practiced neuroradiology, and responses were stratified as neuroradiologists vs non-neuroradiologists.

AI Tool and Workflow Context

The evaluated system was an FDA-cleared and commercially available deep learning algorithm for ICH detection (CINA version 1.0; Avicenna.ai) integrated into the reading workflow for noncontrast head CT. The tool was intended to assist radiologists in identifying suspected ICH during image interpretation and, depending on workflow configuration, could also support prioritization. In practice, radiologists could view AI-generated overlays during interpretation, and the system functioned as an adjunctive diagnostic support tool within routine workflow. The tool did not replace radiologist interpretation, and final clinical interpretation remained the responsibility of the reading radiologist. Because intended use and actual workflow exposure are both relevant to interpretation of user perceptions, we frame these findings as perceptions arising during routine use of the tool in this implementation context.

Survey Instrument

The survey included 15 Likert items spanning the following domains: perceived reliability, false positive burden, workflow integration, time impact, medicolegal concerns, adoption preferences, and self-reported behaviors during AI use. Responses were captured on a 5-point scale ("strongly agree," "agree," "neutral," "disagree," and "strongly disagree"). Items were developed for face validity based on prior operational experience and relevant human factors concepts, but the instrument was not a formally validated psychometric measure. Accordingly, results were interpreted on the face of each item as descriptive measures of respondent perceptions.

XSL•FO
RenderX

Prespecified End Point and Statistical Analysis

To limit overinterpretation from multiple comparisons, one primary end point was prespecified: agreement with the following statement: "The extra time spent reviewing AI false-positive studies outweighs the benefits." This end point was selected because false positive burden was considered a central determinant of usability and adoption in a high-volume teleradiology environment.

All other item-level subgroup comparisons were considered exploratory. Responses were summarized as agreement proportions, defined as the percentage selecting "agree" or "strongly agree." We report proportions with 2-sided 95% CIs using Wilson intervals. For subgroup comparisons, we used Fisher exact tests on dichotomized responses ("agree" or "strongly agree" vs all other responses). Because responses were condensed from a 5-point scale to a binary end point for interpretability and consistency with implementation-focused survey reporting, some resolution was necessarily lost. Therefore, we interpret subgroup analyses as descriptive and hypothesis generating. False discovery rate control for exploratory subgroup comparisons was applied using the Benjamini-Hochberg procedure. Analyses were performed in Python (version 3.13.5; Python Software Foundation) using exact tests and Wilson interval estimation with *SciPy* (version 1.17.0) and *statsmodels* (version 0.14.6).

Qualitative Analysis

Optional free-text comments were reviewed qualitatively to identify recurring implementation themes. Comments could map to more than one theme. Representative excerpts were selected to illustrate the most common concerns raised by respondents.

Results

Respondent Characteristics

A total of 65 radiologists completed the survey, including 23 (35.4%) neuroradiologists and 42 (64.6%) non-neuroradiologists. Full quantitative results across all survey items are provided in Table 1.

XSL•FO
RenderX

Table 1. Agreement proportions across survey items ("agree" or "strongly agree") overall and stratified by neuroradiology training. The prespecified primary end point is item 7 (N=65)[a].

Item number	Question	Total, n (%; 95% CI)	Neuroradiologists (n=23), n (%)	Non-neuroradiologists (n=42), n (%)	*P* value	*q* value
1	The AI[b] tool correctly identifies most cases of intracranial hemorrhage.	21 (32.3; 22.2-44.4)	8 (34.8)	13 (31.0)	.79	.92
2	False-positive alerts from the AI are infrequent enough to be acceptable.	12 (18.5; 10.9-29.6)	4 (17.4)	8 (19.0)	>.99	>.99
3	The AI rarely misses clinically important hemorrhages.	28 (43.1; 31.8-55.2)	10 (43.5)	18 (42.9)	>.99	>.99
4	I trust the AI output when it agrees with my own interpretation.	33 (50.8; 38.9-62.5)	11 (47.8)	22 (52.4)	.80	.92
5	I trust the AI output when it conflicts with my initial impression.	2 (3.1; 0.8-10.5)	0 (0)	2 (4.8)	.54	.90
6	Using the AI has reduced my overall interpretation time per head CT[c].	7 (10.8; 5.3-20.6)	1 (4.3)	6 (14.3)	.41	.90
7	The extra time spent reviewing AI false-positive studies outweighs the benefits.	22 (33.8; 23.5-46.0)	12 (52.2)	10 (23.8)	.03	—[d]
8	If the AI labels a study as negative, I tend to scrutinize it less thoroughly than usual.	4 (6.2; 2.4-14.8)	0 (0)	4 (9.5)	.29	.90
9	The AI reduces the risk that I will overlook a subtle hemorrhage on a busy shift.	23 (35.4; 24.9-47.5)	7 (30.4)	16 (38.1)	.60	.90
10	Frequent false positive alerts make me second-guess my decisions.	20 (30.8; 20.9-42.8)	4 (17.4)	16 (38.1)	.10	.75
11	Overall, the AI has improved the quality of care our patients receive.	13 (20; 12.1-31.3)	4 (17.4)	9 (21.4)	.76	.92
12	I feel legally vulnerable if I override an AI recommendation.	21 (32.3; 22.2-44.4)	6 (26.1)	15 (35.7)	.58	.90
13	The AI integrates smoothly into our PACS[e]/reporting workflow.	32 (49.2; 37.5-61.1)	13 (56.5)	19 (45.2)	.44	.90
14	I would recommend continued use of this AI tool in our practice.	19 (29.2; 19.6-41.2)	5 (21.7)	14 (33.3)	.40	.90
15	I would like additional feedback or training to use the AI tool optimally.	13 (20; 12.1-31.3)	3 (13.0)	10 (23.8)	.35	.90

[a]Between-group comparisons were conducted using Fisher exact tests. False discovery rate control across exploratory subgroup comparisons was applied using the Benjamini-Hochberg procedure; *q* values are reported for exploratory items.

[b]AI: artificial intelligence.

[c]CT: computed tomography.

[d]Not applicable. Item 7 was the prespecified primary end point; *q* values were not applied to this item.

[e]PACS: picture archiving and communication system.

Perceived Reliability and False Positive Burden

Agreement that the AI correctly identified most cases of ICH was 32.3% (21/65; 95% CI 22.2%-44.4%). Agreement that the AI rarely missed clinically important hemorrhages was somewhat higher at 43.1% (28/65; 95% CI 31.8%-55.2%). In contrast, only 18.5% (12/65; 95% CI 10.9%-29.6%) agreed that false-positive alerts were infrequent enough to be acceptable, indicating that perceived false positive burden was a prominent limitation.

The prespecified primary end point was also consistent with this pattern. Overall, 33.8% (22/65) of respondents (95% CI 23.5%-46.0%) agreed that the extra time spent reviewing examinations with false positive AI alerts outweighed the benefits of the system. These radiologists endorsed the view that false positive workload offset the tool's net value in routine use. Overall agreement across survey items is shown in Table 1.

Trust in AI Output and Perceived Workflow Impact

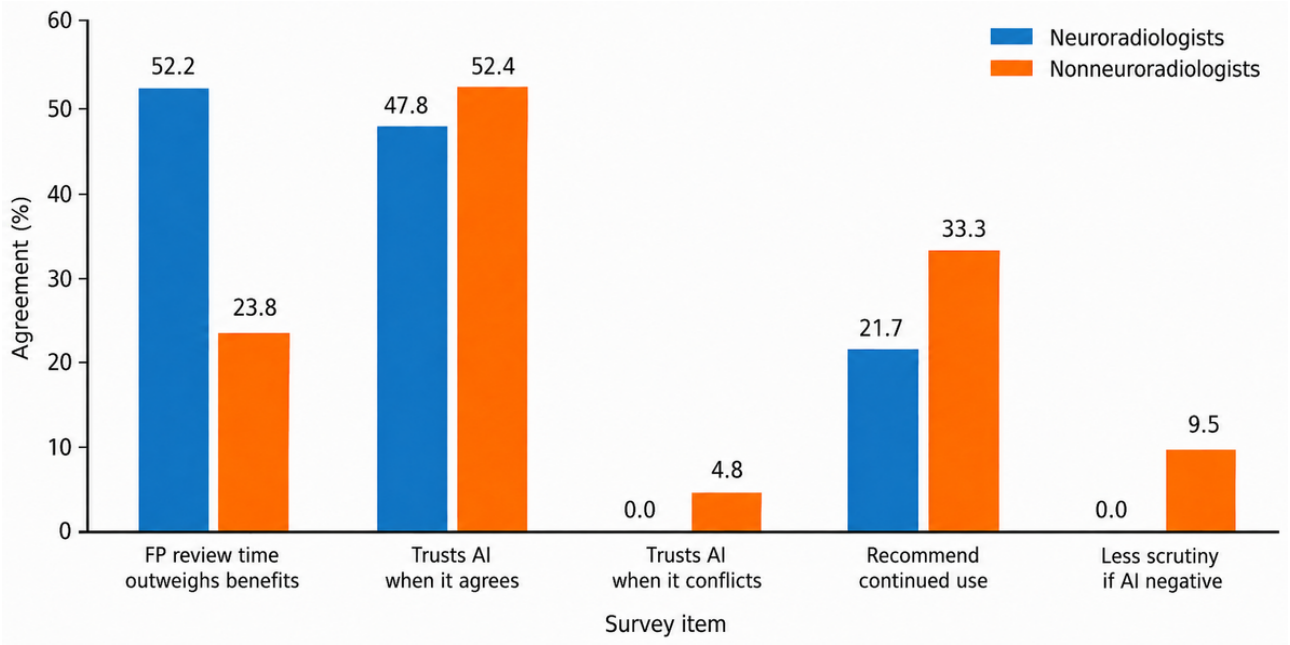
Responses suggested strongly conditional trust in the AI output. Half (33/65, 50.8%) of respondents (95% CI 38.9%-62.5%) agreed that they trusted the AI when it agreed with their own interpretation. In contrast, only 3.1% (2/65; 95% CI 0.8%-10.5%) agreed that they trusted the AI when it conflicted with their initial impression. This asymmetry suggests that

XSL•FO
RenderX

respondents were much more likely to experience the AI as confirmatory than as persuasive in discrepant cases.

Perceived workflow benefit was limited. Only 10.8% (7/65) of respondents (95% CI 5.3%-20.6%) agreed that AI use reduced their overall interpretation time per head CT. Similarly, 35.4% (23/65; 95% CI 24.9%-47.5%) agreed that the AI reduced the risk that they would overlook a subtle hemorrhage on a busy shift, indicating that perceived detection support was present for some respondents but did not translate into broad perception of time savings.

Self-Reported Behaviors, Quality Perceptions, and Medicolegal Concerns



Self-reported reduced scrutiny after a negative AI result was uncommon. Only 6.2% (4/65) of the respondents (95% CI 2.4%-14.8%) agreed with the statement that, if the AI labeled a result as negative, they tended to scrutinize it less thoroughly than usual. Because this was a self-reported perception and not a direct behavioral measurement, we interpreted it narrowly as a descriptive response to the survey item.

Frequent false-positive alerts were also associated with self-reported second-guessing. A total of 30.8% (20/65) of the respondents (95% CI 20.9%-42.8%) agreed that frequent false-positive alerts made them second-guess their decisions. Only 20% (13/65; 95% CI 12.1%-31.3%) agreed that the AI improved the quality of care that patients received. Agreement that the AI integrated smoothly into the picture archiving and communication system or reporting workflow was 49.2% (32/65; 95% CI 37.5%-61.1%), suggesting mixed perceptions of integration. Recommendation for continued use of the tool was endorsed by 29.2% (19/65; 95% CI 19.6%-41.2%). Concern about legal vulnerability when overriding AI output was reported by 32.3% (21/65; 95% CI 22.2%-44.4%). Additional feedback or training to use the tool optimally was desired by 20% (13/65; 95% CI 12.1%-31.3%).

Subgroup Findings by Neuroradiology Training

Neuroradiologists more frequently endorsed the primary end point than non-neuroradiologists (12/23, 52.2% vs 10/42, 23.8%; unadjusted *P*=.03). For exploratory items, patterns were broadly similar between groups. Agreement with trusting the AI when it agreed with the reader's interpretation was 47.8% (11/23) among neuroradiologists and 52.4% (22/42) among non-neuroradiologists. Trust in conflicting AI output remained rare in both groups (0% vs 2/42, 4.8%). Self-reported reduced scrutiny after an AI-negative result was reported by 0% of neuroradiologists and 9.5% (4/42) of non-neuroradiologists. Recommendation for continued use was reported by 21.7% (5/23) of neuroradiologists and 33.3% (14/42) of non-neuroradiologists. After false discovery rate correction, no exploratory subgroup differences remained statistically significant. Descriptive subgroup comparisons for selected survey items are shown in Figure 1.

Figure 1. Descriptive comparison of agreement by subspecialty training for selected survey items. Bars show the percentage of respondents selecting "agree" or "strongly agree" among neuroradiologists and non-neuroradiologists for selected items related to false positive (FP) burden, trust in artificial intelligence (AI) output, recommendation for continued use, and reported less thorough than usual scrutiny of AI-negative results. These subgroup comparisons are descriptive; no exploratory subgroup differences remained statistically significant after false discovery rate correction.

Qualitative Themes From Free-Text Comments

Free-text responses reinforced the quantitative findings and highlighted recurring implementation concerns.

Theme 1: Artifact- and Calcification-Driven False Positives Dominated the User Experience

Many respondents attributed false-positive alerts to parafalcine calcification, skull-adjacent artifacts, motion, or streak artifacts and described these alerts as disruptive or time-consuming.

XSL•FO
RenderX

Theme 2: Perceived Utility Was Limited Unless the Tool Meaningfully Changed Triage

Several respondents indicated that the system primarily identified obvious hemorrhages and offered limited incremental value for experienced readers, although some suggested that workflow-level prioritization or routing features might improve perceived utility.

Theme 3: Latency and Inconsistent Availability Reduced Usefulness

Multiple respondents noted that AI output was not always available at the time of dictation or arrived too late to be helpful.

Theme 4: False-Positive Alerts Increased Second-Guessing and Consultation Burden

Some comments suggested that false-positive AI flags triggered unnecessary consultation or additional cognitive burden.

Theme 5: Medicolegal Concerns Influenced Acceptance

Respondents expressed discomfort with the possibility that delayed or discrepant AI outputs could create liability concerns.

Theme 6: Respondents Wanted Better Localization, Higher Specificity, and More Training

Suggested improvements included more precise localization, lower false positive rates, better timing, and implementation feedback or training.

Aggregated Themes

Aggregated qualitative themes and representative excerpts are summarized in Table 2.

Table 2. Qualitative themes from free-text responses. Comments could map to more than one theme; counts reflect the number of comments mentioning each theme at least once (N=65)[a].

Theme	Description	Count, n (%)	Representative excerpt
False positives or low specificity	Frequent false-positive alerts, commonly attributed to artifacts or calcification; perceived as disruptive and time-consuming	22 (33.8)	“False positives are too frequent...”
Limited utility, discontinue, or low value	Negative overall sentiment, including requests to discontinue the tool or concerns that its value did not justify its burden	13 (20)	“Please remove AI completely.”
Latency or availability	AI[b] output was sometimes delayed or unavailable at the time of dictation or interpretation	7 (10.8)	“Sometimes AI image made available very late...”
Medicolegal concerns	Concerns about legal vulnerability, accountability, or liability if the AI output appeared after sign-off or conflicted with their interpretation	5 (7.7)	“It could potentially ‘frame’ me.”
False negatives or missed hemorrhages	Concern that the tool could miss subtle hemorrhages, particularly smaller or less conspicuous bleeds	4 (6.2)	“I have seen several false negatives.”
Positive or supportive comments	Explicitly positive feedback or support for continued use despite limitations	4 (6.2)	“The AI ICH tool is great!”
Triage, prioritization, or assignment routing	Suggestions that the tool might be more useful if integrated into prioritization or routing workflows	3 (4.6)	“Positive studies should be assigned...and prioritized.”
Consultation burden or second-guessing	Reports that false-positive AI alerts increased consultation burden or second-guessing	3 (4.6)	“I frequently get consults.”
Training or feedback requests	Requests for additional training, implementation guidance, or feedback on use	2 (3.1)	“I would like additional training.”

[a]Aggregated qualitative findings from optional free-text comments are summarized. Because individual comments could mention more than one concern, counts are not mutually exclusive and reflect the number of comments mentioning each theme at least once.

[b]AI: artificial intelligence.

Discussion

Principal Findings

In this survey of radiologists exposed to an FDA-cleared ICH AI detection tool in a national teleradiology environment, 3 findings stood out. First, false positive burden was a central driver of dissatisfaction: fewer than 1 in 5 respondents found false-positive alerts infrequent enough to be acceptable, and one-third (22/65, 33.8%) agreed that time spent reviewing false-positive alerts outweighed the tool’s benefits. Second, perceived workflow benefit was limited: only approximately 1 in 10 respondents reported reduced interpretation time despite a larger minority reporting that the tool might reduce the risk of missing subtle hemorrhages during busy shifts. Third, trust in the AI output was strongly conditional. Respondents were willing to trust the AI much more often when it agreed with their own interpretation than when it conflicted with it.

Taken together, these findings suggest that the practical value of this implementation was constrained less by the abstract idea of AI assistance than by the combined effects of false positive burden, timing, and workflow integration. In other words, the tool appears to have been experienced more as an additional signal to manage than as a consistently efficiency-enhancing aid.

XSL•FO
RenderX

Relationship to Prior Work

These results are consistent with a growing literature showing that post-deployment experience with clinical AI may differ substantially from laboratory or regulatory performance summaries [2-6]. In radiology and other clinical settings, user acceptance is shaped not only by sensitivity and specificity but also by local disease prevalence, the timing of alerts, the interpretability of outputs, and how often the system changes action in a useful direction [5,6]. Scaringi et al [6] described how real-world deployment can produce an "accuracy paradox" in which acceptable technical performance is experienced as poor because positive alerts carry a high false discovery burden in a low-prevalence setting. That framework is highly relevant in this study, where many respondents perceived the false positive rate as a major practical barrier.

These findings also align with human factors literature on alarm burden and trust in automation. High alert burden and repeated false-positive alerts can result in cognitive overhead, desensitization, and reduced perceived usefulness of decision support systems [7,8]. Meanwhile, trust in automation is often selective rather than global; clinicians may accept AI as supportive when it confirms a preexisting judgment but remain reluctant to defer to it when it conflicts with their own assessment [10,11]. Our survey findings fit that pattern closely. However, importantly, because we measured perceptions rather than observed task performance, our data support cautious description of conditional trust patterns, not stronger causal inferences about AI-driven decision change.

Interpreting the Self-Reported Behavior Item Cautiously

A survey item about scrutinizing AI-negative results less thoroughly does not establish a behavioral phenomenon in the same way that a controlled multi-reader study could. Accordingly, we interpret this result narrowly. The 6.2% (4/65) agreement rate should be read only as the proportion of respondents who self-reported less thorough scrutiny after a negative AI result on that item. It should not be construed as direct evidence of automation-induced complacency or measurable diagnostic underreading. This distinction is important, particularly because self-report on professionally sensitive behaviors may be influenced by social desirability bias [9,10].

At the same time, the item remains informative as a perception signal. Even a small minority of respondents endorsing reduced scrutiny suggests that how negative AI outputs are presented, timed, and contextualized may matter. Future work using controlled reader studies, audit-based designs, or prospective workflow observation would be better suited to determining whether and when AI output measurably alters vigilance or diagnostic behavior.

Why False Positive Burden Matters So Much in Teleradiology

The teleradiology environment may amplify the operational importance of false positives. High case volume, rapid turnaround expectations, and distributed communication structures can magnify the cost of reviewing spurious alerts or revisiting already completed interpretations. In such settings, an alert that does not change management may still consume attention, create uncertainty, or generate downstream consultation. The free-text comments in this study point to precisely these burdens: artifact-driven overcalls, delayed output, second-guessing, and extra communication work.

This observation has practical implications for how radiology AI tools should be tuned and evaluated. In some settings, maximizing sensitivity may be appropriate, particularly when AI outputs are used to support prioritization or highlight potentially urgent findings; however, if the resulting false positive burden is too high, this may erode clinician acceptance even when the tool performs as intended at a regulatory or technical level [3,4,6]. Therefore, a workflow-sensitive implementation strategy may matter as much as the operating characteristics of the algorithm itself.

Implications for Implementation

Several implementation lessons emerge from these data. First, specificity matters. The comments suggest that calcification, streak artifacts, motion, and skull-adjacent findings were recurrent sources of false-positive alerts. Improving discrimination in these common failure modes could meaningfully improve user acceptance. Second, interpretability matters. If discrepant alerts are to influence radiologist behavior in a useful way, users may need clearer localization, confidence communication, or other forms of contextual explanation rather than a generic positive signal [4,9]. Third, timing matters. Decision support that appears after a case has effectively been interpreted is less likely to help and more likely to create noise or ambiguity. Fourth, workflow design matters. Some respondents suggested that the tool's value might be enhanced by workflow-level prioritization or routing features in addition to its use as an overlay during interpretation.

Subgroup Findings and Their Interpretation

Neuroradiologists were more likely than non-neuroradiologists to endorse the primary end point that false positive review time outweighed benefits, but this finding should be interpreted cautiously. It was the only subgroup result meeting nominal significance, and no exploratory subgroup differences remained significant after false discovery rate correction. Therefore, the most appropriate interpretation is descriptive and hypothesis generating rather than confirmatory. It is possible that subspecialty training influences tolerance for false positives, perceived incremental value, or expectations of tool performance, but this survey was not designed to establish those mechanisms.

Strengths and Limitations

A strength of this study is that it captured the views of radiologists exposed to the tool in routine clinical practice rather than in an artificial test setting. The inclusion of both structured survey items and free-text comments helped contextualize quantitative responses and identify concrete implementation barriers.

This study also has several limitations. First, the findings are based on self-reported perceptions rather than objective

XSL•FO
RenderX

measures of diagnostic performance, reading time, or patient outcomes. Second, the survey instrument was not formally validated, so items should be interpreted at face value rather than as established scales of latent constructs. Third, dichotomizing Likert responses improved interpretability but reduced response granularity. Fourth, the sample reflects a single organizational implementation and may not generalize to other workflows, prevalence environments, or AI products. Fifth, responses may be affected by selection bias and social desirability bias, particularly for items concerning vigilance or reliance. Finally, subgroup analyses were exploratory, and the study was not powered to make strong claims about differences by neuroradiology training.

Conclusions

Radiologists using an FDA-cleared ICH AI detection tool in a national teleradiology environment reported substantial false positive burden, limited perceived time savings, and strongly conditional trust in AI output. Self-reported reduced scrutiny after negative AI results was uncommon but endorsed by a minority of respondents. The findings suggest that the real-world value of radiology AI tools depends not only on whether they detect disease but also on whether they do so with sufficient specificity, appropriate timing, and workflow-compatible presentation to earn sustained clinician acceptance.

Abstract

Background: Digital health interventions for psychosis, like SloMo, leverage smartphone technology to help transfer learning from therapy to real-life situations. Usage relies on motivation, recall, and awareness. Wearable devices that track physiological signs of stress can boost engagement by encouraging the use of coping strategies when most needed.

Objective: This study aims to co-design an integrated user interface for wearable technology and the SloMo mobile app, and explore its usability, acceptability, engagement, and preliminary clinical outcomes for individuals with psychosis through a feasibility study.

Methods: A co-design team developed the wearable augmented SloMo app using the Double Diamond framework. The team included 10 experts by experience based across three UK National Health Service (NHS) mental health trusts, who had completed SloMo as part of a randomized controlled trial, and were purposively recruited to ensure a range of demographic backgrounds. Users tested the app for 8 consecutive weeks during a 5-month data collection period in 2018, providing feedback that guided iterative improvements. Self-reported engagement, usability, and acceptability were collected through quantitative ratings and interviews, evaluated through qualitative content analysis. Assessments of paranoia and well-being were completed pre- and post use, summarized descriptively, with change scores calculated and evaluated for reliable change.

Results: The Spire Stone clothing-adhered biosensor, which monitors respiratory rate and stress physiology, was chosen to augment SloMo. A minimum viable product of an integrated interface was developed. Feedback identified that users needed the technology to be easy to use, secure, and tailored to them through user control. Eight (8/10, 80%) users reported that the wearable prompted increased use of the SloMo app's features and other coping strategies. Self-reported engagement varied according to EBE user experience of the technology: higher use of the technology (n=3) was associated with higher usefulness (25% reduction in paranoia, SD 6%) and acceptability (84% satisfaction, SD 13%). Conversely, individuals that engaged with the device less (n=7) did not find it as useful (11% increase in paranoia, SD 17%) and were only modestly satisfied (63%, SD 20%).

Conclusions: Wearable technology is acceptable and can be integrated with a digitally supported therapy for psychosis to promote engagement and potentially support management of difficulties. However, further development work is needed to ensure acceptability and usefulness across a broader range of user needs.

Introduction

SloMo is a digitally supported cognitive behavioral therapy for psychosis (CBTp) that reduces paranoia [1]. It was developed to address the limitations of traditional psychological therapies for psychosis in relation to access, experience, and outcomes [2]. SloMo achieves this through targeting fast-thinking habits related to jumping to conclusions and belief inflexibility biases, which are established causal mechanisms in paranoia [3,4]. User experience is improved through co-design to leverage the capabilities of digital technologies [2,5]. SloMo consists of one-to-one sessions with a trained therapist, supported by a web-based therapy platform. Between sessions, the mobile app supports the individual to implement strategies independently, therefore providing continuity between therapy and daily life.

Between session practice, or "homework," is a fundamental component of CBTp [6], facilitating the generalization of therapeutic learning into real-life contexts. Such practice has shown to be predictive of successful outcomes in cognitive behavioral therapy (CBT) [7]. The availability, portability, and acceptability of smartphones means mobile apps are well placed to support skill practice in everyday life [8]. However, completion of tasks between sessions requires motivation, recall, understanding, and perceived benefits [9]. Difficulties in self-initiated behavior and planning can prevent effective use of strategies [10]. Relatedly, early experimental evaluations of SloMo showed its effects were moderated by cognitive difficulties, such as working memory problems, and negative symptoms [4].

Elevated levels of stress and anxiety present a further barrier to task completion, by detrimentally impacting functioning and cognition [11]. Early feasibility testing of SloMo demonstrated that individuals had greater difficulty remembering to use SloMo between sessions when distressed, and desired discrete prompts to help monitor their stress and encourage use of strategies [2]. User engagement or adherence, the extent to which users are willing to use and continue to use an intervention as intended, may influence effectiveness [12]. Consequently, approaches to improving engagement have been a significant focus to realizing the potential of digital health interventions and progress real-world implementation [13-15].

In psychosis, physiological parameters, such as heart rate variability, can provide an indicator of the onset of worsening paranoia [16]. Detection of elevated stress, anxiety, and paranoia could therefore prompt use of relaxation techniques or other coping strategies available via SloMo. However, consistent self-monitoring of stress can be challenging and effortful. Difficulties in identification of emotional states (ie, alexithymia) are common for people with psychosis [17]. Wearable devices provide a potential solution for detecting and managing stress through continuous passive monitoring of physiological signals. Accompanied by biofeedback and guidance via the technology or a linked device (eg, smartphone), this can support behavior change before stress escalates [18,19]. For SloMo users, notification of elevated physiological signs of stress could increase emotional awareness, providing opportunity to interrupt fast thinking habits, and support use of alternative slower thinking or coping strategies.

To be used and successfully integrated into daily life, wearable technologies must be usable, useful, and acceptable to the user [20]. Usability refers to the ease of use of the technology, including both the device itself and the app interface. Usefulness is the extent to which the device can achieve its intended purpose, ie, accurate monitoring and supporting self-management of difficulties. Acceptability encompasses factors that impact the user's willingness to use the technology, such as comfort, perceived value, and enjoyment. Poor usability risks impeding rather than augmenting outcomes [14]. This is of particular importance for individuals from marginalized groups who may be more likely to experience technology-related inequalities in access, use, and confidence [21]. For people with severe mental health needs, for whom privacy and data misuse concerns are common, security and trustworthiness of wearable technologies are especially important [22].

Inclusive, human-centered co-design (iHCD) is a method that places the user at the center of the design process: the needs of users representing a wide range of characteristics, abilities, and perspectives are explored, and design solutions incorporating these are iteratively tested and improved [23,24]. Transdisciplinary iHCD that includes experts by experience (EBE, ie, individuals, such as service users or carers, who have lived experience of the target problem), enhances adherence to digital interventions [25], promotes ethical usage [26], and is crucial for ensuring technologies are fit for purpose and meet the needs of diverse users [5]. This study adopted the Double Diamond process, a Human-Centered Design (HCD) framework using inclusive people-centered approaches [27,28].

The aims of this study were to (1) describe the development of a minimum viable product for an integrated user interface designed for wearable technology and the SloMo mobile app through co-design; and (2) conduct a feasibility study to explore usability, acceptability, engagement, and preliminary clinical outcomes of the developed technology, for individuals with psychosis.

Methods

This study was nested within the SlowMo randomized controlled trial (RCT) [1]. The first version of the therapy was "SlowMo," however spelling has since been updated to "SloMo" in line with feedback from individuals with lived experience of psychosis [5]. The RCT is referred to as SlowMo and the therapy as SloMo here forward.

Co-Design Team

A project team consisting of experts by experience (n=10), designers (n=4), software developers (n=5), clinicians (n=6), and researchers (n=5) participated in the co-design.

Ten individuals, who had previously received SloMo therapy as part of the trial and therefore had experience of the SloMo software, were invited to participate as EBE Co-Designers. In accordance with iHCD, purposive, and stratified sampling was applied with the aim of ensuring representation across trial sites,

XSL•FO
RenderX

ethnicity, age, and levels of technology confidence. EBEs were recruited from the 3 trial sites of London, Sussex, and Oxford. Eligible participants for the trial were: 18 years or older; had persistent (≥3 months) distressing paranoia; a diagnosis of schizophrenia spectrum psychosis; capacity to provide informed consent; and sufficient English to participate in trial processes. Participants were excluded if they had profound visual or hearing impairment, were unable to engage in assessments, were currently receiving psychological therapy for paranoia, or had a primary diagnosis of substance use disorder, personality disorder, organic syndrome, or learning disability. For further details of eligibility assessment, refer to Garety et al (2021) [1]. EBEs were invited to participate in this study following completion of all RCT research procedures (ie, 24-week follow-up assessment).

Characteristics of the EBEs are reported in Table 1. At baseline, persecutory ideation severity ranged from average (22) to very severe (62; see Measures: Green Paranoid Thought Scale [GPTS] [29]). Well-being scores were typically lower than the general population average (range 31 to 51; Warwick-Edinburgh Mental Wellbeing Scale [WEMWBS] [30]). Participant data from the RCT was extracted to facilitate description of the group and to inform preliminary understanding of who may benefit from SloMo augmentation with wearable technology. All EBEs completed all 8 sessions of SloMo therapy. Confidence and frequency of smartphone use (excluding calls) before SloMo were rated from 0 (Not at all; Never) to 100 (Totally; All the time). Confidence ranged from 11 to 95 (mean 67.0, SD 26.8), and frequency from 10 to 100 (mean 70.6, SD 27.6). In the RCT, a clinically observable response to SloMo therapy (defined as a 20% improvement in symptoms [31]) was seen for six (6/10; 60%) for paranoia (total GPTS), and two (2/10; 20%) for well-being (WEMWBS). The EBEs therefore represented a diverse subgroup of those who had completed SloMo therapy, with regards to demographics and technology attitudes and behaviors.

Table . Baseline demographic and clinical characteristics of EBE[a] co-designers (n=10).

Sociodemographic characteristic	Values
Age in years, mean (SD)	43.8 (11.0)
Sex, n (%)	
Male	8 (80.0)
Female	2 (20.0)
Ethnicity, n (%)	
Black, Black British, Black Welsh, Caribbean, or African	4 (40.0)
White	4 (40.0)
Asian, Asian British, Asian Welsh	1 (10.0)
Other ethnic group	1 (10.0)
GPTS[b], mean (SD)	
Total	76.1 (27.0)
Part A - referential ideas	37.8 (13.4)
Part B - persecution	38.3 (14.1)
WEMWBS[c], mean (SD)	
Total	39.7 (11.2)

[b]GPTS: Green et al [29] Paranoid Thought Scale.

[c]WEMWBS: Warwick-Edinburgh Mental Wellbeing Scale.

Intervention: SloMo

In SloMo therapy, an online therapy platform, accessed using a laptop or tablet, is used during one-to-one sessions with a trained therapist. A native Android mobile app supports strategy practice between sessions, with reminders and individualized content. An Android device, with the SloMo app installed, was provided to all participants for participation in the RCT and this study. This study included use of the mobile app software only, as EBEs had completed the full SloMo therapy prior to their involvement. Due to the early stage of development, access to the SloMo app was restricted to the supplied Android handset only, and was not available on the participant's own smartphone or alternative devices (eg, iOS).

The SloMo mobile app is described in detail elsewhere [2]. Key features include (1) a home screen where users can view personalized worries and safer thoughts; (2) a "Slow Down" function in which users are encouraged to notice worries, and use SloMo tips to help them to slow down to find ways of feeling safer; (3) a summary of therapy sessions and learning through "My Journey"; and (4) two behavioral coping enhancement activities: FlowMo, in which users are visually guided through an exercise to promote slow-paced breathing, with an expanding and shrinking bubble, and GoMo, a

XSL•FO
RenderX

distraction activity in which users are tasked with popping bubbles by tapping as they appear. FlowMo and GoMo were novel additions to the SloMo app, providing opportunity to intervene in the moment in response to elevated stress.

Ethical Considerations

The study was granted ethical approval through notice of substantial amendment of the RCT, which was reviewed and approved by the National Health Service Health Research Authority and London-Camberwell St. Giles Research Ethics Committee (16/LO/1862). After completion of all RCT procedures, eligible participants were provided with an information sheet and gave written, informed consent for participation in this substudy. Deidentified participant research data were held separately to personally identifiable information on secure servers accessible only to those in the research team. Participants were reimbursed £20 (GBP £1=US $1.43 as of February 1, 2018) for each meeting attended.

Procedure

Enrolment to the substudy commenced an average of 52 (SD 32) days after the SlowMo RCT 24-week follow-up assessment meeting, and 135 (SD 36) days after the posttherapy assessment.

Co-Design Procedures

The 4-phase Double Diamond framework [27], outlined below, was followed using a hybrid waterfall-agile approach, appropriate to the context of digital healthcare [5]. Following selection of the device, EBEs tested the technology for an 8-week period, contributing to all stages of the Double Diamond. The data collection period lasted 5 months, between February and July 2018.

Discover

The "Discover" phase is a divergent process focused on developing a broad understanding of the problem from multiple perspectives, while being informed by the existing evidence base. Initially, this phase consisted of "desk research" led by the designers, reviewing the existing market of wearable technologies to select an appropriate device for the augmentation of SloMo. Appropriateness was considered according to existing empirical evidence of acceptability to users, stress monitoring performance, feasibility of integration with SloMo, and compatibility with the previously identified user requirements for SloMo [2]. These prior co-design insights from SloMo therapy also informed the development of an initial wearable integration interface prototype. Designers, developers, and clinicians conducted testing of the wearable technology and prototype performance to identify improvements and bug fixes necessary before EBE testing.

EBEs were provided with the chosen wearable technology, shown how to use it, and asked to wear the device during the day over an 8-week period. Each EBE was provided a smartphone handset set-up with their own user profile from SloMo therapy (ie, tailored according to their own previously identified worries and safer thoughts). They were informed that they would receive feedback regarding stress levels through the mobile device. Handsets had a wireless internet connection for data transfer during the period of their involvement. Initial insights into attitudes and experience of the wearable were obtained through qualitative feedback at baseline and after one week of use. The EBEs also completed measures of paranoia, well-being, and were asked about attitudes towards monitoring stress and using technology.

EBEs completed the initial meeting with a study research worker at a time and location convenient to the individual, such as at home, their care team base, or at the research premises. Each meeting lasted up to one hour. If preferred, after initial set-up, interim qualitative feedback was collected remotely via telephone call. EBEs were asked at each meeting if they consented to audio recording, and written notes were produced by the research worker subsequently to summarize their feedback. If consent was not provided, the research worker took detailed written notes during the meeting. Questionnaire measures were completed on paper, with the support of the research worker as needed.

Define

The "Define" phase is a convergent process in which insights from the Discover phase were reviewed by the developers, designers, clinicians, and researchers, and synthesized to articulate user needs for the SloMo-wearable interface and a preliminary design brief for the solution. Throughout the co-design process, the study lead (AH) was responsible for the collation of EBE insights and ensuring user needs were refined accordingly, in collaboration with the interdisciplinary team.

Develop

The "Develop" phase is a divergent process in which a wide range of ideas for addressing the design brief are considered. Early-stage prototype solutions are iteratively developed, tested, and refined. Initial ideas in this phase were generated by the designers, software developers, and researchers. A series of software development sprints facilitated the iterative implementation of preferred solutions into the interface prototype, shaped by the ongoing collection of qualitative feedback from EBEs running in parallel. Decisions regarding which solutions should be kept were informed by both quantitative (ie, frequency of shared opinion) and qualitative content of feedback.

Deliver

In the "Deliver" phase, a convergent process is employed to develop the optimized solution into a higher fidelity prototype as the "minimum viable product" for further testing and release. The prototype was then tested and evaluated by the EBE group in a feasibility study. Usability and acceptability of the optimized interface were evaluated qualitatively and quantitatively through interviews and a user experience survey (UES). EBEs undertook reassessments of paranoia and well-being to support preliminary evaluation of the potential usefulness of the technology.

Measures

Stress Monitoring and Technology Use Attitudes

A semistructured interview was conducted during the Discover phase to understand the EBEs' attitudes to monitoring stress

XSL•FO
RenderX

and using technology (see Section 1 in Multimedia Appendix 1).

Usability and Acceptability

Semistructured Interview

Acceptability of the wearable device integration for SloMo was assessed at each follow-up meeting. Qualitative data regarding EBEs' views (ie, perceived helpfulness, concerns, and suggestions for improvement) and usage (ie, self-reported engagement; in what ways it is or is not being used, and likelihood of continued use) of the Spire Stone (Spire Health) and the SloMo app were elicited through a semistructured interview (Section 2 in Multimedia Appendix 1).

User Experience

User experience was assessed by the UES (see Multimedia Appendix 1; adapted from Ben-Zeev et al [32], as used in the SloMo RCT [1]). The UES is a 10-item measure consisting of 3 subscales assessing usefulness, usability, and enjoyment. Items are rated on a 0 (totally disagree) to 10 (totally agree) scale. Ratings are summed for each subscale and a percentage score calculated. The total score represents an overall measure of user satisfaction.

Usefulness

Paranoia

Paranoia was assessed using the GPTS [29]. The GPTS consists of two 16-item self-report subscales: part A—assessing referential ideas; part B—persecutory ideation. Items are rated on a 5-point scale (range 16 to 80 for each scale), with higher scores indicating greater difficulty. Internal reliability of the GPTS is considered excellent, with a reported Cronbach α of >0.9 [29,33].

Well-Being

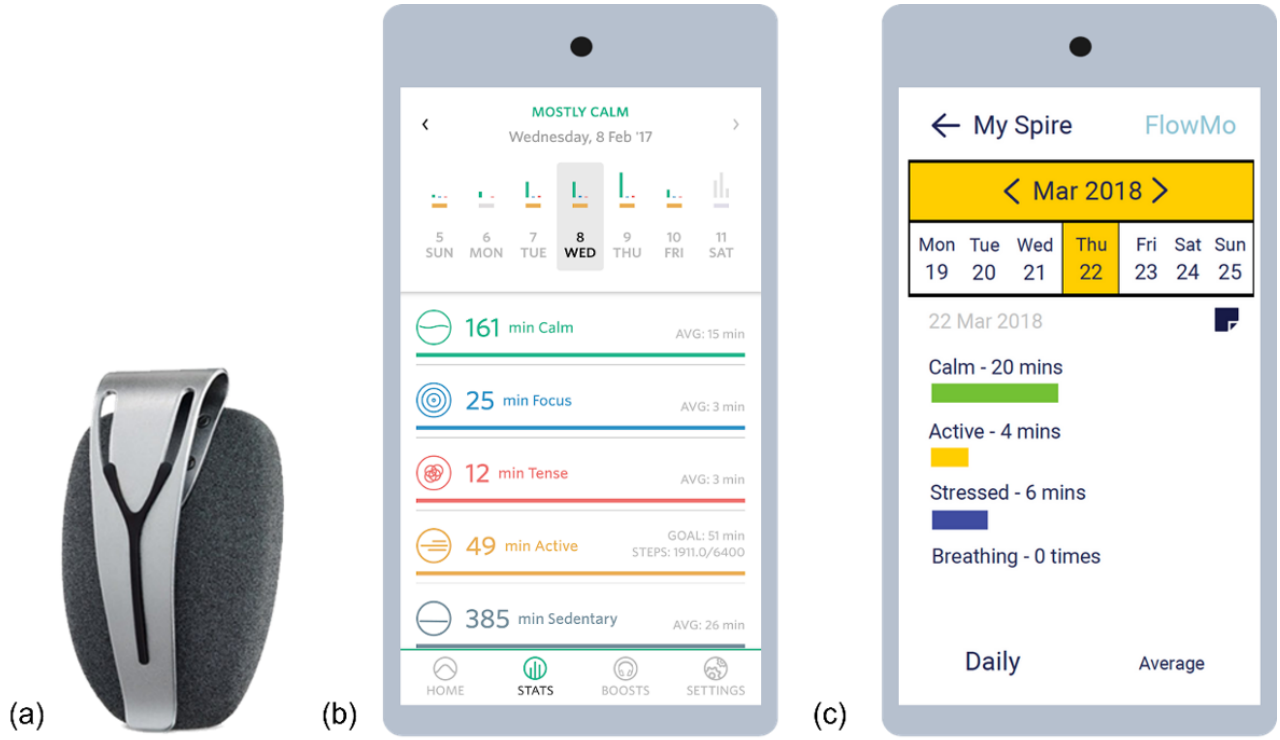
Well-being was assessed using the WEMWBS [30], a 14-item self-report scale. Items are rated on a 5-point scale (range 14 to 70), with higher scores indicating better well-being. Very strong internal reliability has been reported (Cronbach α=0.93; [33]). A score of 42.9 or lower has been used to indicate poor psychological well-being [33].

Data Analysis

A combination of conventional and directed approaches to qualitative content analysis [34] was used to summarize usability and acceptability feedback. The lead author (AH) first read and reread all feedback for familiarization with the data. Using NVivo software (Lumivero), key details related to the EBE's user experience of the technology was highlighted. Preliminary codes were generated inductively and refined through iteration. Final codes were organized into categories according to whether they related to usability, acceptability, or usefulness. Frequency of participant responses for each code supported development decisions. Following identification of patterns during the initial inductive coding phase, qualitative feedback reflecting the extent of use of the technology was coded to indicate "lower," "mid," or "higher" engagement (see Table S1 in Multimedia Appendix 1).

Descriptive statistics were reported as frequency n (%) for categorical variables and mean (SD) for continuous variables. Change scores were calculated for paranoia and well-being outcomes between baseline and 8-week follow-up and evaluated for reliable change and a clinically observable response. The reliable change index (RCI) was calculated using the equation described by Jacobsen and Traux [35] (see Table S2 in Multimedia Appendix 1). A 20% reduction in symptoms was considered to represent a "clinically observable response," as has been used previously to signify at least "minimal improvement" [31]. An explorative subgroup analysis was conducted to investigate patterns of engagement according to EBE characteristics and outcomes, with mean GPTS, WEMWBS, and UES scores estimated, stratified by engagement level.

Results



Discover

Wearable Technology

Desk research identified a range of wearable technologies that were easily accessible and commercially available. Considered solutions for the augmentation of SloMo included: wrist-worn bands and smartwatches, headsets, skin-adhered patches, in-earphones, clothing-embedded sensors, and smartphone software. The Spire Stone, a clothing-adhered biosensor commercially available until 2020, was selected to augment SloMo (Figure 1A) [36]. The Spire Stone had a publicly available API that enabled integration with the SloMo app, was financially feasible, and was considered discrete to wear relative to other devices.

XSL•FO
RenderX

Figure 1. (A) Spire clothing-adhered biosensor; (B) example nonadapted Spire smartphone app interface; (C) example SloMo app-My Spire interface.

The Spire Stone continuously monitored respiratory rate variability and compared this to the individual's median values after a period of calibration. Significant and sustained changes were interpreted as signals of cognitive-emotional state changes [37]. Feedback summarizing one-minute state intervals was presented to the wearer via a linked smartphone app, labeled as: "calm" (slow and consistent breathing), "focus" (moderately fast and consistent breathing), and "tense" (fast and erratic breathing) [18]. The device recorded the number of steps, inferring "active" compared to "sedentary" minutes. The wearer was also delivered in situ biofeedback notifications through device vibrations, to alert to sustained periods of states or sedentary behavior, aiming to facilitate self-regulation of stress levels. The Spire Stone was used previously to augment stress management interventions [18], and has demonstrated acceptability and usefulness [38]. Spire has reported strong correlations between their devices and "gold standard" medical device measurement of respiratory rate [39].

The nonadapted, commercially available Spire mobile app interface (Figure 1B) was also installed on the handsets provided to EBEs. Therefore, during the user testing, EBEs had the option to use either the Spire or SloMo wearable app, depending on their needs. Hereafter, we use "the technology" to refer to the integrated Spire Stone and linked SloMo wearable app.

Co-Design Feedback

Key themes regarding user needs related to acceptability, usability, and usefulness were identified from the EBEs' initial impressions of the technology. Illustrative quotes are presented in Table 2.

XSL•FO
RenderX

Table . Illustrative quotes representing EBE feedback on acceptability, usability, and usefulness for phase 1 (discover).

Quote ID	EBE[a]	Feedback
Acceptability		
1	2	Understanding can be useful […] validating your experiences: this is why you're feeling this way
2	3	I guess technology can make it more accurate to read how stressed you are and people who do not notice how they are feeling this could be a good way
3	8	Found the Spire app quite confusing to look at and said there were too many things going on, this put him off using it again
4	1	If someone was more stressed, it might annoy that person and highlight their anxieties for them
5	6	…Unhelpful to notice that she was feeling anxious as this would make her feel more anxious
6	1	Found the vibrations difficult to manage at work
7	3	Would use it more if [I] had more routine in [my] life, and at the moment [I'm] avoiding stressful situations and [do] not go out much so there is no point in wearing it when at home.
8	6	I trust you guys that you won't give me something with lasers in
9	2	[The Spire] looks like a microphone […] it might be recording
10	3	…can be hacked, and people can use if for harmful reasons to induce stress from the technology itself.
Usability		
11	10	There are too many alerts […] but it's not clear what the alert was for.
12	6	People who are worse at technology… or in the height of anxiety might not be able to know which are buttons or not, so could be made clearer.
Usefulness		
13	3	I don't notice that I'm tense when I'm doing certain things, but it appears that at times I'm flustered, which is helpful to know
14	4	When you are paranoid, you are in a vacuum so a bubble [notification] coming up breaks that vacuum
15	5	…like the simplicity [of FlowMo], puts me in a calm state […] you take a pill for a headache and a breath for anxiety.
16	7	[FlowMo] stops me going over the edge and calm down.
17	9	Maybe I'm just so used to feeling tense that it doesn't bother me that much
18	1	It wasn't that helpful to be told multiple times by the spire that you're 'feeling tense' and found it quite frustrating [it] was still 'feeling tense' after having done the breathing exercise

[a]EBE: expert by experience co-designer.

XSL•FO
RenderX

Acceptability

At baseline, most EBEs (n=7) perceived value in becoming more aware of emotions through monitoring of physical sensations (example quotes; Q 1 - 2). Three EBEs enjoyed being able to track progress and receive feedback and valued visually simpler displays to reduce confusion (Q3). Some (n=3), however, noted that increasing focus on stress levels through the technology could unhelpfully exacerbate difficulties (Q4-5). Two EBEs cited difficulty integrating into current routines, conversely either due to busyness (Q6) or limited activity levels (Q7). While the majority did not report concerns about the trustworthiness of the technology (Q8), 2 shared suspicions that there could be malicious intentions behind it (Q9-10). Nonetheless, both remained willing to continue using the device within the study.

Usability

Though most felt sufficiently competent in using the technology and reported they found it easy to use, two raised concerns that those less confident may have difficulties. After initial use, some reported a lack of clarity from the app and difficulty knowing what Spire Stone vibrations were signaling (n=2, Q11). One EBE described difficulty initiating the FlowMo breathing exercise when experiencing distress (Q12). Five reported issues with the technology that impacted use: the need for a second smartphone handset, poor battery life, and issues with synchronization between the Spire Stone and the app.

Usefulness

EBEs (n=6) described how using the technology to identify when they were feeling stressed supported self-management (Q13-14), including use of the SloMo app's wider features (n=6). Positive feedback was given on breathing exercises (n=6) in SloMo (FlowMo) or the Spire app, and GoMo (n=3), presenting an opportunity for relaxation, distraction, and prevention of worries worsening (Q15-16). Recommendations were given for the SloMo app to have further opportunities for relaxation and distraction, such as through calming sounds, music, or visuals, and games to have more variation (n=3). Monitoring and goal setting for activity levels within the Spire app were viewed as positive and motivating by some (n=3). While most (n=5) noted some accurate detection of difficult moments, 3 noted discrepancy and the technology overreporting stress, hypothesized to be due to desensitization by one EBE (Q17). In addition, the technology was noted to lack responsivity to efforts to reduce stress levels (n=2, Q18).

Define and Develop

Insights regarding user needs from the Discover phase were reviewed, synthesized and prioritized into 7 problems to be addressed through the co-design work (Table 3). Iterative development sprints enabled the testing and refinement of solutions within the SloMo wearable app interface (Table 3, Figure 1C).

Table . Redefined problems identified through phase 2 (define) and associated design solutions tested in phase 3 (develop).

Problem	Design solution to meet user requirements
Self-monitoring and self-management of stress can be challenging and effortful	The SloMo-Spire integration should be easy to use and access, through clear controls, navigation, and language. A diary function for note-taking and goal-setting supports users in self-management, monitoring, and motivation.
A focus on the experience of high stress can increase anxiety for users	Increased user controls enable the option to turn off "stress" state display and feedback. Notifications encourage users to recognize changes in emotion, rather than focusing solely on negative states.
Frequent notifications to alert to changes in emotional state through vibration lack clarity and meaning	Users can adjust notification time and frequency settings; users are provided with clear visual feedback on respiratory data. Vibration alerts have a corresponding visual, written app notification to prompt user action (ie, slowing down thoughts, FlowMo, or GoMo).
Feedback on emotional states that is misaligned with the user's own perception can be experienced as frustrating, confusing, and detrimental to trust	Simplification of data feedback to combine "focus" and "tense" states into one "stressed" state. SloMo app notifications neutrally prompt user reflections on current safety and distress to facilitate awareness and self-management.
Coping enhancement activities without variation and personalization offer limited opportunity for relaxation and/or distraction	Expansion of coping enhancement activities through the addition of sounds and music to FlowMo, and additional difficulty settings in GoMo.
Digital mental health intervention software may present challenges for those who are less technologically confident or experiencing acute anxiety	Users should be offered a clear demonstration, and additional support or repetition may be required to ensure confidence in use. The SloMo wearable app interface requires clear, easy-to-use buttons to activate coping activities.
Wearable technology can be a source of suspiciousness and paranoia	Users should be offered information regarding the purpose, function, and security of the technology, tailored according to individual concerns. This information should be easily accessible within the SloMo software.

Deliver

Qualitative Feedback

Illustrative quotes are presented in Table 4.

XSL•FO
RenderX

Table . Illustrative quotes representing EBE[a] feedback on acceptability, usability, and usefulness for phase 4 (deliver).

Quote ID	EBE	Feedback
Acceptability		
19	6	Was very excited to see her suggestions about relaxing noises being added […] really liked the forest noises in particular, as it reminded her of home
20	4	Finding it more enjoyable using the updated version […]using both levels on GoMo
21	5	Stopped using and made him worry that information might be broadcast to others […] He liked the updated app. The 'About SloMo' section reassured him [about] confidentiality and security, he would read for reassurance.
22	9	Has become habit to put on in the morning and play about with later on to see how he has been feeling
23	2	More positive about explaining the device and what it does to other people, and them being able to accept it
24	7	'Cause if the person's like me it would help them 100%. 'Cause like, I feel alright since I've been using it. It's helped me through all the bad times I've been using it, it's helped me.
Usefulness		
25	6	The app/device itself is not enough to remove the distress but it is great for helping notice her distress and take extra steps to alleviate it. […]
26	4	Spire will help clients deal with things better in between seeing their CPN or make them see CPN less often by supporting people in self-managing experiences
27	6	When you're on your own, it makes you feel like […] someone is actually there to say 'you can do these things.'
28	10	Learning [the] breathing without looking at the app […] can see it in his mind's eye and after a while won't need the app.
29	2	Found it the most frustrating that the app couldn't pick up on the distress his voices were expressing. He felt like the app made him look like a liar, as the distress experienced by the voices wasn't being picked up.

[a]EBE: Expert by Experience co-designer.

Acceptability

EBEs commented on liking the updated SloMo wearable app interface with regards to its simplicity and visual appeal (n=3). Changes made through the co-design process received positive feedback, specifically regarding the addition of relaxing sounds to FlowMo (n=2, Q19) and difficulty levels to GoMo (n=4, Q20) to better facilitate coping in response to wearable prompts. Some EBEs (n=4) expressed discomfort or inconvenience related to the wearable device type, with preference for alternatives (eg, wrist-worn and smartphone embedded). While 4 noted concerns related to intrusiveness, data privacy or app security, availability of in-app related information to provide clarity and reassurance was valued (Q21). EBEs described developments over time such as successful integration into daily life and habitual use (n=4, Q22), and becoming increasingly comfortable discussing the technology with loved ones (n=2, Q23). Six EBEs perceived that others with similar difficulties would be likely to benefit (Q24). The UES demonstrated overall positive ratings of acceptability (mean 72.7%, SD 28.1%) and enjoyment (mean 68.3%, SD 20.6%).

Usability

Several EBEs (n=4) commented on the ease of use of the technology. However, one user continued to feel they lacked technological skills or interest to benefit and wanted the app to

XSL•FO
RenderX

be more interactive or include 2-way communication with a person (eg, therapist) for support (P2). Limitations of the technology continued to impact experience, such as synchronization issues (n=2), inconvenience of requiring two handsets (n=1), and battery or charging issues (n=1). Responses to the UES demonstrated overall positive usability (mean 68.3%, SD 17.4%).

Usefulness

The majority of EBEs viewed the technology to be effective in facilitating self-management of difficulties (n=8) and reducing distress (n=4). While several noted the worn device did not solve the difficulty itself (n=3), it instead enabled them to become aware, prompting them to "do something differently," such as using the SloMo app's features (n=4), or engaging in other strategies (Q25). Four EBEs likened the app to an interim alternative to support from others (eg, a therapist, or community psychiatric nurse, Q26-27). Some described how they had begun to generalize learning to other contexts when not using the app (n=3, Q28). Three EBEs found there continued to be inaccuracies between the wearable feedback and their own perception, and for one this related specifically to the experience of hearing voices (Q29). Across the whole group, changes in outcomes were highly variable for both paranoia (total GPTS change mean −3.0, SD 18.1) and well-being (WEMWBS change mean −1.6, SD7.44).

Engagement

EBE feedback indicated varying levels of engagement with the technology through the co-design period. Three were categorized as "higher" usage, indicating they wore the Spire Stone and engaged with the technology for most days throughout the co-design period ("wearing the spire device every day from the moment she wakes up to moment she goes to bed," P4). Four indicated use for several days each week, or most weeks of the period and were considered "mid" usage. Three had limited engagement, using the technology for only a small proportion of the 8-week period ("didn't really use the app at all in last few weeks," P2).

EBE characteristics in relation to usage were explored to facilitate understanding of who may engage with and benefit from wearable augmentation of digital interventions, such as SloMo (Table S3 in Multimedia Appendix 1). Both female EBEs reported higher usage, however, each engagement group otherwise represented a range of ages, ethnicities, and smartphone confidence. As shown in Table 5, higher frequency users reported the most severe paranoia at baseline, while well-being scores were slightly lower for low frequency users at baseline.

Table . Mean pre- and postintervention scores for usefulness and acceptability outcome measures, by level of self-reported engagement.

Outcome, mean (SD)	Engagement level					
	Lower (n=3)		Mid (n=4)		Higher (n=3)

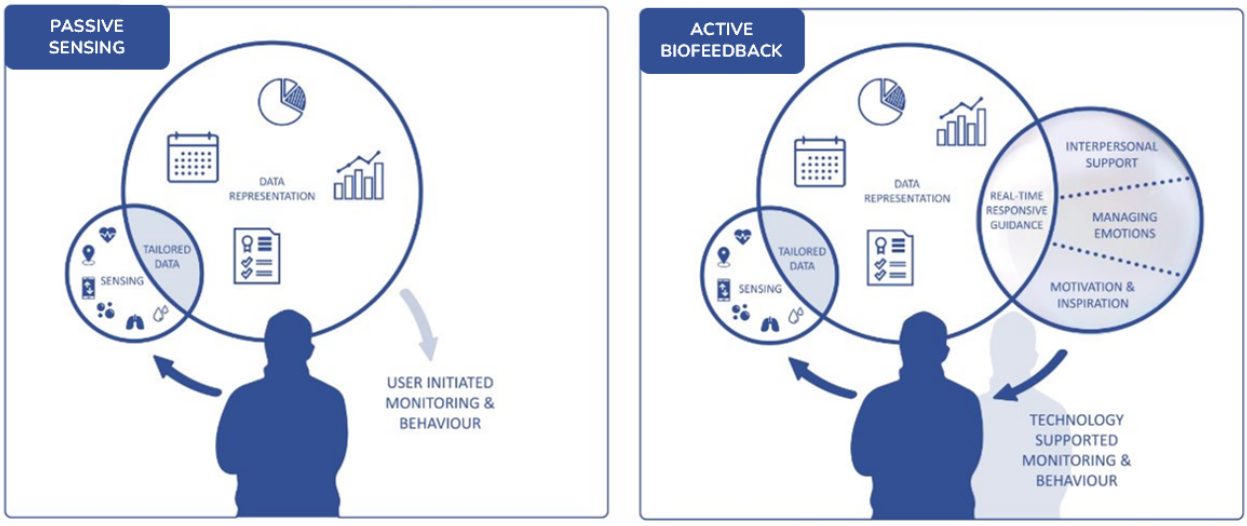
Level of engagement differed according to the technology's usefulness and acceptability to the user. Those who used the technology most also experienced improvement in total paranoia scores at 8-week follow-up (clinically observable response, n=2; reliable change; RC; n=1; see Table S3 in Multimedia Appendix 1). In contrast, a pattern was observed that lower and mid frequency users reported a slight deterioration, although this did not meet threshold for reliable change. Well-being scores remained consistent overall regardless of engagement, however one higher, and one mid frequency user reported a reliable deterioration in well-being. Similarly, acceptability data provided by UES responses aligned with self-reported usage, such that those that engaged more were also most satisfied, while low frequency users were least.

Discussion



Principal Findings

This study is the first to explore the user experience of wearable technology integrated with an existing digital therapy for paranoia in people with psychosis. A minimal viable product was first developed, comprising a user interface that integrated the wearable technology with the SloMo mobile app. Most users found the developed technology to be usable, acceptable, and enjoyable to use (mean agreement>68%, SD 20%). Some EBEs reported using the technology frequently and had higher overall user satisfaction (agreement 84%, SD 13%), finding the wearable to be discrete, secure, robust, accurate, and useful, and reported reductions in paranoia. For other EBEs who described using the technology less often, modest user satisfaction was reported (47%, SD 22% to 76%, SD 4%) and there was no marked impact on paranoia. There was encouraging early evidence that, for some, wearables might promote engagement with a therapy app to support management of paranoia, at least in the short term, and even in the absence of therapist support.

The findings highlight the potential for responsive, wearable technology to improve engagement. Almost all EBEs (8/10, 80%) reflected that when using the Spire device, they also used the SloMo app more frequently. There are known challenges for engagement and retention in digital mental health interventions over time [40,41]. Strategies that are tailored and prompt intervention engagement when it is most needed may optimize effects and enhance subjective usefulness. The longer-term effectiveness of SloMo is not yet known and is currently being evaluated in an implementation-effectiveness study (ClinicalTrials.gov ID NCT06568081). The current study suggests that wearable integration may be a plausible way of encouraging ongoing use if engagement is found to decline after formal therapy completion.

For people with psychosis, to date, wearable technology has most commonly been used as a tool for assessment, monitoring, and diagnosis [42]. There is great interest in the potential of digital phenotyping (ie, passive sensing) through smartphones to detect and prevent relapse [43]. However, our inclusive, user-centered design research suggests that people want technology to provide secure, accessible, and responsive support to assist self-management, and are reluctant for this to involve the sharing of personal data without sufficient clarity and reassurance. This is consistent with the findings of a study exploring perspectives of people with psychosis on passive sensing, highlighting the importance of fully informed consent, choice, and autonomy [44]. Similarly, despite an initial focus on monitoring stress in this study, EBE feedback demonstrated this emphasis to be undesirable to some. Instead, a preference was shared for the wearable to help increase awareness of "calm" and "active" states, and the associated activities and strategies that support this. Wearable technology including active biofeedback, not solely passive monitoring, may be key to realizing the promise of digital health in innovating the treatment of psychosis (see Figure 2).

Figure 2. Wearable therapeutics offering biofeedback as a preferred method by EBE co-designers for supporting monitoring of symptoms and behavior change, relative to passive sensing only.

The participating EBEs represent a diverse group in relation to age, ethnicity, technological confidence, and paranoia severity. Engagement and user experience were not impacted by these factors. Notably, as a group, people who reported using the

XSL•FO
RenderX

technology most had the most severe paranoia at the outset. While some EBEs expressed concerns about the trustworthiness and safety of wearable technology, it did not deter them from continuing to use it. Reassurance, gaining familiarity over time, and availability of accessible written information regarding data privacy and security were viewed as helpful solutions to these concerns. Concerns regarding "service users feeling suspicious or paranoid" are cited as the most common barrier to mental health professionals recommending the use of digital mental health interventions (38). This study demonstrates that this concern may risk preventing access for those who could benefit.

In keeping with the early stage of the work, technological challenges were common, with the group reporting technical issues (7/10, 70%), usability problems (5/10, 50%), discomfort (4/10, 40%), and discrepancy with their own perceived emotional state (4/10, 40%). Advancements in wearable technologies may alleviate some of these challenges. However, an exacerbated discrepancy between self-reported and physiological stress levels in people with psychosis has been reported previously [45]. Biofeedback should be suggested cautiously, for example, "You may be feeling stressed; would you like to slow down?" This approach avoids damaging the person's trust in the technology.

Limitations and Future Directions

The EBE co-designers involved in this study represent a small, but diverse group of individuals with regards to age, ethnicity, technological confidence, and attitudes towards technology. All EBEs had engaged in SloMo therapy prior to involvement and had completed therapy with high rates of adherence. To this extent, the study's findings represent the views of people who engaged well, with prior knowledge of SloMo, and may differ from those who may be less engaged with digitally supported talking therapy. Furthermore, as the same group of EBEs were involved throughout the co-design process, acceptability ratings may be higher due to the implementation of their own recommendations for improvements. Conversely, EBEs were not involved in the initial selection of the Spire Stone wearable device. Consultation regarding user priorities for the device at an earlier stage may identify an alternative, more acceptable device to users and may facilitate improved engagement.

The experiences and outcomes reported were highly variable. Females were underrepresented in the group; however, both female EBEs used the technology frequently, reported high satisfaction, and benefitted in terms of paranoia improvements. Higher engagement and satisfaction with digital interventions for psychosis by female users has been noted previously [13], and was similarly found in the SlowMo RCT [1]. This indicates a clear need for development work to further optimize the wearable augmentation of SloMo to ensure acceptability for a wider range of people, particularly nonfemale users.

Baseline data was collected subsequent to the 24-week follow-up for the SlowMo RCT. In the RCT, participants typically experienced benefits to paranoia and well-being following SloMo therapy that were maintained at follow-up [1]. To this extent, most EBEs in the current study commenced participation having already achieved clinical benefit from SloMo therapy. Less engaged users experienced fluctuations in paranoia, as is expected in this population [46], though levels remained in keeping with the SlowMo treatment group average at 24-week follow-up. Furthermore, the fluctuation for these groups did not exceed the recommended minimally clinically significant response used in meta-analyses of CBTp [31]. Regardless, potential iatrogenic harms should continue to be explored in future work.

Exploratory post hoc investigations in relation to patterns of engagement were conducted based on coding of qualitative descriptions by the EBEs. The patterns observed correspond to the objective data collected in this study, such that use of a digital health technology is influenced by a complex system of interacting components including acceptability (eg, beliefs, knowledge, and affective attitude), usability, and usefulness [20]. Objective measurement of engagement (eg, technical usage data) and a priori operationalization of engagement levels would strengthen future similar investigations.

Reflective of the technology available at the time of study delivery, the reliability for "stress detection" was limited: the device could identify changes in breathing patterns but was insufficient in accurately determining whether these changes reflected genuine distress. Accordingly, the Spire Stone was reported as inaccurate in stress signal detection by several EBEs, impacting the perceived usefulness of the integrated technology. Advancements in wearable technology are rapidly developing [47,48] and may offer an improved solution that enhances trust, usefulness, and therefore the overall acceptability of mental health interventions.

Conclusions

This study demonstrates that wearable technology can be integrated into SloMo, a digitally supported therapy for psychosis. Involving those with lived experience in the development of digital mental health interventions is crucial to ensuring alignment with user needs. While standalone, passive monitoring of stress was not viewed as useful by EBEs, people were positive about the potential utility of integrating wearables with digital interventions to facilitate self-management of difficulties. People may use therapy apps more frequently when wearable devices are added, which is important because the experience and outcomes of current psychological therapies for psychosis need to be improved. However, wearable technology outcomes currently remain variable. Development work is needed to broaden acceptability, usability, and usefulness for a wide range of people.

Acknowledgments

We would like to thank Ed Matthews, Jonathan West, and Nassia Inglessis, Healthcare Lab, Helen Hamlyn CentreCentre for Design who contributed to the design of the first version of SloMo. We would also like to acknowledge Evolyst Limited who are

XSL•FO
RenderX

the software developers for SloMo version one. We are grateful to the research team members involved in the study and are indebted to the people with psychosis who have contributed to development.

The legal manufacturer of the SloMo mobile app is King's College London.

Funding

This work was primarily funded by the Wellcome Trust through their Pathfinder award (109586/Z/15/Z) and was assisted by two further funding bodies. First, the National Institute for Health Research and Medical Research Council have supported the research through their Efficacy and Mechanism Evaluation funding of the SlowMo trial (ISRCTN32448671). Second, the King's Commercialisation Institute has funded the development of an app, Mo, targeting well-being in the general population. This has assisted the work as several aspects of Mo's functionality have been repurposed for the SloMo wearable app. AH, MC and TW acknowledge funding from the Maudsley Biomedical Research Centre at South London and Maudsley NHS Foundation Trust and King's College London.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Sleep quality is a strategic public health priority and a key factor in the study of circadian rhythms and chronotypes. Nursing students are a particularly vulnerable population group.

Objective: The objective of this study was to evaluate the effects of a brief group-based cognitive behavioral therapy for insomnia (CBT-I) intervention on sleep quality and circadian-related outcomes among first-year nursing students using ambulatory circadian monitoring.

Methods: This study is a 2-arm pilot randomized clinical trial conducted at a private university in Madrid, Spain, from October 2022 to March 2023. First-year nursing students aged 18 to 25 years were recruited in October 2022 using convenience sampling and randomly assigned to an experimental group (n=20) that received a cognitive-behavioral intervention using an active-constructive learning methodology to improve sleep quality and a control group (n=20) that followed their usual daily routine. Primary outcomes were objective sleep quality assessed using the Kronowise 3.0 ambulatory circadian monitoring system and subjective sleep quality assessed using the Pittsburgh Sleep Quality Index (PSQI). The objective Kronowise assessment was characterized by the continuous circadian rhythm and sleep parameters generated by the device. Participant satisfaction with the intervention was evaluated using an adapted 12-item Likert-type satisfaction questionnaire administered after the intervention. Measurements were collected preintervention and postintervention over 7-day monitoring periods. Adjusted analyses were performed using analysis of covariance, with treatment group as the fixed factor and baseline values, smoking status, school schedule, and coffee consumption as covariates. Treatment effects were summarized using regression coefficients (β), 95% CIs, and partial eta-squared (η^2). The study was conducted in accordance with the CONSORT (Consolidated Standards of Reporting Trials) statement.

Results: Forty students (n=34, 85% female; mean age 19.9, SD 1.8 y) were randomized equally into the intervention and control groups. Adjusted analyses showed generally small treatment effects for objective circadian rhythm and sleep outcomes. The largest treatment effect was observed for self-reported sleep latency (β=−19.78 min, 95% CI −33.83 to −5.74; partial η^2=0.194). Sleep duration (β=36.32 min, 95% CI −5.01 to 77.64; partial η^2=0.086) and sleep efficiency (β=8.75%, 95% CI −0.97 to 18.47; partial η^2=0.090) also favored the intervention group, although CIs indicated considerable uncertainty around these estimates. Participants reported high satisfaction with the intervention, with 65% (13/20) rating the program as “very good.”

Conclusions: This pilot randomized controlled trial provides preliminary evidence that a brief group-based CBT-I intervention may improve selected subjective sleep outcomes, particularly sleep latency, among first-year nursing students. Objective circadian rhythm and sleep outcomes showed generally small treatment effects. Given the exploratory nature of this pilot study, adequately powered randomized controlled trials with longer follow-up are needed to confirm these preliminary findings.

Introduction

Sleep is an essential physiological process for physical restoration and cognitive functioning. Sleep quality is closely linked to circadian rhythm regulation and is a key determinant of physical and psychological health. Adequate sleep quality is associated with well-being and daytime functioning, whereas poor sleep quality has been linked to adverse health outcomes, including anxiety, depression, hypertension, and metabolic disorders [1-3]. Because sleep quality reflects both behavioral and circadian processes, it is an important indicator for understanding sleep-wake regulation and overall circadian health [4].

It is estimated that 1 in 3 adults has a sleep disorder [5], and university students are a particularly vulnerable population due to academic demands, irregular schedules, and lifestyle-related factors that may disrupt healthy sleep patterns. Poor sleep quality in this population has been associated with fatigue, impaired concentration, emotional distress, and poorer academic performance [6]. Nursing students may be especially vulnerable because of the demanding academic workload, early clinical exposure, and the need to adapt to unfamiliar practice environments, all of which may increase stress and contribute to sleep disruption [7,8]. This vulnerability may be particularly relevant during the first academic year, when students are adapting to university life while facing increased academic and professional expectations.

Given the limitations of pharmacological approaches for sleep problems, nonpharmacological strategies have gained increasing attention [9]. Cognitive behavioral therapy (CBT) is supported by strong evidence as an effective intervention for improving sleep outcomes [10], and psychoeducational approaches have shown promise in promoting healthy sleep behaviors in nonclinical populations [11,12]. In university settings, psychological interventions have often focused on sleep-related symptoms associated with anxiety or depression rather than on sleep health promotion itself [13]. In addition, most studies have relied primarily on self-reported outcomes, with limited attention to objective indicators of circadian functioning such as motor activity, thermoregulation, and environmental synchronization (ES) [14]. This gap is particularly relevant for nursing students, who frequently experience sleep disturbances [15] and may benefit from behavioral interventions targeting maladaptive sleep-related habits and beliefs [16]. Although the efficacy of cognitive behavioral therapy for insomnia (CBT-I) is well established in clinical populations, less is known about its effects among nonclinical university students when delivered in group-based formats. In addition, most intervention studies in this field rely primarily on measures such as the Pittsburgh Sleep Quality Index (PSQI) [17]. Ambulatory circadian monitoring (ACM) offers the possibility of continuously assessing sleep-wake patterns and circadian regulation in real-world settings, providing a more comprehensive evaluation of behavioral intervention effects than self-report measures alone [18-21].

Although there are studies associated with poor sleep quality in nursing students [15], the evidence regarding the feasibility and acceptability of brief, group-based CBT-I interventions implemented as part of university health promotion programs for first-year nursing students remains limited. Besides, no previous studies have designed and evaluated interventions to improve sleep quality in this group using a wearable wristband device. Therefore, this pilot study aimed to explore the preliminary impact of a group-based CBT intervention on sleep quality among first-year nursing students. Specifically, the objectives were (1) to explore the preliminary effects of the intervention on sleep quality outcomes and (2) to assess participant satisfaction with the intervention. We hypothesized that, compared with the control group, participants receiving the intervention would show preliminary improvements in sleep quality from baseline to postintervention, as assessed through ACM and self-reported sleep quality.

Methods

Design

This study is a single-center, single-blind (data analysts), 2-arm pilot randomized clinical trial comparing 2 conditions: the intervention group, which receives a CBT-based intervention targeting sleep quality, and the control group, which receives no intervention. The randomization procedure was performed using a computer-generated random number sequence (Sealed Envelope software, version 1.21.0) and was assigned to participants' academic record numbers to randomly designate participants to 1 of the 2 groups (intervention or control group). Random permuted blocks were also used to reduce the predictability of the random sequence and guarantee a 1:1 allocation ratio. This sequence was stored in a password-protected table and was hidden from other researchers during the study.

The study is registered at ClinicalTrials.gov with reference number NCT05273086, and the study protocol has been published [22]. This study was performed according to the CONSORT (Consolidated Standards of Reporting Trials) statement (Checklist 1).

Study Setting, Recruitment, and Sampling

The study was conducted at a private university located in Madrid (Spain) during the 2022 to 2023 academic year. Participants were recruited in October 2022, and the study lasted from October 2022 to March 2023, when the postmeasure tests were carried out.

A convenience sampling method was used. Eligible students were informed about the study through an in-class presentation delivered by the research team, during which the study aims, procedures, duration, eligibility criteria, voluntary nature of participation, and confidentiality safeguards were explained. Students who expressed interest in participating were screened according to the inclusion and exclusion criteria. Those who met the eligibility criteria and agreed to participate provided written informed consent before baseline assessment and randomization.

The eligibility criteria of this study were as follows: the inclusion criteria were students aged between 18 and 25 years who were enrolled in the first year of a nursing degree during

XSL•FO
RenderX

the 2022 to 2023 academic year. Participants were excluded if they were diagnosed with a prior mental pathology, a sleep disorder, or both, and were treated with or without medication (hypnotics, sedatives, or melatonin); were taking medications to aid sleep; or were combining work and study.

Participants were not restricted to individuals with clinically diagnosed sleep disorders because the intervention was conceived as a universal sleep health promotion program for first-year nursing students. The objective was to promote healthier sleep-related habits and behaviors in a population exposed to academic demands and future shift-work schedules, rather than to diagnose or treat clinical or subclinical sleep disorders. This approach is consistent with current strategies aimed at promoting healthy sleep at the population level [23].

Sample Size Calculation

This study was designed as a pilot randomized controlled trial. Pilot studies are intended to assess feasibility and estimate key parameters for the design of a definitive trial, such as outcome variability and effect size estimates. Therefore, a formal a priori sample size calculation based on statistical power was not performed.

The methodological literature [24,25] on pilot studies suggests sample sizes ranging from 12 to 35 participants per group for this type of design. Although the protocol planned to recruit 60 participants, only 40 eligible students were enrolled during the recruitment period. This sample size also allows for the estimation of preliminary parameters with reasonable precision, in line with approaches focused on estimation rather than hypothesis testing. The findings of this study may inform the sample size calculation of future fully powered randomized controlled trials.

Intervention

Control Group

The control group continued with its normal routine. They did not attend any sessions; they only completed the pre-post measurements.

Intervention Group

Participants allocated to the intervention group received a structured group-based CBT-I–informed program specifically adapted for first-year nursing students within a university health promotion context. The intervention protocol was developed by the research team based on established cognitive behavioral sleep intervention principles and was previously described in the published study protocol [22]. The protocol integrated evidence-based components, including sleep psychoeducation, cognitive restructuring, behavioral stimulus control, and sleep hygiene strategies, delivered using active-constructive learning methodologies designed to promote participant engagement and self-reflection. The intervention group was subdivided into 2 groups of 10 participants to facilitate interaction and individualized discussion. The program consisted of 2 face-to-face 90-minute sessions delivered over 2 consecutive weeks during November and December 2022.

The first session focused on sleep psychoeducation and cognitive restructuring, including basic concepts of sleep physiology and circadian regulation, identification of biological and behavioral factors influencing sleep, and guided self-assessment of individual sleep patterns and habits. Participants were encouraged to reflect on their own sleep-related behaviors between sessions. The second session focused on behavioral skill development, including sleep hygiene education, stimulus control strategies, and practical behavioral adaptations tailored to participants' self-reported routines and baseline sleep assessments.

The intervention was delivered by a PhD candidate in biology, specialized in sleep neurophysiology, chronobiology, and circadian rhythms, and by a registered nurse (PhD) with expertise in health promotion and healthy lifestyle education. Both providers had training in sleep health and cognitive behavioral strategies for sleep. Intervention materials and procedures were reviewed by the research team before implementation to ensure consistency with the published protocol. Additional details regarding session content, intervention materials, and implementation procedures are provided in Multimedia Appendix 1.

Outcome Measures

Primary Outcomes

In accordance with the trial registration (ClinicalTrials.gov NCT05273086), the prespecified primary outcomes were objective sleep quality, assessed using the Kronowise 3.0 ACM system, and subjective sleep quality, assessed using the PSQI.

The Kronowise system provides a multidimensional assessment of sleep quality and circadian function through validated continuous circadian rhythm and sleep parameters, rather than a single global categorical score. Accordingly, the objective sleep outcome was characterized using these continuous parameters, which together describe sleep quality and circadian health.

In this study, sleep and circadian rhythms were monitored using the Kronowise 3.0 device (Kronohealth, S.L.) for 7 consecutive days (including weekends) in participants' homes during the preintervention period and for another 7 consecutive days during the postintervention period, in both the intervention and control groups, with a difference of 19 days between the 2 monitoring periods. The technical characteristics of the device have been described in several studies [14,26,27], and the analysis of its monitoring parameters was obtained from a population of 244 healthy volunteers aged 14 to 86 years using the Kronowizard platform and the Circadianware program, following the methodology of Madrid-Navarro et al [27] from the University of Murcia.

The primary signals recorded by the Kronowise system were surface temperature, acceleration, position, and exposure to light (TAPL). Peripheral skin temperature of the wrist is a recognized, validated circadian rhythm marker [28], suggesting that an increase in peripheral skin temperature is associated with drowsiness [29], whereas a decrease in core temperature is due to redistribution of heat from the interior to the periphery [30]. The triaxial motor acceleration shows the intensity of physical

XSL•FO
RenderX

activity and the time in movement, calculated as the sum of the absolute values of 300 acceleration vectors. Changes in posture reflect postural changes according to inclination axes (horizontality vs verticality) to identify immobility and the amplitude of movements during periods of activity vs rest. Light exposure is measured in 3 spectral bands (visible, blue [460 - 480 nm], and infrared [>700 nm]). All these variables were recorded at a sampling rate of 10 Hz (for acceleration and time in motion), 1 Hz (for skin temperature and light exposure), and 0.033 Hz for wrist position, generating 23 million raw data points over 7 days, condensed to 230,000, which were stored in 30-second stretches for later analysis. From these primary variables, the integrated variable TAPL is obtained as a modification of thermometry, activity, and body position, which expresses the level of general physical and mental activation and has been proved to be accurate for the estimation of individual sleep variables [20]. In TAPL, temperature is inverse to acceleration, position, and light exposure and, in global terms, acquires values between 0 and 1. Absolute values of 0 or close to 0 indicate low general activation (with high values of skin surface temperature), whereas high values close to or equal to 1 reflect high levels of activation corresponding to a maximum state of wakefulness, exposure to light, and movement (with low values of temperature). Given the objective of the investigation, TAPL V5 was used to obtain the mean value of this variable during the 5 consecutive hours of minimum values, that is, during sleep. TAPL V5 values range from 0.01 (5th percentile) to 0.07 (95th percentile), with a positive effect if it reaches lower values.

Circadian Parameters

The analysis of circadian parameters is related to sleep quality, and alterations may indicate chronodisruption [7]. All of these parameters range from 0 to 1, and their interpretation is based on previously published standardization procedures and normative values, including the 5th and 95th percentile reference values [20,21,26,27]. The interdaily stability (IS) regularity index, which is an indicator of the interdaily variability of the circadian rhythm, was calculated. The IS requires repeated measurements over several days because low values or values close to 0 indicate greater sleep fragmentation, whereas high values or values close to 1 indicate perfect stability. Relative amplitude normalized (RAN) is the normalized relative amplitude of the rhythm, calculated as the difference between M10 (average of the 10 consecutive hours with the maximum values of variables that rise during wakefulness) and L5 (average of the 5 consecutive hours with the minimum values of variables that fall during sleep), meaning that the higher the amplitude, the more robust the rhythm. The ES is the parameter related to the person's chronotype and indicates the degree of synchronization between the period of sleep or rest and the center of natural darkness, taking the official summertime of the country where the participant lives as a reference. In Spain, this central time of darkness during daylight saving time is 2 AM. Low values or values close to 0 indicate that the central hour of sleep is far from the central hour of darkness, whereas high values or values close to 1 indicate that the center of sleep is close to or coincides with the central hour of darkness. The main circadian rhythm robustness parameter is the circadian health score (CHS), described in 2019 [26], which integrates IS, RAN, and ES. CHS is the primary sleep quality indicator of the ACM technique and the main marker of circadian strength, which behaves inversely to chronodisruption when it has a value close to 1, implying a high-amplitude, nonfragmented, and stable rhythm.

Sleep Quality Parameters

Although sleep-wake parameters were detected with the above indices, specific sleep indicators were analyzed. These indicators were temperature 2 hours before sleep, temperature during sleep, exposure to total light and blue light 2 hours before sleep, sleep latency and actual sleep time, sleep activity time, number of awakenings, and sleep efficiency. Sleep latency refers to the time in minutes to sleep onset, actual sleep time is the time spent objectively asleep, and sleep activity time is expressed as the average time in seconds during which movement is detected. The number of awakenings is the average number of movements detected for ≥30 seconds per hour of the recorded sleep interval, and sleep efficiency refers to the percentage of time asleep as opposed to the time in bed.

Chronotype

Chronotype refers to categories defined by the differences in activity and alertness between morning and evening. These categories are determined in relation to the 2019 Munich test, which classifies them into extreme matutine, matutine, indefinite, vespertine, and extreme vespertine [31].

Subjective Sleep Quality

The PSQI [17] contains 19 items and 7 clinically important components related to sleep quality: subjective sleep quality, sleep latency, sleep duration, sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction. Responses are reported based on a 5-point Likert-type scale ranging from 0 to 4. Overall, sleep scores of 5 or less are considered good quality, whereas scores of 5 or more are considered low quality. The PSQI version used is validated in the Spanish university framework by de la Vega et al [32] with a Cronbach α of 0.72. The questionnaire was delivered to all participants twice (before and immediately following the intervention).

Independent Variables

Independent variables were selected to characterize factors known to influence sleep quality and circadian regulation in young adults and university populations, including sociodemographic characteristics, lifestyle habits, physical activity, and contextual factors that may act as potential confounders or moderators of sleep-related outcomes. Satisfaction was additionally assessed to explore the acceptability of the intervention in this pilot study. Questionnaires on sociodemographic data and lifestyle factors were prepared ad hoc by the researchers.

First, sociodemographic data and anthropometric variables included date of birth, age, sex, and sleep habits during the study, including whether the participant slept alone or with someone. Participants reported their weight (kg) and height (cm) for BMI calculation. Second, lifestyle factors included

XSL•FO
RenderX

tobacco consumption (cigarettes per day), alcohol consumption (daily, weekly, and sporadic), drug consumption (yes/no and type), consumption of stimulating drinks (eg, coffee, sugary drinks, and energy drinks), and consumption of nonstimulating sweetened beverages. Third, physical activity was assessed using the simplified version of the International Physical Activity Questionnaire (IPAQ) [33]. The questionnaire consists of 7 questions assessing frequency, duration, and intensity of moderate and intense physical activity during the previous 7 days, as well as walking and sitting time during a working day. The questionnaire is classified into low, moderate, and high physical activity based on metabolic equivalent task minutes per week. The higher the score, the more physically active the profile. The questionnaire has been validated, with a mean reliability of 0.80 [33]. Fourth, satisfaction with the program was assessed using a questionnaire adapted from the proposal by Azpeleta et al [34], consisting of 12 questions with responses based on a 5-point Likert scale. Higher scores indicated greater satisfaction.

Data Collection

Data collection was conducted at 2 time points: baseline (preintervention) and immediately after completion of the intervention (postintervention). At baseline, eligible participants completed self-administered questionnaires assessing sociodemographic characteristics, lifestyle factors, physical activity, and sleep quality through the PSQI. Following questionnaire completion, participants were fitted with the Kronowise 3.0 wearable device and received standardized instructions for its use during the 7-day ambulatory monitoring period.

Participants wore the device continuously for 7 consecutive days, including weekdays and weekends, during their usual daily routines in their home environment. At the end of each monitoring period, devices were returned to the research team for data download and processing using the Kronowizard platform.

After baseline data collection, participants were randomized to either the intervention or control group. Following completion of the intervention period, both groups underwent a second 7-day monitoring period under the same conditions and completed the postintervention PSQI. Participants allocated to the intervention group additionally completed the satisfaction questionnaire immediately after the intervention. All assessments and device management procedures were coordinated by an independent investigator trained in study procedures and not involved in outcome analysis.

Ethical Considerations

This study was approved by the Research Ethics Committee of the Camilo José Cela University (code: 06 - 22-UCJC-Sleep) on April 1, 2022. All participants were informed of the duration and characteristics of the study, as well as its voluntary nature. No financial or nonfinancial compensation was provided to participants for study participation.

Participants were free to leave the study at any time, without further consequences. The utmost professionalism and absolute confidentiality were always ensured, in accordance with the European Regulation (EU) 2016/679 on the protection of natural persons and the processing and free movement of data, the Framework Law 3/2018 on the protection of personal data and guarantee of digital rights, and the Law 14/2007 on biomedical research. Only the main project researcher had access to the encrypted database, data processing, and free movement, in accordance with the Framework Law 3/2018 on the protection of personal data and guarantee of digital rights and Law 14/2007 on biomedical research. Only the main project researcher has access to the encrypted database.

Data Analysis

A descriptive analysis was made of all the variables included in the study. Categorical variables were analyzed using absolute and relative frequencies, whereas continuous variables were described using mean (SD) if the variable followed a normal distribution or median (IQR) if the variable followed a nonnormal distribution. Normality was checked using graphic methods (histogram) and statistical methods (Kolmogorov-Smirnov test or Shapiro-Wilk test).

A bivariate analysis was performed to compare the control group and the intervention group, using the Student *t* test (1-tailed) or the Mann-Whitney *U* test for continuous variables according to the distribution of the variable and the chi-square test or Fisher exact test for categorical variables when necessary. For pre-post comparison, the Student *t* test was used for paired samples, the Wilcoxon test was used for continuous variables, and the McNemar test was used for categorical variables. Effect size for parametric comparisons was estimated using Cohen *d* [35]. For nonparametric analyses, effect size was calculated as *r* based on the standardized *Z* statistic ($r = Z / \sqrt{N}$) proposed by Rosenthal and Rubin [36], where N represents the total sample size. Effect sizes were interpreted according to Cohen conventional thresholds for *d* (0 - 0.3 for small, >0.3 - 0.8 for moderate, and >0.8 for large effect) and *r* (0 - 0.3 for small, >0.3 - 0.5 for moderate, and >0.5 for large effect).

To account for baseline imbalances between groups, adjusted analyses were additionally performed using analysis of covariance. For each continuous sleep and circadian outcome, the postintervention value was entered as the dependent variable, treatment group (intervention vs control) as the fixed factor, and the corresponding baseline value of the outcome as a covariate. Smoking status, school schedule, and coffee consumption were additionally included as covariates because these variables differed between groups at baseline. Adjusted treatment effects (regression coefficients [β]), 95% CI, *P* values, and partial eta-squared (η^2) were estimated. Because baseline differences were identified between the intervention and control groups, the adjusted analysis of covariance models were considered the primary analytical approach for estimating treatment effects, whereas the unadjusted bivariate analyses were retained as complementary analyses.

In accordance with the trial registration, the prespecified primary outcomes were objective sleep quality, assessed using the Kronowise system, and subjective sleep quality, assessed using the PSQI. The continuous circadian rhythm and sleep parameters generated by the Kronowise system were analyzed to provide a detailed characterization of the objective sleep outcome. Given

XSL•FO
RenderX

the pilot nature of this trial, analyses of these individual parameters were considered exploratory and hypothesis-generating. Therefore, no formal adjustment for multiple comparisons was applied, and findings from these analyses should be interpreted as exploratory rather than confirmatory.

Results

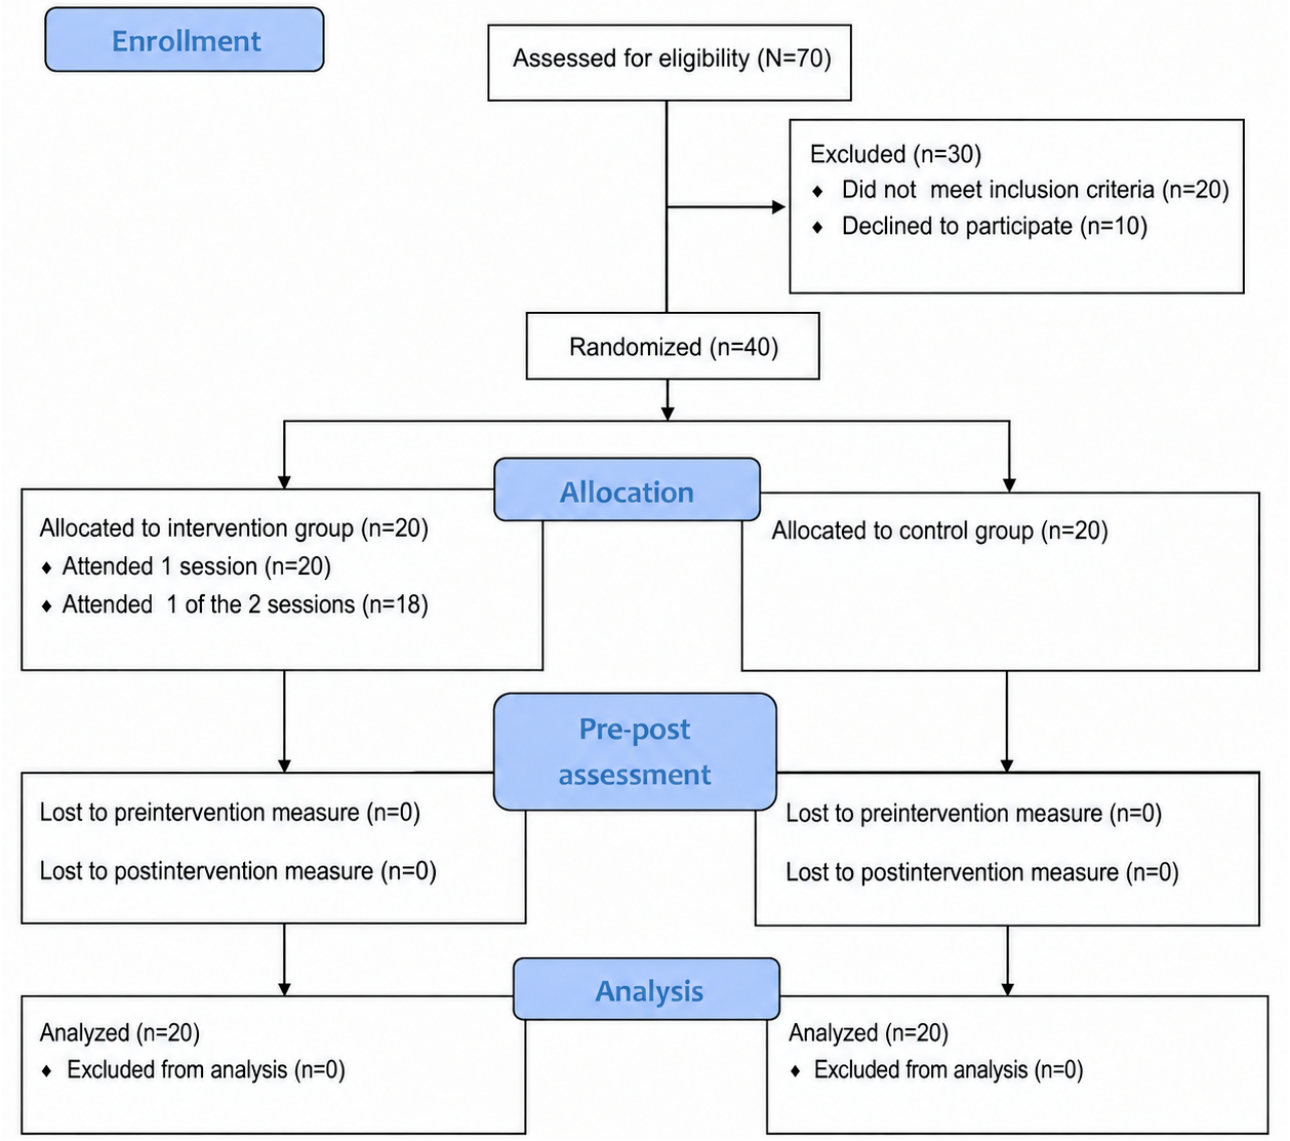

Figure 1 shows the CONSORT flow diagram of the study. A total of 70 students were assessed for eligibility. Twenty students were excluded because they did not meet the study criteria, most frequently due to melatonin use, combining work and study, or being outside the eligible age range. Of the 50 eligible students, 10 declined participation or did not complete the informed consent process. Reasons for nonparticipation were not systematically recorded. Consequently, 40 participants were enrolled and randomized. Of these, 20 were allocated to the intervention group (n=16, 80% female) and 20 to the control group (n=18, 90% female). The overall mean age was 19.9 (SD 1.8) years. The mean age was lower in the intervention group compared with the control group (mean 19.6, SD 1.8 vs mean 20.2, SD 1.8, respectively). Cohabitation of students during the study was mostly in a family setting (n=12, 60%) compared with 8 (40%) students residing outside the family environment, with no statistically significant difference.

The total sample was distributed in academic dedication schedules of 50% (20/40) morning shifts (8:30 AM to 1:30 PM) and 50% (20/40) in afternoon shifts (3:30 PM to 8:30 PM), with a statistically significant relationship (P=.01). The most prevalent BMI category in both groups was normal weight (31/40, 77.5%), with a mean of 23.1 (SD 3.8) kg/m^2 (Table 1).

Among 40 students, 37.5% (n=15) were active smokers, with a higher proportion of smokers in the intervention group than in the control group, a mostly daily consumption pattern (n=10, 66.7%), and a statistically significant median daily consumption (P=.04). A total of 67.5% (n=27) consumed alcohol on a regular basis, with no significant differences between the 2 research groups (Table 2). Almost 8 out of 10 participants reported daily coffee consumption, with higher consumption in the control group (18/20, 90%) than in the intervention group (12/20, 60%), which was statistically significant (P=.03), with a median consumption of close to 2 coffees per day in both groups. Almost 3 out of 10 students reported consuming energy drinks daily, with slightly higher consumption in the control group than in the intervention group (5/20, 25% vs 4/20, 20%). Overall, 45% of the participants were sedentary, with a median of 7 hours sitting per day. The sedentary condition was the highest proportion in both groups in terms of the type of physical activity they engaged in daily.

[a]The total sample included 40 participants (20 per group). For behavior-specific variables, such as alcohol and tobacco consumption, data refer only to participants reporting the corresponding behavior; therefore, frequencies may not add up to the total sample. Continuous variables with nonnormal distributions are presented as median (Q1–Q3); range.

[b]For alcohol type, participants could report more than one category; therefore, frequencies and percentages do not necessarily add up to the total sample or 100%.

Adjusted treatment effects for circadian rhythm, objective sleep, and subjective sleep outcomes are presented in Table 3. For objective circadian rhythm parameters, adjusted treatment effects were uniformly small (partial η^2=0.004 - 0.047), and the corresponding 95% CIs were compatible with little or no intervention effect. Similarly, objective sleep and environmental outcomes showed generally small effect sizes (partial η^2=0.004 - 0.065), with CIs indicating considerable uncertainty around the estimated treatment effects. In contrast, subjective sleep outcomes showed larger adjusted effects. The intervention was associated with a shorter self-reported sleep latency (β=−19.78 min, 95% CI −33.83 to −5.74), corresponding to a large effect size (partial η^2=0.194). Sleep duration (β=36.32 min, 95% CI −5.01 to 77.64; partial η^2=0.086), sleep efficiency (β=8.75%, 95% CI −0.97 to 18.47; partial η^2=0.090), and the global PSQI score (β=−1.20, 95% CI −3.18 to 0.78; partial η^2=0.061) also favored the intervention group, although the CIs were compatible with a range of plausible effects. Unadjusted bivariate analyses are provided in Multimedia Appendix 1.

Objective sleep monitoring indicated that the predominant baseline chronotype in both groups was intermediate (ie, neither clearly morning nor evening type). Following the intervention, a shift toward a more evening-oriented chronotype was observed in both groups (Table 4).

Satisfaction with the intervention received and with the participation of the expert (Table 5) was mostly “very good” in all the items evaluated. Satisfaction with the intervention was very good for 63% of the survey and good for 35%.

Discussion

Principal Findings

The present pilot randomized controlled trial explored the preliminary effects of a brief group-based CBT-I–informed intervention delivered as a sleep health promotion program for first-year nursing students. Overall, the intervention showed more favorable effects on subjective sleep outcomes, particularly self-reported sleep latency, whereas objective circadian rhythm and sleep parameters assessed through ACM showed small and imprecise treatment effects. Participants also reported high satisfaction with the intervention, supporting the feasibility and acceptability of implementing this type of program within a university setting.

The pattern of findings observed in this study may be explained by the characteristics of both the intervention and the study population. Unlike most CBT-I trials, which recruit participants with clinically significant insomnia symptoms, this intervention was delivered as a universal health promotion strategy to first-year nursing students regardless of their baseline sleep status [10,12,13]. Consequently, participants may have had relatively limited objective circadian impairment at baseline, reducing the opportunity to detect measurable physiological improvements over the short intervention period. At the same time, increasing participants' awareness of sleep-related behaviors and promoting healthier sleep habits may have influenced their perception of sleep before producing detectable changes in objective circadian regulation [37].

The characteristics of the intervention itself should also be considered when interpreting these findings. Standard CBT-I programs are typically delivered over multiple sessions and incorporate individualized behavioral components, including stimulus control, sleep restriction, cognitive therapy, and the systematic review of sleep diaries, which are considered core mechanisms of treatment effectiveness [38,39]. By contrast, our intervention consisted of 2 face-to-face group sessions designed as a pragmatic university-based health promotion program rather than as an intensive therapeutic intervention. This lower treatment intensity may have been sufficient to increase participants' awareness of healthy sleep practices and influence their perception of sleep while being insufficient to induce sustained behavioral changes that could be reflected in objectively measured circadian outcomes during the relatively short follow-up period [40,41]. Furthermore, participant engagement with the behavioral recommendations outside the classroom was not formally assessed. Consequently, it remains unclear to what extent the absence of objective effects reflects the limited intensity of the intervention, suboptimal adherence to the recommended behavioral changes, or a combination of these factors, all of which are recognized determinants of CBT-I effectiveness [39,42].

The discrepancy between subjective and objective outcomes deserves particular attention. Participants in the intervention group reported improvements in sleep latency, with trends toward better perceived sleep duration and sleep efficiency, whereas objective monitoring did not demonstrate corresponding improvements. Similar discrepancies between subjective and objective sleep measures have been described previously in young adults and may reflect the fact that these instruments capture different aspects of sleep [37]. The discrepancy between subjective and objective outcomes should also be interpreted in light of the study design. Because participants were aware of their group allocation and the control group received no active intervention, subjective outcomes were more susceptible to expectancy effects, increased awareness of sleep behaviors, facilitator attention, and group interaction. Consequently, the observed improvements in subjective sleep outcomes may partly reflect nonspecific effects associated with participation in the intervention, in addition to the specific therapeutic components of CBT-I [43]. In contrast, objectively measured circadian outcomes are less directly influenced by participants' expectations and therefore provide a complementary perspective on intervention effects.

Our findings are broadly consistent with previous studies evaluating CBT-I and behavioral sleep interventions in university students. Randomized trials and systematic reviews have generally reported greater improvements in subjective sleep outcomes than in objective sleep measures, particularly when interventions are implemented in nonclinical student populations [13,40,44]. However, direct comparisons should be interpreted cautiously because studies differ substantially in intervention intensity, treatment duration, participant characteristics, and outcome assessment. Moreover, most previous studies have relied primarily on self-reported questionnaires or conventional actigraphy [13]. By incorporating multidimensional ACM alongside validated subjective measures, the present study provides a more comprehensive evaluation of behavioral intervention effects under real-world conditions and highlights the value of assessing both perceived and physiological dimensions of sleep [45].

Although the objective circadian outcomes did not demonstrate consistent intervention effects, these findings should not be interpreted as evidence that behavioral sleep interventions are ineffective in university populations. Rather, they suggest that a brief group-based health promotion program may be insufficient to modify physiological circadian regulation over a short period in generally healthy young adults. Future trials should evaluate whether greater intervention intensity, individualized behavioral support, reinforcement sessions, longer follow-up, and systematic assessment of participant adherence improve both subjective and objective sleep outcomes [44]. Such research may also help clarify the temporal relationship between changes in perceived sleep and objectively measured circadian outcomes.

One of the main strengths of this study is the combined assessment of subjective sleep quality and multidimensional objective circadian monitoring using a validated ambulatory wearable device under free-living conditions. This approach enabled continuous assessment of sleep and circadian function beyond self-reported outcomes—an aspect that has been infrequently incorporated into behavioral sleep intervention studies in university populations. In addition, the randomized controlled design and the high levels of participant satisfaction support the feasibility and acceptability of implementing sleep health promotion programs among first-year nursing students.

XSL•FO
RenderX

Overall, this pilot trial suggests that a brief, group-based, CBT-I–informed intervention is feasible, well-accepted, and may improve selected subjective aspects of sleep among first-year nursing students. However, measurable changes in objective circadian outcomes were not observed under the conditions evaluated. These findings support the need for adequately powered randomized controlled trials incorporating active control groups, longer follow-up periods, adherence assessment, and more intensive or individualized behavioral interventions to better establish the effectiveness of sleep health promotion programs in university populations.

Limitations

One of the main limitations of this study was the lack of blinding for participants and facilitators, which is common in behavioral interventions and may introduce bias. Additionally, the absence of an active control group may affect internal validity and potentially lead to an overestimation of the intervention effects. Although the use of a usual-care control enhances ecological validity in a university context, it does not account for nonspecific effects inherent to group-based interventions, such as therapist attention, peer interaction, and participant expectations. Furthermore, the face-to-face group format itself may have contributed to the observed outcomes through contextual or placebo effects, which cannot be ruled out.

The inclusion of an active control condition (eg, group-based education sessions without CBT-I components) would have allowed for more rigorous control over these nonspecific effects. Therefore, the findings should be interpreted with caution. In addition, the group-based format of the intervention did not allow for individualized tailoring based on the specific sleep characteristics identified during preintervention assessment. Although key aspects of sleep behavior were addressed, more personalized approaches may yield stronger effects.

Furthermore, although mediation analysis was prespecified in the study protocol, it was not performed due to the limited sample size and the absence of multiple follow-up assessments required to establish temporal relationships between potential mediators and outcomes. As a result, the mechanisms through which the intervention may have influenced sleep- and circadian-related outcomes could not be explored. Future, adequately powered trials that incorporate repeated measurements over time should investigate potential mediating pathways underlying intervention effects.

In addition, the study may be subject to selection bias. Participants were recruited from a single cohort of first-year nursing students at one university, and participation was voluntary. Consequently, students with greater interest in sleep-related issues or health-promoting behaviors may have been more likely to participate. This may limit the representativeness of the sample and reduce the generalizability of the findings to other student populations, academic disciplines, or educational settings.

Although participants were randomly allocated, some baseline differences were observed between groups in variables such as smoking status, school schedules, and caffeine consumption. While additional adjusted analyses were performed and yielded results consistent with the primary findings, residual confounding cannot be completely excluded given the small sample size characteristic of this pilot study.

Future research should aim to incorporate active control conditions, larger sample sizes, and more individualized interventions. Further studies are also needed to determine the clinical relevance of changes observed in circadian parameters and to validate multidisciplinary approaches based on individual sleep and circadian profiles. Finally, this pilot trial was not intended to address implementation at the institutional level. Future implementation studies are needed to evaluate scalability, resource requirements, and cost-effectiveness before broader adoption can be considered.

Conclusions

This pilot randomized controlled trial provides preliminary evidence that a brief group-based CBT-I intervention may improve selected subjective sleep outcomes among first-year nursing students. The largest treatment effect was observed for self-reported sleep latency, whereas objective circadian rhythm and sleep outcomes generally showed small treatment effects with wide CIs, reflecting considerable uncertainty around the estimated effects. Participants reported high levels of satisfaction with the intervention, supporting the feasibility and acceptability of this approach within a university setting. Given the exploratory nature and limited sample size of this pilot study, adequately powered randomized controlled trials with longer follow-up are needed to confirm these findings and to better define the magnitude and durability of the intervention effects.

Abstract

Background: Most people make no health or lifestyle changes before pregnancy, missing a key opportunity to improve outcomes. Consequently, nearly half of UK pregnancies are unplanned, disproportionately affecting underserved groups and widening health inequalities. Digital health interventions (DHIs) offer promise but require systematic, theory-driven development to ensure effectiveness and real-world applicability.

Objective: This study aimed to use Intervention Mapping to codevelop and pilot Orchid, a novel DHI designed to support people of reproductive age to understand their pregnancy preferences and develop a reproductive life plan (RLP).

Methods: We used Intervention Mapping steps 1 - 4 to guide the systematic, theory-informed codevelopment of Orchid. A multidisciplinary planning group and codevelopment group of 21 members of the public contributed throughout. At step 1, previous research and a scoping review of existing RLPs informed the program goals and logic model of the problem. During step 2, we identified performance objectives and behavioral determinants to specify practical strategies for each target behavior. At step 3, we applied the Capability, Opportunity, Motivation–Behavior (COM-B) model and relevant behavior change techniques to guide intervention design. Finally, at step 4, Orchid was co-designed as a website and mobile app providing users with a pregnancy preference group and prediction of pregnancy, a dynamic RLP, tailored evidence-based information, and optional goal-setting features to support behavior change. Orchid was piloted between January and May 2025 to explore its feasibility and acceptability in health care settings. Interviews with users, nonusers, and health care professionals were conducted and quantitative data from users were collected.

Results: These findings indicate that implementation was feasible, and health care professionals found it acceptable to recommend Orchid to patients, though noted barriers including time constraints and competing priorities. Overall, 153 people signed up to Orchid; 68% (72/106) of eligible users received a pregnancy preference group and 27% (32/119) of eligible users completed a full RLP. Users were positive about Orchid, appreciating its content and design, noting that Orchid contained a wealth of information about reproductive health presented in an easy-to-understand manner. They valued the autonomy, convenience, and privacy afforded by the digital format, and found it acceptable to be recommended Orchid within a health care setting. Orchid uptake was lower than anticipated, and use was limited; this was partly expected given the short pilot period, but feedback also suggested targeted recruitment and navigation improvements could enhance uptake and engagement.

Conclusions: Orchid is the first co-designed DHI to support reproductive health across the life course. Its systematic development, theoretical foundation, strong user involvement, and positive pilot testing position it as a promising, scalable innovation to support reproductive health, deliver credible information in accessible formats, and promote preventative, community-based care across the National Health Service.

Introduction

Background

Within the United Kingdom, nearly half of all pregnancies are unplanned [1], and abortion rates are at an all-time high [2]. These trends suggest that reproductive health services are failing to meet people's needs. Contraceptive use remains inconsistent, with almost 1 in 5 women of reproductive age in England reporting using no contraception or unreliable methods [3], and the use of hormonal contraception is decreasing [4]. Unplanned pregnancies are disproportionately concentrated among underserved populations [5], including those living in poverty and individuals from ethnic minority groups, and are associated with a range of adverse outcomes such as preterm birth, involvement of children's social care services, financial adversity, and health inequalities [6]. As such, unplanned pregnancy remains a significant public health concern and a key driver of disparities in maternal and child health.

At the same time, the health of individuals entering into pregnancy (whether planned or unplanned) presents additional challenges. More than 90% of women in the United Kingdom have at least one modifiable risk factor associated with adverse pregnancy outcomes [7] including maternal and neonatal morbidity and mortality. Yet, the majority of women, and their partners, make no health or lifestyle changes in preparation for pregnancy [8]. This lack of planning and preparation represents a missed opportunity to optimize health before conception, improve pregnancy outcomes, and reduce longer-term risks for both parent and child. Contributing to this gap is the fact that discussions around pregnancy preferences and preconception health are not routine in health and social care settings [9,10], even for people with preexisting conditions, those taking medications, or those with social risk factors.

Furthermore, reproductive health discourse and interventions often overlook the role of men, despite evidence linking paternal nutrition, body composition, and lifestyle behaviors to sperm quality and offspring health outcomes [11,12]. This underscores the need for a more inclusive, holistic approach to reproductive health.

There is an unmet and expressed need among people of reproductive age for better support with their reproductive health [9,13]. Combining this need with the challenges outlined above highlights the importance of adopting a more proactive, person-centered approach to supporting reproductive decision-making. Reproductive life planning [14] offers such an approach, enabling individuals to reflect on their reproductive intentions, align these with their health and life circumstances, and access the information and care needed to achieve their goals.

While health care professionals have a vital role to play in delivering this support, additional approaches are needed to extend reach and accessibility. Digital health interventions (DHIs) offer a promising approach, with emerging evidence suggesting that they can overcome barriers of distance, accessibility, stigma, and judgment [15] and can improve preconception health [16]. However, evidence on their effectiveness in supporting contraception use remains limited [17,18].

The development of any new DHI should follow a systematic, theory-driven process to maximize its potential for effective real-world implementation. In line with Medical Research Council guidance on complex interventions [19,20], such development should be reported transparently to strengthen the evidence base, enhance reproducibility, and allow others to assess its relevance across contexts. Despite these imperatives, the intervention development phase remains relatively underreported, which poses issues with transparency, quality, and user-centeredness [21].

Aim

This paper aims to describe the systematic development and pilot testing of Orchid, a novel DHI to support people of reproductive age to understand their pregnancy preferences and develop a reproductive life plan (RLP).

Methods

Development of Orchid Using Intervention Mapping Framework

Our development of Orchid followed the Intervention Mapping (IM) framework [22], as used by other digital health programs [23].

Step 1: Needs Assessment

Establish and Work With a Planning Group

Our planning group, that met weekly, was comprised of 2 female researchers (JH and CS) who had led the development work underpinning Orchid, 3 female clinicians (HC and MST [2 general practitioners] and AH [sexual and reproductive health doctor]) affiliated with the team, and a male software developer.

While previous work was focused on women, early input from the codevelopment group highlighted that including men would be important both to reduce the disproportionate burden placed on women and to address the underrepresentation of men in reproductive health research. Therefore, we created a codevelopment group of 21 public members (males and females, aged 16 - 45 y, with diverse ethnicities, relationship statuses, sexuality, and family sizes, living across the United Kingdom). Members were recruited from existing Public and Patient Involvement groups and the school where Orchid was piloted.

Conduct Mixed Methods Needs Assessment

We conducted primary research on the feasibility and acceptability of different ways of assessing pregnancy preferences, followed by a scoping review, to explore the existing evidence on RLPs [24], to identify key goals for Orchid.

Primary Research

The Pregnancy Planning, Preparation, and Prevention Study (P3 Study) explored ways of assessing women's feelings and preferences regarding a future pregnancy [25]. Within its cohort, 80% of women expressed a preference for exploring their pregnancy preferences digitally [9]. This preference was consistent across different age groups and was further validated

XSL•FO
RenderX

through qualitative research involving in-depth discussions with women [13] and reflects findings from other studies [26]. Qualitative work with health care professionals [13] (HCPs) reinforced that a digital tool providing accessible reproductive health information could usefully extend support beyond clinical encounters. Although HCPs viewed discussions about pregnancy preferences as acceptable and valuable, many reported lacking the confidence, training, and time to deliver them effectively [13].

The P3 study also evaluated the psychometric performance and predictive validity of the UK version of the Desire to Avoid Pregnancy (DAP) scale [27] and found it to be a valid and reliable measure of women's desire to avoid pregnancy, as well as highly predictive of pregnancy within the next 12 months (sensitivity 78% and specificity 81% [27,28]).

Scoping Review

We carried out a scoping review of the published and gray literature to map the evidence on RLPs [24]. Most studies and gray literature originate from the United States, primarily within clinical settings. Across the literature, 21 different RLPs were identified, with many based on the 2006 Moos RLP [29]. Digital RLPs were scarce, with none currently available in the United Kingdom.

Acceptability of RLPs was consistently high across studies; users were overwhelmingly positive about being asked about reproductive life planning. However, evidence of effectiveness was limited. There was minimal evidence of the application of behavior change theory in the development of the RLPs, with only 3 tools (all digital) describing the inclusion of specific behavior change theories [30-32].

Identify Program Goals

The needs assessment helped to identify the program goals: to create a digital tool (app and website) to help people of reproductive age understand their pregnancy preferences, support them to develop and implement an RLP, and increase awareness of reproductive health. The aim is to support users to achieve their reproductive health goals, reduce unintended pregnancies, increase pregnancy preparations, and empower decision-making.

Create a Logic Model of the Problem

We created a logic model (Table S1 in Multimedia Appendix 1) of the problem from the findings of our scoping review and previous research.

Step 2: Selecting Behavioral Determinants and Performance Objectives

Informed by the results of our needs assessment and input from our codevelopment group, we identified specific performance objectives for subpopulations, based on reproductive preferences. For example, taking folic acid for those actively planning a pregnancy or consistent and correct contraceptive use for those wishing to avoid pregnancy. See Table S2 in Multimedia Appendix 1 for more examples.

Our scoping review identified 5 key behavioral determinants that are underlying drivers of behavior change: (1) knowledge [30], (2) self-efficacy [31,32], (3) social support [31], (4) intrinsic motivation [30], and (5) autonomy [30]. We explored the relationships between performance objectives and behavioral determinants and identified change objectives and practical strategies for each target behavior.

Step 3: Identifying Theory-Based Intervention Methods and Practical Applications

We applied the Capability, Opportunity, Motivation–Behavior (COM-B) model [33] when developing Orchid. This model was selected because each of the behavioral determinants we had identified (knowledge, self-efficacy, social support, intrinsic motivation, and autonomy) aligns with one or more of the COM-B components, providing a comprehensive framework for influencing behavior change within Orchid. We systematically mapped each component of the COM-B model to Orchid's proposed content and features, linking them to the specific objectives identified during the planning phase (Table 1). This ensured that theory directly informed Orchid's design, aligning practical features with the mechanisms expected to support behavior change. We also identified several behavior change techniques [34-37], including goal setting and reminders, feedback, habit stacking, action planning, information, and education. These techniques were incorporated into Orchid to support the COM-B framework, enhance engagement, and increase the likelihood of successful behavior change.

XSL•FO
RenderX

Table . Mapping the COM-B[a] model components as applied to Orchid against the preconception and contraception pathways.

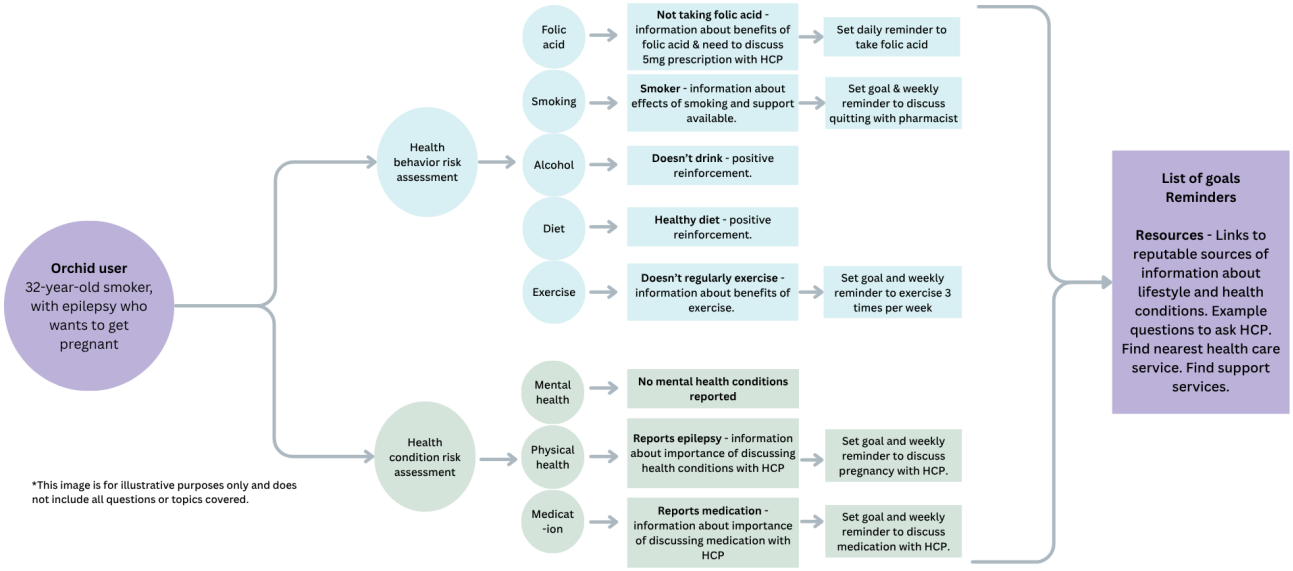
Orchid intervention	COM-B components	Link to behavior change
Preconception		
Evidence-based questionnaire or risk assessment	• Psychological capability • Reflective motivation	• Builds awareness and knowledge of health status. • Prompts self-reflection and understanding of risk factors that may need addressing.
Informational content on health optimization	• Psychological capability • Reflective motivation	• Enhances users' knowledge and skills to make informed decisions. • Supports internal motivation by linking actions to outcomes.
Access to relevant resources	• Physical opportunity • Psychological capability	• Enhances opportunity by increasing access to information.
Find your nearest health care provider or support groups	• Social opportunity • Physical opportunity	• Enhances opportunity by increasing access to services and connecting users to support systems.
Goals and reminders for preconception behaviors	• Reflective motivation • Automatic motivation	• Supports planning and habit formation. • Reminders and prompts maintain engagement and drive action.
Positive reinforcement messaging	• Automatic motivation	• Builds positive associations, rewards behavior, and sustains engagement over time.
Contraception		
Personalized contraceptive questionnaire	• Psychological capability • Reflective motivation	• Builds understanding of contraceptive choices and helps users make informed decisions that fit their lifestyle, increasing likelihood of consistent use.
Educational content on contraception	• Psychological capability • Reflective motivation	• Enhances knowledge, increasing competence and confidence to choose and use contraception effectively.
Access to relevant resources	• Physical opportunity • Psychological capability	• Increases access to credible information and reduces barriers.
Goals and reminders for contraceptive use	• Automatic motivation • Reflective motivation	• Encourages habit formation and planning, reducing forgetfulness, and promoting consistent use.
Action planning for contraceptive scenarios	• Psychological capability • Reflective motivation	• Builds self-regulation and coping strategies, increasing users' ability to maintain contraceptive use across variable contexts.
Find your nearest health care provider	• Physical opportunity • Social opportunity	• Improves access to professional support and normalizes help-seeking behavior.

[a]COM-B: Capability, Opportunity, Motivation–Behavior model

Step 4: Program Development and Pilot Testing

Development of Orchid Prototype

Between November 2022 and February 2023, we codeveloped a prototype of Orchid. This incorporated the DAP scale and a digitized pregnancy prediction algorithm [28] to present users with a pregnancy preference group, their likelihood of pregnancy, and tailored resources. Throughout the process, our codevelopment group emphasized the importance of ensuring that Orchid is inclusive of all users, including men, and expressed a desire for Orchid to be available as both an app and a website to enhance accessibility.



Development of Orchid Version 1

Starting with the Orchid prototype and guided by the COM-B model, program goals, and aims, we worked collaboratively with our program team and codevelopment group to build the RLP component of Orchid (Figure 1). Our public contributors worked with us throughout to enhance accessibility and

XSL•FO
RenderX

engagement. They played a central role in shaping the content and user pathways; their input led to substantial expansion of the scope to encompass sexual health, menstrual health, menopause, cancer awareness, and decision-making. The codevelopment of Orchid was an iterative process using a mixture of online group meetings (n=3) and surveys (n=10) from February to December 2024.

Figure 1. Walk-through of Orchid preconception Reproductive Life Plan pathway. HCP: health care professional.

Users are required to sign in to Orchid to protect their data and ensure confidentiality. They then answer a series of questions about their reproductive preferences (DAP Scale) [38]. Based on their answers, users are assigned a pregnancy preference group (eg, Planner, Preventer, and Pauser) and given a personalized pregnancy prediction. This prediction is generated by an algorithm (developed by JH) that combines DAP responses with selected sociodemographic characteristics to calculate the likelihood of becoming pregnant in the next year [39]. Full details on pregnancy preference group classification and the pregnancy prediction algorithm are provided in the Multimedia Appendix 1.

Users are then guided down a dynamic pathway of questions that adapts based on their answers to create a comprehensive RLP. Relevant, evidence-based information is provided along the pathway and signposted in the Resources section. As users move down the pathway, they can set optional to-do items and reminders, aimed at assisting users to take action to achieve their goals. For details, see Figure 2 for an overview of Orchid.

Pilot Testing to Explore Acceptability and Feasibility

We conducted a pilot between January and May 2025 to explore the acceptability and feasibility of implementing Orchid in health care and educational settings. We collaborated with our codevelopment group to develop the ethics application for this study, codeveloping recruitment materials, such as posters and SMS text messages, participant information sheets, topic guides, and lesson plans. This paper focuses on the health care pilot; the school pilot is detailed separately [40].

Health Care Pilot

We piloted Orchid in 3 National Health Service (NHS) health care settings in Greater London: a GP practice, a sexual health clinic, and a women's health hub (WHH). The pilot ran for 5 months with GP and sexual health clinic sites launching in January 2025, followed by the WHH in February 2025. All study locations concluded activity at the end of May 2025.

Each site received a 1-hour training session from a clinician prior to the launch of Orchid, covering how and why to ask about pregnancy preferences, the principles of reproductive life planning and preconception health, and an introduction to Orchid and the pilot study. The content and style of the training program were based on Normalization Process Theory (NPT) [41,42] and COM-B [33]. The NPT constructs of context, mechanisms, and outcomes were considered, particularly aiming to present a coherent message that was cognitively engaging and included suggestions for collective action in that context. A presentation was adapted for each training site and an electronic copy of the slides was provided afterward. We delivered the training in person at 2 sites and online at the third. In total, 36 HCPs attended the training.

Patients (aged 18 - 50 y) were invited to use Orchid through 3 methods: text messages sent via Accurx (used only at the GP site), posters displayed in the waiting rooms (GP and sexual health clinic), and HCP recommendations during clinical consultations (all sites).

At the GP practice (the only site with a defined patient list), text messaging served as the primary recruitment method. Overall, 4456 eligible patients were identified and contacted in 2 batches: the first half received an initial invitation on January 8, 2025, and the second half on January 16, 2025. All patients were recontacted on February 7, 2025, followed by a targeted reminder sent on April 30, 2025, to 939 patients who had attended an appointment in the previous 2 months. In contrast, precise numbers of eligible patients could not be determined for the sexual health clinic or WHH, as neither holds a registered patient list. However, the sexual health clinic sees approximately 60 - 80 patients per day, while the WHH sees around 20 - 30 patients per week (with many ineligible for Orchid due to age criteria).

Orchid User Quantitative Data

Within Orchid, we collected quantitative data on uptake, completion of Orchid, sociodemographics of users, recruitment method, and location. Completion was defined as reaching the end of a personalized RLP pathway. Users were grouped according to their pregnancy preferences as follows: Planner (wants a pregnancy now), Undecided (has not decided whether they want children), Postponer (wants children in the future), Pauser (has at least 1 child and would like another in the future), Finisher (has all the children they want), and Preventer (does not want children). Quantitative data were analyzed using Stata/MP 18 (StataCorp).

Health Care Professional Interviews

HCPs from each of the 3 participating sites were recruited via email. To be eligible for an interview, HCPs were required to have attended the Orchid training.

Orchid User and Nonuser Interviews

We recruited Orchid users and nonusers through separate strategies to ensure representation of both groups. All registered Orchid users were invited to participate via email. Information about interviews was also included on posters displayed at sites. Nonusers were identified and invited through GP-sent Accurx text messages; patients received an initial message asking whether they had accessed Orchid, and those who responded "no" were asked about their reasons for nonuse and invited to take part in an interview. For details, see Figure S1 in Multimedia Appendix 1 for a flow diagram outlining the participant recruitment process.

All interviews were conducted via Zoom (Zoom Communications, Inc), audio-recorded with participant consent, and transcribed verbatim by a member of the research team. Following data familiarization, we collaboratively developed a shared coding framework for the user and nonuser interviews through group discussions, drawing on our research questions and early impressions from the transcripts. Using this common framework, user interviews were coded by CS and nonuser interviews by JH. In parallel, HCP interviews were analyzed using a separate coding framework informed by NPT [41], with coding undertaken by HC. To ensure analytic consistency, the full team met regularly to discuss emerging codes, compare interpretations, and refine frameworks as needed. These meetings supported iterative theme development and enabled us to explore differences and commonalities across user, nonuser, and HCP accounts, ensuring that all final themes were firmly grounded in the data. Qualitative data were analyzed in NVivo 14 (Lumivero).

Qualitative data collection concluded once all users, nonusers, and eligible HCPs who responded and consented had been interviewed.

Ethical Considerations

Ethical approval for the health care pilot was granted by the NHS London, Riverside Research Ethics Committee (Ref: 24/LO/0421). Informed consent was obtained from all Orchid users; they were provided with a participant information sheet and were required to provide consent before using Orchid. Informed consent was also obtained from all users, nonusers, and HCPs who participated in an interview. Participants who took part in interviews were given a £25 (US $33) voucher.

All user data collected through Orchid were handled in accordance with data protection regulations. Email addresses were stored separately from the main dataset, and all analytical

XSL•FO
RenderX

data were pseudonymized prior to analysis. All data were stored in the University College London Data Safe Haven and were only accessible to authorized members of the research team.

Results

All data presented are new and unique to this manuscript.

Health Care Professional Interviews

We conducted in-depth interviews with 10 HCPs. The NPT [41] framework was used to analyze the data, exploring the effectiveness of the training, the likelihood of adoption, implementation, and sustainment of Orchid. Outcome data were limited by the short-term nature of the pilot project, and we therefore focused on the intervention performance.

Training was feasible in all 3 clinical settings and was scheduled during each site's regular training program. In-person sessions were preferred to live online training, but HCPs agreed that online was sometimes more practical. Most HCPs found the training stimulating and understood the importance of the topic. New learning and increased confidence were commonly reported, and HCPs appreciated receiving detailed practical tips that they could immediately incorporate into their clinical practice. The inclusion of men in the RLP message was novel for most and several specifically commented on their cognitive engagement with the training, saying,

> *I thought the training was great, because it actually got me thinking differently.* [CC05]

Most HCPs said that being able to use Orchid within the training would have increased their confidence in sharing the tool with patients:

> [MP02]

Despite this, most HCPs found signposting patients to Orchid acceptable, although some demonstrated limited engagement; one HCP said,

> *I've discussed it with some patients, but I haven't found any leaflets... I'm kind of forgetting … about it.* [CC05]

Many HCPs felt that reminders or brief refresher sessions would be useful:

> *Just like a little nudge for people sometimes … just kind of brings it back up to the top of your memory.* [CC02]

and emphasized the need for more collective action to support sustained uptake of Orchid. Having a local champion at a site was seen as valuable in maintaining momentum, as illustrated by one HCP:

> *So [name] … works in the clinic, I know she just gets [the leaflets] out and puts them on the desk as well, so, so everybody hopefully knows about it and brings it up.* [WHH02]

HCPs found it feasible to incorporate opportunistic RLP and preconception information into certain consultations, particularly those relating to women's health, baby clinics, vaccination clinics, chronic disease clinics, and male fertility. One HCP noted

> *It doesn't take long … anything related to women's health is really easy.* [WHH01]

However, HCPs agreed that it was more challenging to introduce these topics in other consultations:

> *It's just difficult to talk contraception when somebody comes for something completely different.* [WHH01]

and many acknowledged that such discussions were not always possible:

> *You have your agenda of keeping the patient safe, and they have their agenda of what they want to get sorted out, and then this is like another thing to add into the mix.* [MP04]

Overall, views were mixed on the impact on consultation times; while some HCPs were hesitant to raise the topic for fear of it leading to a longer consultation, others acknowledged that Orchid could "save time maybe because … we can refer directly to the app and say, look, we have good information there" (MP01).

Importantly, where HCPs had mentioned Orchid to patients, the response was consistently positive:

> *I have recommended Orchid to a few patients, and they've been really interested in it.* [WHH02]

At the GP practice, text messages were used to promote Orchid. While HCPs were supportive of this method of recruitment, "I think the text message is absolutely excellent," they did share concerns about potential pitfalls:

> *Sometimes I do get patients worrying that the texts they're getting are scams and lots of people don't speak … or can't read English.* [MP04]

Orchid Users' Quantitative Data

In total, 153 people signed up to Orchid, of whom 109 (71%) were females and 44 (29%) were males. Most people found out about Orchid via a text message from their GP (102/153, 66.6%), followed by clinical consultation (19/153, 12.4%) and posters in waiting rooms (15/153, 9.8%). The most common reason for using Orchid was "I want reliable information" (48/153, 31.3%), followed by "just curious" (36/158, 23.5%). Sociodemographic data of Orchid users can be seen in Table 2.

[a]HE: higher education.

[b]GCSE: General Certificate of Secondary Education.

Of the 106 nonpregnant female users, 72 (68%) received a pregnancy preference group (Table 3). Of the 119 people who were eligible to complete an RLP pathway (3 pregnant females, 72 females who received a pregnancy preference group, and 44 males), 32 (26.9%) did so (Table 3). There was no difference in completion by ethnicity. More details of who was eligible for the different features can be found in the Multimedia Appendix 1.

Table . Percentage of Orchid users in each pregnancy preference group and Reproductive Life Plan pathway.

Groups	Orchid users in each group, n (%)
Pregnancy preference group[a] (n=72)	
Planner	26 (36.1)
Undecided	24 (33.3)
Postponer	11 (15.3)
Pauser	5 (6.9)
Finisher	4 (5.6)
Preventer	2 (2.8)
Reproductive Life Plan pathway[b] (n=66)	
Currently trying	7 (10.6)
1 year	12 (18.2)
2 - 4 years	8 (12.1)
5+ years	3 (4.6)
Not sure when	6 (9.1)
Not sure if	13 (19.7)
Don’t want	11 (16.6)
Currently pregnant or expecting	6 (9.1)

[a]Pregnancy preference groups: Planner (wants a pregnancy now), Undecided (has not decided whether they want children), Postponer (wants children in the future), Pauser (has at least one child and would like another in the future), Finisher (has all the children they want), and Preventer (does not want children).

[b]Reproductive Life Plan pathways: users who are currently pregnant or expecting, currently trying to conceive, users who would like to have a child within 1 year, within 2 - 4 years, or in 5+ years, users who want a child but are unsure when, are unsure if they want children, or do not want (more) children.

User and Nonuser Interviews

In total, 5 users and 2 nonusers were interviewed, and we also received written feedback (via Accurx text messaging) from 2 additional nonusers.

Background of Users and Nonusers Interviewed

A total of 4 users interviewed were female and one was male. Users ranged in age from 22 to 35 years, and none had children, although all expressed a desire to have them in the future. Several users had experience with reproductive health conditions, including polycystic ovary syndrome, irregular menstrual cycles, and fibroids. The 2 nonusers interviewed were both female and aged 40 - 49 years; 1 had children and did not want any more, while the other had never been pregnant and did not want children. We have no sociodemographic information on the 2 nonusers who provided written feedback via text message.

Digital Reproductive Health Information

While most users felt confident discussing reproductive health with HCPs, they noted that clinicians often lacked the time or sometimes the specific knowledge needed to answer all questions or provide tailored advice. As a result, users liked the idea of receiving information about reproductive health digitally and felt that digital tools such as Orchid would be a way of overcoming some of these barriers. Users viewed digital tools as a direct and convenient method of accessing information and found that digital content was often more personalized. Users also felt that digital tools would allow “much more productive conversations with a health professional” (U05), as it would

XSL•FO
RenderX

help "answer … questions before … seeing a doctor … and then know … what I'm looking for from the doctor" (U04).

Orchid Recruitment

The primary method of recruitment for the interviewed users was through text messages sent by their GP, with most agreeing that this was an effective approach as receiving the message directly from their GP made it feel official and trustworthy.

Most users chose to visit or download Orchid because they were intrigued by the tool's focus on providing information about reproductive health, with some expressing particular interest due to personal circumstances, such as wanting to learn more about preparing for pregnancy or managing reproductive health conditions. However, 1 user and 3 of the nonusers thought that Orchid was primarily for "women who are wanting to be pregnant" (U02), with the nonusers citing this as the reason why they had not used Orchid, as pregnancy was not something they currently wanted.

Orchid Use

Users were divided on whether they accessed Orchid through the app or the website. Website users typically did so because they were unaware that an app was available or preferred to explore the web version before committing to downloading the app.

Ongoing use of Orchid was limited, with most users reporting that they accessed it only once or twice, primarily to complete the questions and review relevant information. None of the users engaged with the goal or reminder features within the app, citing that goals were either not relevant to their current needs or they were unaware that they could set them. Some users did follow links to external "useful resources" [U05] to find out more information about topics discussed within Orchid. Users also indicated that they would return to the app in the future, particularly if their circumstances changed (eg, if they began actively trying for a pregnancy) and would then be more likely to use features such as goal setting and reminders.

Despite limited use, users reported learning new information from Orchid, particularly regarding preparing for pregnancy. For example, one user reported that Orchid had "chang[ed] my outlook on planning" (U04), while another noted that they had begun taking supplements because of the information provided in Orchid.

Orchid Feedback

Overall, users were positive about Orchid, appreciating both its content and design. They noted that the app contained a wealth of useful information about reproductive health, presented in an easy-to-understand manner. Users also praised the app's look and feel, describing the design as nice and simple, "well laid out" (U05) and "easy to navigate" (U01). They valued the adaptive flow of questions, which personalizes the experience based on users' answers, and appreciated the ability to "go back up the path and say … I've changed my mind" (U02), allowing Orchid to adjust as their needs or decisions changed.

In addition to the positive feedback, users also identified several areas where Orchid could be improved. Many wanted more varied content, such as images and videos, as well as more comprehensive explanations and additional topics. Some users found navigating the web-based version on a mobile phone challenging, and users reported difficulty locating where to download the app. Despite these issues, all users said that they would recommend Orchid to friends and family.

Discussion

Principal Findings

This study set out to codevelop and pilot Orchid, a novel DHI, to support people of reproductive age to understand their pregnancy preferences and form an RLP. Guided by the IM framework [22], we codeveloped Orchid through iterative co-design with end users and a multidisciplinary clinical academic team. The pilot study, conducted across 3 NHS settings, demonstrated that integrating Orchid into real-world clinical contexts was feasible and acceptable. HCPs were generally comfortable recommending Orchid to patients, and users valued its content and design. Although uptake was lower than anticipated, the data collected provide important insights for refinements needed for wider implementation.

Using IM [22] enabled transparent, evidence-based codevelopment grounded in behavioral theory and user needs. The structured process supported iterative refinement and ensured alignment between Orchid's purpose, content, delivery, and intended behavior change outcomes, avoiding assumption-led development. By mapping performance objectives and determinants to theory-based methods, grounding Orchid in COM-B [33], and incorporating behavioral determinants identified in the literature [24], we specified hypothesized mechanisms of action aligned with behavior change techniques shown to increase engagement [43]. This systematic approach enhances transparency and has been associated with improved DHI quality and effectiveness [44,45]. IM's emphasis on needs assessment and stakeholder involvement further ensured that Orchid was relevant, inclusive, and user-centered, which was reflected in strong acceptability among health professionals and diverse users [46,47].

Implementation within health care settings proved feasible, with training integrating well into existing sessions and HCPs generally finding it acceptable to recommend Orchid. However, barriers emerged, including time constraints, competing clinical priorities, and difficulty raising reproductive health in unrelated consultations, which are common concerns [13,48,49]. Users found it acceptable to be recommended Orchid and valued its digital format due to the convenience, autonomy, and privacy it affords, consistent with previous findings [13].

Uptake was lower than expected, a common challenge in digital health research [50,51]. Feedback from those who received a GP text message but did not sign up uncovered a perception that Orchid was primarily for people planning a pregnancy, despite our efforts to use neutral "reproductive health" messaging. This highlights the need for tailored recruitment strategies that clearly communicate relevance, though evidence on personalized recruitment remains mixed [52]. Digital recruitment remains cost-effective [50], suggesting optimization

XSL•FO
RenderX

is worthwhile [50]. HCPs valued the training but reported that the lack of a live demonstration limited their confidence in signposting, echoing wider evidence that successful DHI implementation requires practical exposure [53]. Addressing these factors is likely to improve recruitment in future roll-outs.

Engagement with Orchid during the pilot was limited, with infrequent use of goal-setting and reminder features. While partly expected due to the short pilot period, users reported barriers such as navigation challenges and not realizing Orchid could be downloaded as an app (where the goal-setting features are optimized). Despite this, users gained new knowledge and described ways in which Orchid informed their reproductive decision-making or led to behavior change, suggesting that even brief interventions can have a meaningful impact [54], as others have also found across a range of health conditions [51,55]. As part of IM step 4 [43], we will refine pathways through Orchid, reduce friction points, and expand features to support more sustained engagement, ahead of larger-scale evaluation (steps 5 and 6).

Existing RLP studies [56] demonstrate high acceptability but limited evidence of effectiveness [56], with most studies focusing on process outcomes, such as knowledge, rather than behavior change outcomes [24]. However, the OptimalMe study [57] found increased use of folic acid and reduced alcohol intake in women planning a pregnancy [57], while digital contraceptive interventions appear to be associated with increased uptake of effective contraception [58], especially post pregnancy, though this is not always the case [59]. As the first UK co-designed, theory-driven, digital RLP integrating reproductive preferences with both contraception and preconception pathways, Orchid fills longstanding gaps in scope, theory, and digital innovation.

As a feasibility and acceptability pilot, this study is limited. Key outcomes, including ongoing engagement, behavior change, and effectiveness, require evaluation in future stages. Additional limitations include the lack of sampling frames at 2 sites, preventing response rate calculation or assessment of generalizability, and uncertainty around exposure to different recruitment methods. The absence of a live app at the time of training may have reduced HCP signposting, and limited visibility of the app means we cannot draw conclusions about platform preference.

Orchid's systematic development, theoretical foundation, and extensive end-user involvement represent key strengths commonly associated with effective DHIs [19,20,33,44,45,54]. Together, these features position Orchid well to function as an effective intervention for improving reproductive health [60]. Our emphasis on inclusivity is reflected in the diversity of both the codevelopment group and pilot users, including people from more deprived areas, speakers of languages other than English, global majority populations, men, and nonbinary people. The varied pregnancy preferences among users show that Orchid serves diverse needs. A particularly notable strength is Orchid's explicit inclusion of men, a group often overlooked in preconception and reproductive life planning. The fact that nearly one-third of users were male highlights demand for male-inclusive reproductive health support and demonstrates Orchid's reach among underserved groups, aligning with emerging evidence that systematically codeveloped DHIs demonstrate greater acceptability and effectiveness [19,20,33,44,45,54].

Orchid has been designed to support national priorities for digital transformation and preventative care, reduction of unplanned pregnancy, and improvements in maternity outcomes. The diversity of pilot users supports our aim of equitable reach. The NHS 10-Year Plan for England [61] prioritizes digital innovation, prevention, and strengthened primary care, and Orchid aligns with each of these aims. By offering accessible, evidence-based reproductive health information and supporting people to articulate and act on their reproductive intentions, Orchid has the potential to enhance digital health literacy, reduce service pressures, and improve patient-provider interactions. By addressing inconsistent contraception use, lack of proactive reproductive life planning, and low awareness of preconception health actions, Orchid can contribute to reducing unplanned pregnancy and improving maternal and neonatal outcomes, as well as longer-term health and development of parents and children.

Conclusion

Orchid is the first DHI co-designed to support reproductive health across the life course in the United Kingdom. The development and pilot testing of Orchid demonstrate the value of using IM to create a theory-driven, codeveloped digital tool for reproductive health. The findings of our pilot suggest that Orchid is both feasible to implement and acceptable to health care providers and users, while highlighting areas for refinement to enhance engagement and relevance. Insights from the pilot will directly inform iterative improvements and the design of a larger-scale implementation evaluation study to evaluate effectiveness. With its evidence-based foundation, user-centered design, and alignment with national health priorities for prevention and digital transformation, Orchid holds promise as a scalable DHI to support reproductive decision-making, reduce unplanned pregnancy, and contribute to better maternal, parental, and child health outcomes across the NHS.

Acknowledgments

We would like to thank our codevelopment group for their vital contributions and insightful feedback throughout the development of Orchid. Their collaboration was instrumental in shaping this project. We also thank Roshni Wadhwa for her support in the development of Table 1.

Abstract

Background: Self-injurious thoughts and behaviors, including suicidal ideation, planning, attempts, and nonsuicidal self-injury, are a significant public health concern among college students. Community college students face elevated mental health risks and persistent barriers to traditional services, particularly those from underserved and ethnoracially minoritized backgrounds, underscoring the need for scalable, accessible digital mental health interventions.

Objective: This study conducted a mixed methods evaluation of the initial reactions of college students to a novel technology-enhanced suicide prevention intervention (TE-SPI), with particular focus on feedback regarding a mobile app prototype (BRITE) designed to support coping skill use and mood monitoring, as well as proposed nondemanding caring contact text messages.

Methods: A mixed methods approach using the technology acceptance model (TAM) was used to assess the TE-SPI among 20 ethnoracially diverse college students (mean age 22.8, SD 3.9) from a community college (n=10) and a 4-year university (n=10). Participants were shown the BRITE app prototype on a study iPad and asked to provide feedback on its perceived ease of use, usefulness, and relevance to student needs. Quantitative measures assessed initial impressions of satisfaction and usability, while qualitative analyses examined participants' reactions to the app prototype and preferences regarding potential caring contact text messages.

Results: Participants generally reported favorable initial impressions of the BRITE app prototype, with 90% (18/20) describing it as helpful and 85% (17/20) user-friendly; 90% (18/20) also indicated that they would recommend it to peers in distress. Qualitative feedback supported these findings, highlighting the app's perceived accessibility, relevance to student life, and potential usefulness during moments of distress. Participants also offered concrete suggestions for app refinements (eg, mood scale customization, gamification, and language options) and for useful caring contact messages they would want to receive. In total, 55% (11/20) of participants said that they would want to receive text messages as part of TE-SPI, while 25% (5/20) reported maybe or possibly wanting to receive messages.

Conclusions: Findings offer preliminary insight into how college students perceive the BRITE app prototype and proposed caring contact message, highlighting concrete feedback for app refinement prior to real-world testing. This study provides early user feedback that can inform further development of the TE-SPI model. Future research should examine actual use, acceptability, feasibility, and clinical impact among diverse college students.

Introduction

Background

Suicide is the second leading cause of death among college-age adults [1]. Additionally, self-injurious thoughts and behaviors (SITBs)—encompassing both thoughts and behaviors involving suicidal intent, as well as deliberate self-injury without intent to die—constitute major public health issues. Data show that in the United States, 11% of college students have experienced suicidal ideation, 5% have made a suicide plan, and 2% have attempted suicide in the previous 12 months [2], and self-harm ranked third for young people ages 10 - 24 years in the most recent Global Burden of Disease Survey [3]. Each year approximately 93,000 young adults (ages 18 - 24 years) present to emergency departments for SITBs [4]. Furthermore, suicide rates for this age group have remained particularly high over the last decade and have disproportionately increased among ethnoracially minoritized groups in the United States [1,5]. Previous research identifies elevated symptoms of anxiety and depression as key risk factors associated with the risk of suicide among college students [6,7], particularly if left untreated [8].

Mental Health Challenges in College Students

College students represent a diverse group of students with varying mental health profiles and needs depending on individual characteristics, socioecological characteristics, and college contexts underscoring the importance of considering student context and cultural relevance when developing mental health interventions for this population. Among the college student population, the subgroup of students attending community colleges reports higher traumatic life events, poorer physical health, and more severe psychological concerns compared to students at 4-year institutions [9-11]. Ethnoracially minoritized students and low-income populations, who make up a significant portion of the community college student body, are also less likely to engage with behavioral health services and are more likely to drop out of treatment [12-15]. Community college students who transfer to 4-year academic institutions also experience elevated risk for mental health outcomes, including SITBs, because they face several stressors as they navigate new campus climates, build social networks, and adjust to academic expectations at 4-year academic institutions [16,17]. In fact, data show that transfer students report significantly higher levels of depression, social anxiety, and educational and family-related distress compared to nontransfer students [18]. Contextualizing treatments to address the needs of community college students, including those who transfer to 4-year institutions, can lead to higher treatment engagement.

The diverse mental health challenges faced by community college students, along with limited access to resources, highlight the urgent need for innovative suicide prevention strategies. A few of the common barriers faced by community college campuses include financial restrictions, staff shortages, long waiting lists, vague and unstandardized crisis response guidelines, and limited student outreach [9,19,20]. In addition, some students choose not to report their mental health symptoms or seek professional support during a crisis as a result of perceived stigma, apprehension, or feeling that they may be a burden. To address this gap, novel evidence-based digital mental health interventions present a promising solution, particularly for underresourced community colleges.

Digital Mobile Apps for Suicide Prevention

Digital mental health interventions may bolster mental health care on college campuses and can promote skills that mitigate risk for SITBs [21-23]. Mental health apps have potential for offering timely support, especially given widespread reports of time constraints, perceived inconvenience associated with traditional face-to-face services, and the high levels of comfort and acceptance of technology among students [15,21,22,24]. Digital tools also have the potential to reduce suicide risk by providing discreet support for individuals struggling with mental health issues who may be hesitant to seek out resources and can offer a range of intervention components, including support for crisis intervention, mood tracking, and coping strategies, which can help users manage their symptoms [25]. Additionally, digital tools allow for continuous monitoring and support, offering timely interventions during moments of crisis. By integrating features such as direct links to crisis hotlines and emergency contacts, digital tools can ensure that users receive the necessary assistance promptly. From a research standpoint, user data collected can also offer objective insights on usability, guiding iterative updates and improvements. Overall, digital mental health tools can play a crucial role in suicide prevention by making resources more accessible and tailored to individual needs.

Despite the rapid growth of digital mental health tools, few are designed with the unique needs of college students in mind. In particular, rigorously tested apps for suicide prevention have primarily focused on adolescents who present to acute care settings. For example, BlueIce, an app with mood ratings and personalized features to improve mood (ie, using cognitive behavioral therapy and dialectical behavior therapy skills), was specifically codeveloped with adolescents with lived experience, and the phase 1 open uncontrolled trial found that nearly three-quarters of participants had reductions in self-harm at 12-week follow-up [26]. Similarly, not all evaluations of suicide prevention apps include ethnoracially minoritized samples, with the exception of the iBobbly app, a suicide prevention app for Indigenous Australian youths and young adults [27]. As Ramos et al [15] highlight, most existing app evaluation frameworks fail to account for critical diversity, equity, and inclusion factors such as literacy, cultural relevance, and technology access, which limits the effectiveness and equity of digital interventions. This gap underscores the need for more inclusive, accessible, and clinically guided digital tools. Indeed, community college students remain significantly underrepresented in suicide research, particularly around research that focuses on the development of digital mental health and suicide prevention tools, underscoring a significant gap and the urgency to address current SITB disparities for at-risk college students [28].

Technology-Enhanced Approach to Suicide Prevention

Combining the promise of digital interventions with a “human touch” has shown promise for increasing use of digital interventions, an important goal given that low use limits intervention exposure and benefits and has been a problem in

XSL•FO
RenderX

trials of prior interventions [29-32]. In an effort to optimize intervention use and value, we pilot-tested a technology-enhanced suicide prevention intervention (TE-SPI). Through TE-SPI, we aimed to adapt a previously validated safety planning and emotion regulation smartphone app, initially designed for adolescents [25,33,34], for use among college students. To increase engagement within this population, we added a new component, caring contact text messages, which are nondemanding messages of care designed to increase feelings of connection and support postcrisis [35-37]. Caring contacts have demonstrated high feasibility and acceptability among adults when delivered via email or text [38,39]. Although some data indicate a 1-year benefit in reducing self-reported suicide attempts [37,40], evidence remains mixed regarding its effect on suicide mortality or self-harm–related emergency department and hospital visits. Moreover, there is limited research on its effectiveness among diverse college student populations. Therefore, this project presents formative prototype evaluation data based on participant feedback to inform the adaptation and refinement of 2 synergistic intervention components for college students at risk for SITBs.

Technology Acceptance Model

The technology acceptance model (TAM) has been widely used to study the implementation of new technologies and digital tools, including pilot trials for mental health apps [41,42]. The TAM framework, based on the theory of reasoned action [43], posits that an individual's behavior (ie, use of a digital tool) is influenced by their attitudes and perceptions. We used TAM as a guiding framework to understand how college students perceived the components of a TE-SPI. More specifically, according to the TAM, 2 key factors predict an individual's engagement and use of new technology: perceived ease of use and perceived usefulness [41]. Perceived ease of use refers to how easily a user believes that they can learn and use the technology without difficulties, while perceived usefulness pertains to the belief that the new technology can enhance their daily routines [41]. However, an individual's perception of new technology can also be significantly shaped by their social environment and context [44]. For instance, perceptions may change based on friends' or family members' reactions and experiences with the digital tool, and community college students might find digital tools more beneficial if they are contextualized to their experiences and needs.

This Study

This mixed methods study aimed to explore the perceptions of college students of a TE-SPI designed to reduce distress and improve mental health well-being. We used the TAM framework to examine the perceived ease of use and perceived usefulness of the TE-SPI. The primary research questions guiding the study were:

- Question 1: What are community college students' perceptions of the TE-SPI features?
- Question 2: What is the perceived usability of the TE-SPI? (ie, what are the aspects and factors, in terms of functionality and utility, that students find useful?)
- Question 3: What aspects of the TE-SPI do students find more engaging?
- Question 4: What factors may influence the decisions of community college students to use the TE-SPI?

Methods

Research Design

Procedures and Participants

This substudy is part of a large research study examining the Screening and Treatment for Anxiety & Depression (STAND) system of care in a community college setting. The STAND system of care was developed as part of the University of California, Los Angeles (UCLA) Depression Grand Challenge to be a scalable approach to preventing, identifying, and treating anxiety and depression [45]. The STAND study was approved by the institutional review board at UCLA (IRB #22 - 0205). Participants were recruited from a local community college (East Los Angeles Community College [ELAC]) and a Transfer Student Center for community college students at a 4-year university (UCLA), enhancing student diversity over that afforded by a single community college site. Recruitment was from the fall of 2022 through the winter of 2023. Participants from ELAC were recruited through a listserv of students interested in participating in STAND-related research studies, and UCLA participants were recruited using outreach through informational presentations and flyer postings at the Transfer Student Center. Study eligibility criteria included (1) currently enrolled at ELAC or UCLA as a transfer student, (2) owning a smartphone, and (3) English proficiency. Eligible students interested in participating were screened on the phone and provided oral consent. Participants then scheduled an interview date with the study staff to complete the semistructured interview and brief surveys. All participants received a US $25 e-gift card for their participation in the study.

To ensure participant safety and confidentiality, participants were informed during the consent process that they could decline to answer any questions or stop the interview at any time without penalty due to the sensitive nature of the study topics (eg, distress, depression, and anxiety). Research staff conducting the interviews were trained to recognize signs of distress and to pause or discontinue the interview if participants became notably distressed. Research staff were also trained to assess the participant's well-being and offer additional support and mental health resources to all participants. Additionally, limits of confidentiality were clearly communicated to participants, including mandated reporting requirements related to risk of harm to self or others. A safety protocol was activated when participants disclosed current active suicidal ideation, particularly with intent or plan. The safety protocol included a risk assessment and safety planning by a licensed clinical psychologist, although there were no cases in this study that required the use of the safety protocol.

In total, 14 students from ELAC and 13 students from UCLA were eligible to participate in the study and provided oral consent. A total of 4 participants from ELAC and 3 from UCLA were excluded from the study due to failure to attend their scheduled semistructured interviews. Therefore, 20 participants were included in the analysis. Participants (N=20) in the study

XSL•FO
RenderX

were between the ages of 19 and 32 (mean 22.8, SD 3.9) years. The sample consisted of both community college students (n=10) at ELAC and transfer students at UCLA (n=10).

Data Collection

College students participated in the study in person or virtually using a secure videoconferencing platform (Zoom, UCLA Health System Protected). Participation consisted of completing a semistructured interview and 2 brief online surveys with a research staff. Semistructured interviews lasted up to 45 to 60 minutes each (average time was approximately 36, SD 12.8 minutes) and were audio-recorded and stored in a secure UCLA Box folder. Prior to starting the semistructured interview, participants were asked to complete the first brief online survey administered via Qualtrics inquiring about their demographic background, mental health use, and previous digital tool use for mental health concerns. Next, participants were introduced to the technology TE-SPI components, specifically (1) the BRITE app, which includes mood and distress ratings, a menu of distress tolerance and emotion regulation skills [25,33], and a coping or safety plan that students can turn to when needed to cope effectively (eg, when distress is high or increasing); and (2) caring contacts (brief nondemanding text messages aimed at providing connection to the intervention team and support [46]). As part of the prototype demonstration, participants were informed that both the BRITE app and caring contacts are designed to be introduced by a mental health provider. Next, the participants were given a study iPad and received a demonstration of how they would be onboarded to get access to the app (ie, after completing a safety plan with a clinician, although the development of a safety plan was not conducted as part of the demonstration). Then, students were given a tutorial on how they could create and individualize their account or profile to use the various features including (1) mood ratings, (2) use of coping activities, and (3) how to activate the support feature. Following this process, participants were given time to explore the app on the study iPad and were encouraged to ask questions regarding app features. After having time to review the app, participants were asked to share their perceptions and feedback on the app features. Next, the concept of caring contacts was presented with various examples, and participants were asked to share their perceptions and feedback on the BRITE app and caring contact TE-SPI components. Feedback for the clinician session to develop a safety plan was not included as part of the feedback, given its already established feasibility and acceptability in college samples [47]. Throughout the interview process, the research staff used a semistructured interview protocol to guide the participant through each of the questions. Following the interview, participants completed the second brief quantitative survey inquiring about their perceptions of the TE-SPI components and overall satisfaction questions. At the end of the study, all participants were sent information regarding campus and community mental health resources and received a US $25 e-gift card as compensation for participating in the study.

Ethical Considerations

This substudy was conducted separately from the STAND trial and reviewed and approved by the institutional review board at UCLA (IRB #22‐0244). All procedures complied with institutional and federal ethical standards. Informed consent was obtained from all participants prior to study participation. Participants were informed that their participation was voluntary and that they could decline to participate or withdraw from the study at any time without penalty. Additionally, to protect participants' privacy and confidentiality, all identifying information was removed from the study data prior to analysis.

Materials and Measures

TE-SPI Materials

BRITE App

The BRITE app includes (1) the development of a coping plan with a clinician, designed to support effective coping strategies that include evidence-based suicide prevention intervention tools; (2) mood and distress ratings; (3) a menu of distress tolerance and emotion regulation skills; and (4) a reaching out feature for support during distress. On the BRITE app, users are prompted to rate their mood or distress daily, but they can also self-initiate their own ratings. After entering a mood and distress rating into the app, users are provided with potentially helpful skills and activities (ie, mindfulness and distress tolerance skills) that they can complete independently to improve their mood or reduce their level of distress. If participants choose to complete the suggested activities, they are asked again to rate their mood and distress level after completing the suggested activities. Participants can personalize their profiles in the BRITE app by uploading photographs, videos, or links to websites and can update their coping plan with individualized warning signs, coping skills, and phone contacts for interpersonal support and clinician contact. Although participants were not asked to download the BRITE app onto their phones, they were given time to review all features of the tool via an iPad that was provided to them for use during the interview. See Kennard et al [25,33] for more details on the development of the digital tool (BRITE app), which was primarily developed for adolescents in acute care settings (ie, inpatient hospitalization).

Caring Contacts

Additionally, the TE-SPI model adds caring contacts in addition to the BRITE app to create a unified platform. Caring contact messages are brief, low-cost, nondemanding expressions of care—typically delivered via text, email, phone, or mail (eg, "Hey there, I'm wishing you well. I hope you're taking good care of yourself.")—and are traditionally sent by a care provider or care team to remind individuals that support is available and to promote connection [36,46]. As part of the TE-SPI model, the concept of caring contacts was introduced to participants. In this study, the study interviewer explained the approach for these messages as well as who and when these messages would be sent. Students were also provided with example messages such as "Hey, I've enjoyed working with you. Hope your day is going okay so far." Students were then asked about their perceptions of this approach, whether they would like to receive such messages, and were asked to share an example of a caring contact message that they would find meaningful and helpful during moments of distress.

Measures

Mental Health Status

Current symptoms of depression and anxiety were assessed using the Patient Health Questionnaire 2-item (PHQ-2) and the Generalized Anxiety Disorder 2-item (GAD-2 [47,48]). Both the PHQ-2 and GAD-2 measures were used to descriptively characterize the mental health symptom profile of the sample and were not used for hypothesis testing or subgroup analyses. The PHQ-2 is a self-report measure of depression symptoms over the last 2 weeks. The 2 items from PHQ-2 were the following: "Over the last 2 weeks, how often have you been bothered by having little interest or pleasure in doing things?" and "Over the last 2 weeks, how often have you been bothered by feeling down, depressed, or hopeless?" Response options ranged from 1=not at all to 4=nearly every day. The measure has good internal consistency and concurrent validity [47,49]. The GAD-2 is a self-report measure of anxiety symptoms over the last 2 weeks. The GAD-2 includes the following 2 items: "Over the last 2 weeks, how often have you been bothered by feeling nervous, anxious or on edge?" and "Over the last 2 weeks, how often have you been bothered by not being able to stop or control worrying?" Response options ranged from 1=not at all to 4=nearly every day. The measure has strong psychometric properties and has been found to be reliable [47,49]. Both items from the PHQ-2 and GAD-2 were summed separately, and a score of 3 was used as the cutoff for identifying possible cases of depression and generalized anxiety disorder, respectively [47,48,50]. The PHQ-2 (α=.826) and GAD-2 (α=.928) measures have strong internal consistency in our sample.

Feasibility and Acceptability

Feasibility and acceptability were assessed using both quantitative and qualitative indicators, including participant ratings of usability, satisfaction, perceived usefulness, engagement with app features, and qualitative feedback regarding BRITE app and caring contacts' relevance, accessibility, and suggested refinement.

Technology Use

To examine participants' overall technology use, we formulated questions to inquire about their access to a cell phone or smartphone, data plan, how often participants carry their phone, and specifics on how much time they spend on their mobile device (time measured in total minutes per day) for the following activities: texting, talking, emailing, surfing the web, playing games, social media apps, and mental health apps. Sample questions included "Do you have a smartphone?" and "How often do you carry your phone with you?." Additionally, participants were instructed to list the mobile apps that they frequently use and the type of features they found useful.

Digital Intervention Barriers

The Digital Intervention Barriers Scale-7 [44] was used to assess participants' perception of the TE-SPI, specifically their perceptions of engagement, motivations for use, and if the digital tool was adequate (not too long or too short). This measure asked students to "Please indicate the extent to which you agree or disagree with the following statements." Statements included (1) "I didn't understand the tasks or things I was supposed to do on the app.", (2) "I thought the app wasn't engaging.", (3) "It would be difficult to keep myself motivated to use the app.", and (4) "I thought the length of the app wasn't adequate (too long or too short)." The answer choices participants were able to choose from for all 4 questions were 1=totally disagree, 2=disagree, 3=neutral, 4=agree, and 5=totally agree. Participant responses were scored by obtaining a sum, with higher scores indicating more barriers to future use and engagement with the digital tool. Three items from the original Digital Interventions Barriers Scale-7 were omitted, given that students were not asked to download the app during this phase of the study. The omitted items were (1) "I had technical problems with my technology (eg, device, internet, platform).", (2) "I forgot to use the app.", (3) "The app didn't seem to be helping me." This measure has been found to have high internal consistency and criterion-related validity [44]. The internal consistency of the 4 items was high (α=.783).

Satisfaction With the BRITE App Component of TE-SPI

Using a questionnaire developed by the University of Pittsburgh [51], we assessed participants' satisfaction of the digital tool, by administering the following questions: (1) "If you started to feel really stressed and upset, do you think you would use the BRITE app?" with the following answer choice for participants to choose from 1=no, 2=possibly, 3=probably, 4=definitely, and 5=prefer not to answer; (2) "If a friend was in need of mental health care for depression or suicidal thoughts or behaviors, would you recommend the BRITE app to help them cope?" with the following answer choices: 1=definitely not, 2=no, I don't think so, 3=yes, I think so, 4=yes, definitely, and 5=prefer not to answer; (3) "How often do you think you would use the BRITE app if it were available to you during the month after it was introduced to you?" with the answer choices being: 1=never, 2=once or twice, 3=3 or 4 times, 4=5 or 10 times, and 5=more than 10 times; (4) "Do you think you would be more likely to use the BRITE app if you received messages reminding you of the app?" with the following answer choices: 1=no, I would find these messages annoying, 2=no, but the messages would not bother me, 3=maybe, 4=possibly, and 5=yes. After asking each of these questions, participants could provide additional written feedback or reasoning for their answer choices. The satisfaction with BRITE score was obtained by creating a composite score that summed all 4 questions in the measure.

Poststudy Satisfaction and Usability

To obtain more information regarding participants' experience with the TE-SPI components, they answered items from the Poststudy System Usability Questionnaire [42]. The Poststudy System Usability Questionnaire has been used in previous suicide prevention trials for adolescents after a hospitalization [34]. The questionnaire consists of 6 items that identify system usability. Participants rated questions on a 7-point Likert scale, ranging from 1=strongly disagree to 7=strongly agree. The following questions were asked: (1) "Overall, I am satisfied with how easy it is to use BRITE app."; (2) "The information provided in the BRITE app such as on-screen messages, and other documentation like links or pictures for the topic activities,

XSL•FO
RenderX

was clear."; (3) "The information provided in the BRITE app, such as notifications to rate my distress or mood with emojis, was clear."; (4) "I like interacting with the BRITE app program."; (5) "I needed to learn a lot of things before I could get going with the BRITE app."; and (6) "The information provided, such as the coping plan for BRITE users, was clear." This measure is reliable with a Cronbach α that spans from 0.83 to 0.96 [51,52]. A composite sum score was created, such that a higher score indicated higher satisfaction and perceived usability. An additional question was added to assess participants' perceptions of caring contacts. Specifically, participants were asked "Do you think you would be more likely to use the BRITE app if you received text messages from your mental health provider?," with the following answer options: 1=no, I would find them annoying, 2=no, but the messages would not bother me, 3=maybe, 4=possibly, and 5=yes.

Data Analysis

Quantitative Analysis

Descriptive analyses were conducted using SPSS (version 25; IBM Corp) software. We carried out descriptive statistics to obtain frequencies and percentages, means, and medians along with SDs and ranges for all quantitative measures.

Qualitative Analysis

For the qualitative analyses, all interview audio recordings were auto-transcribed using Microsoft Word software, and the transcripts were then reviewed individually by 2 independent researchers (NJ and JLM) to verify accuracy. Errors from the transcripts were fixed, and any identifiable participant information was removed. Additionally, the supervising researcher (NJ) checked each transcript for errors. The transcripts were then used for data coding.

A rapid qualitative coding approach was used from the health services literature [53], which prioritizes the efficient delivery of information to guide decision-making, particularly during preimplementation phases. First, the team developed a codebook with domains that were identified by the TAM framework. Then, using deductive and inductive strategies, coders identified additional codes and themes beyond the predefined TAM domains. After the codebook was finalized, 2 trained members independently applied domain analysis and created a summary template for each transcript. After all transcripts were coded and summarized, a matrix method was used to efficiently summarize and explore themes across all interview transcripts [54]. Themes were derived through comparison across structured summaries and matrix-based synthesis. This approach generates contextually rich information while being time efficient, and it facilitates continuous improvement and adaptation of intervention development [53].

The qualitative team did not use qualitative coding software, as the rapid matrix method was conducted using structured summary templates and team-based synthesis. The team conducted weekly meetings to review interview content, compare coding decisions and interpretations, resolve discrepancies through discussion, and refine the analytic approach. Using a rapid qualitative analysis process, each interviewer independently completed a standardized summary template following each interview (Multimedia Appendices 1 and 2), which included structured domains, initial content summaries, preliminary codes, and interpretive reflections [49]. These completed templates were compiled and reviewed by 2 researchers (NJ and JLM), who collaboratively synthesized responses across participants using a matrix method approach to identify key patterns and emerging themes. These themes were iteratively refined through weekly team discussions to compare summaries and interpretations and solve discrepancies to ensure consistency and representativeness across participants. Disagreements in coding were resolved through consensus-based discussion among the qualitative research team. A second review of the interviews for supporting quotes and thematic consistency was also carried out by the research team. Themes were finalized through iterative team discussions and comparison across structured matrix summaries to ensure consistency and alignment with participant responses. Throughout this process, analytic memos documenting observations and methodological reflections were completed after each interview and integrated into final thematic interpretation to enhance rigor and contextual grounding. Given the exploratory aims of the study, the sample size was considered sufficient to identify preliminary patterns in participant perceptions and inform future refinement of the TE-SPI. The data findings were considered sufficient to identify preliminary patterns relevant to intervention refinement. Furthermore, the analysis prioritized identification of salient patterns in participant feedback rather than quantification of theme prevalence.

The identified category themes were organized according to the TAM [41]. These themes helped focus the analysis, ensuring that key aspects of the data were systematically examined and aligned with the research questions. The research team defined and named the themes based on TAM (ie, perceived ease of use and perceived usefulness), then connected relevant quotes to these codes and organized them according to the model. The final step of the data analysis process was to produce a concise summary to address the research questions.

Results

Descriptive Analyses

Participants (N=20) in the study were between the ages 19 and 32 (mean 22.8, SD 3.9) years. The sample consisted predominantly of female participants (14/20, 70%). Participants were community college students (n=10) at ELAC and transfer students at UCLA (n=10). In terms of academic standing, 5% (1/20) of the participants were freshmen, 25% (5/20) were sophomores, 50% (10/20) were juniors, 5% (1/20) were seniors, and 1 participant preferred not to answer. For ethnicity, 55% (11/20) of participants identified as Hispanic or Latinx, and 45% (9/20) identified as non-Hispanic or Latinx; for race categories, 10% (2/20) identified as American Indian or Alaska Native, 25% (5/20) as Asian, 25% (5/20) as White, 20% (4/20) as multiracial, 10% (2/10) as other, and 2 students preferred not to answer the race category question. Data on participants' ethnicity and racial background were assessed separately. Participants who identified as Hispanic or Latinx may also be represented within the racial categories. Background information

XSL•FO
RenderX

was also collected, including previous treatment use and previous mental health app use. Half of the sample (10/20, 50%) reported that they had obtained counseling and therapy or seen a psychiatrist for their mental health in the past 12 months. Furthermore, participants (3/20, 15%) reported that they had used a digital tool for their mental health in the past. See Table 1 for additional demographic information.

Table . Participant demographics and characteristics (N=20)[a].

Variables	Values, n (%)
Age (years)	
19 - 25	16 (80)
26 - 32	4 (20)
Gender identity	
Male	5 (25)

GAD-2[c] (score of 3 and above)	8 (40)
Received mental health treatment	
Yes	10 (50)

[a]Ethnicity was assessed separately from race. Participants who identified as Hispanic/Latinx may also be represented within the racial categories.

[b]PHQ-2: Patient Health Questionnaire 2-Item.

[c]GAD-2: Generalized Anxiety Disorder 2-Item.

XSL•FO
RenderX

Regarding the mental health status of the participants in this study, data on self-reported symptoms indicated a mean composite score of 1.75 (SD 2.00) on the PHQ-2 (depression) and 2.45 (SD 1.82) on the GAD-2 (anxiety). A total of 4 (20%) participants were above the PHQ-2 screening threshold, suggesting possible elevated symptoms of depression and/or anhedonia, and 8 (40%) students scored above the GAD-2 threshold, indicating possible elevated anxiety symptoms. In total, 12 (60%) students scored above the screening threshold, indicating possible elevated symptoms for anxiety or depression. These results are presented to provide context regarding the sample's mental health profile and were not used to examine the differences in the perceptions of the intervention.

Perceived Ease of Use: BRITE App

Overview

This study examined initial user perceptions of the TE-SPI components using the TAM framework. Most participants perceived the BRITE app prototype as easy to interact with, with 75% (15/20) strongly agreeing and 5% (1/20) agreeing that they understood how to engage with it. Additionally, 85% (17/20) found the app features engaging (totally agreed: 13/20, 65% and agreed: 4/20, 20%). Potential motivation to use the app varied, with 50% (10/20) strongly agreeing, and 20% (4/20) agreeing that they would stay motivated to use it if they downloaded the app on their phone, while 15% (3/20) remained neutral, and 15% (3/20) disagreed. Regarding the app's feature set, 65% (13/20) strongly agreed, and 15% (3/20) agreed that it provided an adequate number of resources. See Table 2 for additional information on participant ratings.

Participants also rated their initial satisfaction with the app's ease of use: 35% (7/20) strongly agreed, 40% (8/20) somewhat agreed, and 20% (4/20) agreed that the app features were easy to use, while only 5% (1/20) remained neutral. Interaction with the app was well received, with 35% (7/20) strongly liking it, 40% (8/20) somewhat liking it, and 5% (1/20) disliking it. Regarding clarity, 60% (12/20) strongly agreed, and 30% (6/20) somewhat agreed that on-screen messages and activity links were clear. For distress and mood rating notifications, 45% (9/20) strongly agreed, 40% (8/20) somewhat agreed, and 10% (2/20) remained neutral about their clarity. Similarly, 70% (14/20) strongly agreed, and 20% (4/20) somewhat agreed that the personal coping plan information was clear, while 5% (1/20) found it unclear. See Table 3 to see more student feedback that was received on the app's perceived ease of use.

Table . Digital Intervention Barriers Scale (N=20)[a].

Question	Please indicate the extent to which you agree or disagree with the statements				
	Totally disagree, n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Totally agree, n (%)
I didn't understand the tasks or things I was supposed to do on the app.	15 (75)	1 (5)	—[b]	2 (10)	2 (10)
I thought the app wasn't engaging.	13 (65)	4 (20)	1 (5)	1 (5)	1 (5)
It would be difficult to keep myself motivated to use the app.	10 (50)	4 (20)	3 (15)	2 (10)	1 (5)
I thought the length of the app (ie, number of features) wasn't adequate (too long or too short).	13 (65)	3 (15)	3 (15)	—	1 (5)

[a]Three items from the original Digital Interventions Barriers Scale-7 were omitted, given that students were not asked to download the app during this phase of the study. The omitted items were (1) I had technical problems with my technology (eg, device, internet, and platform), (2) I forgot to use the app, and (3) The app didn't seem to be helping me.

[b]Not endorsed.

RenderX

Table . Poststudy System Usability (N=20).

Question	Please rate the statement about your experiences with the app on a scale of 1 to 7 with 1 being strongly disagree and 7 being strongly agree.						
	Strongly disagree, n (%)	Somewhat disagree, n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Somewhat agree, n (%)	Totally agree, n (%)
Overall, I am satisfied with how easy it is to use the BRITE app.	—[a]	—	—	1 (5)	4 (20)	8 (40)	7 (35)
The information provided in the BRITE app, such as on-screen messages, and other documentation like links or pictures for the coping activities, was clear.	—	1 (5)	—	—	1 (5)	6 (30)	12 (60)
The information in the BRITE app, such as notification to rate my distress or mood with emojis, was clear.	—	—	—	2 (10)	1 (5)	8 (40)	9 (45)
I liked interacting with the BRITE app program.	—	—	1 (5)	3 (15)	1 (5)	8 (40)	7 (35)
I needed to learn a lot of things before I could get going with the BRITE app.	8 (40)	6 (30)	—	4 (20)	—	1 (5)	1 (5)
The information provided, such as the personal coping plan for the BRITE users, was clear.	—	1 (5)	—	—	1 (5)	4 (20)	14 (70)

[a]Not endorsed.

Look and Feel

During the semistructured interviews, participants were asked to provide qualitative feedback on the TE-SPI components. They shared their opinions on the BRITE app prototype aesthetic elements, such as the font, color scheme, and navigation (see Table 4for sample quotes and Multimedia Appendix 3 for images of the app prototype) as well as feedback on caring contact messages that they would find helpful and useful. The overall consensus we obtained based on student feedback was that the BRITE app was perceived as user-friendly, though some students expressed a desire for a broader range of emotions in the mood and distress rating scale. Some participants noted difficulty in identifying and connecting with the emotions represented by the tool's emojis. One student mentioned:

> *I think about the distress rating thing ... it's hard to quantify. If there were other ways expressing [the emoticon] ... or a number or a short sentence that you can put into categories to understand the displayed emotions.*

XSL•FO
RenderX

Table . Themes identified across domains[a].

Technology acceptance model components and subtheme	Sample quote	Participants mentioning related subtheme, n (%)
Perceived ease of use		
Look and feel	"I think the colors and the fonts are good ... they're really big ... And I like how it has like characters in it" [Transfer student]	16 (80)
Look and feel	"I think it was easy to navigate in general because you can just go on the menu, and then you can find exactly what you're looking for" [Transfer student]	11 (55)
Look and feel	"I think it's a fun app, it definitely feels like it could make an impact" [Transfer student].	2 (10)
Perceived accessibility	"If I don't have like a like a social support system that I can rely on at that moment, and if I feel like I need to somehow reframe my thoughts or ... just ease the mind a bit from like the negative stuff that's going on in my mind, I will use it personally" [Community college student].	1 (5)
Perceived accessibility	"I would use the [BRITE app] because it'll be more accessible and since I already carry my phone on a daily basis, I could use it while waiting for transportation, a class gap ..." [Transfer student].	6 (30)
Perceived usefulness		
Tool use in moments of distress	"Maybe just when I'm feeling down ... I can just go back to the app ... Also the stuff like breathing, sleeping, and exercising ... maybe it will just remind me to these things and to distress from everything" [Transfer student]	3 (15)
Tool use in moments of distress	"When I want to release my stress ... my emotions ... I want to tell someone how I feel ... no one wants to just look at a [digital tool] like when they're sad" [Community college student].	6 (30)
Tool use in moments of distress	"I think we believe that going to therapy is more than enough, but maybe this could be an additional tool to therapy ... You know, therapist aren't available 24 hours a day ... so this would be a helpful tool in those times" [Transfer student].	1 (5)
Interactive components	"I think about the distress rating thing ... it's hard to quantify. If there were other ways expressing the emoticons ... or a number or a short sentence that can put into categories to understand the displayed emotions" [Transfer student].	7 (35)
Interactive components	"I would definitely say ... It sounds like it would be helpful. Like I think the section where you can upload images and things that are important to you. I thought that it would be pretty useful" [Community college student, female, 25 years].	3 (15)
Interactive components	"Me personally, like I'm someone who uses my phone on dark mode, so to incorporate that it would be a big thing" [Community college student].	2 (10)

[a]Perspectives were included from a small number of participants (eg, 1 or 2), when they offered a unique perspective that added to the conceptualization of the overall theme.

To address this, several participants suggested changing the scale by incorporating numerical values or descriptive labels for the emoticons, which would help users more accurately select their current emotions. For example, one student shared:

Maybe adding more emotions besides these faces ... It doesn't look like there is a neutral face and I can't tell if one expression is crying or sleeping.

XSL•FO
RenderX

Participants also recommended additional features to enhance the app's functionality. These recommendations included a calendar and journal feature for tracking mood, distress, and customization options, such as adding an avatar. The app's lack of a dark mode, which is a visual display setting that changes the light background and dark text of an interface to a dark background with light text, was another point of concern. Participants expressed the importance of this feature for nighttime use to reduce eye strain. Their comments included:

> *I guess adding a dark mode, in case it's nighttime ... It won't sting my eyes and there are some people that get very sensitive to light.*

Another student noted: "Absolutely, these days, maybe like a dark mode interface could help." Overall, results on perceived ease of use highlight that this sample of students reported a high level of ease in using the BRITE app. They recommended that adding features like a dark mode and expanding the emotion rating scale would significantly enhance the tool's perceived ease of use.

Perceived Accessibility

Participants were also asked broadly about any sociocultural and developmentally related considerations of the BRITE app. In general, participants expressed that the overall feel of the tool felt culturally congruent and relevant to the college student context. Participants felt that young adult users could easily connect and relate to the content in the app. College students expressed that the language was straightforward and easy to understand; however, a few participants recommended adding a feature that allows users to translate the language in the app to the language they prefer to speak so that it could be more inclusive, especially for international students. Concerning this topic, a participant noted the following:

> *Maybe you could in the future ... translate the different words ... so that more people can feel inclined to use it. Maybe they don't speak English, you know ... so they want to have it in their own language ... So in the beginning, when you first get on the app maybe ask, "Please select your language."*

In addition to language, some participants discussed that the BRITE app was appropriate for college students, as it was easily accessible. A participant shared the following: "I would use the[app] because it'll be more accessible and since I already carry my phone on a daily basis, I could use it while waiting for transportation, a class gap ..."

The BRITE app's accessibility and convenience appeared to be particularly appealing to this student population. Participants shared examples of how the app could fit naturally into their college life routine, making it easy to use during gaps of time, such as waiting for transportation or between classes. This convenience factor highlights a significant advantage of mental health mobile apps, as they can be well integrated into daily habits without requiring students to set aside much dedicated time. It is possible that the app can increase use frequency by turning typically unproductive periods into opportunities for digital mental health content interaction. Overall, this participant feedback emphasized the potential advantages of digital tools available on phones as an avenue to promote mental health engagement among community college and transfer students.

Perceived Usefulness

Overview

Participants completed a usability questionnaire that provided valuable insights into their perspectives on the perceived usefulness of the TE-SPI components. In terms of use during moments of distress, half of the participants (10/20, 50%) indicated that they would definitely use the app if they felt distressed or upset. When asked if they would recommend the BRITE app to a friend needing mental health care for depression or more severe distress (ie, having thoughts of suicide), 50% (10/20) responded, "yes, I think so," and 40% (8/20) responded "yes, definitely." Regarding potential use in the first month of availability, 45% (9/20) of participants stated they would use the app 3 to 4 times, 35% (7/20) would plan to use it 5 to 10 times, and 15% (3/20) would expect to use it more than 10 times. When participants were asked if they would engage more with the BRITE app if they received caring contact messages, 55% (11/20) said "yes," 25% (5/20) said "possibly or maybe," and 20% (4/20) stated that the messages would not increase their overall motivation to use the app. When asked to elaborate on their ratings, one student mentioned:

> *We're are always connected to our phones, and at this age it is basically an extension of ourselves. I think reminders [text messages] would be helpful because notifications are a good way to get more engagement with the app.*

Another participant said: "If I was reminded, then I would have an inclination to return [to the app] since it gave me a reminder to go on," while another stated: "I tend to forget things, it [text messages] would help to keep on track." During the qualitative interviews, participants were also asked to elaborate on their perceptions of caring contacts by providing suggestions of caring contact messages that they would find useful (see Table S1 in Multimedia Appendix 4 for additional suggestions provided by participants). Overall, the survey feedback from students suggests a varied perception of the TE-SPI's perceived usefulness, with a clear indication that caring contact messages could enhance user engagement, although with some reservations regarding the frequency and content of the caring contact messages. See Table 5 to see more students' input on the perceived usefulness of the app.

Table . Satisfaction or qualitative questions (N=20).

Questions	Values, n (%)
If you start to feel really stressed and upset, do you think you would use the BRITE app?	
No	1 (5)
Possibly	4 (20)
Probably	5 (25)
Definitely	10 (50)
Prefer not to answer	—[a]
If a friend were in need of mental health care for depression or suicidal thoughts or behaviors, would you recommend BRITE to help them cope?	
Definitely not	—
No, I do not think so	1 (5)
Yes, I think so	10 (50)
Yes, definitely	8 (40)
Prefer not to answer	1 (5)
Do you think you would be more likely to use the BRITE app if you received messages reminding you of the app?	
No, I would find these messages annoying	4 (20)
No, but the messages would not bother me	—
Maybe	2 (10)
Possibly	3 (15)
Yes	11 (55)
How often do you think you would use the BRITE app if it were available to you during the month after it was introduced to you?	
Never	1 (5)
Once or twice	—
3 or 4 times	9 (45)
5 or 10 times	7 (35)
More than 10 times	3 (15)

[a]Not endorsed.

Tool Use in Moments of Distress

Participants offered insights into the usability of the app, particularly highlighting its potential as a support mechanism during times of emotional distress. One participant explained: “When I am at the point of you know getting down emotionally, I’d want to use it right before getting to that point.” Another student shared how there can be distressful moments in life and how the TE-SPI could help her get distracted from unhelpful and negative thoughts:

> *Sometimes there are moments where I need to de-stress or ... I need to distract myself from one specific thought or reoccurring thoughts, like flashbacks from the past and stuff ... But it [the BRITE app] would be a good distraction for me ... to distract my negative thoughts to something maybe useful.*

Another theme to emerge involved perceptions that the BRITE app can serve to augment and/or replace traditional treatment contacts and/or other forms of social support. For example, one participant noted:

> *I think we believe that going to therapy is more than enough, but maybe this could be an additional tool to therapy ... You know, therapist aren’t available 24 hours a day ... so this would be a helpful tool in those times.*

Another student stated:

> *If I don’t have like a social support system that I can rely on at that moment, and if I feel like I need to somehow reframe my thoughts or ... just ease the mind a bit from like the negative stuff that’s going on in my mind, I will use it personally.*

However, other students felt differently. Some stated that they would not want to engage with the tool if they were having low mood. One student stated:

> *When I want to release my stress ... my emotions ... I want to tell someone how I feel ... no one wants to just look at a [digital tool] like when they’re sad.*

Another participant explained that they would not choose to use the app during joyful moments, as it would be a reminder of times when they weren’t happy, stating: “I guess I wouldn’t

XSL•FO
RenderX

want to use it when I'm happy because it would remind me of all the times, I was not happy."

Overall, students highlighted various reasons as to when they would feel more inclined to use a digital mental health tool, with some students reporting that they would use it during moments of distress, while some reporting that they would avoid the tool when their mood and levels of distress improved. The consensus among participants suggests that they would use the tool sporadically, primarily as a tool for managing negative emotions. To exemplify this topic, a participant stated the following:

> *I could see myself using it once a week or so. I mean like I said, maybe I should be doing more and more daily mental health check-ins, but generally, I do like self-help when I'm like feeling bad. So, when I'm feeling good, I don't know if I would need it.*

The student feedback suggests that the TE-SPI components, including the BRITE app, may be a valuable tool when traditional social support is unavailable, as it helps reframe negative and unhelpful thoughts. However, the tool's utility appears to be situational, with students reporting that they would be less inclined to use it when they are in a positive state.

Interactive Components

Participants expressed a willingness to use the app to explore and engage with suggested coping activities such as practicing mindfulness, including an affective savoring the moment activity and breathing exercises, as well as tracking their mood and distress. A participant noted the following: "Yeah, I think this could be good, like a daily check-in and like resources here but I think I would be more inclined to use it if I could customize it more." Another participant highlighted the significance of the activities, stating:

> *I think breathing exercises would help a lot. And then ... maybe the meditation part. I think the activities would probably be the main reason why I use it [the BRITE app] and the mood tracker. I think tracking your mood is really important.*

Overall, most students reported that they would use the tool primarily to practice coping skills to reduce distress, with a special interest in activities focused on meditation or mindfulness and improving sleep quality.

Attitude Toward TE-SPI and Recommendations

During the qualitative interviews, participants were asked what would motivate them to use the app and if they would incorporate the tool into their daily lives. Many students answered that incentives and interactive games would further motivate them to engage with the digital tool. Furthermore, although the app currently includes badges that are administered based on participation, a few students suggested that incentives would be a great way to motivate and reinforce users to continuously use the tool since it could promote a sense of accomplishment and reward. For instance, a participant suggested that users could accumulate rewards over time based on tool use: "I think you would need something to get them [users] to use it more often ... gift cards or little things here and there ... maybe if they use the [BRITE app] this many times and it adds up over time, this is the amount they get."

Similarly, another participant shared:

> *I know people tend to get bored of apps. Unless it's like a social media app ... Maybe you could add games ... Maybe you could have a leaderboard or something.*

Some participants suggested the value of adding a live chat and journaling feature that could increase usability. For example, a participant stated:

> *I like to journal a lot. I do journal on my iPad, and I do write on my phone in the notes because I have everything connected, so can I just go back and forth. But that's what would motivate me to use it.*

Others expressed that a live chat feature for crisis support would be great for users, especially if they are unable to get a hold of their mental health provider, and the live chat feature could help them to connect to a crisis hotline volunteer who could help users in times of distress. An example of this feedback is: "... if you guys do end up adding the live chat, I think it will be a good app ... either just to talk to someone ... or ask for advice ..." Overall, the participants indicated that the integration of incentives and interactive features (eg, games, journaling, and live chat) would enhance their motivation to use the app.

Discussion

Principal Findings

This study contributes to the growing literature on digital mental health interventions by conducting a mixed methods evaluation of college students' perceptions of a novel, multicomponent, TE-SPI, intended for diverse college students. Unlike many mobile mental health apps that offer only standalone self-monitoring or psychoeducation, the BRITE app prototype was designed to integrate safety planning, personalized coping tools, and mood tracking, features rarely combined in a single app or digital tool, particularly for underserved student populations. A key distinction of the TE-SPI model is the integration of both the BRITE app with caring contact text messages, adding a "human touch" that may enhance perceived engagement and relevance. Using the TAM framework with the overarching aim of examining perceived usability and utility of the TE-SPI components and a qualitative rapid coding analysis methodology, our study identified salient themes related to student perceptions and preferences for optimal design features for community college students. Our study intentionally selected a diverse sample of community college students with varying levels of anxiety and depression to focus on those at elevated risk for developing future suicidal thoughts and behaviors, allowing us to examine how students at elevated risk perceived these resources during the prototype demonstration. Although participants reported possible elevated symptoms of depression and anxiety, this study was not designed or powered to examine whether symptom severity influenced perceptions of the intervention. Therefore, future research should explore whether differences in depression and anxiety symptoms are

XSL•FO
RenderX

associated with actual use, usability, and perceived usefulness of digital mental health tools.

Our findings align with prior work, suggesting that students value apps that are accessible, low-burden, and offer features such as mood tracking, skill reminders, and personalization [55]. Participants indicated a perceived willingness to use a tool like the BRITE app, particularly during times of stress, for activities such as mindfulness or meditation and mood tracking. However, they also noted that their anticipated use of this particular app would likely vary depending on their individual circumstances, such as being too busy with other responsibilities. This underscores the importance of designing features that align with users' daily needs and preferences, as well as considering strategies that may support sustained use in future real-world testing. The feedback from students regarding the app's look and feel emphasized the importance of user-friendliness and a desire for customization features, underscoring the observation that different students are likely to use the app differently and desire different features, including alternate approaches to presenting the mood monitoring descriptors, personalization features (eg, calendar, journaling, and dark mode options), interactive games to motivate app use, and live chat functionality that could link students to other resources such as the crisis hotline. Satisfaction ratings with the BRITE app components were high, as previously found in a sample of hospitalized suicidal adolescents [25]. Still, ongoing evaluation of user engagement metrics and satisfaction surveys will be important for future optimizations to ensure that the app remains relevant and effective in supporting the mental health of college students. Because participants in this study did not use the app over time, these ratings should be interpreted as reflecting initial impressions of the prototype rather than sustained engagement or real-world use.

Participants emphasized the importance of culturally responsive content and ease of integration into daily routines. Notably, the caring contacts were especially well received, echoing prior research suggesting that students benefit from brief, nonintrusive messages that convey connection and care [56]. Importantly, participants responded to example or proposed caring contact messages rather than receiving caring contacts as part of the intervention. Underscoring the value of a "human touch," participants felt it would be important to ensure that these messages felt authentic and human-driven, rather than automated or impersonal, to foster a sense of connection and trust among users. In addition, participants provided examples of caring contact messages that could be implemented in future caring contact interventions with this population. Participants' feedback regarding language translation options reflects the potential need to accommodate diverse linguistic backgrounds and highlights the importance of accessibility and inclusivity. Additionally, incorporating culturally and developmentally relevant content and resources could further enhance user engagement and relevance for diverse college students. It could also promote inclusivity within the app for ensuring that users feel both represented and supported in this digital space.

Limitations and Future Directions

While this study offers formative insights into the initial perceptions of 2 of the TE-SPI components (BRITE app and caring contacts) among ethnoracially diverse college students, several limitations should be noted. First, although the sample was diverse and sufficient to provide contextually rich preliminary feedback, it was relatively small and drawn from one segment of the transfer student or community college student population, which may limit generalizability to broader student populations. Second, participants did not download the BRITE app and did not actually receive the caring contact text messages over time as part of the study; rather, they interacted with a guided demonstration and provided feedback based on brief exposure to a prototype. Accordingly, findings reflect initial perceptions of the proposed intervention components rather than real-world feasibility, engagement, acceptability, or clinical benefit. This is particularly important, given prior findings that show app use tends to decline over time, even among students who initially express interest [56]. Additionally, the quantitative assessment in this study focused primarily on the BRITE app, with feedback on caring contacts derived largely from the qualitative interview data and only a single survey item. Therefore, conclusions regarding caring contacts are especially preliminary, and future research should evaluate this component using more robust quantitative approaches. Additional research is also needed to clarify student reactions to the clinician-guided coping or safety planning session during which the app was populated, and perceptions of this intervention component designed to offer a "human touch." Third, the study did not assess longitudinal app use or how mental health symptoms impacted perceptions of the intervention. Without data on repeated use, in-the-moment engagement, or clinical impact, conclusions about the intervention's effectiveness and acceptability in the real-world remain limited. This study also was not designed to estimate intervention effects or to provide effect size estimates for powering a future effectiveness trial. Instead, its primary contribution is formative and allowed for the identification of user-perceived barriers, facilitators, and priorities for refinement that can guide the next implementation phase. Incorporating ecological momentary assessment, via daily mood ratings in the app, and use analytics will be key to understanding how students engage with different features over time [57] and can help evaluate whether sustained use reduces suicide risk or improves mental health functioning among college students. Finally, while participants offered actionable recommendations to enhance personalization (eg, language translation, gamification, and live chat) during the qualitative interviews, these features were not part of the current prototype. Iterative development and testing of these enhancements may increase user engagement and cultural relevance, particularly for students from historically underserved backgrounds. As prior research has shown, users' trust and sustained engagement are influenced not only by app content and functionality but also by transparency about data use, perceived credibility, and institutional endorsement [58]. Future work should focus on establishing trust with participants on how data collection is stored to reinforce transparency and ethical standards, ultimately enhancing intervention relevance, acceptability, and long-term

XSL•FO
RenderX

impact on student mental health. Importantly, the qualitative findings highlight specific design and implementation issues, such as preference for customization features on the BRITE app or authentic caring contact text messages, that can be incorporated into the next iteration of the TE-SPI and evaluated prospectively in a more rigorous trial. More broadly, future studies should move beyond prototype feedback to test the intervention as delivered, including whether students download the app, engage with it over time, receive caring contact messages, and find the full provider-supported intervention acceptable and useful in real-world settings.

Conclusions

This study provides preliminary feedback on a TE-SPI featuring the BRITE app—a mobile app prototype supporting coping skills use and proposed caring contact text messages among a sample of college students, who often have high unmet mental health needs and low access to treatments. In line with recent recommendations [15], TE-SPI was designed to be low-burden, contextually relevant, and responsive to the specific challenges faced by structurally marginalized students, including limited access to culturally competent care and high academic stress. The high satisfaction and perceived usability reported in response to the prototype demonstration suggest that this approach may warrant further refinement and testing as a digital intervention that could complement traditional mental health services by providing immediate, accessible, and scalable support. Given the persistent challenges in accessing mental health care on college campuses, integrating digital approaches such as the study TE-SPI into campus service infrastructures—such as counseling centers, health centers, peer support programs, and crisis response services—may be worth exploring once the intervention has been tested under real-world conditions. Moreover, the TE-SPI was designed with considerations for cultural responsiveness, accessibility, and implementation in low-resource settings [59]. Future research is needed to test the TE-SPI in a larger, more diverse student population and to evaluate actual use, acceptability, feasibility, and its impact on risk for suicidal and self-harm thoughts and behaviors. Collaboration with universities, mental health professionals, and technology developers will be key in further developing the TE-SPI approach and scaling digital interventions for broad adoption. By leveraging digital solutions like TE-SPI, mental health care providers can extend their reach beyond clinical settings, offering timely and evidence-based support to students when and where they need it most. If effectively integrated into real-world mental health services, such approaches have the potential to become a critical component in improving mental well-being and reducing suicide risk in vulnerable college populations.

Acknowledgments

The authors would like to thank all the students who participated in their study and provided feedback on their technology-enhanced suicide prevention intervention tool. The authors also thank the developers of the BRITE app, including DB and Dr Beth Kennard, for graciously sharing their work and allowing their team to consider adaptations to serve our college student demographic. No generative AI tools were used in the writing, analysis, or preparation of this manuscript.

Funding

Funding support to Jocelyn Meza, Joan Asarnow, and Juliane Martinez came from Project 3 (project leads Jocelyn Meza and Joan Asarnow), a substudy of the ALACRITY Center Grant (P50MH126337-01; awarded Michelle G Craske and Kate Wolitzky-Taylor [multiple principal investigators]). Funding for the original BRITE app came from the ETUDES Center at the University of Pittsburgh (P50MH115838-02; awarded to David Brent [principal investigator]).

Data Availability

The dataset generated and analyzed in this study is not publicly available due to the sensitive nature of the data and the need to protect participant confidentiality. Data may be made available from the corresponding author on reasonable request.

Abstract

Background: The utility of online engagement in enhancing quality of life and mitigating social isolation among older adults is well documented. However, its relationship with cognitive functioning, particularly through online engagement, requires further exploration.

Objective: This study investigated whether active online engagement via the Virtual Senior Center (VSC) program was associated with subjective memory capability among older adults and whether subjective memory capability was associated with psychological well-being and loneliness.

Methods: This study included a cross-sectional sample of 53 homebound older adults participating in the VSC program, which offers diverse online classes to promote social interaction. Path analysis was conducted to examine the associations among online engagement, subjective memory capability, quality of life, and loneliness.

Results: Increased participation in VSC activities was associated with higher subjective memory capability (β=0.29, 95% CI 0.04-0.54; *P*<.02). Subjective memory capability was associated with better quality of life (β=0.29, 95% CI 0.04-0.54; *P*<.001) and lower loneliness (β=0.29, 95% CI 0.04-0.54; *P*<.003). No direct associations were observed between online engagement and quality of life or loneliness.

Conclusions: Subjective memory capability was associated with better quality of life and lower loneliness. Although online engagement had no direct association with quality of life and loneliness, the observed indirect pattern suggests that subjective memory capability may represent a psychologically meaningful pathway through which structured online engagement relates to well-being. These findings highlight the potential of digital platforms to complement traditional forms of socialization, particularly for older adults facing physical or geographic barriers to interaction.

KEYWORDS

online engagement; homebound older adults; subjective memory ability; social relationships; digital inclusion

Introduction

Background

In an increasingly digital society, online engagement, which is defined as active participation in digital platforms for social interaction, information sharing, and learning, has emerged as a key factor influencing the well-being of older adults. Given the potential of digital health technologies to mitigate social isolation and promote cognitive health, understanding the impact of online engagement on cognitive function is critical, particularly for homebound or mobility-challenged older adults [1,2].

Existing research has reported that active online engagement is associated with reduced feelings of isolation, which are prevalent among older adults, and has been examined in relation to cognitive functions such as memory. For example, older adults who use online platforms for social interaction have reported higher perceived quality of life and cognitive function [3,4]. However, there remains a notable gap in understanding the association between online engagement and subjective memory capability, defined as an individual's self-assessment of everyday memory functioning, and how these factors relate to overall well-being among older adults [5,6]. Many previous studies have focused on general internet use or access rather than participation in structured, program-based online engagement designed to promote sustained social and cognitive interaction [7,8]. As digital health and online community-based interventions continue to expand, understanding how structured engagement contexts relate to cognitive self-perception and well-being represents an important area for further investigation.

XSL•FO
RenderX

Given the growing interest in digital therapeutics and telehealth interventions, it is important to explore how online engagement contributes to cognitive self-perception and well-being among older adults. This study examined the association between participation in the Virtual Senior Center (VSC) program and subjective memory capability and social well-being among homebound older adults. Specifically, this research aimed to answer the following questions:

1. Does participation in a VSC influence older adults' subjective memory capability?
2. Does increased online engagement lead to improved social connectedness and well-being?
3. How does self-perceived memory capability mediate the relationship between online engagement and well-being?

It was hypothesized that greater participation in VSC activities would be positively associated with subjective memory capability and that subjective memory capability would be associated with higher quality of life and lower loneliness. This study contributes to the broader discussion of digital inclusion and cognitive health interventions by examining these relationships within a structured online engagement program for a homebound population. By focusing on subjective memory capability as a psychological mechanism, this study offers practical insights for designing digital health interventions and community-based programs targeting socially isolated older adults.

Literature Review

Research on internet communication technology in aging populations has highlighted the potential of online engagement to enhance social interaction, reduce isolation, and support psychological well-being [7,9]. Older adults who actively use online platforms for social interaction have reported higher life satisfaction, improved mental health, and better perceived cognitive outcomes than those who remain digitally disconnected [8,10].

Despite the recognized benefits of online engagement for mental health, studies examining its relationship with cognitive function and memory perception remain limited. Much of the literature has focused on the psychosocial aspects of general internet use, such as reducing loneliness and enhancing social connectedness [11,12]. Less attention has been paid to structured, program-based online engagement designed to promote sustained social and cognitive interaction. More recent studies suggest that such structured online engagement may be associated with cognitive benefits, including subjective memory capability and other indicators of cognitive self-perception [13,14].

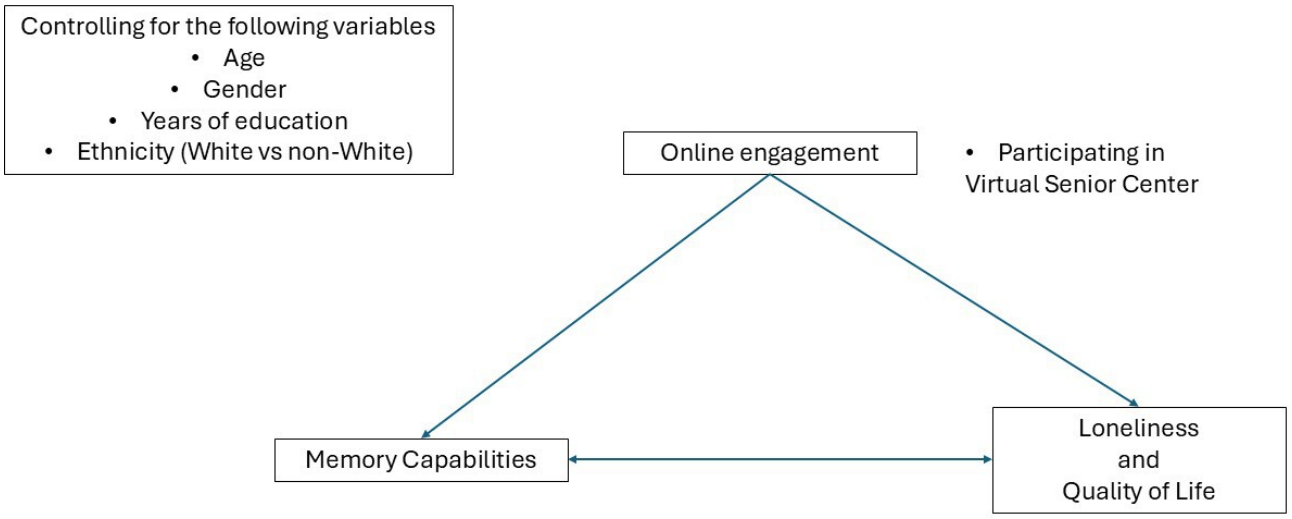
The VSC program in this study was developed to provide older adults with structured online activities, including educational courses, group discussions, and interactive social experiences. Unlike passive internet browsing or unstructured social media use, the VSC emphasizes scheduled and socially interactive participation. As a community-based platform, it facilitates ongoing engagement among older adults who may face barriers to in-person interaction. Specifically, the facilitator leads each class and encourages participants to engage and lead the group. In contrast to studies focusing on general internet use, the VSC represents a structured program-based approach to online engagement, making it a useful context for examining how sustained participation in organized digital activities relates to cognitive self-perception and well-being.

Prior studies have reported that tailored digital interventions may support cognitive engagement among older adults. For example, the Internet-Based Conversational Engagement (I-CONECT) program found that structured online socialization significantly improved cognitive performance in older adults [13,14]. In a similar way, the VSC reflects an interactive, community-based approach that may be relevant to digital health interventions targeting older adults who face barriers to in-person engagement.

Theoretical Framework

This study is grounded in 2 complementary theoretical frameworks that help explain how online engagement may relate to cognitive self-perception and well-being in older adults. Cognitive reserve theory posits that engaging in intellectually stimulating activities helps build cognitive resilience, thereby maintaining cognitive function and delaying the onset of cognitive decline [15]. Research has shown that older adults who participate in structured cognitive and social activities, such as online discussions, memory training, and digital learning platforms, demonstrate better cognitive performance and self-perceived memory capabilities [13,14]. Digital interventions, including internet-based cognitive training and virtual social engagement, have been found to foster cognitive reserve, particularly among older individuals at risk of social isolation [1,2].

Complementing this perspective, socioemotional selective theory suggests that, as individuals age, they become more selective in their social interactions, prioritizing emotionally meaningful relationships and experiences [16]. Studies have demonstrated that older adults tend to prefer digital communication tools that facilitate socially enriching interactions, such as video calls and virtual communities, over passive internet browsing or impersonal interaction [3,4]. Online platforms such as the VSC cater to these preferences by providing structured, interactive environments where participants can engage in meaningful social and cognitive activities. Research on digital health interventions has highlighted that programs designed around socioemotional needs and cognitive engagement, such as the I-CONECT program, are particularly effective in maintaining cognitive function and improving emotional well-being in older populations [13,14] (see Figure 1 for the theoretical model).



Given the increasing importance of digital inclusion, addressing disparities in digital access and engagement is critical [17]. Socioeconomic status, health conditions, age, and living arrangements all influence older adults' ability to benefit from online engagement [9,18-20]. This study examines the role of online engagement in supporting older adults who choose to age in place, particularly those with physical impairments that limit their access to in-person socialization. By facilitating virtual social interactions and providing access to cognitively stimulating activities, online engagement has the potential to

XSL•FO
RenderX

enhance subjective memory capability and overall quality of life for these individuals.

By integrating cognitive reserve theory and socioemotional selective theory, this study provides a comprehensive framework for understanding the dual role of digital engagement in promoting cognitive self-perception and emotional well-being among older adults.

Figure 1. Theoretical framework.

Methods

Participants and Recruitment

This study examined a cohort of 53 community-dwelling, homebound older adults participating in the VSC program, an online engagement platform designed to support social interaction and cognitive health. Participants were recruited through community aging services, older adult centers, and digital literacy outreach programs targeting older adults at risk of social isolation due to physical impairments, socioeconomic constraints, or mobility limitations.

These partnering organizations identified and referred individuals who experienced difficulty participating in in-person social activities, including those with limited mobility or chronic health conditions. Therefore, they represent a convenience sample of individuals enrolled in the VSC program during the study period.

To be eligible for the study, participants had to (1) be aged 55 years or older and residing in a community setting, (2) have access to a computer with internet connectivity (provided if necessary), (3) be enrolled in the VSC program and actively participating in its activities, and (4) report no clinically diagnosed severe cognitive impairments or neurodegenerative conditions (eg, Alzheimer disease).

Although the program primarily serves older adults aged 55 years or older, the final sample included participants ranging from 47 to 98 years, reflecting real-world enrollment patterns within the VSC program (ie, individuals with disabilities). This study focused on older adults who were dual eligible for Medicaid and Medicare, a population often characterized by low income, greater medical complexity, and increased health vulnerability [21-24]. To ensure equitable participation, participants were provided with computers; internet access when needed; and initial onboarding support, including assistance with logging into sessions and basic troubleshooting. When participants experienced technical difficulties, staff members could resolve the issues remotely without physically visiting their location to expedite the resolution process.

Study Design and Measurement

This study used a cross-sectional design, collecting data over a 6-month period (August 2017-January 2018) using a structured online questionnaire distributed through the VSC platform. Participants completed the survey after at least 3 months of engagement with the program to ensure that they had sufficient exposure to VSC activities before reporting on their experiences.

Ethical Considerations

This study was approved by the WCG institutional review board affiliated with Yeshiva University (IRB00023382). All participants provided informed consent prior to participation. Participant privacy and confidentiality were strictly maintained throughout the study, and all data were de-identified prior to analysis.

Measurement

Subjective Memory Capability

Participants' self-perceived memory function was assessed using the Metamemory in Adulthood (MIA) capacity subscale [25-27]. The MIA measures self-assessed memory performance in areas such as name recall, event tracking, and appointment remembering (eg, "I am good at remembering names," "I am good at remembering birth dates," and "I have no trouble keeping track of my appointments"). This validated measure has been widely used in aging research and has demonstrated moderate correlations with objective cognitive function [28].

Loneliness and Social Engagement

Loneliness was measured using the University of California, Los Angeles (UCLA), Loneliness Scale–Short Form [29,30],

XSL•FO
RenderX

which assesses perceived social connectedness and feelings of isolation (eg, "I feel lack of companionship" and "I feel left out"). Given that older adults in this study were homebound, the short version of the UCLA scale was selected to reduce respondent burden while maintaining validity [31].

Quality of Life

Quality of life was measured using the Older People's Quality of Life Questionnaire (eg, "I enjoy my life," "I am happy most of the time," and "I feel lucky compared to most people") [32-34]. This scale captures emotional well-being, social relationships, and life satisfaction, making it a comprehensive measure for assessing the impact of online engagement.

Online Engagement

Online engagement was quantified through the number of hours per week spent on the VSC platform, categorized into 1 to 3 hours, 4 to 6 hours, and 7 hours or more of participation. These data were extracted from VSC activity logs and reflect participation in structured online sessions (eg, classes and discussions) rather than passive internet use.

Rationale for Self-Reported Measure

While objective cognitive measures (eg, neuropsychological assessments) were not included in this study, research has shown that subjective memory capability is strongly associated with cognitive performance and can serve as a reliable predictor of cognitive decline [35,36]. This study focused on perceived cognitive capability rather than objective performance, consistent with research emphasizing subjective well-being and self-perception in the digital health context [8].

Statistical Analysis and Power Considerations

To enhance the robustness of the estimates, bias-corrected bootstrapping was used, a technique chosen for its ability to provide more accurate CIs in path analysis [37]. This procedure, based on 5000 bootstrap samples, has been shown to provide more accurate CI estimates in mediation and path models than percentile bootstrap methods [38,39]. Further, it allows for indirect effects within the model without type 1 errors, which are often associated with percentile bootstrap methods [37,40]. In the path analysis, standardized path coefficients and explained variance (R^2) were reported to describe the strength and explanatory contribution of the modeled associations [41,42]. Effect size indexes designed for mean differences (eg, Cohen *d*) were not applicable because the analyses focused on associations among continuous variables rather than group comparisons.

Results

Overview

Table 1 shows that the participants' average age was 77.86 (SD 11.55; range 47-98) years. The sample was approximately 72.1% (31/43) White individuals, 23.3% (10/43) African Americans, and 4.7% (2/43) Asian individuals. Only 1.9% (1/53) of the participants stated that they were Hispanic. Most participants (41/50, 82%) were female, and male individuals accounted for 18% (9/50). Participants' educational levels were as follows: 34% (16/47) had a 2-year college degree, 25.5% (12/47) had a master's degree, 25.5% (12/47) had a high school diploma, and 14.9% (7/47) had a bachelor's degree. Most participants maintained their social network or contact via phone (34/53, 64.2%), and 28.3% (15/53) reported engaging with others mainly through the VSC program. Only 7.5% (4/53) of the participants reported engaging with others in person.

The average score on the MIA capacity subscale [25] was 39.00 (SD 10.06; range 14-61). The average score on the UCLA Loneliness Scale was 7.69 (SD 3.60; range 0-12), and the mean score on the Older People's Quality of Life Questionnaire was 13.22 (SD 3.45; range 3-19).

Path Analysis

Path analysis revealed, as Figure 2 shows, that online engagement significantly increased older adults' subjective memory capability (β=0.29, 95% CI 0.08-0.50; *P*<.02). Individuals' memory capability was positively associated with both quality of life (β=0.90, 95% CI 0.09 - 0.57; *P*<.0001) and loneliness (β=0.37, 95% CI 0.18-0.57; *P*<.003). While demographic factors did not significantly influence participation in the VSC program, there were no direct effects on online engagement and quality of life and loneliness (refer to the full report in Table 2).

Discussion

Interpreting the Role of Subjective Memory Capability

This study examined the association between structured online engagement and subjective memory capability among older adults participating in a VSC program. The findings suggest that increased participation in VSC activities was positively associated with subjective memory capability, which, in turn, was significantly linked to higher quality of life and reduced loneliness. However, online engagement was not directly associated with well-being measures, indicating that subjective memory capability plays a key mediating role.

A central finding of this study is the indirect effect of online engagement on well-being through subjective memory capability. While previous research has examined the benefits of online engagement for reducing social isolation and loneliness [8,11], our findings highlight a different pathway. Online engagement may be associated with cognitive self-perception, which may, in turn, relate to emotional and social well-being.

This aligns with prior studies showing that a positive self-view of memory capability can improve confidence in cognitive abilities, leading to greater social participation and engagement in intellectually stimulating activities [1,35]. The VSC program may provide an environment where older adults can reinforce their cognitive self-efficacy through structured interactions, online discussions, and virtual socialization.

Given the increasing emphasis on digital health interventions for aging populations, this study underscores the need for more tailored cognitive engagement programs that explicitly target memory self-perception and self-efficacy rather than focusing solely on social connectedness.

Comparisons With Prior Digital Interventions

Our findings align with results from the I-CONECT study that demonstrated that internet-based social interaction interventions can enhance cognitive functions in older adults [13,14]. Similarly, research on cognitive training apps and digital learning platforms has suggested that active digital engagement can reinforce cognitive reserve and maintain subjective cognitive function in aging populations [3,6].

However, this study differs in its approach by focusing on a blended intervention integrating social and cognitive engagement. Unlike traditional cognitive training programs emphasizing memory exercises or problem-solving tasks, the VSC model incorporates structured discussions, interactive virtual activities, and peer-to-peer engagement. This approach may provide a more sustainable and engaging format for older adults, particularly those who may not actively seek cognitive training but can benefit from embedded cognitive engagement within social participation. These findings suggest that digital health interventions targeting cognitive well-being should combine socialization, structured engagement, and cognitive stimulation to maximize effectiveness [7,8].

Implications for Digital Health and Aging Care

The results have several implications for digital health initiatives and gerontological practice. Structured online engagement programs such as the VSC could be incorporated into broader telemedicine and aging care strategies to support older adults in maintaining cognitive and social well-being. Given the growing prevalence of digital health platforms, integrating online engagement as a recognized intervention in aging services may help address social isolation and support cognitive well-being among older adults, particularly those who are homebound or facing mobility challenges [9,17].

Beyond integration into health care, the findings also emphasize the need for more user-centered digital platforms designed specifically for older adults. Digital interventions should prioritize features that enhance cognitive self-efficacy, such as interactive discussions, virtual memory exercises, and personalized engagement experiences. Ensuring accessibility and ease of use is equally critical as digital literacy and technological barriers remain challenges for many older adults. Addressing disparities in digital access through training programs, affordable technology, and support networks will be essential in expanding the reach and effectiveness of online engagement programs [18,19,43].

Limitations and Future Research

While this study provides valuable insights, several limitations should be considered. The cross-sectional design limits the ability to establish causality among online engagement, subjective memory capability, and well-being. Future research using longitudinal data would clarify how sustained digital participation influences cognitive and emotional outcomes over time. Additionally, while subjective memory capability is a

XSL•FO
RenderX

widely used measure in cognitive aging research, incorporating objective cognitive assessments would strengthen the findings and allow for a more comprehensive evaluation of the impact of online engagement [36,44].

The relatively small sample size presents another limitation as it restricts the generalizability of the findings to broader populations of older adults. Given the modest sample size, the findings should be interpreted as exploratory and hypothesis generating, and replication in larger samples is warranted. Future research should also explore comparative analyses of different online engagement models, including cognitive training applications, telehealth platforms, and interactive digital communities, to determine which approaches are most effective in supporting cognitive and social well-being.

Conclusions

This study examined the potential of structured online engagement programs to enhance cognitive self-perception, influencing emotional and social well-being among older adults. The findings reinforce the importance of subjective memory capability as a key mediator in the relationship between digital engagement and overall well-being. As digital health and telemedicine evolve, integrating interactive and cognitively engaging online experiences into aging care models may provide scalable solutions for promoting cognitive and social health in older populations. Expanding access to well-designed and inclusive digital programs will ensure that older adults can fully benefit from the advancements in digital health and online interventions.

Abstract

Background: In Bangladesh, as well as throughout the world, children's screen time has significantly increased. Children spend a lot of time on the internet and digital screens for entertainment, education, and communication, which has increased their daily screen time. However, the potential detrimental impacts of excessive screen time on children's mental, physical, and social health have drawn attention.

Objective: This study aimed to explore the effect of high exposure to screens on the health and mental well-being of school-going children and adolescents in Dhaka, Bangladesh.

Methods: This cross-sectional descriptive study was conducted from July 2022 to June 2024. A total of 420 school-going children and adolescents aged 6 to 14 years were enrolled from 3 English-language and 3 Bangla-language schools in Dhaka using a stratified random sampling technique. Anthropometric measurements, a semistructured questionnaire, and the Pittsburgh Sleep Quality Index, the Development and Well-Being Assessment scale, and the Strengths and Difficulties Questionnaire, all of which were validated in Bangla, were used to gather data. We considered students who were exposed to screens for less than 2 hours a day as the low-exposure group and those who were exposed for more than 2 hours a day as the high-exposure group.

Results: A total of 83.3% (350/420) of the students were in the high-exposure group, and their average screen time per day was 4.6 (SD 2.3) hours. Eye problems were reported by 35.7% (150/420) of the students, and a significant difference was found between the low- and high-exposure groups. In total, 96% (144/150) of the students with eye problems were from the high-exposure group, whereas 4% (6/150) were from the low-exposure group. Headaches were reported by 80% (336/420) of the students, and they were common in the high-exposure group (279/336, 83%). Moreover, students from the high-exposure group had a short duration and poor quality of sleep (mean 7.3, SD 1.4 hours), which was statistically significant. Furthermore, obesity was more predominant in the high-exposure group (P<.001). Our study revealed that, overall, 31% (130/420) of the students had at least one mental health problem and 9.8% (41/420) had more than one mental health problem using the Development and Well-Being Assessment scale, and mental health problems were greater in the high-exposure group than the low-exposure group. Although behavioral problems such as conduct issues (119/420, 28.3%) and peer difficulties (121/420, 28.8%) were observed among the participants, no statistically significant difference was found between the 2 groups.

Conclusions: A collaborative and coordinated multistage approach is essential to create effective and acceptable guidelines and policies for the optimum and positive use of digital screens for the children of Bangladesh. Further prospective studies on a larger scale can be conducted to determine the impacts of screen time on aspects of health.

screen time; high exposure; Strengths and Difficulties Questionnaire; Pittsburgh Sleep Quality Index; Development and Well-Being Assessment scale; Bangladesh

Introduction

The increasing availability and accessibility of digital devices have significantly influenced children's lifestyles worldwide. Screen time, defined as the amount of time spent using devices such as televisions, computers, tablets, and smartphones, has become an integral part of modern childhood [1]. While moderate and purposeful screen use can offer educational benefits and entertainment, excessive and uncontrolled screen

XSL•FO
RenderX

time is emerging as a major public health concern due to its potential negative impact on physical, mental, and social well-being, especially among school-going children. One of the primary concerns related to excessive screen time is its contribution to a sedentary lifestyle. Screen-based activities often replace physical activities, leading to decreased energy expenditure and increasing the risk of childhood obesity. Studies have demonstrated a strong correlation between prolonged screen time and higher BMI in children, with television viewing and digital gaming being notable contributors [2]. Furthermore, prolonged inactivity during screen use negatively affects cardiovascular and metabolic health, increasing the likelihood of developing conditions such as insulin resistance, hypertension, and dyslipidemia later in life [3]. Beyond weight-related issues, excessive screen time has been associated with musculoskeletal problems, such as poor posture and repetitive strain injuries. Extended use of handheld devices and computers can lead to neck, shoulder, and back pain, as well as long-term spinal alignment issues in growing children [4]. Sleep disturbances represent another critical concern in the context of excessive screen time. Exposure to the blue light emitted by screens, especially in the evening, can suppress melatonin production, disrupting circadian rhythms and delaying sleep onset. Insufficient and poor-quality sleep not only affects physical growth and immune function but also impairs cognitive performance and emotional regulation [5].

The implications of excessive screen time are not confined to physical health; it also significantly affects mental health and well-being. Research has indicated that more screen use is linked to higher rates of anxiety, depression, and emotional dysregulation among children and adolescents [6]. Higher durations of screen use are associated with increased risks of internalizing feelings such as sadness and withdrawal, as well as externalizing problems, including aggression and irritability [7]. The relationship between screen time and mental health is complicated, and it is frequently influenced by the context and goal of screen use. For example, passive activities such as binge-watching television are more strongly linked to adverse outcomes than active activities such as engagement with educational content or video calls that promote meaningful interactions [8]. The influence of these negative factors can cumulatively impact academic outcomes and overall health tremendously [9,10].

The social dimensions of screen time are equally important to consider. Excessive engagement with digital devices often reduces opportunities for face-to-face interactions, which are critical for developing communication and interpersonal skills during formative years. Prior studies suggest that excessive screen time often comes at the expense of time spent engaging in family activities, playing with peers, or participating in community events. Essential social skills such as empathy, communication, and conflict resolution—all of which are best acquired through face-to-face interaction—may be hampered by changes in behavior. Children who spend prolonged periods on screens may struggle with interpreting nonverbal cues and establishing meaningful connections, ultimately affecting their ability to build and sustain relationships [11]. Furthermore, exposure to inappropriate or violent content can normalize aggression and antisocial behaviors, further impairing social health outcomes [12].

The responsible use of technology plays a crucial role in children's education, creativity, communication, and skill development [13]. Certain educational programs can positively impact children, especially those from disadvantaged backgrounds [13]. However, excessive screen time can lead to neurobiological stimulation, affecting the hypothalamic-pituitary-adrenal axis and dopaminergic pathways, which are linked to reward processing [14]. Recognizing these risks, the World Health Organization (WHO) recommends no screen time for children under 2 years, a maximum of 1 hour a day for those aged 2 to 5 years, and less than 2 hours a day for children over 5 years [15].

However, a survey in Bangladesh found that 18.9% of children use screens for more than 6 hours daily and 48% do so for approximately 4 hours. Factors such as rapid urbanization, lack of recreational spaces, and safety concerns contribute to increased indoor activities, pushing children toward excessive screen use. With digital media becoming a central part of children's lives, it is crucial to understand its impact on their physical, mental, and social well-being. Thus, this study aims to examine the association between screen time and children's health, focusing on patterns of use associated with psychological challenges, to inform policies and interventions that promote balanced screen use and healthier lifestyles among school-going children in Dhaka, Bangladesh.

Methods

Study Design and Participants

This descriptive cross-sectional study was carried out from July 2022 to June 2024. Six schools were purposively chosen from the list of schools in the Dhaka North City Corporation and Dhaka South City Corporation. Following a screening process based on the students' exposure to digital screens and viability, 3 English-language and 3 Bangla-language schools were chosen. After obtaining permission from the school authority, a public notice was posted on the notice boards of the schools requesting students and their parents to schedule a meeting with the person conducting the research. Students who met the inclusion criteria—age between 6 and 14 years (grade 2 to grade 8) and having or not having access to gadgets such as portable gaming devices, smartphones, tablets, televisions, PCs, laptops, and gaming consoles—were chosen for the study. Following a thorough explanation of the study and provision of parents' informed written agreement, both eligible students and their parents were invited to participate. Students who had psychological impairments, including depression, anxiety, or attention-deficit/hyperactivity disorder, that impacted their well-being or who had certain preexisting mental health disorders were excluded.

We recruited 420 students in total, 70 (16.7%) from each school and 10 (2.4%) from each grade level (2 - 8), using a stratified random sampling method. The 420 participants were divided into 2 groups: one group had 70 (16.7%) students who spent less than 2 hours a day in front of devices, and the other group

XSL•FO
RenderX

included 350 (83.3%) students who spent more than 2 hours a day in front of devices. The WHO and other international health regulatory agencies established the cutoff of less than 2 hours a day for children older than 5 years [15]. To collect data at the school premises, a trained team consisting of 2 field research assistants and 1 field research supervisor was involved.

Data Collection Instruments

Overview

A semistructured pretested questionnaire was developed for both students and parents, and a pretest of the questionnaire was conducted on the field site on 30 nonstudy students. We conducted face-to-face interviews with parents and students at the school. It usually took 30 minutes for the students, and the interviews with the parents lasted approximately 60 minutes. We gathered information from parents about their children's screen time, digital screen use patterns, and sociodemographic factors. Additionally, using a self-reported questionnaire, information on typical physical health issues such as headaches, back discomfort, neck pain, and eye difficulties was gathered from the students. The comments from students about their physical health were first divided into 4 categories: "No," "Sometimes," "Often," and "Most of the time." These groupings were then merged into 2 broader categories: "No" and "Yes," where "Yes" included the responses "Sometimes," "Often," and "Most of the time."

The mental health status of the students was measured using the standardized Bangla-validated Development and Well-Being Assessment (DAWBA) scale. Social behavior and emotional problems were measured using the Bangla-validated Strengths and Difficulties Questionnaire (SDQ). Finally, the quality of sleep was measured using the Bangla-validated Pittsburgh Sleep Quality Index (PSQI). The standard pre-established parameters that apply to a healthy child were compared to the health metrics obtained from each scale.

Anthropometric Measurements

Students' height and weight were measured by a trained field research assistant, converted to *z*-scores, and then grouped based on the WHO BMI-for-age growth chart's cutoff points for those aged 5 to 19 years. These measurements were standardized before and during data collection. All BMI values, which were calculated by dividing the student's body weight by the square of their height, were categorized using the WHO cutoff criteria. According to the WHO BMI chart, the following categories apply to both boys and girls aged 6 to 14 years: underweight (<15 kg/m^2; –1 SD), normal weight (15 - 25 kg/m^2), overweight (25 - 30 kg/m^2; +1 SD), obese (30 - 40 kg/m^2; +2 SD), and severely obese (>40 kg/m^2; +4 SD) [16]. Three consecutive measures were taken, and the averaged value was used during data analysis.

SDQ Measure

The SDQ is a brief behavioral screening tool for students, where parents rate their children's psychological traits over the previous 6 months. It includes 5 categories: emotional symptoms, conduct issues, hyperactivity and attention deficiency, peer relationship problems, and prosocial behavior, each scored on a 3-point scale (0 - 2). The total score (maximum of 40) reflects overall behavioral challenges, whereas prosocial behavior is scored separately (maximum score of 10). The SDQ was translated into Bangla and validated in Bangladesh by Mullick and Goodman [17] in 2001.

PSQI Measure

The Bangla PSQI was used to evaluate overall sleep quality. Students completed this self-reported questionnaire, which assigns scores from 0 to 3 across various subcategories, including subjective sleep quality, sleep duration, sleep latency, habitual sleep efficiency, disruptions, sleep medicine use, and dysfunction during the day. A score of 5 or more indicates poor sleep quality, and the maximum score is 21 [18].

DAWBA Measure

To evaluate mental health problems, we used the DAWBA, a widely used questionnaire among children and adolescents aged 5 to 17 years. The structured questions and open-ended verbatim accounts were assessed by DAWBA raters to generate *International Classification of Diseases, 10th Revision*, or *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*, psychiatric diagnoses. In this analysis, we used the Bangla version of the DAWBA that was validated by Mullick and Goodman [19] in 2005.

Statistical Analysis

Data were imported into Microsoft Excel for statistical analysis, cleaned, and then exported into SPSS (version 20; IBM Corp) and Stata (version 15.1; StataCorp). Two main groups were formed among the participants: those with high exposure (>2 hours a day) and those with low exposure (<2 hours a day). A comparative analysis was then carried out across several variables, such as demographic characteristics, screen time, and health metrics. For categorical data, chi-square tests for independence were used to evaluate differences between groups, and for continuous data with nearly normal distributions, an unpaired 2-tailed *t* test for differences between proportions was used. A significance threshold of a *P* value of less than .05 was used to assess statistical significance.

Ethical Considerations

This study was approved by the institutional review board of icddr,b (protocol PR-22002). Confidentiality and anonymity were maintained throughout the study. Parental permission was obtained through informed written consent for all participants aged 6 to 14 years. Additionally, assent was obtained from students aged between 11 and 14 years. Every respondent received information in Bangla on their rights regarding their voluntary involvement in the study and their ability to leave the interview at any point while it was being conducted.

Results

Sociodemographic Characteristics of the Study Participants

The study included 420 students based on screening criteria, of whom 350 (83.3%) were categorized in the high-exposure group (using digital devices for more than 2 hours daily) and 70

XSL•FO
RenderX

(16.7%) were categorized in the low-exposure group. The students were aged between 6 and 14 years, with a mean age of 10.9 (SD 1.9) years, with just over half of them (n=213, 50.7%) being male. The average daily screen time of the parents was 3.9 (SD 2.7) hours, and the average daily screen time of the students was 4.6 (SD 2.3) hours according to their own statement. Table 1 presents detailed information on the sociodemographic characteristics of the study population.

Table . Sociodemographic characteristics of the study participants (N=420).

Characteristic	Overall	Low exposure (<2 h/d; n=70)	High exposure (>2 h/d; n=350)
Students' age (y), mean (SD)	10.9 (1.9)	11.2 (1.8)	10.9 (1.9)
Students' sex, n (%)			
Male	213 (50.7)	35 (50)	178 (58.9)
Female	207 (49.3)	35 (50)	172 (49.1)

Prevalence of Physical Symptoms by Screen Exposure Level

The prevalence of physical symptoms among study participants with high and low exposure is shown in Table 2. Of the 420 students included in the study, 150 (35.7%) had eye problems. Of these 150 affected students, 144 (96%) belonged to the high-exposure group, whereas only 6 (4%) were from the low-exposure group, showing a statistically significant association (P<.001). Among all participants, 80% (336/420) reported headaches, 65.7% (276/420) experienced indigestion, and 81.2% (341/420) reported abdominal pain. Additionally, 45.7% (192/420) reported neck pain, 31.9% (134/420) reported back pain, and 48.6% (204/420) reported changes in appetite. These symptoms were more prevalent in the high-exposure group, although the differences were not statistically significant. Hearing difficulties (14/420, 3.3%) and diabetes (4/420, 1%) were the least frequently reported symptoms among the high-exposure group.

Screen Time and Obesity by Level of Exposure

The mean BMI for the study population was 19.3 (SD 4.7) kg/m^2 (Figure 1). Students with high exposure to digital screens had an average BMI of 20.0 (SD 4.7) kg/m^2 compared to 15.96 (SD 2.08) kg/m^2 in the low-exposure group, which was statistically significant (P<.001). Additionally, students categorized as being overweight (42/420, 10.1%), obese (16/420, 3.8%), or severely obese (4/420 (0.9%) were predominant in the high-exposure group (P<.001) compared to the low-exposure group.

XSL•FO
RenderX

Figure 1. Screen time and obesity in the low- and high-exposure groups.

Association Between Screen Time and Behavior by Exposure Level (SDQ)

The SDQ analysis revealed that, of the 420 students, 119 (28.3%) exhibited conduct problems, 121 (28.8%) had peer relationship problems, 66 (15.7%) reported emotional issues, 73 (17.4%) experienced hyperactivity, and 28 (6.7%) exhibited prosocial behaviors. Overall, most students fell within the normal range for these domains. However, among students classified as borderline or abnormal, most were in the high-exposure group. For example, in the peer relations domain, 28.8% (121/420) of the students were classified as abnormal, of whom 87.6% (106/121) were in the high-exposure group, whereas only 12.4% (15/121) were in the low-exposure group. Despite these trends, none of the SDQ domains showed statistically significant associations with screen time. Table 3 illustrates the relationship between screen time and the SDQ among the low- and high-exposure groups.

XSL•FO

	Normal	347 (82.6)	61 (17.6)	286 (82.4)	
	Borderline/abnormal	73 (17.4)	9 (12.3)	64 (87.7)	
Peer relation problems					.13
	Normal	299 (71.2)	55 (18.4)	244 (81.6)	
	Borderline/abnormal	121 (28.8)	15 (12.4)	106 (87.6)	
Prosocial behavior					.86
	Normal	392 (93.3)	65 (16.6)	327 (83.4)	
	Borderline/abnormal	28 (6.7)	5 (17.9)	23 (82.1)	

[a]Percentages in these columns are calculated with the value in the "Overall" column as the denominator.

Association Between Screen Time and Sleep Quality by Exposure Level (PSQI)

The correlation between sleep and screen time in the low- and high-exposure groups according to the PSQI is shown in Table 4. The overall average sleep latency for all participants was 20.3 (SD 14.7) minutes, with the high-exposure group showing significantly longer latency (mean 21.1, SD 15.4 minutes) than the low-exposure group (mean 16.3, SD 10.1 minutes; *P*=.01). Additionally, the average sleep duration was significantly shorter in the high-exposure group (mean 7.3, SD 1.4 hours) than in the low-exposure group (mean 9.0, SD 1.4 hours; *P*<.001), indicating poorer sleep quality among students with higher screen exposure. An evaluation of the PSQI components revealed significant differences in sleep duration between the 2 groups (*P*<.001). Other components, such as breathing difficulties, bad dreams, sleep disturbances, and daytime dysfunction, were also more prevalent in the high-exposure group than in the low-exposure group.

Table . Correlation between sleep and screen time in the low- and high-exposure groups according to the Pittsburgh Sleep Quality Index (PSQI).

PSQI variable	Low exposure (<2 h/d; n=70)	High exposure (>2 h/d; n=350)	*P* value
Sleep latency (min), mean (SD)	16.3 (10.1)	21.1 (15.4)	.01
Sleep duration (h), mean (SD)	9.0 (1.4)	7.3 (1.4)	<.001
Waking up in the middle of the night, n (%)			.01

Association Between Screen Time and Mental Health by Exposure Level

The correlation between student mental health and screen time in the low- and high-exposure groups according to the DAWBA scale is shown in Table 5. The DAWBA scale revealed that 31% (130/420) of the students reported at least one mental health issue, including specific phobia, generalized anxiety, depression, deliberate self-harm, hyperactivity, awkward behavior, and troublesome behavior. Additionally, 9.8% (41/420) of the students were identified as having more than one mental health problem. Notably, of the students with at least one mental health issue, 86.9% (113/130) were from the high-exposure group (screen use exceeding 2 hours per day). Similarly, among those with more than one mental health problem, 92.7% (38/41) belonged to the high-exposure group. The association between screen time and mental health problems showed borderline statistical significance, with a *P* value of .05.

Table . Correlation between student mental health and screen time in the low- and high-exposure groups according to the Development and Well-Being Assessment scale (N =420)[a].

	Overall, n (%)	Low exposure (<2 h/d; n=70), n (%)	High exposure (>2 h/d; n=350), n (%)	*P* value
No mental health problems	249 (59.3)	50 (71.4)	199 (56.9)	.05
At least one mental health problem	130 (31.0)	17 (24.3)	113 (32.3)	.05
More than one mental health problem	41 (9.8)	3 (4.3)	38 (10.9)	.05

[a]Mental health problems assessed: specific phobia, generalized anxiety, depression, deliberate self-harm, hyperactivity, awkward behavior, and troublesome behavior.

Discussion

Principal Results and Comparison With Prior Work

We found that a large majority of students (350/420, 83.3%) were exposed to digital screens for more than 2 hours per day and that higher screen exposure was strongly associated with poorer health outcomes. Nearly all students with eye problems (144/150, 96%) belonged to the high-exposure group (*P*<.001). Students with high screen time also had significantly higher BMI, with overweight (42/420, 10.1%) and obese (16/420, 3.8%) status concentrated almost entirely in this group (*P*<.001). In addition, high screen exposure was linked to poorer sleep, characterized by longer sleep latency and significantly shorter sleep duration (mean 7.3, SD 1.4 hours vs mean 9.0, SD 1.4 hours; *P*<.001). Finally, almost one-third of the students (130/420, 31%) had at least one mental health problem, with the vast majority (113/130, 86.9%) occurring among students with high screen exposure (*P*=.05).

In this study, the mean age of the participants was 10.9 (SD 1.9) years, with 49.3% (207/420) of the students being female. In a similar study, participants had a mean age of 10.9 (SD 1.16) years, and 47.7% were female [20]. Our study also found that the mean screen time per day was 4.6 (SD 2.3) hours from the students' perspective, which was similar to the parents' perspective (mean 4.5, SD 2.4 hours). Seguin et al [21] reported similar findings, which were a mean screen time of 5.9 (SD 3.4) hours per day. In addition, a systematic review showed that, overall, screen time among children aged 6 to 10 years and adolescents increased by 1.4 hours per day and 0.91 hours per day (in the year 2020-2021), respectively, compared to the pre–COVID-19 era [22]. The lockdown regimen during the pandemic brought a huge change to screen time duration and patterns in the daily routines of children. With regard to physical symptoms, 80% (336/420) of students in our study were found to have headaches. A recent study reported that there was a statistically significant association between increased screen time duration and headache, as well as dry eyes (*P*=.04 and *P*=.02, respectively) [23].

We found statistically significant associations between screen time duration and BMI. Similar findings were reported in Austria, where screen time was significantly associated with a higher BMI (*P*=.002) [24]. In contrast, a study in Pakistan demonstrated that there was no association between mean screen time and BMI (*P*=.64) [25]. The disparities may be attributable to various confounding factors such as food traditions and lifestyle.

In this study, as per the SDQ, in terms of prosocial behaviors, it was observed that only 6.7% (28/420) of the students were in the category of abnormal scores overall, with 7.1% (5/70) and 6.6% (23/350) in the lower- and higher-exposure groups, respectively. However, a study conducted on rural Chinese school-going children revealed that 10.5% of the participants belonged to the abnormal prosocial behavior category [26]. These differences may be due to other mental health problems as the community where the aforementioned study was conducted may have had various familial conflicts with lower levels of social support. In addition, previous research does show that screen time above the threshold is linked with increased abnormalities in behavior.

Regarding sleep habits and patterns, we found that duration of sleep was associated with screen time duration (*P*<.001). In a previous study in India, it was observed that both sleep efficiency and sleep duration were associated with screen time duration (*P*=.003 and *P*=.001, respectively) [27]. Another study reported that, among children who were exposed to screens for more than 2 hours a day, 61.8% had a PSQI score lower than 5 [28]. Multiple mechanisms suggest that screen time and media use are linked to sleep disturbances. There are several stimulating programs and contents that increase the activity level of the nervous system, inhibiting relaxation and leading

XSL•FO
RenderX

to anxiety and/or resulting in raised alertness and trouble falling asleep [29].

In the last decade, changes in screen use patterns and duration, type of content, type of device used, and parental monitoring have occurred. As a result, various types of studies have assessed the relationship between multiple aspects of screen time and/or device use and different facets of physical, mental, and social health in children, adolescents, and young adults, as well as academic performance outcomes and overall well-being. A study published in 2024 among children aged 6 to 10 years on screen addiction revealed that the group with high screen exposure showed statistically significant differences in screen addiction, distraction, and sedentary factors ($P<.05$) [30]. Another study reported that children who had greater exposure to screens, along with shorter sleep duration and lower physical activity levels, had poorer health-related quality of life [31]. In addition, a relevant study illustrated that children with exposure to screens for more than 2 hours per day had an increased likelihood of reported behavioral problems and poorer vocabulary [32].

It is worth mentioning that screen use widely varies across contexts. For instance, for academic purposes, screen time can exceed the recommended duration on certain days. This can be observed in the case of meeting deadlines or acquiring knowledge, where the screen is the only medium available. Another point to be kept in mind is the type of media being "overused" [33]. All in all, the context, platform, regimen, and secular trends should play a role in determining screen time duration.

Limitations

First, the 6 schools included in this study (3 in Bangla and 3 in English) may not adequately reflect the wider differences in resources between urban and rural environments. Second, there may have been recall bias because data on technological interactions were gathered through in-person interviews. Future studies on the effects of screen time ought to consider a wider range of settings and demographics. Study designs other than cross-sectional should be used, and extensive analyses involving other covariates should be conducted.

Strengths

Despite the aforementioned limitations, the study's strength lies in its innovative examination of the association between varying levels of screen exposure (low vs high) and the physical, mental, and social well-being of Bangladeshi students, particularly given that children with low exposure to digital screens are increasingly difficult to find. Furthermore, this study offers an insightful comparative analysis because it included students from Bangla- and English-language schools. The findings can inspire and inform parents, legislators, and educational authorities, emphasizing supporting students' healthier use of digital devices and more balanced lifestyles. More investigation is needed, possibly using longitudinal or experimental designs to examine causal relationships.

Conclusions

The findings of this study improve our knowledge of strategies to lessen the detrimental effects that excessive digital screen time has on children's mental health and well-being. Educators, parents, legislators, and children themselves must all be involved to create effective screen use guidelines. By holding workshops and seminars, schools can effectively teach children about responsible screen use and enforce a balanced screen time policy. To improve their children's well-being, parents must be aware of the dangers of excessive screen time as well as the advantages of active supervision. Accessible mental health resources, such as support groups and counseling, can also assist students in reducing the stress and anxiety associated with screen time. Additional research must be conducted to promote the development of comprehensive guidelines for screen time.

Abstract

Background: Telehealth was essential for maintaining care continuity during the COVID-19 pandemic, leading to its rapid adoption across the United States. Telehealth has been heralded as a strategy for improving health care access and reducing health disparities, especially for community-dwelling older adults who face significant barriers to in-person care. However, data on telehealth use among socially and financially vulnerable older adults are limited, and little is known about characteristics associated with telehealth use in this population.

Objective: Guided by the Systems Engineering Initiative for Patient Safety (SEIPS) 3.0 framework, this study examined factors associated with postpandemic telehealth use among older adults living at home and receiving publicly funded home- and community-based services (HCBS), considering HCBS receipt as an indicator of social and financial vulnerability.

Methods: This cross-sectional study included older adults aged 65 years or older living at home with available telehealth use data who participated in the 2021 - 2022 survey wave of the National Core Indicators-Aging and Disabilities Adult Consumer Survey. We used complete-case multivariable logistic regression, adjusting for sociodemographic and health-related factors with state-level random intercepts, to examine associations between telehealth use and covariates of interest (age, sex, race/ethnicity, zip code, rural-urban commuting area code, internet access, self-perceived overall health, medical transportation access, living alone, number of known non–Alzheimer disease and related dementias [ADRD] diagnoses, known ADRD diagnosis, and HCBS program/payer type). Based on the regression results, we estimated bivariate associations between internet access and key sociodemographic variables (age, sex, race/ethnicity, and zip code rural-urban commuting area) using the Pearson chi-square test. Findings were organized and interpreted through the SEIPS 3.0 framework.

Results: Of the 3680 participants, 1467 (40%) were telehealth users and 2213 (60%) were nonusers. Significantly lower odds of telehealth were observed for older adults in older age groups, males, Black individuals, those living in nonmetropolitan areas, and recipients of Older Americans Act services (odds ratios [OR] between 0.66 and 0.80). Individuals with more than one known non-ADRD diagnosis (OR 1.49, 95% CI 1.02 - 2.17) and those with an ADRD diagnosis (OR 1.33, 95% CI 1.07 - 1.66) had higher odds of telehealth use. Internet access was strongly associated with telehealth use (OR 2.51, 95% CI 2.15 - 2.92). Follow-up bivariate analyses between internet access and sociodemographic characteristics revealed that those of younger age, females, and White individuals had higher levels of internet access.

Conclusions: Differences in telehealth use among older HCBS recipients are associated with multiple individual, technological, and organizational factors. Interpreted through the SEIPS 3.0 framework, these findings underscore the importance of viewing telehealth use as the outcome of multiple features of the health care system. Future research should clarify the mechanisms driving variation in telehealth use to identify and address barriers to telehealth adoption among vulnerable older adults.

KEYWORDS

telehealth; older adults; home- and community-based services; aging in place; internet access

Introduction

During the COVID-19 pandemic, telehealth emerged as a key strategy for maintaining continuity of care amid lockdowns and social distancing measures [1-3]. Consequently, American patients and providers alike became more accepting of telehealth [4-7], contributing to a rapid increase in its use across the United States [8-10]. This surge in telehealth activity—defined as the use of telecommunications technology to provide health care remotely [11]—has since facilitated the continued integration and expansion of telehealth in United States health care delivery [9,12,13]. As its use has grown, telehealth has been increasingly viewed as a means of improving health care access and addressing potential disparities in health outcomes [14-17]. Proponents of telehealth emphasize its potential for significantly reducing cost and access barriers to care, especially for those who are medically vulnerable, geographically isolated, and socially marginalized [14-17]. For this reason, telehealth is seen as a particularly promising approach for improving access to both routine geriatric care and specialty care for chronic and complex conditions among community-dwelling older adults [17-19]. Across the United States, many older adults lack access to in-person care due to health and mobility-related challenges, combined with structural and sociodemographic factors that drive health disparities, including those related to race, ethnicity, socioeconomic status, and rurality [20-26]. For these individuals in particular, telehealth may be a promising strategy for improving access to health care and potentially reducing disparities [27].

Despite this promise, data on the demographics and characteristics of older telehealth users are limited, and it remains unclear whether telehealth improves access to care for older Americans. Available data indicate that, overall, telehealth use is relatively low among older adults, with only about one-third using telehealth [28,29]. Importantly, telehealth serves a wide range of functions beyond the management of diagnosed conditions. It is used for screening/triage, routine monitoring, medication review, mental health services, and supportive or social follow-up, services that are highly relevant for many older adults [1,6,19]. The fact that telehealth use remains relatively low among older adults despite these broad potential applications underscores the need to better understand the factors that shape telehealth use.

Broad, overarching analyses on telehealth use among older adults may conceal underlying differences in telehealth access and use driven by individual factors, such as age, sex, health status, and preference, as well as organizational and environmental factors, including health care systems, geographic location, and access to infrastructure that supports telehealth use (eg, broadband internet). These sets of factors, and their interactions, likely influence telehealth use among older adults. Recent data show that among American adults broadly, older age, male sex, rurality, and lack of internet access are negatively associated with telehealth use [30-32]. An emerging literature suggests these factors are also associated with telehealth use among older adults; however, older adults are also disproportionately affected by additional barriers to telehealth use, including inexperience with technology, lack of social support for managing telehealth technology, physical disability, and dementia [33-35]. More research is needed to identify the factors associated with telehealth use among older adults, with particular attention to conditions that contribute to potential disparities in access and use.

One such population is older adults who receive publicly funded home- and community-based services (HCBS). This group is particularly important to examine with respect to telehealth use because their substantial care and social needs make them likely to benefit from remote care while at the same time leaving them vulnerable to barriers that may limit telehealth use. HCBS are a broad range of services (such as personal care, homemaker, meal delivery, adult day care, and transportation services) designed for older adults with physical and/or cognitive functional impairments to receive care in their own homes or communities rather than in nursing homes or other institutional settings [36].

In the United States, HCBS are delivered through several publicly funded program types that vary in their structure, degree of integration with the formal health care system, and scope of benefits [37]. Major HCBS programs include Medicaid 1915 (c) waiver-funded HCBS, services authorized under the Older Americans Act (OAA) and administered by local Area Agencies on Aging (AAAs), managed long-term services and supports (MLTSS), and fully integrated care models such as the Program of All-Inclusive Care for the Elderly (PACE) [36]. Medicaid-funded HCBS programs, MLTSS, and PACE are directly connected to health care financing and typically include coverage of medical services alongside long-term services and supports. In contrast, OAA-funded services provide supportive services—such as meals, transportation, and referrals—rather than direct medical care.

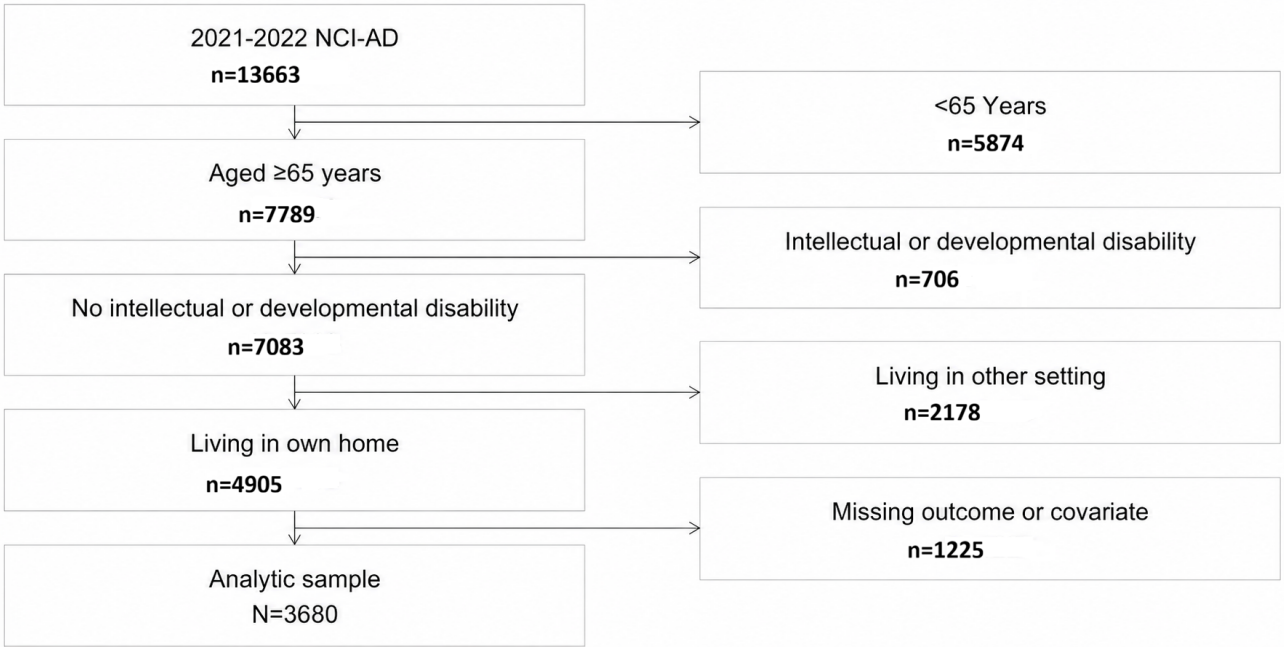
More than 4.5 million older adults in the United States use HCBS [37]. This group represents a high-need population with complex health care needs, and their receipt of publicly funded HCBS serves as an indicator of their financial and social vulnerability [36]. At the same time, HCBS recipients are insured and already integrated into formal health care delivery systems, enabling examination of telehealth use among vulnerable older adults without the confounding factor of basic access to health insurance.

This study examines telehealth use among older adults who receive publicly funded HCBS and live in their own or family home. We approach this question using a human factors lens, asking not simply whether older adults adopt telehealth but how system elements at the individual, organizational, and environmental levels are associated with its use. To this end, we use the Systems Engineering Initiative for Patient Safety (SEIPS) 3.0 framework [38], a human factors model that conceptualizes health care outcomes, such as telehealth use, as emerging from interactions among persons, tools and

XSL•FO
RenderX

technology, environments, and organizations. In this study, SEIPS is used as an organizing framework to classify measured variables reflecting person characteristics (eg, age, sex, and health status), tools and technology (eg, internet access), environmental context (eg, rurality), and organizational features (eg, HCBS program type). This framework is well suited for understanding telehealth use among community-dwelling older adults receiving HCBS, whose social and financial vulnerability warrants careful attention to the individual, environmental, technological, and organizational factors that shape their interactions with the health care system.

We examine patterns of postpandemic telehealth use among older HCBS recipients using data from the National Core Indicators–Aging and Disabilities (NCI-AD) Adult Consumer Survey. It is important to note that the NCI-AD dataset reflects real-world reported telehealth use and does not indicate whether participants were explicitly offered telehealth by their providers or payers. This study therefore focuses on patterns of reported use among individuals with potential access through their existing service networks, providing insight into which subpopulations of older adults are—or are not—being reached by telehealth in practice. These findings can inform efforts to identify subpopulations of older adults who are underrepresented among telehealth users and the systems-level barriers that may limit their engagement with telehealth. Such data are essential for beginning to identify opportunities to expand telehealth among medically vulnerable older adults and ensure telehealth reaches its full potential for improving access to care.



Methods

Data Source and Study Sample

This study used cross-sectional data from the 2021‐2022 cycle of the NCI-AD Adult Consumer Survey, which aims to evaluate and monitor the effectiveness of publicly funded HCBS and other long-term care services and supports for older adults and individuals with disabilities. State participation in the NCI-AD is optional. Participating states administer NCI-AD to a representative sample of HCBS recipients each year. The NCI-AD survey consists of 2 sections. The first section gathers background information such as demographics, health conditions, and service use, typically sourced from state administrative records. The second section is a direct-conversation consumer interview and survey that collects person-centered data on the HCBS recipient's health, functional abilities, and care experiences. If an HCBS recipient cannot participate, a close proxy may complete portions of the survey that collect objective, observable information.

We focused on the 2021‐2022 wave of the NCI-AD Adult Consumer Survey because it provided the most recent data and reflects telehealth use during the postpandemic period when telehealth use has largely stabilized [39]. The 2021‐2022 survey included 13,663 participants from 15 states (Colorado, Delaware, Georgia, Indiana, Kansas, Michigan, Minnesota, Missouri, New Jersey, Ohio, Oklahoma, Tennessee, Texas, Washington, and Wisconsin). For the present analysis, we focused on recipients of publicly funded HCBS aged 65 years and older, who lived in their own or family home, did not have an intellectual or developmental disability, did not receive a nursing facility waiver, had nonmissing telehealth use data, and had complete covariate data (described below), resulting in a final analytic sample of 3680 participants. Figure 1 shows the detailed participant flow diagram. The percentage of missing data was below 10% for all individual items, including telehealth use. In total, 85% of participants with nonmissing telehealth data had complete data and were included in the complete-case regression analyses.

Figure 1. Flow diagram for construction of the analytic sample. NCI-AD: National Core Indicators–Aging and Disabilities.

RenderX

Telehealth Use

The primary dependent variable of interest, telehealth use, was determined by an interview question that asked participants to report if they had ever communicated with health professionals via videoconferencing or telehealth. Possible responses were "yes," "no," "don't know," or "unclear/refused/no response." All "yes" responses were categorized as telehealth users, and "no" responses were considered nontelehealth users. All remaining responses were categorized as missing and excluded from the analyses.

Covariates

Covariates were selected based on the broader health care and telehealth literature and aligned with the SEIPS 3.0 human factors framework. As described previously, SEIPS 3.0 conceptualizes health care outcomes, such as telehealth use, as emerging from interactions among persons, tools and technology, environments, and organizations. Consistent with this framework, covariates were grouped according to these elements.

Person factors reflect the individual characteristics, capabilities, and experiences that shape how individuals interact with and navigate health care systems. This category included demographic characteristics (age, sex, and race/ethnicity); self-perceived overall health; lives alone; number of known non–Alzheimer disease and related dementias (ADRD) diagnoses; known ADRD diagnosis; and response type (self vs proxy response). We classified age into a categorical measure describing age group, including 65 - 74 years, 75 - 84 years, and ≥85 years; sex was categorized as female or male (no participants selected a sex other than male or female); and race and ethnicity were grouped as Black or African American, Hispanic or Latino, White, and multiple race/ethnicity. Age, sex, and race/ethnicity were populated from the background administrative section of the NCI-AD.

Self-perceived overall health was determined through the NCI-AD interview, with possible responses of poor, fair, good, very good, and excellent. The covariate "lives alone" indicates whether the participant lives independently, with participant interview responses categorized as "yes" for those living alone and "no" for those residing with others. The number of known non-ADRD diagnoses refers to the count of medical conditions excluding ADRD (including brain injury, cancer, chronic obstructive pulmonary disease, stroke, diabetes, hypertension or high blood pressure, heart disease, physical disability, and mental health diagnoses). ADRD was accounted for separately under the covariate known ADRD diagnosis, which included all individuals with a recorded ADRD diagnosis. ADRD and non-ADRD diagnoses were obtained from state administrative records when available or from participant reports, both linked to the NCI-AD survey dataset. Administrative records included provider-documented diagnoses (eg, *ICD-10* [*International Statistical Classification of Diseases, 10th Revision*] diagnosis codes or I4200 or I4800 Minimum Data Set fields). Finally, the covariate *proxy response* refers to whether the individual completed the interview independently through self-response or if a close proxy provided the answers on their behalf.

Tools and technology are the physical and digital resources that enable or constrain how individuals engage with health care systems. Within this framework, we examined internet access, which represents a foundational technological tool that enables older adults to interact with the health care system through telehealth. In the NCI-AD survey, internet access was defined as the availability of internet service at home, a coffee shop, or somewhere else the participant spends time during the day. This item was assessed via direct interview, with participant interview responses categorized as "no or sometimes" and "yes."

Environmental factors encompass the external conditions that shape how individuals interact with health care systems. These factors include geography, built environment, and community resources, which can either support or constrain care delivery and access. In this study, environmental factors included zip code rural-urban commuting area (RUCA) classification and medical transportation access. Zip code RUCA classification was used to approximate participants' geographic environment and degree of rurality and was classified into 4 levels, including metropolitan (areas with a population of 50,000 or more), micropolitan (areas with a population of between 10,000 and 49,999), small town (areas with a population under 10,000 that have commuting ties to an urban area), and rural (areas with no commuting ties to any urban area). Medical transportation access was assessed by the interview question, "Do you have transportation to get to medical appointments when you need to?" Participants could respond with "no," "sometimes," or "yes." Responses of "no" and "sometimes" were grouped to represent participants with at least some transportation barriers, while "yes" responses were retained as a separate category to represent those who have consistent access to transportation for in-person care. This variable was conceptualized as an environmental factor capturing the physical and community-level conditions that influence an individual's ability to access health care.

Organizational factors refer to the health care delivery organizations in which the patient journey occurs, characterized by workflows, policies, resource allocation, and interorganizational coordination that may influence patients' telehealth use. In this study, organizational factors were included as HCBS program type, which refers to the HCBS program administering or providing services as indicated by administrative records, classified into 3 categories, including PACE/MLTSS, OAA, and Medicaid. We combined PACE and MLTSS due to the small number of PACE participants (PACE: n=55; MLTSS: n=1259) in our sample and the shared characteristics of both programs. Both PACE and MLTSS operate under a capitated payment structure and are designed to serve older adults requiring long-term care. Since approximately 90% of our analytic sample reported receiving Medicare, consistent with United States census data [40], we focused on other payment types due to the low variance in Medicare enrollment.

Statistical Analyses

Descriptive statistics were used to summarize the analytic sample of participants with complete data for all included covariates. Bivariate associations between covariates and

XSL•FO
RenderX

telehealth use were assessed using chi-square tests and 2-sample 2-tailed *t* tests. We then estimated the adjusted associations between telehealth use and each of the covariates described using complete-case multivariable logistic regression, in which each coefficient represents the association of a given covariate with telehealth use while holding all other covariates constant. State was included as a random effect in the logistic regression model to account for potential variation in telehealth use across different states. To evaluate the impact of missing data, we conducted a sensitivity analysis using multiple imputation by chained equations [41,42], averaging results across 10 imputed datasets with no missingness (n=4786 per dataset).

Given the strong association between internet access and telehealth use in the complete-case regression analysis, we performed post hoc bivariate analyses on the analytic sample from the complete-case regression model to examine sociodemographic factors that may influence internet access as a potential precursor to telehealth use. We conducted bivariate analyses using chi-square tests to test the independence of internet access and the following factors: age, sex, race/ethnicity, and zip code RUCA classification.

All analyses were performed using R (version 4.4.2; R Project for Statistical Computing). $P<.05$ was considered statistically significant.

Ethical Considerations

This study used deidentified secondary data from the 2021-2022 NCI-AD Adult Consumer Survey. The study was submitted to the University of Minnesota Institutional Review Board and was deemed exempt from human subjects review (STUDY00010799). Because the present analysis used deidentified secondary data, additional informed consent from participants was not required. No compensation was provided to participants for this secondary analysis.

Results

Participant Characteristics

Table 1 presents the complete characteristics of the analytic sample. Percentages shown in Table 1 summarize the characteristics of the analytic sample and are not intended as population estimates; therefore, 95% CIs were not calculated for these descriptive values. The analytic sample included 3680 participants, with 1467 out of 3680 (40%) reporting ever using telehealth and 2213 out of 3680 (60%) reporting never using telehealth. Most participants were female (2667/3680, 72%) and most resided in metropolitan areas (2660/3680, 72%), while smaller proportions lived in micropolitan (528/3680, 14%), rural (219/3680, 6%), or small-town (273/3680, 7.4%) settings. The sample was racially diverse, with 1929 out of 3680 (52%) identifying as White, 858 out of 3680 (23%) as Black, 443 out of 3680 (12%) as Hispanic or Latino, and 450 out of 3680 (12%) as multiple racial/ethnic identities. Overall, 2144 out of 3680 (58%) reported having internet access, while 1536 out of 3680 (42%) reported no or intermittent access. In terms of health characteristics, 3161 out of 3680 (86%) participants did not have a documented ADRD diagnosis, and 2988 out of 3680 (81%) participants had more than one known non-ADRD diagnosis. Self-perception of health varied; most participants rated their overall health as fair (1519/3680, 41%) or good (1176/3680, 32%). About half of participants lived with at least one other person (1937/3680, 53%), and most reported having access to medical transportation (3395/3680, 92%). HCBS program enrollment was distributed among Medicaid (1630/3680, 44%), OAA programs (736/3680, 20%), and PACE/MLTSS (1314/3680, 36%).

Older HCBS recipients who were younger, female, had multiple diagnoses, lived with others, and had a known ADRD diagnosis had higher rates of telehealth use. In contrast, Black individuals and those from nonmetropolitan areas had lower rates of telehealth use compared to their counterparts. Participants with lower perceptions of their overall health tended to be more likely to use telehealth, though this relationship was not significant. Internet access showed a clear pattern with telehealth use: 49% (1047/2144) of those who reported having internet access were telehealth users, while only 27% (420/1536) of those with no or intermittent access reported using telehealth.

Regression Analysis of Telehealth Use by SEIPS Domains

Table 2 presents the full logistic regression model results, with model estimates reported as odds ratios (ORs) and 95% CIs for telehealth use versus no telehealth use. Several significant associations between the covariates and telehealth use emerged from the analysis. Results from the sensitivity analysis using multiple imputation were consistent with those of the complete-case analysis, indicating that missing data did not substantially impact the observed associations.

Person factors showed several notable associations. Among older recipients of publicly funded HCBS, age was significantly associated with telehealth use, with older age associated with lower odds of telehealth use. Using adults aged 65-74 years as the reference group, those aged 75-84 years had an OR of 0.72 (95% CI 0.62 - 0.85), and those aged 85 years and older had an OR of 0.66 (95% CI 0.53 - 0.81). Sex was also significantly associated with telehealth use, with males having significantly lower odds of telehealth use relative to females (OR 0.80, 95% CI 0.68 - 0.94). Racial differences were observed as well: Black participants had significantly lower odds of using telehealth compared to White participants (OR 0.72, 95% CI 0.59 - 0.87), whereas Hispanic or Latino participants and those from other racial backgrounds had similar odds of telehealth use relative to White participants. Additionally, individuals with more than one known non-ADRD diagnosis had higher odds of using telehealth compared to those with no known diagnoses (OR 1.49, 95% CI 1.02 - 2.17). Those with a recorded ADRD diagnosis also had higher odds of telehealth use compared to individuals without an ADRD diagnosis (OR 1.33, 95% CI 1.07 - 1.66).

Technology and environmental factors were also associated with telehealth use. Individuals living in nonmetropolitan areas had lower odds of telehealth use compared to those in metropolitan areas (micropolitan: OR 0.75, 95% CI 0.60 - 0.93; small town: OR 0.67, 95% CI 0.50 - 0.90; rural: OR 0.72, 95% CI 0.52 - 1.00), although the rural estimate should be interpreted with caution because the upper limit of its CI approaches the null value. Internet access was strongly associated with telehealth use, with individuals reporting internet access exhibiting more than twice the odds of telehealth use compared with those with no or intermittent access (OR 2.51, 95% CI 2.15 - 2.92).

Organizational factors—specifically HCBS program type—were associated with differences in telehealth use. Participants receiving services through OAA showed lower odds of telehealth use compared with those enrolled in Medicaid (OR 0.67, 95% CI 0.47 - 0.98), while those receiving PACE/MLTSS had similar odds of telehealth use as Medicaid recipients.

No significant associations were observed between telehealth use and self-perceived overall health, medical transportation access, living alone, and response type (self vs proxy response).

Tools and Technology: Sociodemographic Correlates of Internet Access

Table 3 displays the frequencies of reported internet access, along with the *P* value from the omnibus chi-square test for each sociodemographic characteristic.

[b]RUCA: rural-urban commuting area.

We conducted bivariate analyses to examine how person-level and environmental factors were associated with internet access, a key technology resource for telehealth. Our analysis revealed significant associations between internet access and age (*P*<.001), sex (*P*=.01), and race/ethnicity (*P*<.001). Participants aged 75-84 years and those aged 85 years and older were less likely to report internet access (667/1238, 54% and 300/659, 46%, respectively) than those aged 65-74 years (1177/1783, 66%). Male participants were also less likely than female participants to report having internet access (557/1013, 55% vs 1587/2667, 60%). Among racial and ethnic groups, Black and Hispanic or Latino participants (488/858, 57% and 177/443, 40%, respectively) were less likely to report internet access than White participants (1180/1929, 61%) and individuals from other racial backgrounds (66%, 299/450). No statistically significant association was found between zip code RUCA classification and internet access.

Discussion

Principal Findings

Guided by the SEIPS 3.0 framework, this study is, to our knowledge, the first to report differences in telehealth use among older HCBS recipients through a human factors lens. The SEIPS framework illustrates how health care outcomes emerge not from any single factor, but from the alignment—or misalignment—of people, technologies, organizations, and environments across the broader health care system and the patient journey within it. Applying this lens offers a systems-level perspective for identifying actionable system-level factors that may underlie variation in telehealth use.

The results of this study provide preliminary insight into the multiple system-level elements that may influence who is—and is not—being reached by telehealth. Importantly, the observed associations reflect estimates from a regression model that accounted for all included covariates, estimating each factor's association with telehealth use while adjusting for potentially confounding influences. These adjusted findings provide a clearer view of the factors that may enable or impede telehealth among older HCBS recipients.

Understanding these dynamics is particularly important as telehealth continues to expand, especially among older adults—a population recognized as a priority group for telehealth services due to their complex health needs and challenges [18,19,32,43-45]. Older adults—particularly those receiving publicly funded HCBS—are vulnerable to mobility issues, transportation barriers, chronic conditions, and poverty that make it challenging to access in-person care [46-51]. Health care organizations and policymakers have emphasized the importance of telehealth in geriatric populations for facilitating care access, improving health outcomes, reducing costs, and ultimately promoting health equity [15,52-55].

Taken together, our findings underscore the value of examining telehealth use as a product of multiple factors operating within the broader health care system. In the following sections, we

XSL•FO
RenderX

interpret our findings through the SEIPS 3.0 framework, organized by person, tools and technology, environment, and organizational factors.

Person Factors

In this study, age, sex, race/ethnicity, number of non-ADRD diagnoses, and the presence of an ADRD diagnosis were associated with differences in telehealth use among older HCBS recipients. It is important to note that compared to the broader population of community-dwelling older adults, HCBS recipients generally have more complex care needs and experience social and financial vulnerability. Consequently, the findings presented here extend prior evidence to older adults receiving HCBS.

Age was inversely associated with telehealth use, with individuals aged 85 years and older exhibiting the lowest odds of using telehealth. This finding is consistent with research demonstrating that older adults face a variety of barriers to adopting new technologies, including low digital literacy, technology-related anxiety, limited access to support, and health-related functional limitations [56-58]. Recent evidence demonstrates that these barriers hinder telehealth adoption in older adults [34] but have a more pronounced impact on those of more advanced age [59]. Consistent with our findings, several studies have similarly shown that, within older adult populations, telehealth users tend to be younger than nonusers [60,61].

We also observed sex differences in telehealth use, with males having significantly lower odds of using telehealth than females. This result aligns with other studies demonstrating that older females are more likely to use telehealth than their male counterparts [62-64]. The reasons for these differences are uncertain and may reflect broader sex differences in health care needs and use patterns among older adults [65,66], specifically those receiving HCBS [67,68]. Further research is needed to examine and explain sex differences in telehealth use among older recipients of publicly funded HCBS.

Importantly, our results revealed racial differences in telehealth use. In our sample of older HCBS recipients, Black older adults had significantly lower odds of using telehealth compared to White older adults, consistent with other studies showing lower telehealth use among Black older adults [33,69,70]. This finding may reflect systemic and structural barriers to telehealth access, including pervasive racial and ethnic disparities in access to technology and broadband internet, a relationship further supported by our bivariate analyses showing differences in internet access by race and ethnicity [71-73].

Beyond sociodemographic characteristics, HCBS recipients with more than one non-ADRD diagnosis had significantly higher odds of using telehealth compared to those with no known non-ADRD diagnoses. This finding aligns with prior research showing that individuals with multimorbidity—defined as the presence of 2 or more chronic conditions—are more likely to use telehealth than those with fewer health concerns [74,75]. Multimorbidity often requires ongoing communication with multiple health care providers, making telehealth a valuable option to reduce the burden of frequent in-person visits. Our results reinforce geriatric care recommendations emphasizing telehealth's potential to support older adults with chronic health conditions [45], particularly those who are homebound or have difficulty traveling to medical appointments [76]. This may be especially important for older HCBS recipients with multimorbidity, whose HCBS eligibility reflects high care needs and increased vulnerability to systemic and health-related barriers that limit access to in-person care. Future research should examine how telehealth can be integrated into the care of older HCBS recipients with multiple health conditions and how programmatic or policy changes could promote its use in this population.

Older HCBS recipients with a documented ADRD diagnosis had slightly higher odds of telehealth use than those without an ADRD diagnosis. This finding aligns with prior research showing that telehealth is generally well received and shows promise for people with ADRD and their caregivers [77-79]. For people living with dementia and their caregivers, telehealth can reduce the burden of travel to in-person health care appointments and facilitate more frequent assessments and follow-up care with health care providers [79]. Our results reinforce telehealth's potential value for older HCBS recipients with ADRD while also pointing to opportunities to expand its reach in this population. In our sample, only 46% (241/519) of older HCBS recipients with ADRD reported telehealth use—suggesting that while these individuals were slightly more likely to use telehealth than their counterparts, there remains an opportunity to increase uptake. Future research should explore how telehealth services can meet the unique needs of older HCBS recipients with ADRD.

Finally, several person factors were not significantly associated with telehealth use, including self-perceived overall health, living alone, and whether survey responses were provided by the participant or a proxy. These null findings suggest that, within this population, telehealth use may be more strongly patterned by sociodemographic characteristics and objective health indicators, such as documented diagnoses, rather than by subjective health perceptions or cohabitation status. Viewed together, our findings show that person-level characteristics and capabilities—core components of the SEIPS framework—may influence telehealth use among older adults receiving publicly funded HCBS.

Tools and Technology

Disparities in technology use—including telehealth—are often linked to gaps in broadband internet availability for vulnerable and marginalized older adults [80]. Our results underscore this relationship, revealing a strong association between internet access and telehealth use. In our sample, older adults with internet access had more than twice the odds of using telehealth compared to those with no or intermittent access. This finding aligns with prior research emphasizing the critical role of internet access in enabling telehealth use [28,81,82].

Our findings support the hypothesis that internet access functions as a core technological tool connecting people to health care systems. When absent or unreliable, the broader system's capacity to deliver care through telehealth may be compromised. As telehealth continues to expand, increasing broadband internet access is essential to promote equitable

XSL•FO
RenderX

access to telehealth services, especially for medically, socially, and financially vulnerable older adults [83]. Evidence suggests that state-level funding programs increase broadband availability, highlighting the potential impact of policy interventions on improving internet access [84]. Conversely, municipal and cooperative restrictions have been shown to decrease broadband availability, underscoring the role of regulatory barriers in limiting connectivity, such as state policies that restrict municipalities and electric cooperatives from providing broadband service—often justified as preventing publicly subsidized competition with private internet providers [84]. Targeted policy efforts, such as state and federal initiatives subsidizing broadband internet for low-income and rural populations, could facilitate more equitable telehealth access for vulnerable older adults.

Consistent with patterns observed in the person factors domain, internet access varied significantly by age, sex, and race/ethnicity. Older adults of more advanced age were less likely to have internet access than those aged 65-74 years, which may help explain the lower odds of telehealth use observed in this group. Additionally, males were less likely than females to report having internet access, aligning with our finding of lower odds of telehealth use among male participants. A prior review found mixed evidence regarding sex differences in internet use among older adults, with some studies reporting no sex effect and others showing higher internet access among older men than women [85]. Our findings differ from these results, possibly due to our focus on older recipients of publicly funded HCBS, a population disproportionately composed of women with care needs experiencing social and financial vulnerability [68]. Additional research is needed to characterize age- and sex-related patterns of internet access in this population and their relationship to telehealth use.

Our results highlight differences in internet access by race and ethnicity. In our sample of vulnerable older adults, Black and Hispanic or Latino individuals were less likely to report having internet access than White individuals and those from other racial backgrounds. This finding may help explain why Black individuals had lower odds of telehealth use than their White counterparts in our regression analysis. Interestingly, we found that Hispanic or Latino older adults were less likely to have internet access; however, their odds of telehealth use were comparable to White individuals. These results suggest differing impacts of internet access on telehealth use but generally align with extensive research documenting racial and ethnic disparities in internet access and use [26,71-73]. Addressing these gaps may require targeted programs that expand internet access among minoritized older adults, including those receiving publicly funded HCBS. Such initiatives could serve as precursors to telehealth use by ensuring vulnerable older adults have the technological tools they need to use telehealth.

Unexpectedly, internet access was not significantly associated with zip code RUCA classification. This result contrasts with extensive literature showing lower rates of broadband internet availability and access in rural communities compared to metropolitan areas [86-88]. Furthermore, this finding was unexpected given that in this sample, older HCBS recipients in nonmetropolitan settings demonstrated lower odds of telehealth use compared to those in metropolitan areas. The lack of association between internet access and zip code RUCA may reflect the smaller sample size of rural participants in our analyses. Future research should focus on characterizing internet access and digital disparities among older HCBS recipients, particularly those in traditionally underserved rural areas. Identifying and targeting specific communities with limited broadband internet access could help address gaps in telehealth use by ensuring older adults have access to foundational technology required for telehealth uptake.

Environmental Factors

We found that older adults residing in nonmetropolitan areas had lower odds of using telehealth compared to those in metropolitan areas. Our estimate for rural residents should be interpreted with caution, as the CI included the null value. Likewise, bivariate analyses showed no significant association between zip code RUCA classification and internet access. Together, these findings suggest that, within this sample, rurality alone may not capture the full range of environmental mechanisms shaping telehealth use. Nevertheless, rural older adults remain a population for whom telehealth is viewed as particularly beneficial, given the limited availability of specialty care in rural areas and the challenges of traveling long distances to receive services [89]. Although extensive prior evidence shows that rural older adults experience a persistent digital divide—including lower broadband availability, reduced device access, and lower rates of technology adoption compared to metropolitan peers [90-93]—our findings suggest that rurality alone may not directly translate into lower telehealth use within the HCBS population. This may indicate that other system components, such as person, technology, and organizational factors, help compensate for structural challenges based on environmental context. In this study, the absence of a strong rural effect could reflect offsetting influences—such as targeted initiatives to expand or prioritize telehealth access in local areas. This underscores the complexity of telehealth use as an outcome shaped by multiple system elements rather than a single environmental barrier.

Access to medical transportation was not significantly associated with telehealth use. This may reflect that transportation barriers do not clearly determine whether an older HCBS recipient uses telehealth as an alternative to in-person appointments. However, transportation remains an important environmental resource within the broader health care system, likely interacting with person and organizational factors to influence how older adults access and coordinate care. Taken together, the weak and/or null associations for environmental factors in this study suggest that other system variables may play a larger role in shaping telehealth access.

Organizational Factors

Older HCBS recipients enrolled in OAA had lower odds of telehealth use compared to those enrolled in Medicaid. This difference may reflect underlying organizational differences in how these programs connect participants to the health care system. As mentioned previously, OAA programs, administered by local AAAs, primarily provide supportive services such as home-delivered meals, transportation, and referrals rather than

XSL•FO
RenderX

direct medical care benefits. While these services are vital for many older adults, they do not directly address or translate to formal health care access. At most, OAA services are a "bridge" that supports better care access and coordination [94]. However, variability in local AAA resources and service delivery makes it difficult to draw generalizations about the relationship between OAA services and health care access. From these data, we also cannot determine whether OAA recipients differ meaningfully from other HCBS participants in their care needs, which could also contribute to differences in telehealth use. This uncertainty underscores how multiple system elements—such as person factors (eg, health needs) and organizational interfaces—may work together to shape telehealth use. Based on our findings, it is plausible that OAA programs provide a weaker interface between the person and the medical care system, offering essential social support but less integration with health care delivery pathways, which may result in lower telehealth use.

By contrast, Medicaid, PACE, and MLTSS programs are structured to deliver comprehensive health care with low out-of-pocket costs to eligible older adults, often including telehealth as a covered option. These organizational systems offer a stronger interface between the person and the health care system. Consequently, individuals enrolled in these programs may have clearer pathways to telehealth services compared to those enrolled in OAA.

These findings highlight the importance of considering HCBS recipients' organizational interfaces with the health care system and how they may offer or shape opportunities for telehealth use. Further research is needed to explore telehealth access among older HCBS recipients across different program types. Understanding these organizational dynamics is essential for designing system-level interventions that align HCBS program structures with the evolving role of telehealth.

Strengths and Limitations

Guided by the SEIPS 3.0 framework, this study leverages a unique dataset to examine factors associated with telehealth use among older adults receiving HCBS. This hard-to-reach population offers valuable insights into telehealth use among socially and financially vulnerable older adults, who are considered likely to benefit from these services [14-17]. However, the NCI-AD dataset has limitations, including a lack of information on the type and frequency of telehealth visits, preference for in-person versus telehealth care, telehealth satisfaction, and future intentions to use telehealth. Data regarding reasons for telehealth nonuse are also unavailable. In addition, the dataset does not capture whether participants were explicitly offered telehealth by their providers or payers, which may introduce variability in access opportunities that is not reflected in our analyses. Consequently, we could not analyze more nuanced aspects of telehealth use and nonuse within this sample. Additionally, the cross-sectional nature of the NCI-AD data limits the ability to draw causal inferences. Recall bias may also affect the accuracy of responses, as participants may not accurately report their telehealth and other health experiences. Furthermore, because the dataset primarily captures older adults receiving HCBS, our findings are most applicable to community-dwelling older adults and may not generalize to those residing in congregate settings. Future research should use longitudinal designs to better understand telehealth use and to examine how interactions across SEIPS components influence telehealth access, use, and effectiveness among older HCBS recipients and older adults more broadly.

Conclusion

This study uses the SEIPS 3.0 human factors framework to examine differences in telehealth use among older recipients of HCBS living at home, a socially and financially vulnerable population that may benefit greatly from telehealth services in reducing or removing barriers to in-person health care. Our results show that among older HCBS recipients, older individuals, males, those living in nonmetropolitan areas, Black individuals (relative to White), and OAA recipients (relative to those receiving Medicaid) had lower odds of using telehealth. Individuals with multiple diagnoses and those with a documented ADRD diagnosis had higher odds of telehealth use. Notably, internet access was strongly associated with telehealth use and, in bivariate analyses, was associated with similar sociodemographic factors as those linked to telehealth use, emphasizing the need for expanded broadband internet access to promote equitable telehealth use among vulnerable older adults. Viewed through the SEIPS model, the findings reveal differences in telehealth use as an outcome emerging from multiple system elements rather than any single determinant. Future research should identify and address the potential mechanisms underlying these differences to ensure telehealth fulfills its potential to improve access to care and promote health equity for older Americans.

Abstract

Background: Images play an important role in reducing stigma related to mental health, which often is distorted in the media. In recent years, generative artificial intelligence (AI) has been used to generate images related to mental health. However, first reports suggest that AI-generated images do not depict mental health conditions accurately. In-depth studies on the topic of mental health representations in AI-generated images are still missing.

Objective: The main objective of this study is to analyze and compare the visual representation of depression in mass media and in AI-generated images.

Methods: The methodologies used were discussion groups (15 participants) and a quasi-experimental online survey (792 interviewees), aimed at people with depression and young people.

Results: The results showed that both the images used in the media and those generated by AI reproduced stereotypes and stigmas about depression. However, participants considered AI-generated pictures to be more stereotypical, stigmatizing, and more likely to have a negative impact on people with depression. In contrast, media images were considered more appropriate, realistic, inclusive, and that better reflected the relationship between gender and depression. Statistically significant differences were observed between the control and test groups in both people with depression and young people (P<.001), indicating that when people were aware of what images were AI-generated, they tended to reject them to a greater extent.

Conclusions: Considering the current trend toward the widespread use of AI in mental health communication, it is crucial to promote closer collaborations between science journalists, AI developers, and mental health experts, including patients' associations, as well as a shift toward user-participatory AI design.

Introduction

Background

The worldwide depression incidence increased during 2020 due to the COVID-19 pandemic, although before then, depression already featured as a leading burden of disease globally [1]. According to the World Health Organization, approximately 280 million people have depression worldwide, the equivalent of 5% of the adult population [2]. Young people are among the most affected groups [3-5], with depression rates having doubled from prepandemic estimates [6]. Spain was one of the countries in Europe most affected by COVID-19 infections, complications, and deaths, with young people being among the groups (together with frontline health care workers) with higher prevalence rates of mental health symptoms [7]. The prevalence of depression in Spain increased from 3.06% prepandemic to 12% postpandemic [8]. At an informational level, Google searches for mental health disorders have tripled for some pathologies compared with 2016, which highlights that society needs, and is actively searching for, information on mental health [9].

Mental health stigma and discrimination have been described as having worse consequences than the mental health conditions themselves do [10]. Higher levels of self-stigma in people with mental health issues result in lower treatment adherence [11], which is related to the fact that internalized stigma and treatment-related stigma are negatively associated with seeking help [12]. In Spain, the stigmatization of mental health conditions is prevalent in stereotypes, prejudices, and discrimination associated with people with mental health issues, as shown by a recent systematic review [13].

When studying mental health stigmatization, it is necessary to pay attention to the images that accompany the text, especially

XSL•FO
RenderX

since multiple studies conclude that negative media representations of mental health lead to mental health stigma [14-16]. In light of this, framing images positively or negatively can significantly affect the way audiences react to messages [17]. Positive visual information can reduce stigma related to mental health treatments; improve information, understanding, and effectiveness in identifying symptoms; promote empowerment; and foster better communication between patients, family members, and medical professionals [18,19].

Against this background, it is evident that the media play a key role: they can contribute not only to the creation and perpetuation of stereotypes and prejudices but also to the reduction of stigma surrounding mental health by portraying realistic, balanced, or even positive counterstereotypical examples [20]. In reality, however, mental health coverage by the media is insufficient and often resorts to stigmatizing archive images depicting hopelessness [9]. An analysis of a wide range of media revealed that descriptions of mental illness are often distorted by misinformation, exaggeration, and inaccuracies [14]. Similarly, the media, including news and social media, were found to display mental health issues in a negative light, although an increasing number of balancing stories appeared, mainly in magazines [15]. Images of depression on the social media platform Tumblr mostly depicted crying women, were often very dark-colored, and represented gloominess and sadness [21]. On Instagram, images of public self-disclosure of mental health issues express emotional distress, calls for help, and displays of vulnerability [22].

In this context, artificial intelligence (AI) could become a mental health ally. Studies have reported potential benefits of integrating AI in health communication, which include improving access to health information, supporting health behavior change, addressing diverse community needs [23], or boosting the reach and effectiveness of public health communication strategies [24]. Particularly for mental health, studies show that AI presents opportunities to enhance mental health care, for example, by serving as a complementary tool to bridge gaps in conventional mental health services, especially in areas with limited resources or high social stigma [25], developing algorithms to analyze images and texts shared on social media to diagnose or predict depression [26], or supporting the mental health of health professionals with AI chatbots [27]. However, AI use in mental health also presents some ethical challenges [25,28], as it can make systematic errors in its decision-making processes leading to unfair outcomes, also called bias [29]. First reports suggest that AI-generated images do not depict mental health conditions accurately [30,31] and that they frequently reflect cultural stereotypes and historical visual tropes, including gender biases and stigma [32]. Nonetheless, in-depth studies on the topic of mental health representations in AI-generated images are still missing.

From a theoretical perspective, the social impact of media and AI-generated images can be explained through complementary approaches from media effects research, social psychology, and technology acceptance studies. Framing theory posits that visual elements, such as color, lighting, posture, and scene context, shape how mental health is interpreted, guiding audience attributions of realism, stigma, vulnerability, or social support [17,33,34]. However, media effects are not uniform: reception studies emphasize that individuals actively interpret images through their personal experiences, beliefs, emotional states, and social identities, which may modulate responses across age, gender, and lived experience with depression [35,36]. From a psychosocial perspective, social representations and emotional anchoring processes contribute to the stabilization of shared visual stereotypes of depression in collective memory [37,38]. Finally, differential evaluations of media versus AI-generated images can be interpreted through the technology acceptance model (TAM), which proposes that perceived usefulness and perceived ease of use shape behavioral intentions toward technology [39] and that these perceptions may vary across demographic groups, such as gender and age, due to differences in prior technological experience [40], as well as attitudinal biases toward AI-generated products [41,42].

Study Objectives

The main objective of this study is to analyze and compare the visual representation of depression in mass media and in AI-generated images. To do so, we explore the perceptions of 2 strategic population groups: people with depression and young people. The specific research questions (RQs) are as follows:

- RQ1. How is the representation of depression in media and AI-generated images perceived?
- RQ2. How do the opinions of people with depression differ from the opinions of young people regarding the depiction of depression in media and AI-generated images?
- RQ3. How do people with depression recommend better illustrating depression, and how do these recommendations compare to those by young people?
- RQ4. How do people with depression, as well as young people, receive recommendations from mental health associations regarding how to illustrate depression?

Methods

Two types of methods were implemented: one qualitative (discussion groups) and one quantitative (survey). A mixed methods approach was used because of the greater depth and breadth of information that it can offer compared to using 1 type of method alone [43].

Discussion Groups

In total, 3 discussion groups were organized involving 15 people (13 women and 2 men): one was with people with depression and two with young people. The distribution of the discussion groups organized is available in Multimedia Appendix 1.

Each discussion group had a tailored script approved by the Advisory Board of the project (formed by a mixed group of professionals from the fields of clinical psychology, science journalism, and representatives from mental health associations). A slide show was prepared for discussion groups containing 64 images, of which 30 were found in the media, another 30 were AI-generated, and 4 were related to recommendations from mental health associations.

Media images were obtained from 3 different Spanish newspapers by providing their inbuilt search engine with the

XSL•FO
RenderX

keyword “depression” (in Spanish, “depresión”) on December 18, 2023. The 10 most recent images were selected for each newspaper, spanning from December 15, 2023, to January 4, 2019. The 3 newspapers selected were *La Razón*, *El País*, and *Eldiario.es*. These newspapers represent different ideologies, from more conservative to more left-leaning ideologies, and traditional and online-native media [44]. Out of the 30 images from the media, 22 included women, 7 included men, and 1 was an ungendered illustration. In 6 images, the figure of the person was silhouetted against the light. Eleven images were of celebrities. On 1 occasion, 2 people interacted with each other, while all other pictures contained either a single person or people not interacting. In 2 instances, images depicted a woman holding a baby. Only 1 image was in black and white, and the rest were in color. These images are available in Multimedia Appendix 2.

AI-generated images were obtained from 4 different tools in June 2023: Deep Dream Generator (Stable Diffusion 1.5), DeepAI (Stable Diffusion 1.5), OpenAI (DALL·E 2), and Dream Studio (Stable Diffusion 2.1). Images were created using the prompt “depression.” Standard parameters were applied to generate the images, with no particular filters or prompt settings. Out of the 30 AI-generated images, 10 depicted women, 11 depicted men, and 9 were unknown or ungendered. The most repeated type of image was that of a person sitting down, either with their hands to their head or face, or holding their knees with their arms, looking down (18 images). Eleven pictures were in black and white, and 19 were in color. In addition, 3 were illustrations, and 27 represented realistic pictures. These images are available in Multimedia Appendix 3.

Images recommended by mental health associations were obtained from the guides from the Confederación Salud Mental España, “Style guide on mental health for the media” [45], and from Cochrane, “Choosing images for sharing evidence: a guide” [46].

Discussion groups took place between the 11th and 18th of January 2024. Conversations were registered and later transcribed. The coding and qualitative analysis were carried out via the qualitative research support program ATLAS.ti (version 22).

Ethical Considerations

Before commencing work, the research project was evaluated by a panel of independent experts of the Spanish Foundation for Science and Technology (FECYT), who deemed the data management protocol as adequate. Following this evaluation, a bioethics committee and an ethical protocol were not considered necessary because no high-risk interventions were involved. Before conducting the discussion groups, informed consent was obtained from all participants, who provided it voluntarily and with the full knowledge of the facts.

All appropriate measures have been taken to comply with applicable regulations on the protection of personal data, including the General Data Protection Regulation and the Spanish Organic Law 3/2018 of December 5 on the Protection of Personal Data and Guarantee of Digital Rights [47]. At Universitat Pompeu Fabra, the Institutional Commission for the Ethical Review of Projects was responsible for the ethical assessment and monitoring of research involving human participants, human biological samples, or personal data (including health and clinical data). As this study did not involve any of these elements, ethical review and approval were not required according to institutional and national regulations.

Survey

Based on the qualitative analysis of the discussion groups, a quasi-experimental survey was developed. The insights contributed by discussion groups’ participants offered contextual depth and nuance regarding lived experiences and perspectives. Specific topics that appeared in the discussion groups and that were later transferred to the survey included, among others, how images could be more inclusive, better illustrate the relationship between gender and depression, or could negatively affect people with depression. Based on the most commonly voiced opinions regarding how the images could be improved, a list of options was prepared for the survey asking respondents to select the phrases that could help improve the way depression was illustrated.

The survey consisted of 14 questions and was validated twice before being shared: first, by the Advisory Board of the project; and second, by discussion group participants. The survey is available in Multimedia Appendix 4.

The survey had 2 versions: a test and a control (a mechanism specific to quasi-experimental surveys). In the test version, respondents knew which images were from the media and which ones were AI-generated; in the control version, respondents were not told the difference.

Target respondents were people with depression and young people. The first 7 questions of the survey asked respondents to select up to 5 images out of the 30 presented (15 from the media and 15 AI-generated). The remaining 7 questions were either multiple choice, scale, or open text questions.

The survey was sent to target respondents via an online opt-in panel. The sample was representative of Spanish society in terms of population distribution, encompassing all autonomous communities, age groups, genders, education levels, and population sizes. The data collection period was from the 22nd to 24th of May 2024. A total of 792 responses were obtained—390 from people with depression and 402 from young people. These numbers surpassed the minimum required to obtain a statistical robustness of 95% with an error margin of 5% (achieved at 385 responses for each target group).

Regarding the screening of participants, the first question of the survey asked them whether a doctor had diagnosed them with any mental health condition, and a list of 6 options was offered, including depression. Participants who ticked that option were labeled under “People with depression.” People from this group were not restricted by their age because their defining trait for the purposes of the study was the fact that they had been diagnosed with depression. On the other hand, people who had not been diagnosed with any mental health issues and were 18 to 29 years old were labeled under “Young people.”

XSL•FO
RenderX

Raw data were cleaned in Excel. For statistical analysis, all data were imported into the R software (R Core Team). The data were initially tested for normality, and the corresponding tests were run (Pearson chi-square test, Fisher exact test, logistic regressions, Mann-Whitney *U* test, and Kruskal-Wallis test, specified in text). For all analyses, a statistical threshold of α=.05 was used. Violin plots were used to better represent the full distribution of nonparametric data.

Results

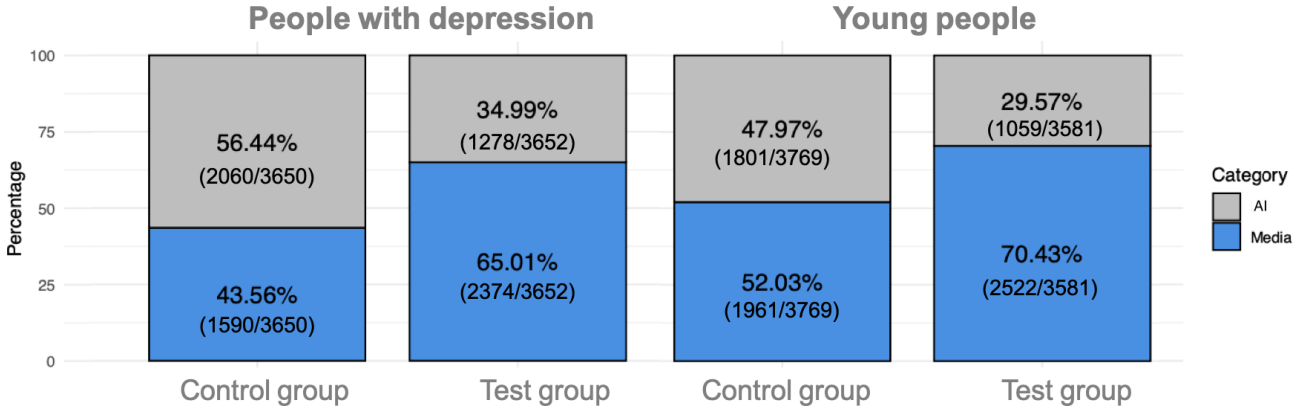
The results are presented following the study's research questions.

How Is the Representation of Depression in Media and AI-Generated Images Perceived?

Both media and AI-generated images reproduce stereotypes and stigma about depression. However, respondents perceive AI-generated images more negatively than media images. In particular, AI-generated images are considered to be even more stereotypical, reproducing stigmas of marginalization or social exclusion and negatively affecting people with depression. In contrast, media images are considered relatively more appropriate, realistic, inclusive, and that represent the relationship between gender and depression better.

How Do the Opinions of People With Depression Differ From the Opinions of Young People Regarding the Depiction of Depression in Media and AI-Generated Images?

To answer this question, we present the results in 2 categories, depending on whether the questions were framed (1) positively or (2) negatively.



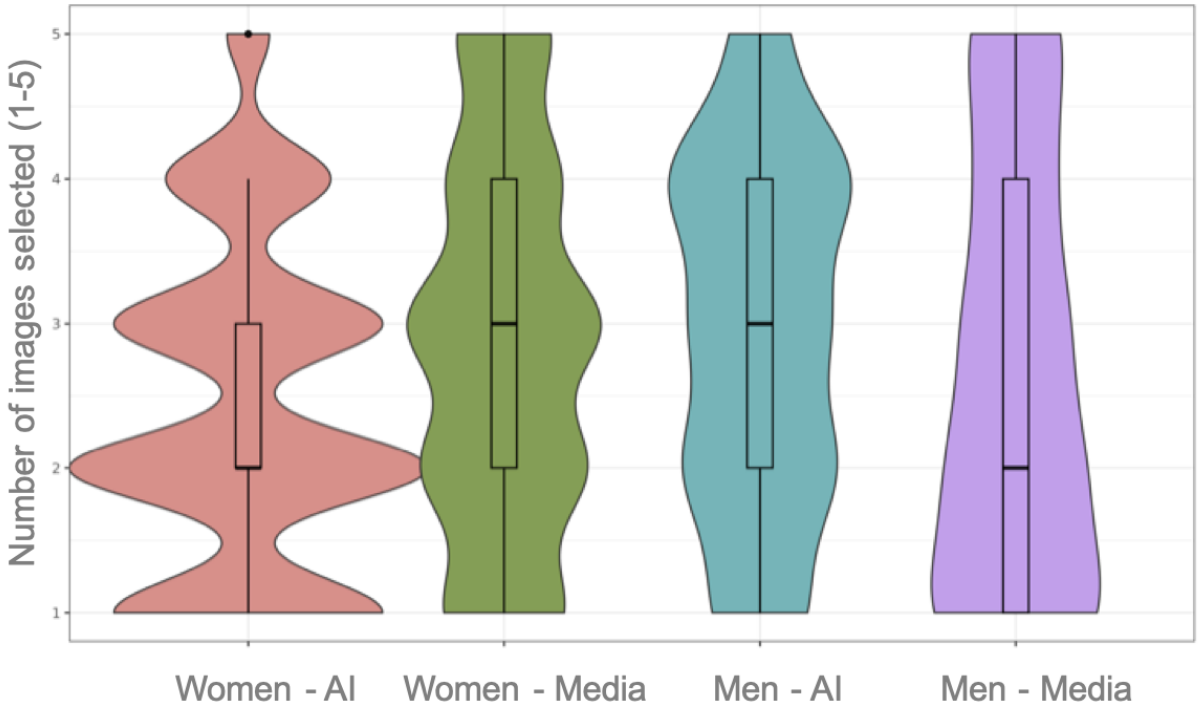
Responses to Positively Framed Questions

The questions that were framed positively asked which images were considered more appropriate, realistic, inclusive, and better represented the relationship between gender and depression.

A nonparametric Pearson chi-square analysis was carried out to examine differences between the test and control groups among people with depression. There were statistically significant differences between the 2 groups (P<.001), with the test group (ie, people who knew which images were from the media and which were AI-generated) choosing media images more frequently (2374/3652, 65.01% chose media; 1278/3652, 34.99% chose AI images). On the other hand, the control group (those who did not know whether images were from the media or AI) selected a higher percentage of AI-generated images (1590/3650, 43.56% chose media; 2060/3650, 56.44% chose AI images).

The same trend was observed in responses from young people (P<.001)—while the test group chose media images more frequently (2522/3581, 70.43% chose media; 1059/3581, 29.57% chose AI), the ratio in the control group was much more balanced (1961/3769, 52.03% chose media; 1801/3769, 47.97% chose AI; Figure 1).

Figure 1. Distribution of answers for positively framed questions regarding media or artificial intelligence (AI)–generated images, segregated by group among people with depression and young people.



The top 3 images selected for positively framed questions among people with depression were all from the media for the test group, whereas the control group included 2 out of 3 that were AI-generated. Among young people, the same was observed: while the test group chose only media images in the top 3 positions, the control group had a more balanced selection. Among people with depression, the first images selected both by the test and control groups represented women sitting down, hiding their face in their arms. Among young people, both the test and control groups selected in the first place the same image, showing a woman holding a baby. Images are available as Multimedia Appendices 2 and 3.

Responses to positively framed questions from people with depression were crossed with their demographic data. In terms of sex, no significant differences were found regarding which images were more appropriate (χ^2_1=1.785; P=.18; ϕ=.02), more inclusive (χ^2_1=0.289; P=.59; ϕ=0), and better represented the relationship between gender and depression (χ^2_1=3.430; P=.06; ϕ=.04). However, when they were asked about which images represented depression more realistically, women chose media images more frequently (χ^2_1=7.877; P=.005; ϕ=.06) Figure 2).

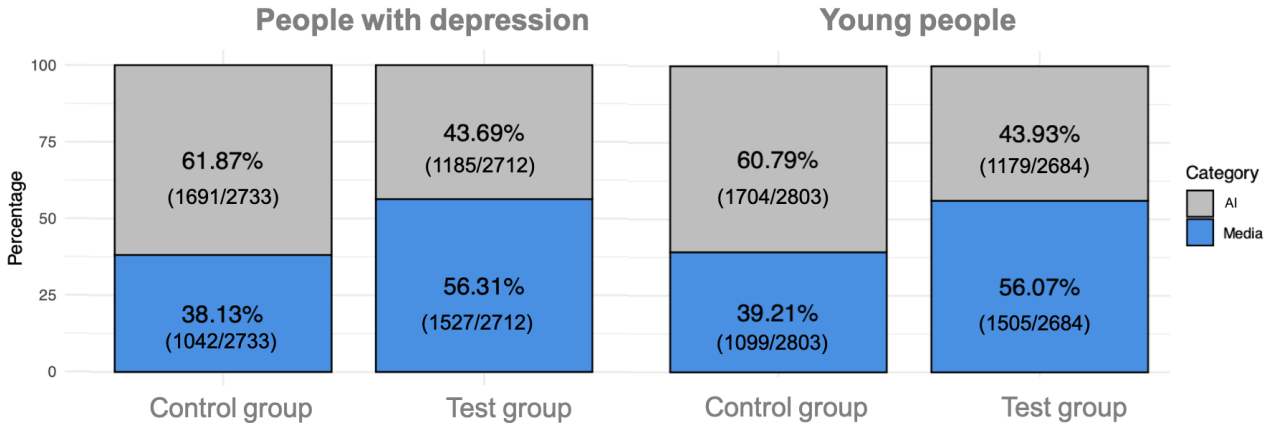
XSL•FO
RenderX

Figure 2. Violin plot for the question "Which images represent depression more realistically?" The Y axis represents the amount of images selected, from 1 to 5. The median for each column is marked with a thicker black line. We can observe how, out of the 5 possible options to select, women had a median of 2 artificial intelligence (AI) images (widest curve of the first column), as opposed to a median of 3 media images (widest curve of the second column). Differences among men were not statistically significant.

Regarding age groups, no significant differences were found in their preference for media or AI-generated images when asked about what images were more realistic (χ^2_5=6.439; *P*=.27; V=0.03) and appropriate (χ^2_5=7.4996; *P*=.19; V=0.04) to represent depression. However, when asked about which images better represented the relationship between gender and depression, 25- to 29-year-olds and 40- to 50-year-olds showed significant differences in selecting media images more frequently (χ^2_1=13.211; *P*<.001; ϕ=.11 and χ^2_1=28.9; *P*<.001; ϕ=.08, respectively). Likewise, when asked about which images were more inclusive, significant differences were found among 35- to 39-year-olds, who chose media images more frequently (χ^2_1=13.111; *P*=.002; ϕ=.17).

The same tests were conducted for young people. In terms of sex, statistically significant differences were observed when asked which were more appropriate to represent depression, with women choosing media images more frequently (χ^2_1=15.085; *P*<.001; ϕ=.09). There were also significant differences when asked about which images were more realistic; in this case, both men and women preferred media images, but women chose media images at a much higher rate (χ^2_1=152.4932; *P*<.001; ϕ=.13) than men did (χ^2_1=4.5533; *P*=.03; ϕ=.04).

Responses to Negatively Framed Questions



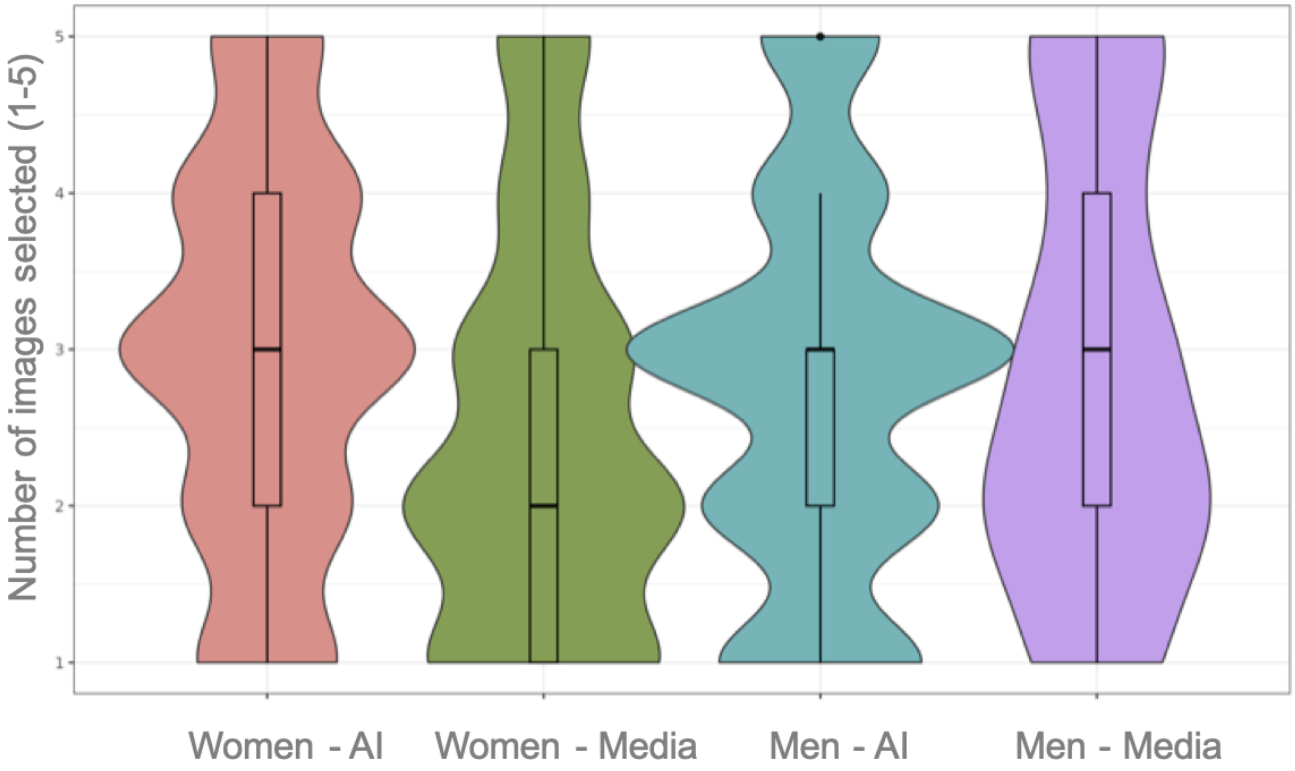
The questions that were framed negatively asked which images were considered more stereotyping, which images reproduced marginalization or social exclusion stigmas, and which images could affect people with depression more negatively.

A nonparametric Pearson chi-square test was used to examine differences between the test and control groups among people with depression. There were statistically significant differences between the 2 groups (*P*<.001): while the test group chose media images more frequently (1527/2712, 56.31% chose media; 1185/2712, 43.69% chose AI), the control group prioritized AI-generated images (1042/2733, 38.13% chose media; 1691/2733, 61.87% chose AI). Although these results follow the same pattern as those observed in positively framed questions, here the test group selected AI-generated images at a higher ratio.

A similar trend was observed among young people's responses. There were statistically significant differences between the test and control groups (*P*<.001)—while the test group selected media images more frequently (1505/2684, 56.07% chose media; 1179/2684, 43.93% chose AI), the control group preferred AI-generated images (1099/2803, 39.21% chose media; 1704/2803, 60.79% chose AI; Figure 3).

XSL•FO
RenderX

Figure 3. Distribution of answers for negatively framed questions regarding media or artificial intelligence (AI)–generated images, segregated by group among people with depression and young people.



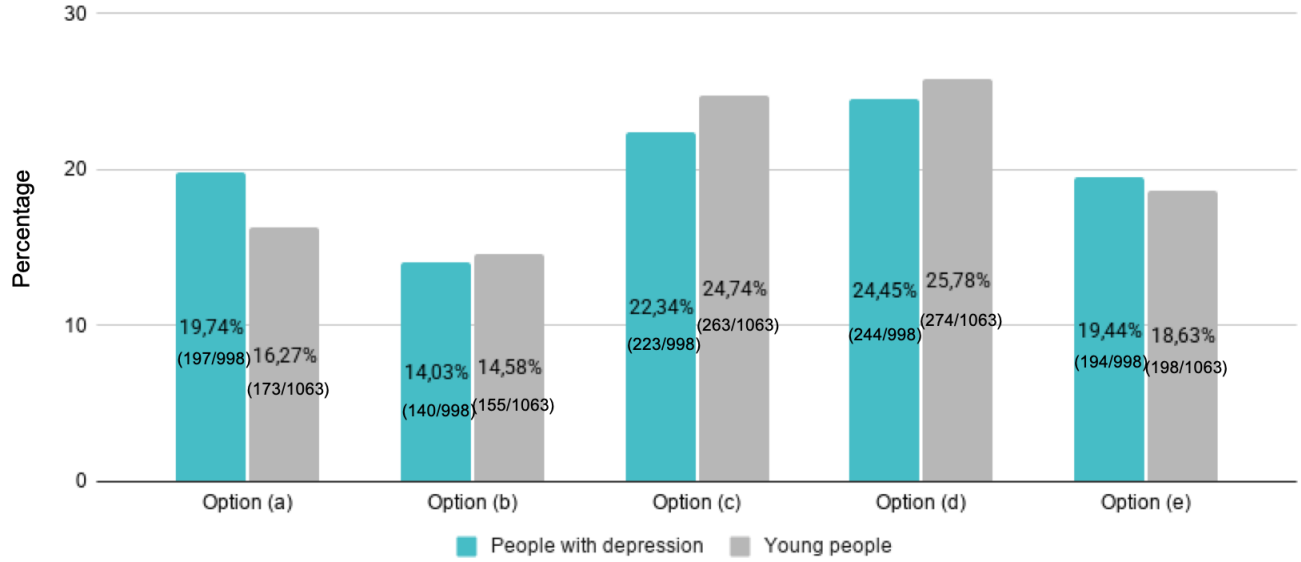
The top 3 images selected for negatively framed questions among people with depression were all from the media among the test group, whereas the control group selected only AI-generated images in the top 3 positions. Among young people, the top 3 images for negatively framed questions followed a similar pattern: all the top 3 images among the test group were from the media, while 2 out of the top 3 images of the control group were AI-generated. Among people with depression, the test group selected in the first place a media image of a woman sitting down, with her elbows to her knees, holding her head with her hands, looking down. The control group selected an AI-generated image of a young man sitting in the street, holding his knees with his arms, facing down. Among young people, the test group selected in the first place a media image of a back-lit silhouetted woman taking a pill. This control group chose the same image as the control group of people with depression. Images are available as Multimedia Appendices 2 and 3.

Responses to negatively framed questions from people with depression were crossed with their demographic data. No significant differences were found on the basis of sex regarding which images were more stereotyped (χ^2_1=0.02806; *P*=.87; ϕ=0), reproduced more stigmas (χ^2_1=0.59149; *P*=.44; ϕ=0) or were more likely to have a negative impact on people with depression (χ^2_1=0.51907; *P*=.47; ϕ=0). Likewise, no significant differences were found on the basis of age for those same questions (χ^2_5=2.8295, *P*=.73, V=0; χ^2_5=10.114, *P*=.07, V=0.05; and χ^2_5=8.6723, *P*=.12, V=0.05; respectively).

The same analysis was conducted for young people's responses. Significant differences were found between sexes (χ^2_1=9.6555; *P*=.002; ϕ=.07), with women choosing AI images more frequently when asked which images were more stereotyped (χ^2_1=18.2141; *P*<.001; ϕ=.04; Figure 4).

XSL•FO
RenderX

Figure 4. Violin plot for the question "Which images are more stereotyped?" The Y axis represents the amount of images selected, from 1 to 5. The median for each column is marked with a thicker black line. We can observe how, out of the 5 possible options to select, women had a median of 3 artificial intelligence (AI) images (widest curve of the first column), as opposed to a median of 2 media images (widest curve of the second column). Differences among men were not statistically significant.



How Do People With Depression Recommend Better Illustrating Depression, and How Do These Recommendations Compare to Those by Young People?

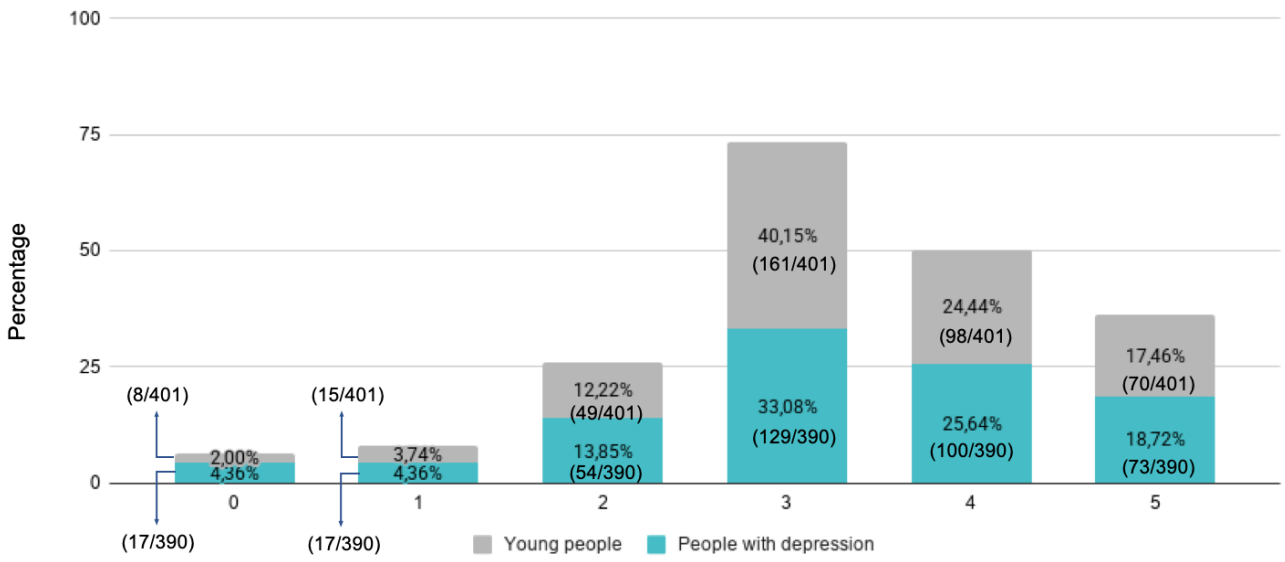
Respondents were asked to select their preferred sentences to help improve the way depression was depicted and were given the following five options: (a) show people with depression who are going about their life, spending time with family, friends, at work, having fun, at an everyday activity, and forth; (b) show more diversity of people in the images (different skin color, gender, age, functional diversity, types of bodies, etc); (c) show that help is available and that there are options for therapy, support, and accompaniment; (d) consider that depression has many degrees and that a single image cannot illustrate all it represents; and (e) consult with mental health specialists when choosing images.

Both people with depression and young people selected option (4) in the first place, "consider that depression has many degrees and that a single image cannot illustrate all it represents" (people with depression: 244/998, 24.45%; young people: 274/1063, 25.78%). In second place, both groups also agreed with option (3), "show that help is available and that there are options for therapy, support, and accompaniment" (people with depression: 223/998, 22.34%; young people: 263/1063, 24.74%). In third place, people with depression chose option (1), "show people with depression who are going about their life, spending time with family, friends, at work, having fun, at an everyday activity, and so forth" (197/998, 19.74%), while young people chose option (5), "consult with mental health specialists when choosing images" (198/1063, 18.63%; Figure 5).

XSL•FO
RenderX

Figure 5. Double bar chart with respondents' opinions (options a to e) regarding recommendations. Options: (a) show people with depression who are going about their life, spending time with family, friends, at work, having fun, at an everyday activity, and so forth; (b) show more diversity of people in the images (different skin color, gender, age, functional diversity, types of bodies, etc); (c) show that help is available and that there are options for therapy, support, and accompaniment; (d) consider that depression has many degrees and that a single image cannot illustrate all it represents; and (e) consult with mental health specialists when choosing images.

Among people with depression, there were no statistically significant differences between the test and control groups ((a) odds ratio [OR]=0.96, 95% CI 0.62-1.47; *P*=.84; (b) OR=0.89, 95% CI 0.58-1.38; *P*=.62; (c) OR=1.27, 95% CI 0.82-1.98; *P*=.29; (d) OR=1.01, 95% CI 0.64-1.58; *P*=.98; (e) OR=0.69, 95% CI 0.45-1.05; *P*=.08), nor when segregated by sex ((a) OR=1.22, 95% CI 0.76-1.99; *P*=.41; (b) OR=1.40, 95% CI 0.86-2.30; *P*=.17; (c) OR=1.29, 95% CI 0.79-2.08; *P*=.31; (d) OR=1.15, 95% CI 0.69-1.89; *P*=.59; (e) OR=0.74, 95% CI 0.46-1.19; *P*=.22). However, differences were observed among age groups for option (a), with 40- to 50-year-olds (OR=2.44, 95% CI 1.21-4.90; *P*=.004) and 25- to 29-year-olds (OR=3.73, 95% CI 1.18-11.78; *P*=.01) being more likely to select this option than people older than 51 years. Among young people, there were no statistically significant differences between the test and control groups ((a) OR=0.96, 95% CI 0.62-1.47; *P*=.84; (b) OR=0.89, 95% CI 0.58-1.38; *P*=.62; (c) OR=1.27, 95% CI 0.82-1.98; *P*=.29; (d) OR=1.01, 95% CI 0.64-1.58; *P*=.98; (e) OR=0.69, 95% CI 0.45-1.05; *P*=.08). However, there were significant differences between sexes, with female respondents choosing more frequently than male respondents options (b) (OR=2.14, 95% CI 1.19-3.98; *P*=.01) and (c) (OR=1.79, 95% CI 1.06-3.02; *P*=.03).



How Do People With Depression, as Well as Young People, Receive Recommendations From Mental Health Associations Regarding How to Illustrate Depression?

Respondents were offered a scale from 0 to 5 to indicate the appropriateness of the images recommended by mental health associations (0="images are very inadequate to represent depression" and 5="images are very adequate to represent depression").

Among people with depression, 44.36% (173/390) responded with ratings between 4 and 5. The most common single rating was 3 (129/390, 33.08%). The average (mean) was 3.27 (SD 1.28), and the median and mode were 3 (IQR 3-4). Young people responded in a very similar pattern: 41.90% (168/401) selected ratings between 4 and 5. The most common single rating was also 3 (161/401, 40.15%). The average (mean) was slightly higher than among people with depression, with 3.34 (SD 1.13), and the median and mode were also 3 (Figure 6).

XSL•FO
RenderX

Figure 6. Stacked bar chart with responses (scale 0 - 5) with respondents' opinions regarding the appropriateness of images recommended by mental health associations.

There were no significant differences among people with depression depending on group (median test group 4, IQR 4-5 vs median control group 4, IQR 4-5; W=19134; *P*=.91), sex (median males 4, IQR 3-5 vs median females 4, IQR 4-5; W=14224; *P*=.19) or region (χ^2_{15}=18.936; *P*=.22). Likewise, for young people, no differences were found depending on group (median test group 4, IQR 4-5 vs median control group 4, IQR 4-5; W=20726.5; *P*=.57), sex (median males 4, IQR 4-5 vs median females 4, IQR 4-5; W=11397; *P*=.08) or region (χ^2_{16}=7.731; *P*=.96). These results were validated with the Mann-Whitney U test and the Kruskal-Wallis test. Although all age groups consider these recommendations positively, people with depression between the ages of 35 to 39 years do so the most.

Discussion

Principal Findings

This study analyzed media and AI-generated images representing depression and complemented that with an exploration of the perceptions of people with depression and young people regarding those images. This study also analyzed how recommendations from mental health associations regarding how depression should be illustrated are perceived by people with depression and young people. This research offers valuable insights into the quality and appropriateness of media and AI-generated images, indicating overt preferences among respondents. The integration of a quasi-experimental survey, including test and control groups, ensures the robustness of the results.

The first research question we set ourselves to address was "How is the representation of depression in media and AI-generated images perceived?" The results indicate that the representation of depression is perceived more negatively in images generated by AI than in images from the media. That is, AI-generated images are perceived as more stereotyping, that they reproduce stigmas of marginalization or social exclusion, and that they affect people with depression more negatively. In contrast, compared with AI-generated images, media images are perceived to be more appropriate, realistic, inclusive, and to better represent the relationship between gender and depression.

However, it must be noted that both media and AI-generated images reproduce stereotypes and stigma about depression. Most media and AI images include characteristics that associations suggest avoiding, such as depicting people alone; without social interactions; staring into space; lying on the floor; covering their faces; or in long, dark hallways [45].

The second research question was "How do the opinions of people with depression differ from the opinions of young people regarding the depiction of depression in media and AI-generated images?" In short, their answers follow a similar pattern in most questions. Let us take a deeper look into each of the groups.

According to the survey results, people with depression tend to favor media images over AI-generated images. This trend is observed particularly strongly in questions that are framed positively (in this case, asking which images are considered more appropriate, realistic, inclusive, and better represent the relationship between gender and depression). People with depression from the test group (ie, those who know which images are from the media and which are AI-generated) clearly prioritize media images over AI-generated ones in positively framed questions. In other words, people from the control group (ie, those who do not know which images are from the media and which are AI-generated) select AI-generated images at a higher ratio than those in the test group. Compared with young people's responses, the same trend is observed: young people from the test group also prioritize media images, or avoid AI-generated images, in positively framed questions, while the difference is less pronounced in the control group. This supports

XSL•FO
RenderX

the idea that when people know which images are AI-generated, they tend to reject them, indicating a negative preconception about AI. This finding coincides with previous research observing a prejudice against AI-generated products [41,42]. However, another interpretation could be that test group participants could identify the more stereotypical images because they had been told in advance which ones were AI-generated.

There are also negatively framed questions, asking which images are considered more stereotyping, reproduce marginalization or social exclusion stigmas, or can affect people with depression more negatively. For these types of questions, people with depression from the test group choose media images more frequently than AI-generated ones, while people from the control group prioritize AI-generated images over media ones. This pattern is the same among young people, who also tend to select a higher ratio of AI-generated images when they cannot distinguish them from the media ones. Interestingly, the differences between the test and control groups do not seem to be influenced by demographic variables, such as sex, age, or region.

It is relevant to note how the framing of a question affects its responses, coinciding with previous literature indicating that audiences' reactions depend on the framing of images [17]. In this study, the results obtained from positively and negatively framed questions followed the same pattern: the test groups always prioritized media images, while the control group favored AI-generated images more frequently. However, in negatively framed questions, control groups select AI-generated images at a higher ratio than test groups do. This could indicate that when people know which images are generated by AI, they tend to associate them more strongly with negative concepts, such as stereotypes or stigma. This interpretation aligns with previous research, as mentioned before, observing a prejudice against AI-generated products [41,42].

The third research question of the study was as follows: "How do people with depression recommend better illustrating depression, and how do these recommendations compare to those by young people?" This question is particularly relevant if we consider that nowadays, AI-generated images do not depict mental health conditions accurately [30,31]; thus, the need for recommendations becomes clear. The survey results indicate that people with depression and young people share similar opinions regarding the proposed recommendations, as they both select the same options in first and second place ("consider that depression has many degrees and that a single image cannot illustrate all it represents," followed by "show that help is available and that there are options for therapy, support, and accompaniment"). For these recommendations, no statistically significant differences are observed among people with depression, either by test and control groups or when segregated by demographic variables.

Among young people, no statistically significant differences are observed between test and control groups; however, when segregated by sex, women choose the second recommendation ("show that help is available and that there are options for therapy, support, and accompaniment") more frequently than men do. This result is supported by the literature showing that men are less inclined than women to seek help for mental health issues [48,49].

The fourth and final research question to address was as follows: "How do people with depression, as well as young people, receive recommendations from mental health associations regarding how to illustrate depression?" Both respondent groups perceive these recommendations positively: from a scale of 0‐5 asking about the appropriateness of the images recommended, the average among people with depression is 3.27 (SD 1.28), which is slightly lower than the 3.34 (SD 1.13) among young people. These results indicate that both people with depression and young people approve of the recommendations provided by mental health associations. This positive result can be interpreted as validation of the recommendations.

The observed gender- and age-related differences in attitudes toward technology use can be interpreted through established theoretical frameworks, such as the TAM. The TAM proposes that perceived usefulness and perceived ease of use shape behavioral intentions, and these perceptions may vary across demographic groups due to differences in prior technological experience [39,40]. This model provides a theoretical basis for understanding why demographic characteristics can lead to systematic differences in technology acceptance, as observed in this study.

In conclusion, there is currently a clear trend toward the widespread use of AI in journalism [50], as well as in science communication [51]. It is not difficult to imagine a future in which AI-generated images will start to appear in the media, in the same way as stock images do today. In this scenario, it is of utmost importance to consider social perceptions and opinions, particularly those of the groups most affected by the use of the new technology. Moreover, and particularly because negative media representations of mental health lead to mental health stigma [14-16], the findings of our study underscore the need for closer collaboration among journalists, AI developers, mental health experts, and patient associations, as well as a shift toward user-participatory AI design. With this study, we aimed to contribute to these considerations by highlighting social perceptions regarding the use of AI tools in the media and providing enough data to guide a more responsible way forward for the benefit of all.

Limitations

Despite the insights offered by this study, some limitations warrant consideration. First, we base our results on a selection of 30 images. Although it is clear that a limit to the number of images is needed to conduct the study, this same limit means that opinions and perceptions are inextricably linked to the images selected. It is possible that a different pool of images could produce dissimilar outcomes.

Second, the authors note that both AI technology and the ethical protocols that guide it evolve rapidly [52], as do people's sentiments about it [53]. This could mean that, in a few years, AI-generated images could reproduce fewer stereotypes, or that people's perceptions of AI-generated images have shifted toward a more positive outlook. With this in mind, this study would

XSL•FO
RenderX

benefit from being repeated over time to monitor whether its results are sustained over time.

Third, the qualitative sample of the discussion groups is not gender-balanced (13 women, 2 men). Since the qualitative phase informed the quantitative one, the authors acknowledge that this gender imbalance may have biased the development of the survey questions.

Fourth, the authors note that the predominantly Spanish cultural context of the study may limit the transferability of results to other cultural environments, where different social norms and practices may be at play.

Fifth, there is a potential confound with study populations. The group "Young people" did not include individuals with depression; however, the group "People with depression" was not restricted by age and therefore also included young people. This constitutes a potential confound of the study populations.

Finally, a methodological limitation of the study is the use of a simplified prompt ("depression") to generate the AI images. This single-word prompt could have increased the probability that generative models defaulted to widely learned, stereotypical visual representations of depression present in their training data. Therefore, the observed tendency for AI-generated images to appear "more stereotypical" could actually be a reflection of the prompting strategy rather than an inherent shortcoming of the generative systems themselves.

Conclusions

Academic literature had reported the impact of AI on mental health communication, but the effectiveness, limitations, and ethical issues of using AI in the communication of mental health, particularly depression, were yet to be studied. Combining qualitative and quantitative approaches, our study offers novel insights into how people with depression and young people perceive the use of AI to generate images of depression. The results show that although both media and AI-generated images are considered to reproduce stereotypes about depression, respondents tend to reject AI-generated images, indicating a certain bias against AI-produced pictures. These results hold substantial implications in the current drift toward the widespread use of AI in mental health communication, highlighting the need to build bridges among science journalists, AI developers, mental health experts, and patient associations.

Acknowledgments

We would like to acknowledge Gerard Romero for his technical assistance with statistical analysis.

As disclosed in the Methods sections, the images generated by artificial intelligence used for this study were obtained from 4 different artificial intelligence tools: Deep Dream Generator, DeepAI, OpenAI, and Dream Studio.

Abstract

Background: More than 20% of perinatal women experience depression, with suicide being a leading cause of maternal death in the United States. Professional societies emphasize the need to identify those at risk of developing perinatal depression to better target preventive care delivery during pregnancy.

Objective: We evaluated receptivity to a machine learning–based predictive screener designed to identify women in the first trimester of pregnancy who were asymptomatic but were at risk for developing moderate to severe depression symptoms later in pregnancy.

Methods: Our participants were adult pregnant women with negative first-trimester depression (Patient Health Questionnaire–9) screens at 1 of 4 obstetric practices. Of the 810 women who were clinically eligible, 787 were successfully contacted via their patient portal. Of these, 289 (36.7%) viewed the screener and 255 (88.2%) completed the 6-question predictive screener. In total, 51 (20%) were identified by the screener as being at risk for developing perinatal depression. Participants were asked a series of follow-up questions regarding the acceptability of the predictive screener and desired preventive resources. Chi-square tests were used to compare demographic characteristics, perceived benefits and concerns, and desired resources between those identified as at risk for depression and those who were not. Differences in acceptability ratings between the two risk groups were determined using nonparametric Mann-Whitney *U* tests.

Results: On a 5-point Likert scale of agreement, participants found the screener questions easy to complete (median score 5, IQR 5-5) and felt comfortable sharing their answers with their obstetric care providers (median 5, IQR 4-5). Key perceived benefits of completing the screener included opportunities to seek preventive care (75/255, 29.4%) and to receive education on depression risk (66/255, 25.9%). Primary concerns about knowing one's risk of future depression included worrying about developing depression (90/255, 35.3%) and a lack of prevention opportunities (39/255, 15.3%). Desired preventive resources included counseling (197/255, 77.3%), mind-body interventions (166/255, 65.1%) such as exercise, and prenatal classes or support groups (81/255, 31.8%).

Conclusions: Participants found the screener acceptable and felt comfortable receiving it through their patient portal. Specific preventive care options were commonly endorsed, several of which are scalable and evidence based. A minority of participants voiced addressable concerns about knowing their risk of developing depression in the future.

prediction algorithm; machine learning; preventive care; predictive screening; patient-centered care; depression; pregnancy; postpartum; mental health

Introduction

More than 20% of US mothers experience depression during pregnancy and the postpartum period, which is consistent with global rates [1,2]. Untreated depression can contribute to long-term health problems [3-5], including cognitive and emotional challenges for children and unhealthy maternal behaviors, such as alcohol or drug use, insufficient physical

XSL•FO
RenderX

activity, and poor diet [6,7]. Furthermore, 1 in 5 women with perinatal depression expresses thoughts of self-harm, with suicide being a leading cause of maternal death [8]. While 40% to 50% of women with perinatal depression have a history of depression, the remainder experience depression onset for the first time during their pregnancy or in the early postpartum period [9,10]. Currently, the United States Preventive Services Task Force recommends early identification of perinatal women at risk of developing depression to facilitate preventive rather than reactive care [11-13]. However, implementing this recommendation requires accurate identification of risk prior to depression onset. This identification is particularly challenging for those without a history of depression, who may not recognize and self-report the onset of early symptoms.

There are documented factors associated with perinatal depression, including pregnancy-related stressors (eg, financial instability, fear of the birth experience, and body image concerns); psychosocial stressors (eg, lack of social support, adverse life events, history of anxiety, and food insecurity); physical health conditions (eg, gestational diabetes and hypertension); and race or ethnicity (eg, Black and Latinx individuals). Nevertheless, little is known about which combination of factors most accurately predicts future risk of developing perinatal depression. Moreover, current perinatal depression screening tools administered during prenatal care are designed to quantify active depression symptoms and do not identify risk factors for future depressive episodes [14,15].

In response to this gap, we developed an interpretable machine learning–based predictive screener that can be administered directly to patients in the first trimester to identify those at risk of developing depression for the first time during pregnancy [16,17]. This 6-question predictive screener was designed to identify individuals who will develop new-onset depression among those who are currently asymptomatic and have no history of depression. The screener was co-designed with clinicians and people with lived experience through an iterative process, including focus groups with providers (eg, obstetricians, family medicine physicians, and behavioral health professionals) and virtual community engagement studios with pregnant and postpartum women, the details of which are described in a prior publication [14]. The predictive screener was shown to have a high degree of accuracy (area under the receiver operating characteristic curve=0.93), sensitivity (0.90), and specificity (0.81) [17]. However, the ultimate usefulness of this risk screening tool will be in its adoption into clinical workflow and its acceptability to the patients completing it. To fully close the loop, successful implementation also requires the provision of preventive care in response to a positive screener score.

A review encompassing 19 systematic reviews and meta-analyses and 152 randomized controlled trials across 26 countries identified therapy-based or physical activity interventions as having a small to moderate effect on the severity of perinatal depression symptoms [18]. Interpersonal and cognitive behavioral therapy are similarly effective for perinatal depression prevention [19-22]. Earlier therapeutic intervention can more effectively address perinatal mental health risk. With developments in predictive screening, there is an opportunity to tailor preventive care to address immediate, pressing risk factors (eg, food insecurity, labor and delivery fears, or lack of social support), while also developing strategies for long-term resilience to manage new and ongoing stressors. However, to date, patient-preferred preventive care options for those at risk of developing perinatal depression have not been documented.

The majority of women receiving prenatal care in our clinical setting access their health care information through a patient portal. As such, deployment of prenatal risk screeners through the patient portal is our standard workflow and is increasingly common in obstetric practices nationally [23-26]. Here, we examined the feasibility of deploying our predictive depression screener through our digital patient portal, as well as patients' receptivity to completing it. To do this, we deployed the screener to women receiving first-trimester prenatal care in our health care system, followed by a survey on their experience with completing it. We also solicited their preferences for preventive care resources.

Methods

Study Design and Setting

Participants were women (aged ≥18 years) receiving prenatal care from 1 of 4 University of Pittsburgh Medical Center obstetric practices. Electronic health records in the participating practices were screened for study eligibility on a weekly basis between October 2024 and January 2025. Eligibility criteria included being in the first trimester of pregnancy and screening negative for active first-trimester depressive symptoms using the Patient Health Questionnaire–9 [15].

Eligible pregnant women were sent an invitation via their patient portal to complete the 6-question predictive screener and subsequent survey questions related to the screener. The invitation contained a unique survey link that expired at the end of the first trimester. Upon accepting the link and completing informed consent, a pregnant woman was considered a study participant. Participants were not provided with a risk score. This allowed for independent validation of the screener in this population through passive observation of depressive symptoms and diagnoses over the course of the pregnancy. However, mental health and other pregnancy resources were provided to all participants, regardless of risk, to reflect best clinical practice.

Measures

Feasibility of screening was assessed by measuring (1) the proportion of pregnant women eligible from the larger clinical population (*eligibility rate*), (2) the number of eligible individuals who engaged with the screener study invitation (*reach*), and (3) the number of completed surveys among those who accessed the survey (*completion rate*).

Acceptability was assessed with a series of Likert-scale questions (1=strongly disagree to 5=strongly agree), which included participant evaluations of screener question clarity ("The screener questions were clear"), ease of completion ("The screener was easy to complete"), and comfort with and honesty in disclosing responses ("I would be comfortable sharing my answers with my provider" and "I would have no concerns about answering the questions honestly," respectively).

XSL•FO
RenderX

Participants were asked about the usefulness of the screener as part of routine prenatal care, including the benefits of knowing the results of the screener ("What would be the *benefit(s) to you personally* of knowing you are likely to develop depression at some point during your pregnancy?"), their preferred method of receiving screener results ("If you completed a screener like this as part of your prenatal care, *how* would you prefer to receive your results?"), perceived helpfulness of knowing depression risk ("How *helpful* would it be to know whether you are likely to develop depression at some point during your pregnancy?"), and any concerns they might have if they were to learn that they were likely to develop depression at some point during their pregnancy ("What *concern(s) would you personally have* about knowing you are likely to develop depression at some point during your pregnancy?"). Participants were also asked to endorse from a prespecified list and/or offer open-ended options for desired preventive care resources ("If you learned you were likely to develop depression at some point in your pregnancy, which of the following resources would you be *most likely to use* if available to you at *low or no-cost*?") and offer any additional thoughts or comments they have about the survey or depression prevention ("We welcome any other thoughts you have about your participation in this survey or preventing depression in pregnancy."). Deployment feasibility and acceptability of the screener were the primary outcomes of this study. Secondary analyses examined differences in attitudes between high- and low-risk pregnant women.

Statistical Analysis

Descriptive analyses used means and SDs for continuous variables (eg, maternal age), medians and IQRs for ordinal variables (eg, Likert-scale responses), and distributions for categorical variables. The study sample was stratified by screener score into those with and without risk of developing moderate to severe depression symptoms. Differences in survey responses by risk category were assessed using chi-square tests for categorical and binary responses. The distributions of continuous and Likert-scale responses were assessed for normality using the D'Agostino-Pearson test. Differences between normally distributed responses were evaluated using 2-sample 2-tailed *t* tests, and nonnormally distributed responses were evaluated using Mann-Whitney *U* tests. Effect size was calculated using Cliff *d*, a robust nonparametric method appropriate for ordinal data such as Likert-scale data [27]. An α level of .05 was used for statistical significance. All respondents completed every survey item, resulting in no missing data. Analyses were performed using Python (version 3.12.4).

Rapid inductive thematic coding was applied to open-ended survey responses by 2 coders, each with qualitative coding experience and one with formal training in rapid qualitative analysis. After reading all open-ended survey responses, the coders cocreated a codebook. Responses were then independently coded. Once independent coding was complete, codes were compared, and discrepancies were discussed until consensus (ie, consistent classification) was reached.

Ethical Considerations

All study procedures were approved by the University of Pittsburgh Institutional Review Board (STUDY24020098) and are reported according to the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines for reporting observational studies [28]. We conducted pretests of the survey with pregnant or recently pregnant colleagues, gathering feedback on the design and clarity of the instructions and survey questions. Participants provided digital consent for study participation and were informed that they could withdraw their consent at any time. They received a US $20 gift card for completing the screener and follow-up survey, which took approximately 10 minutes. All participant data were stored in a confidential and secure manner and access was restricted to authorized members of the research team.

Results

Survey Participants: Reach and Risk

During the study period, 1925 women received prenatal care at one of the participating obstetric practices. Of these 1925 women, 810 (42.1%) had an active patient portal, were at a gestational age of <14 weeks, and had scored <5 on the Patient Health Questionnaire–9 measure of active depression symptoms (*eligibility rate*). Of the 810 sent an invitation through their patient portal, only 2.8% (n=23) did not access it. In total, 36.7% (289/787) who accessed the invitation opened the study link (*reach*) and, of those, 88.2% (255/289) completed it (*completion rate*).

All participants were female with a mean age of 32 (SD 4.5) years. Most were White (217/255, 85.1%) and non-Hispanic (232/255, 91%), married (196/255, 76.9%), and had commercial insurance (196/255, 76.9%). Full demographic information is available in Table 1. Participants were demographically representative of the larger eligible population.

Self-pay or other	15 (5.9)

[a]These thresholds are calculated using income and household size and are based on 215% of the federal poverty line in 2024, which is a standard threshold for receipt of federal or state assistance programs.

[b]Uncertain poverty line labels are for participants whose selected income bracket and household size contain the poverty line value for the given household size.

[c]Race options are not mutually exclusive; therefore, totals exceed 100%.

On the basis of established cutoff scores [17], 80% (204/255) of participants were identified by the predictive screener as having no or minimal depression risk and 20% (51/255) were identified as at risk of developing moderate to severe depression at a later stage of pregnancy.

Acceptability

The predictive screener demonstrated high acceptability among participants. Most agreed or strongly agreed (236/255, 92.5%) that the screener questions were clear (median 5, IQR 4-5), and 97.3% (248/255) reported that the questions were easy to complete (median 5, IQR 5-5). Most (236/255, 92.5%) agreed or strongly agreed that they would feel comfortable sharing the results of the screener with their obstetric care team providers (median 5, IQR 4-5). Similarly, the majority (247/255, 96.9%) agreed or strongly agreed that they would have no concerns about answering the questions honestly (median 5, IQR 5-5).

Table 2 presents acceptability metrics stratified by depression risk category, with those at risk of developing moderate-to-severe depression symptoms being less likely to endorse strong agreement with comfort and ease of honesty in responding to the screener.

Table . Median (IQR) responses to acceptability questions rated on a 5-point Likert scale.

Acceptability statements	No or minimal depression risk[a], median (IQR)	Moderate to severe depression risk[b], median (IQR)	Mann-Whitney *U* statistic	Effect size (Cohen *d*)	*P* value
The screener questions were clear.	5 (4-5)	5 (4-5)	4413.5	−0.15	.04
The screener was easy to complete.	5 (5-5)	5 (4-5)	4337.5	−0.17	.07
I would be comfortable sharing my answers with my provider.	5 (4-5)	4 (4-5)	3939.0	−0.24	.01
I would have no concerns about answering the questions honestly.	5 (5-5)	5 (4-5)	4218.5	−0.19	.04

[a]No or minimal depression risk: n=204.

[b]Moderate to severe depression risk: n=51.

Perspectives on Receiving Depression Screening Scores

Overall, 80% (204/255) reported that the screener was helpful or extremely helpful (median 4, IQR 4-5). Participants largely voiced a preference for receiving screener results through the patient portal (150/255, 58.8%), compared to receiving results in person (76/255, 29.8%) or by phone (13/255, 5.1%). Perspectives did not differ by depression risk.

Perceived Benefits and Risks of Depression Risk Screening

When asked about potential benefits of receiving their depression risk screening score, participants most frequently cited seeking appropriate preventive resources and/or treatments (63/204, 30.9%) and the opportunity to receive education from their obstetric health provider (53/204, 26%). One survey participant wrote that the feedback could help them "reduce risk factors associated with postpartum depression and postpartum psychosis."

Despite generally positive attitudes toward score disclosure, participants also expressed concerns. The most frequently reported concerns included increased anxiety or worry about developing depression (71/204, 34.8%) and worry about the inability to prevent depression (34/204, 16.7%). Several open-ended responses were offered, including concern about parenting ability and emotional connection to children if depression were to occur, premature medication use, and false positives.

Participants at risk of developing moderate to severe depression were significantly more likely than those with no or minimal depression risk to endorse the concern "fear that your health care provider will view you negatively" (5.9% vs 0.5%; *P*=.03). However, at-risk participants were also more likely to cite the ability to identify factors that might be affecting their mood as

XSL•FO
RenderX

a benefit (17.6% vs 5.9%; *P*=.01). Table 3 presents the complete breakdown of perceived benefits and risks.

Table . Breakdown of perceived benefits and risks, stratified by depression risk.

Benefits or concerns	Participants with no depression risk[a], n (%)	Participants with depression risk[b], n (%)	*P* value[c]
Benefits			
Allows you to seek appropriate preventive resources (ie, community resources and/or preventive treatments)	63 (30.9)[d]	12 (23.5)	.39
Provides an opportunity to receive education on pregnancy and postpartum depression, symptoms, and/or warning signs from your health care provider	53 (26.0)	13 (25.5)	.99
Provides information to discuss with your support system (eg, partner, friends, and family) about your needs	29 (14.2)	8 (15.7)	.96
Offers insight into why you might be feeling a certain way	26 (12.7)	4 (7.8)	.47
Helps you identify factors that might be affecting your mood	12 (5.9)	9 (17.6)	*.01*[e]
Gives you and your health care provider an opportunity to discuss depression risk	15 (7.4)	4 (7.8)	.99
Another benefit (open-ended)	1 (0.5)	0 (0.0)	.99
Concerns			
Increased anxiety and/or worry about developing depression	71 (34.8)	19 (37.3)	.87
Worry about your ability to prevent depression	34 (16.7)	5 (9.8)	.32
Fear that the results will be reported to child protective services	10 (4.9)	7 (13.7)	.052
Fear that others (eg, partner, friends, and family) will view you negatively	8 (3.9)	5 (9.8)	.18
Inability to access the right preventive resources	10 (4.9)	3 (5.9)	.99
Concern that your health care provider will doubt your parenting abilities	8 (3.9)	1 (2.0)	.80
Fear that your health care provider will view you negatively	1 (0.5)	3 (5.9)	*.03*
Concern that your provider will not know the appropriate education or resources to offer you	1 (0.5)	2 (3.9)	.19
Another concern (open-ended)	6 (2.9)	1 (2.0)	.99

[a]Participants with no depression risk: n=204.

[b]Participants with depression risk: n=51.

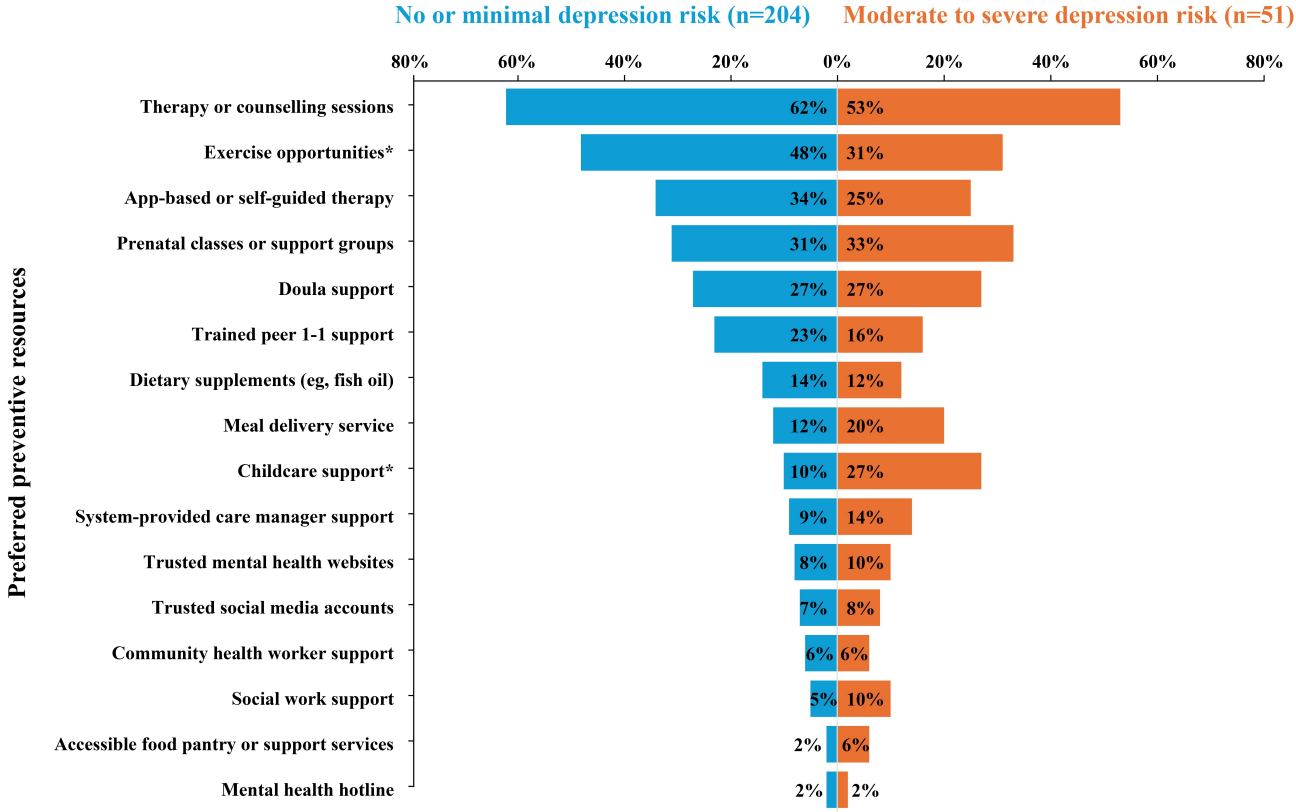
[c]*P* values are determined using the chi-square test to compare perceived benefits and concerns between those with and without first-time onset depression in our sample.

[d]Perceived benefits and concerns are not mutually exclusive; therefore, totals exceed 100% of participants.

[e]Italicized p-values indicate a statistically significant difference between those with no depression risk and those with depression risk.

Desired Preventive Care Resources

When asked about desired preventive health resources, participants endorsed multiple options. Preferred resources included counseling (197/255, 77.3%), with 61.8% (126/197) endorsing in-person therapy and 41.6% (82/197) endorsing app-based delivery. Mind- or body-based interventions (166/255, 65.1%) were frequently endorsed, with “yoga, exercise classes, or gym membership” (114/166, 68.7%) being a highly desired intervention, followed by prenatal classes or support groups (81/255, 31.8%).



Participants (n=61) shared several resources not otherwise listed in open-ended responses. From most to least frequently listed, these included mental health resources for their spouse or support person (eg, “Education for family/spouses so they can possibly help the individual battling depression”), self-care opportunities (eg, “massage”), practical support such as cleaning services or meal preparation (eg, “A service similar to task rabbit that is geared towards pregnancy needs. Perhaps people that could help identify inexpensive sources of second hand furniture/items, assembly help, specific errand support, meal prep/planning for once baby arrives, etc.”), parental leave,

XSL•FO
RenderX

increased medical touchpoints during pregnancy, additional mental health education (eg, books and fact sheets), medication for depression prevention, structural changes (eg, improved health care access and transportation), access to a live mental health support person ("Mental health support chat forums with a licensed counselor"), a more holistic approach to health care, and additional faith or spiritual support.

Figure 1 shows preferred resources stratified by depression risk. Notably, less than 10% (20/204) of those with no or minimal depression risk expressed interest in childcare support compared to more than 25% (14/51) of those at risk of developing moderate to severe depression (χ^2_1=9.52; n=255; *P*=.002). Although highly endorsed by both risk groups, participants with no or minimal depression risk expressed greater interest in exercise opportunities (χ^2_1=3.94; n=255; *P*=.05).

Figure 1. Preferred resources stratified by depression risk. *Substantial differences in resource desirability.

Open-Ended Feedback

After completing the survey, 55.3% (141/255) of participants shared optional thoughts about screener participation and about preventing depression in pregnancy. The most frequent open-ended comments expressed appreciation for the study or confirmed that participants would find a screener of this kind helpful. Additional responses ranged from suggestions for the screener or resources (eg, "A big area of concern for working moms is their jobs. I felt that the questions did not address the concern as much.") to specific stressors (eg, "I think one of the biggest stressors that can contribute greatly to mood in the first trimester is the viability and health/wellness of the baby, i.e., risk of miscarriage or is there any genetic or chromosomal issue?") and barriers to care ("I feel like cost is one of the biggest barriers to seeking help, just ahead of the stigma that still exists."). One participant reported feeling that a discussion of depression may exacerbate depressive symptoms. Those at risk of developing moderate to severe depression more frequently expressed the need for help and social support during pregnancy, while those with no or minimal depression risk largely highlighted the need for depression- and anxiety-specific resources.

Discussion

Principal Findings

This study demonstrates the acceptability of a machine learning–based predictive screener designed to support perinatal depression prevention. Predictive screening is an emerging field, and, to the best of our knowledge, this is the first study to examine receptivity to a predictive mental health screener, to query pregnant women about their desired preventive care options, and to examine differences in desired resources by predicted risk level. While machine learning algorithms are being newly applied to mental health prediction, their ultimate success depends on adoption into clinical workflow, which requires patient engagement and a feasible implementation process [29]. Here, we highlight an approach to evaluating receptivity to such predictive screeners while testing the feasibility of sending the screener through our health care system's digital patient portal.

In this study, pregnant women who completed the screener largely reported positive screener experiences, with over 90% agreeing that it was clear, easy, and comfortable to respond to and that they had no concerns about responding honestly. More

XSL•FO
RenderX

than 80% thought it would be helpful to know their risk of developing depression symptoms during pregnancy, regardless of their risk score. Those at risk of developing moderate to severe depression were slightly more likely to report feeling uncomfortable sharing their honest responses with an obstetric health care provider, suggesting that the screener questions touch on risk factors that are challenging to disclose. Perceived benefits and risks of the screener were similar between the no- or minimal-risk and at-risk groups, with 2 exceptions: those at risk of developing depression reported greater value in the screener for helping them understand contributors to their mood. They also reported greater fear about being judged by their provider. These anticipated challenges may be grounded in stigma and prior experiences of discrimination [30,31].

Deploying the screener through the patient portal reached a little more than one-third of the eligible pregnant women receiving prenatal care in the participating obstetric practices. This suggests that in-person screening may need to be offered as part of a clinical workflow to deploy the screener effectively to a majority of the patient population. However, among those who initiated the screening survey, engagement was encouraging, with almost 90% of participants completing the entire screening process. Thus, if the eligible patient reach is optimized through multiple outreach channels, the screener could have a high completion rate.

Survey participants identified specific perceived benefits and concerns associated with learning about being at risk of developing depression symptoms. The desire for therapy, whether in person or through an app, is reflective of the current best practices for preventive care, which include cognitive behavioral therapy and interpersonal therapy. Notably, participants also reported a desire for exercise opportunities and support groups, echoing research showing the protective effects of physical activity and social support on depression [18,21,32,33]. Child care was highly desired among the study population at risk of developing moderate to severe depression, suggesting that direct tangible support may impact the trajectory of depression risk. Financial stressors during pregnancy have previously been associated with poor outcomes for both mothers and infants. Findings from recent studies of guaranteed income programs for perinatal women show promising evidence of improvements in maternal mental health and infant developmental outcomes associated with alleviating financial stress [32,34-36].

This study contributes to a burgeoning literature on the importance of providing preventive mental health care during pregnancy and the postpartum period [37]. The perinatal period is uniquely vulnerable to depression due to a combination of hormonal changes, novel stressors (eg, pregnancy-related anxiety), and environmental factors [38]. However, up to half of the cases remain undiagnosed [39]. Although women without a psychiatric history are at lower baseline risk, they are more likely to be overlooked when they do experience depression, with lower rates of both depression screening and referral to care [40]. One solution to address the lack of diagnosis is more frequent, routine depression screening [13]. Care navigators dedicated to monitoring mental health symptoms throughout pregnancy, for example, have been shown to improve depressive symptoms among the patients they serve [41,42]. However, to date, there have been no screening tools available to support those professionals in identifying risk among individuals not actively reporting depressive symptoms [11]. If successfully implemented, predictive screeners could make the work of such care navigators more targeted and efficient.

Limitations

This study has several limitations. Eligible participants were limited to those who could be contacted through an active patient portal. Although most of our prenatal patients have an active patient portal account, it is possible that these portals are not frequently accessed. Other studies suggest that individuals with limited health literacy are less likely to use patient portals to access health information [43-45]. Thus, the moderate response rate may introduce selection bias if individuals more familiar with portal-based screening were more likely to participate, whereas those with lower health literacy were less likely to engage. There were some differences in responses by participant risk level. Although these differences seem intuitive (eg, participants with greater depression risk were more likely to find the screener helpful in identifying influences on mood yet were more concerned about potential stigma from providers), they should be interpreted with caution given the modest sample size of the at-risk group and the number of comparisons conducted. The study sample was generally representative of the patient population of the academic medical system in which it was conducted, and the survey was developed using a patient-centered design approach with a diverse population. However, the results cannot be generalized to other health care systems in the United States or to clinics with more diverse patient populations. While the screener showed high accuracy within the sample on which it was built [17], further work is needed to establish independent external validation. Additional research must address how to best implement this screener within our health care system, including a testing workflow to fully close the loop on preventive care. A future goal would be to conduct validation and acceptability research of the screener in non-US populations.

Conclusions

This study is a first step toward understanding how a machine learning–based prevention-focused predictive depression screener can be integrated into a clinical workflow for preventive care. We found that only one-third of the eligible pregnant women in our clinics completed the screener via their digital patient portal. Ultimately, deploying preventive screening tools will require a hybrid digital and in-person screening approach to comprehensively screen all pregnant women who may be at risk of developing perinatal depression. Our risk screener was designed to identify individuals who may need additional evaluation and care from a trained provider. As such, it is intended as a supplement to current prenatal care, allowing for earlier identification of those at risk rather than serving as a replacement for professional mental health evaluation. Our findings suggest that the screener was acceptable to those who completed it. Moreover, participants voiced clear preferences for certain forms of preventive care in response to learning their risk. Participants' preference for receiving predictive depression

XSL•FO
RenderX

screening results through the patient portal suggests a promising approach to expanding access to mental health assessment among individuals already engaged with digital health platforms. Our findings also suggest some next steps on how to inform the clinical workflow to support a more personalized approach to preventive care in pregnancy, leveraging the most endorsed preventive care resources (eg, counseling, peer support groups, exercise, and childcare support) to address the individual risk factors identified by the predictive screener.

Abstract

Background: Taiwan's status as a super-aged society underscores the need for efficient strategies to promote healthy aging. While the benefits of mindfulness-based interventions for sleep and mental health are evident, there is a shortage of cultural adaptations for Taiwan's older adults. Current courses mainly focus on mindfulness-based stress reduction, while neglecting mindfulness-based elder care, and mindful sustainable aging principles. However, the abstract nature of some mindfulness concepts, combined with limited digital support and localized resources, makes it challenging for older adults to engage effectively.

Objective: To enhance healthy aging outcomes in older community-dwelling adults in Taiwan, this study developed an 8-week theory-based mindfulness curriculum that combined the mindfulness-based stress reduction, mindfulness-based elder care, and mindful sustainable aging frameworks with digital health support.

Methods: This research employed a mixed methods feasibility study design. We used the modified Delphi method in phase 1 to reach agreement on curriculum content and digital material selection. Ten older adults participated in the pilot study, which comprised phase 2. We used quantitative measurements to assess mindfulness, sleep quality, cognition, heart rate variability, perceptions of aging, healthy aging perspectives, and physical function and activity at baseline, at weeks 4 and 8, and at a 1-month follow-up. Qualitative interviews were conducted to gather insights into participants' experiences.

Results: Participants achieved significant improvements in mindfulness, sleep quality, aging perception, healthy aging outlook, and physical function during the study (all $P<.05$). Cognition, heart rate variability, and physical activity levels showed no significant changes throughout the study. The qualitative data supported these findings, as participants selected simple practices, such as mindful breathing, which they practiced daily to enhance their emotional well-being and social connections. Participants valued the digital learning materials for aiding their practice; however, some older adults with reading difficulties faced challenges accessing the content.

Conclusions: Using the Delphi method resulted in an acceptable and feasible theory-based digitally supported mindfulness program that improved several indicators of healthy aging in older adults in Taiwan. Our findings need to be validated using longer trials to assess cognitive and physiological effects. Furthermore, digital accessibility requires further development.

Introduction

Taiwan is rapidly becoming a super-aged society, prompting the government to develop long-term care policies aligned with the World Health Organization's (WHO) Decade of Healthy Aging framework [1,2]. Current community programs in Taiwan emphasize physical exercise and cognitive training but lack adequate organized support for mental health and attitudes toward aging [3-5]. The WHO model defines healthy aging as the maintenance of functional abilities alongside the

XSL•FO
RenderX

management of ongoing health conditions and external environmental challenges. Recent research suggests that healthy aging involves 3 key elements—an individual's wellness status, their ability to adapt, and their capacity to resist challenges—all while accounting for the mental and social aspects of aging [2,4,5]. Supporting older adults requires interventions that address both physical and psychological factors to help preserve their intrinsic capacity and functional ability.

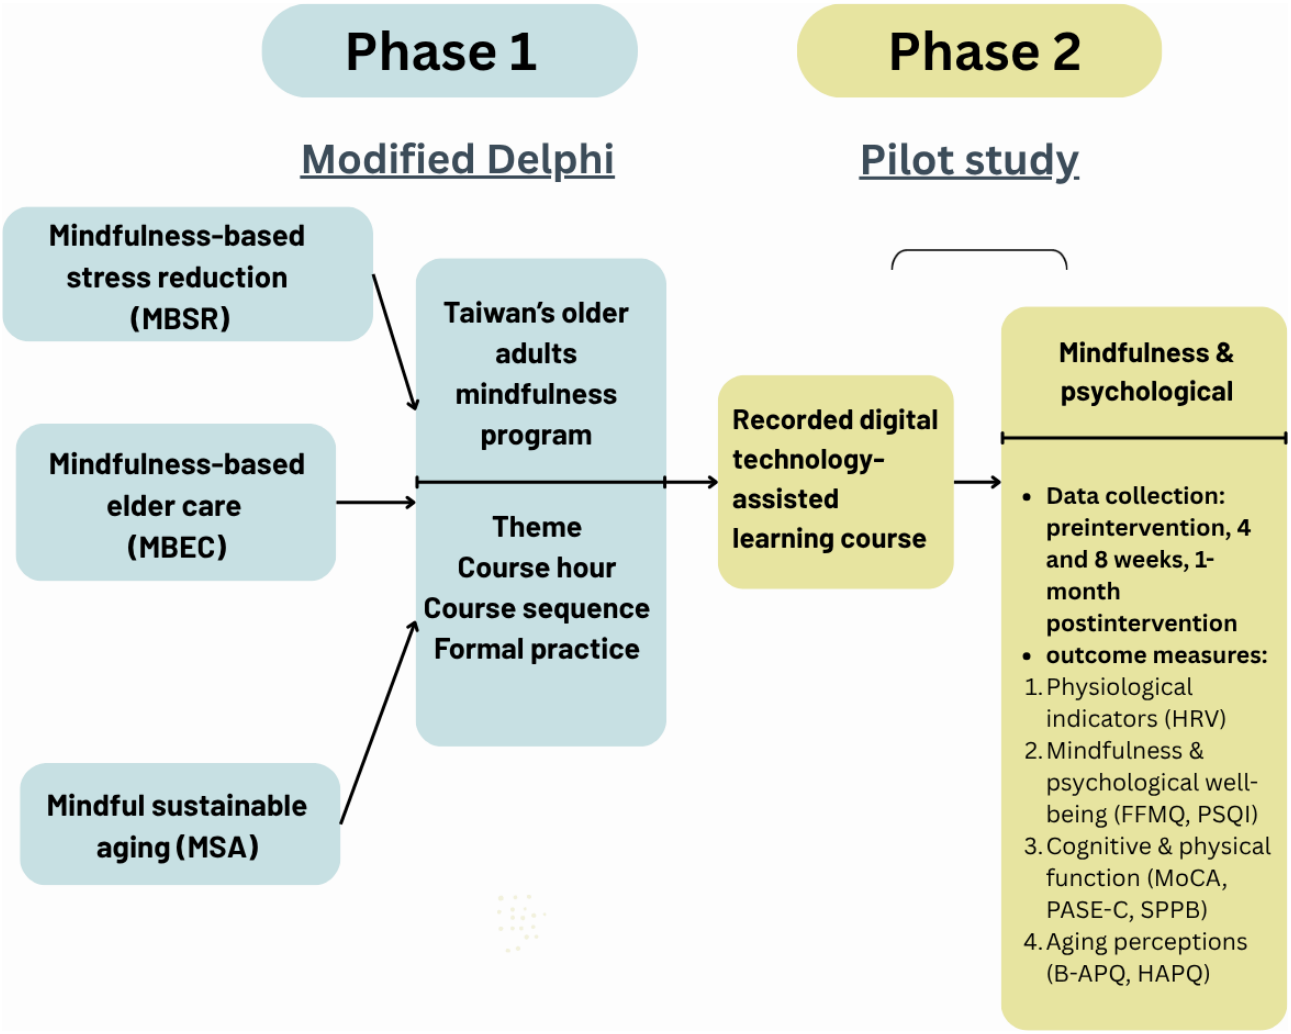
According to Kabat-Zinn [6], mindfulness practice enables individuals to experience the present moment without judgment. Research has indicated that mindfulness practice can improve physical and mental health across different groups [7-11]. Moreover, mindfulness-based stress reduction (MBSR) has been shown to enable participants to reduce stress symptoms, improve sleep quality, and achieve better mental health outcomes [9-11]. Although older adults who participate in mindfulness-based interventions (MBIs) have demonstrated better sleep quality and higher life satisfaction, such programs have not shown positive effects on cognitive functions [12-14]. Mindfulness practices thus have the potential to help seniors during their aging journey, but they require consideration of the particular needs of older adults.

As older adults are still able to learn and develop skills, multiple frameworks have been developed for mindfulness practice during senior years. For example, the mindfulness-based elder care (MBEC) program aims to teach frail older adults and their caregivers to practice mindfulness [15-17]. The mindful sustainable aging (MSA) framework unites successful aging principles with disengagement, transcendence, and activity theory to help older adults maintain their outward activities while developing inner reflection and resilience [18,19]. These approaches, together with the core stress-reduction practices of MBSR [6,9,10], establish a strong theoretical foundation for mindfulness programs that focus on emotional regulation, the acceptance of aging, and the development of purpose for older adults. Community-based programs targeting this population therefore require interventions that combine these particular frameworks to achieve their goals.

The majority of mindfulness programs for older adults in Taiwan use MBSR as their primary format; however, these programs do not directly implement MBEC and MSA principles and thus may not address specific needs of older populations. Older participants may have difficulty understanding abstract concepts such as the "nine attitudes of mindfulness" (ie, nonjudging, patience, beginner's mind, trust, nonstriving, acceptance, letting go, gratitude, and generosity) [20]. Since older adults may lack classroom experience and have limited memory capacity, teachers can facilitate their learning through practical, hands-on activities rather than abstract examples. Additionally, the lack of suitable, culturally adapted, age-friendly materials for older Taiwanese adults can contribute to poor adherence after course completion.

Taiwan's digital health agenda encourages the development of digital learning programs that can be integrated into community-based services for older adults [21]. About half of Taiwanese adults aged65 years and above use the internet, and many are familiar with LINE (LY Corporation), a widely used communication and social media application [21]. Digital platforms incorporating reminder systems may support older adults in monitoring medical treatment schedules and making health-related behavioral changes [13]. However, developers should ensure that digital solutions are accessible to users who have reading difficulties, mistrust of web-based information, or difficulty operating digital systems.

Existing research has demonstrated a lack of mindfulness programs that are culturally adapted for Taiwanese older adults and that integrate basic digital tools while adhering to established principles of mindfulness and healthy aging. To address this gap, this study adopted a mixed methods approach and conducted a feasibility study. Our research team developed an 8-week mindfulness program for community-dwelling older adults in Taiwan, integrating components of MBSR, MBEC, and MSA. Home-practice support was provided through LINE and YouTube. The study had two primary aims: (1) to apply a modified Delphi approach to achieve expert consensus regarding curriculum content and digital educational resources and (2) to assess the program's feasibility, participant acceptance, and initial impact on mindfulness levels, sleep quality, cognitive ability, heart rate variability (HRV), perceptions of aging, physical activity, and overall physical functioning. Based on established evidence-based approaches, an initial digital mindfulness program framework incorporating proven methods was created and adapted to support Taiwanese older adults in managing the psychosocial and functional aspects of healthy aging through digital health support.



Methods

Study Design

The mixed methods feasibility design was based on Creswell and Plano Clark [22] (Figure 1). Phase 1 used a modified Delphi process to develop and validate a theory-based, digitally supported mindfulness curriculum tailored for community-dwelling older adults. Phase 2 consisted of a single-group pilot study with embedded qualitative interviews (QUAN→qual) to evaluate feasibility and acceptability and explore the curriculum's preliminary effects on healthy aging outcomes.

XSL•FO
RenderX

Figure 1. Conceptual and methodological framework of the 2-phase study: Delphi curriculum development and pilot intervention. B-APQ: Brief Aging Perceptions Questionnaire; FFMQ: Five Facet Mindfulness Questionnaire; HAPQ: Healthy Aging Perspectives Questionnaire; HRV: heart rate variability; MoCA: Montreal Cognitive Assessment; PASE-C: Chinese Physical Activity Scale for the Elderly; PSQI: Pittsburgh Sleep Quality Index; SPPB: Short Physical Performance Battery.

Phase 1: Delphi Curriculum Development

Theoretical Framework and Curriculum Design

We used a modified Delphi approach to determine the appropriate format and content of a mindfulness-based program for community-dwelling older adults. The curriculum incorporated 3 theoretical frameworks: MBSR [6], which teaches mindfulness practices and stress reduction for daily life; MBEC [15], which focuses on mindfulness practice in gerontological care settings; and MSA [19], which promotes mindfulness to help individuals improve adaptability and resilience in later life. The curriculum development process also included the creation of digital learning resources. These resources supported participants between in-person program sessions, facilitated adherence to home practices, and enhanced the intervention's ecological validity.

Participants

Experts were purposefully recruited from professional networks and academic institutions. Eligible participants included certified mindfulness instructors, physicians, nurses, physical and occupational therapists, schoolteachers, health educators, and case managers with a minimum of 2 years of experience in mindfulness instruction or elder care (Table S1 in Multimedia Appendix 1).

Procedure

The Delphi process was administered via mailed questionnaires across 3 sequential rounds conducted over approximately 6 months, with each round lasting approximately 2 months, including time for qualitative feedback synthesis and item revision. During the first round, the experts reviewed the curriculum materials and provided qualitative suggestions, which were synthesized and transformed into structured items. In the subsequent 2 rounds, experts rated these items quantitatively and offered additional feedback. This iterative process continued until consensus was achieved. The finalized 8-week curriculum and digital learning materials were then implemented and evaluated in phase 2 at a community care station in Chiayi City.

Data Analysis

Descriptive statistics were calculated for the Delphi survey responses. For each curriculum item, the median, IQR, and percentage of experts rating the item as "suitable" or "very

XSL•FO
RenderX

suitable" were calculated. Consensus was defined a priori as an IQR≤1.0 and at least 80% agreement among experts [22]. Items that did not reach consensus were revised according to experts' comments and resubmitted in the next round. This process continued until response stability was achieved.

Phase 2: Pilot Intervention Study (QUAN→Qual)

Quantitative Study

The second phase comprised a single-group pilot intervention involving 10 community-dwelling older adults. Participants completed standardized assessments at 4 time points: baseline (P0), week 4 (P1), week 8 (P2), and 1-month postintervention (P3). The repeated-measures longitudinal design allowed examination of both the immediate and long-term effects of the intervention on healthy aging outcomes.

Digital Support Component

The intervention combined in-person instruction with digital and communication tools to support participants in their mindfulness practice between sessions.

Two platforms were used:

- YouTube content: short instructor-recorded videos and audio-guided sessions demonstrating core practices—such as mindful breathing, body scans, gentle stretching, and mindful walking—were made available through YouTube. Participants could access these materials at home to support independent practice and reinforce what they had learned in class (Figure 2).
- LINE reminders and group chat: A LINE group was created for the class to facilitate communication. Brief practice reminders and encouraging messages were sent to participants up to 3 times daily (morning, noon, and evening), along with links to relevant YouTube content and simple emotional support cards. The group also provided a means for participants to ask questions, share experiences, provide mutual support, and maintain engagement between sessions (Figure 3).

This hybrid format combined the social advantages of in-person sessions with accessible, age-appropriate digital tools already familiar to participants. The perceived usefulness of these digital components was assessed through postprogram qualitative feedback; objective engagement metrics, such as video view counts or message read rates, were not collected.

XSL•FO
RenderX

Figure 2. Older adult using digital learning materials on the YouTube platform.

XSL•FO
RenderX

Figure 3. LINE app group for mindful practice and real-time interaction.

Qualitative Component: In-Depth Interviews

One week after completing the 8-week program, all participants were invited to take part in face-to-face, in-depth interviews to discuss their experiences with the curriculum and digital support materials. Interviews were conducted in a private room at the community care station by the course instructor, who was trained in mindfulness facilitation and qualitative interviewing. Sessions lasted approximately 30 minutes and followed a semistructured interview guide (Multimedia Appendix 2), encompassing questions regarding participants' personal experiences, any benefits they experienced, and their recommendations for improvements.

To minimize social desirability bias arising from the instructor-participant relationship, participants were assured that their responses would not affect their continued participation or access to services. They were encouraged to share both positive and negative experiences and reminded that they could decline to answer any question. With participants' consent, the interviews were audio-recorded and transcribed verbatim in Mandarin; field notes were taken during or immediately after each session. Transcripts were reviewed for accuracy prior to analysis.

Participants

Participants were recruited from a community care station in Chiayi City offering frailty prevention and disability-delay programs. Recruitment was initiated through announcements at Long-Term Care Service C Stations, followed by referrals from social workers and case managers. These stations are community centers that provide primary long-term care by

XSL•FO
RenderX

integrating disability prevention strategies, connecting preventive care with active aging programs to reduce physical decline, promoting health and well-being, and improving quality of life [1].

The eligibility criteria were as follows: (1) aged 65 years or older, (2) able to communicate in Mandarin or Taiwanese and participate in group discussions, (3) owning and regularly using a smartphone and being familiar with the LINE application, and (4) willing and able to attend all scheduled sessions during the intervention period. The exclusion criteria included (1) a prior diagnosis of cognitive impairment (eg, dementia), (2) severe hearing, speech, or communication difficulties that would prevent participation in group activities, and (3) severe or unstable physical conditions that would make participation unsafe or impractical. Ten older adults were ultimately enrolled in the pilot study.

Ethical Considerations

Each participant signed a written consent form prior to study participation. We received ethical approval for this study from the Chang Gung Medical Foundation institutional review board (number 202400087B0). Before data collection, the research team explained the study objectives, procedures, participants' rights, and measures to protect confidentiality and research data to all eligible participants. Participation was voluntary, and participants were assured they could discontinue at any stage of the study without penalty or negative impact. Original paper documents were kept in locked cabinets at the study institution. After the removal of personally identifiable information, research data were maintained in institutional cloud-based storage systems and on password-protected computers, and access was restricted to approved members of the research team. Data will be preserved until 2027 and subsequently destroyed in accordance with institutional data management requirements. A signed copy of the informed consent form was provided to each participant. To acknowledge their time and contribution, participants received a NT$100 gift voucher, approximately US $3, for each completed study-related task.

Measures

Quantitative Outcome Measures

Quantitative data were collected at all 4 time points (P0-P3) using the following validated instruments:

- Mindfulness: Taiwanese version of the Five Facet Mindfulness Questionnaire (T-FFMQ; 39 items, higher scores indicate greater mindfulness) [7,23].
- Cognitive function: Taiwanese version of the Montreal Cognitive Assessment (MoCA; score: 0‐30, higher scores indicate better cognition) [24,25].
- Sleep quality: Chinese Pittsburgh Sleep Quality Index (PSQI; global score: 0‐21, higher scores indicate poorer sleep) [26,27].
- Perceptions of aging: Chinese Brief Aging Perceptions Questionnaire (B-APQ) [28-30].
- Healthy aging perspectives: Healthy Aging Perspectives Questionnaire (HAPQ) [31].
- Physical activity: Chinese Physical Activity Scale for the Elderly (PASE-C) [32].
- Physical function: Short Physical Performance Battery (SPPB; score: 0‐12) [33].
- HRV: standard deviation of normal-to-normal (SDNN) and low frequency (LF)/high frequency (HF) ratio measured with a Taiwan Food and Drug Administration–approved BEATINFO heart rate sensor and application.

We selected these measures to capture multiple domains of healthy aging, including psychological, cognitive, and physical dimensions. Multimedia Appendix 3 provides detailed descriptions of each instrument and its psychometric properties.

Data Analysis

Quantitative and Qualitative Data Analysis

Quantitative and qualitative data were analyzed separately before integration. Descriptive statistics (mean, SD, frequency, and percentage) were used to characterize participants' demographic data. Because of the small sample size and nonnormal distribution of the repeated-measures data, we employed the Friedman test for within-group comparisons across the 4 time points. For statistically significant results, post hoc pairwise comparisons were conducted to determine which time points showed meaningful changes. Statistical significance was set at $P<.05$ (2-tailed). All analyses were performed using SPSS Statistics version 25 (IBM Corporation). All 10 participants completed the 8-week intervention, all 4 quantitative assessments, and the postprogram interviews. Given no missing outcome data, analyses were conducted using complete cases (n=10) without the need for imputation.

Qualitative Analysis

We conducted thematic analysis following Braun and Clarke's 6-phase framework (familiarization, coding, theme development, review, definition, and reporting) [34]. Two researchers individually coded the transcripts and resolved discrepancies through discussion. Codes were organized into subthemes and overarching themes reflecting participants' experiences with the curriculum and digital practice materials. We applied investigator triangulation and peer debriefing methods, maintaining a coding decision audit trail to enhance trustworthiness. The selected quotes effectively represent the themes and use pseudonyms to protect participants' identities.

Integration of Quantitative and Qualitative Findings

At the interpretation stage, quantitative and qualitative findings were merged to develop a comprehensive understanding of the feasibility, acceptability, and preliminary effects of the mindfulness curriculum.

Results

Phase 1: Delphi Consensus

The modified Delphi process yielded strong expert consensus on the 8-week mindfulness curriculum (Tables 1 and 2). Qualitative feedback from round 1 was synthesized and used to revise items in subsequent rounds. In rounds 2 and 3, all items received strong consensus, with median scores of 4 and IQRs ≤1.0 across sessions. By round 3, agreement remained high, with at least 88% of experts rating each session as "suitable" or "very suitable" (Table 2). These results supported the

XSL•FO
RenderX

curriculum's content validity and expert acceptability, including its digital learning materials, and justified advancing to pilot feasibility testing.

Phase 2: Pilot Study

Recruitment, Retention, and Missing Data

Ten older adults participated in the pilot study. All completed the 8-week mindfulness program, the quantitative assessments at all 4 time points (P0-P3), and the postprogram qualitative interview. There was no attrition, and quantitative analyses were conducted using complete cases (n=10).

Participant Characteristics

All 10 participants were community-dwelling older women with an average age of 77.4 (SD 6.2) years. The majority were retired and had attained a junior high school education or below (n=7, 70%), with monthly incomes under NT $20,000 (US $645; n=9, 90%). Most had experienced widowhood (n=7, 70%) and practiced Buddhism while living with either children or spouses (n=7, 70%). They had multiple chronic health conditions, including musculoskeletal disorders (n=5, 50%), hypertension (n=4, 40%), diabetes (n=3, 30%), and cardiovascular diseases (n=3, 30%). All participants maintained complete independence in their activities of daily living (mean 100, SD 0; Table 3).

Quantitative Outcomes

Table 4 presents medians and IQRs for all outcomes across the 4 time points (P0-P3). Friedman tests revealed statistically significant changes over time in mindfulness (FFMQ), sleep quality (PSQI), aging perceptions (B-APQ), healthy aging perspectives (HAPQ), and physical function (SPPB). No significant changes were observed in cognitive function (MoCA), physical activity (PASE-C), or HRV indices (SDNN and LF/HF ratio).

Mindfulness levels also increased over time. Median FFMQ scores rose from 139.50 (IQR 102.25-155.75) at baseline to 150.00 (IQR 141.75-156.25) at week 8 and 155.00 (IQR 136-164.25) at follow-up (χ^2_3=11.57, *P*=.009). Post hoc comparisons indicated significantly higher mindfulness at follow-up than at baseline (P3>P0), suggesting sustained improvement in mindfulness skills after the intervention.

XSL•FO
RenderX

Table . Changes in healthy aging outcomes across 4 time points.

Variable[a]	Baseline (P0) median (IQR)	Week 4 (P1) median (IQR)	Week 8 (P2) median (IQR)	Follow-up (P3) median (IQR)	χ^2 (df)	*P* value	Post hoc

PASE-C[k]	105.16 (89.67-150.36)	91.36 (61.25-165.01)	67.02 (57.35-139.94)	118.52 (73.19-127.96)	2.03 (3)	.57	—
SPPB[l]	12.00 (11.50-12.00)	11.50 (11.00-12.00)	12.00 (11.75-12.00)	12.00 (12.00-12.00)	8.37 (3)	.04	—

[a]PSQI: lower scores indicate better sleep quality. FFMQ, B-APQ, HAPQ, and SPPB: higher scores indicate more favorable outcomes.

[b]HRV: heart rate variability.

[c]SDNN: standard deviations of normal-to-normal.

[d]Not applicable.

[e]LF/HF ratio: low frequency/high frequency ratio.

[f]FFMQ:Five Facet Mindfulness Questionnaire.

[g]MoCA: Montreal Cognitive Assessment.

[h]PSQI: Pittsburgh Sleep Quality Index.

[i]B-APQ: Brief Aging Perceptions Questionnaire.

[j]HAPQ**:** Healthy Aging Perspectives Questionnaire.

[k]PASE-C: Physical Activity Scale for the Elderly.

[l]SPPB: Short Physical Performance Battery.

Sleep quality improved markedly: median PSQI scores decreased from 8.50 (IQR 2.75-11.25) at baseline to 3.50 (IQR 1.00-6.25) at week 8 and 2.50 (IQR 1.00-4.50) at follow-up (χ^2_3=15.03, *P*=.002). Post hoc comparisons showed significantly lower scores at P2 and P3 than at P0, indicating progressively better sleep.

Perceptions of aging and healthy aging perspectives also became more positive. Median B-APQ scores increased from 3.25 (IQR 2.96-4.06) at baseline to 4.23 (IQR 3.57-4.80) at follow-up (χ^2_3=10.88, *P*=.01), with post hoc tests indicating higher scores at P3 than P0. Median HAPQ scores increased from 3.14 (IQR 3.01-3.22) at baseline to 3.78 (IQR 3.52-3.94) at week 8 and 4.13 (IQR 4.09-4.69) at follow-up (χ^2_3=20.70, *P*<.001), with significantly higher scores at P2 and P3 compared with P0.

Physical function remained high and showed small but statistically significant variation over time: median SPPB scores were 12.00 (IQR 11.50-12.00) at baseline, dipped slightly to 11.50 (IQR 11.00-12.00) at week 4, and returned to 12.00 (IQR 11.75-12.00) at week 8 and to 12.00 (IQR 12.00-12.00) at week 12 (χ^2_3=8.37, *P*=.04).

By contrast, cognitive function (MoCA) remained consistently high (≈29.0) at all time points, and median PASE-C and HRV indices (SDNN and LF/HF ratio) fluctuated without a clear trend. None of these variables changed significantly over time (all *P*>.05).

Qualitative Outcomes

Thematic analysis of the postprogram interviews revealed 5 main themes, each with several subthemes, describing the physical and psychological sensations experienced after participating in the digitally supported mindfulness program (Table 5):

- Enhanced physical and psychological well-being: participants reported greater relaxation, better sleep, and improved emotional regulation.
- Transformation of daily routines: mindfulness practices gradually shifted from occasional use to habitual strategies for coping with discomfort and stress in everyday life.
- Memorable practices and preferred activities: simple, accessible practices (eg, deep breathing, bed-based stretching, and mindful eating) were viewed as most useful and sustainable.

XSL•FO
RenderX

- Positive life changes and social connectedness: participants described adopting healthier behaviors, shortening periods of negative emotions, and experiencing reduced loneliness through group interactions.
- Program evaluation and suggestions: the overall satisfaction was high. Digital tools (LINE and YouTube) were perceived as helpful, although some participants with reading difficulties needed family assistance to access online content and requested continued classes.

Taken together, the qualitative findings indicate that participants experienced meaningful benefits from the digitally supported mindfulness program, including improved relaxation, emotional regulation, and social connectedness. Accessible practices centered on breathing and yoga were most consistently adopted into daily life. Although digital tools were widely valued for supporting home practice, a subset of participants reported accessibility challenges, highlighting the need for age-friendly digital solutions.

XSL•FO
RenderX

Table . Themes, subthemes, and illustrative quotes from qualitative interviews.

Theme and subtheme	Illustrative quote
Enhanced physical and psychological well-being	
Improved relaxation and sleep	• *Sometimes when I cannot fall asleep, I just take deep breaths and stretch my legs in bed. Soon, I feel more comfortable and can fall asleep.* (participant C) • *Prior to participating in this course, I experienced significant difficulties with sleep; however, following the practice sessions, my sleep quality has shown gradual improvement.* (participant H)
Emotional stabilization and stress relief	• *When I am busy and feel upset, I just take a few deep breaths. It really helps me relax, and my mood improves.* (participant A)
Transformation of daily routines	
From passive learning to habitual practice	• *At first, I often forgot. But when I saw the YouTube videos in the LINE group, I remembered and did the exercises at home.* (participant F)
From reactive to proactive coping	• *When my chest hurt, I first thought about doing deep breathing. I tried hard to breathe in, and after a while, I felt better.* (participant B)
Memorable practices and preferred activities	
Breathing as a core practice	• *Deep breathing is the most useful. I can do it anywhere, and it calms me quickly.* (participant H)
Bed-based and stretching exercises	• *I like the bed exercises the most. Even when it's cold, I can do them under a blanket. They really loosen my body.* (participant D) • *During my stretching exercises, I have started to focus closely on the sensations in my body with each movement, especially to pinpoint the exact areas where I feel exertion.* (participant E)
Mindful eating and slow chewing	• *Now I chew more slowly and carefully. It helps me taste the food and prevents me from choking.*"(participant G)
Positive life changes and social connectedness	
Adoption of healthier behaviors	• When I experience a negative mood, I practice mindful walking in the park to help alleviate it. (participant F) • *I eat slower, drink more water, and keep moving every day. It's a real change for me.* (participant E)
Improved emotional regulation	• *When bad things happen, I shorten the time I feel sad or angry. I try not to hold onto it for too long.* (participant D)
Reduced loneliness and enhanced social ties	• *Coming here and practicing with others makes me feel less lonely. At home, I would think too much.* (participant H)
Program evaluation and suggestions	
High satisfaction and appreciation	• *I really enjoy these classes. The teacher's voice is very soothing.* (participant G)
Role of digital technology	• *I don't read well, so I rarely check the YouTube videos myself. My daughter helps me open them.* (participant I)
Desire for continuity	• *I hope you can come again regularly. If we keep practicing together, we won't forget.* (participant A)

XSL•FO

Discussion

Principal Findings

In this mixed methods feasibility study, we developed and piloted an 8-week digitally supported mindfulness curriculum integrating MBSR, MBEC, and MSA frameworks for community-dwelling older adults in Taiwan. Assessments at 4 time points revealed significant improvements in mindfulness and sleep quality, along with more positive attitudes toward aging. However, physical function showed only a slight (but significant) improvement, and no significant changes were observed in cognitive function, physical activity, or HRV indices. The quantitative data were supported by the qualitative interview results, which indicated that participants developed more effective relaxation and emotional regulation techniques and became more capable in daily activities and interpersonal relationships. Overall, the findings indicated that the program was successful, with participants providing positive feedback on both culturally adapted content and digital support components.

The program integrated MBSR with MBEC and MSA frameworks while adapting content to the cultural and educational contexts of older adults in Taiwan. Mindfulness interventions offered via structured courses and digital platforms require careful cultural adaptation [35], and research highlights the importance of incorporating cultural values, language, social interaction styles, and accessible technology to enhance participant engagement and overall effectiveness [36-38]. In this study, we used 3 strategies to address reported barriers related to low literacy and abstract mindfulness concepts: simplified language, locally relevant exercises, and embodied practices. Participants described the LINE reminders and YouTube videos as useful digital tools that facilitated between-session practice. However, some participants reported the need for family assistance to access and use the materials due to limited reading ability. These findings highlight both the potential and practical challenges of digital support for older adults and underscore the importance of age-friendly, accessible interface design.

The observed improvement in sleep quality is consistent with participants' descriptions of using breathing techniques and gentle stretching to manage sleeplessness. By reducing presleep cognitive arousal and facilitating relaxation, these practices likely contributed to the marked decline in PSQI scores. This finding aligns with previous research showing that mindfulness training improves sleep quality by supporting emotional regulation and reducing stress-related hyperarousal symptoms, which can affect older adults [39].

Improvements in aging perceptions and healthy aging perspectives reflect the cognitive reappraisal and acceptance techniques emphasized by both the MBEC and MSA approaches. Mindfulness practices enable individuals to distance themselves from unpleasant thoughts, cultivate self-compassion, and recognize meaningful moments throughout their day. Participants reported experiencing shorter episodes of negative emotions as they learned to manage difficult situations, which align with an adaptive aging orientation. This transition may have significant health implications, as individuals who believe they are aging well tend to preserve their physical abilities and remain active in later life [2,4].

Factors Contributing to Unchanging Variables

Median SPPB scores remained high throughout and showed a small but statistically significant improvement, whereas physical activity levels assessed by the PASE-C did not change significantly. This outcome is consistent with previous studies demonstrating that mindfulness training produces variable improvements in physical movement quality, balance, and mobility [14,40,41]. The curriculum focused on teaching safety and awareness during light exercise rather than increasing overall exercise duration; consequently, changes in short mindful movement sessions—such as bed-based stretching and mindful walking—are unlikely to be captured by the PASE-C, which primarily measures the frequency of leisure activities and household tasks. Although mindfulness training does not aim to increase activity duration, it can facilitate improvement in movement quality and physical awareness during these exercises.

Despite participants' numerous positive subjective reports, no statistically significant improvement was observed in cognitive function as measured by MoCA. This finding is likely attributable to the ceiling effect. Participants showed normal cognitive abilities at baseline, as their MoCA scores were already near maximum and concentrated within a narrow range. The MoCA test fails to detect small changes in executive function and attention that mindfulness may produce in cognitively healthy older adults under specific conditions. Future research should include a more diverse group of participants who remain under observation for an extended period while using various cognitive tests to measure the effectiveness of interventions [12].

The HRV indices (SDNN and LF/HF ratio) did not show significant variations. However, HRV can fluctuate widely owing to factors such as the testing environment, breathing patterns, body position, measurement timing, and concurrent medications. Meta-analytic research indicates that mindfulness practices have small and variable effects on HRV, which are influenced by vagal nerve function [42,43]. Future studies should aim to determine when physiological changes occur by employing larger sample sizes, longer observation periods, and standardized resting-state measurement protocols.

Limitations

Several study limitations should be noted. First, the small sample size (N=10) and single-site recruitment reduce the statistical power and generalizability of the findings. Second, since the majority of older adults at the Long-Term Care Service C Stations are female, all participants were women, restricting the applicability of findings to older men [44]. Third, the PASE-C instrument lacked the sensitivity to detect changes in mindful light-intensity movements, which likely contributed to the null finding in physical activity levels. Finally, although digital tools supported program engagement, several participants with limited literacy required family assistance to access online materials,

XSL•FO
RenderX

emphasizing the need to create digital solutions that are both age-friendly and inclusive.

Links With Prior Evidence, Implications, and Future Directions

Our findings support previous studies showing that mindfulness programs benefit older adults' sleep quality and mental health [12] by demonstrating that similar gains are achievable within a digitally supported, community-based format that also enhances aging-related perceptions and functional outcomes. This hybrid learning model—combining weekly in-person sessions with LINE reminders and instructor-recorded videos—offers a potentially cost-effective approach to sustaining home practice and maintaining engagement in real-world settings, addressing common challenges to program adherence [13].

Based on this pilot study, findings should be interpreted as preliminary evidence of feasibility and perceived usefulness rather than as a basis for immediate large-scale implementation. The program structure may nonetheless inform future evaluations at Long-Term Care Service C Stations and other community-based aging services, serving as a potential model for incorporating brief mindfulness practices—such as mindful breathing, chair-based stretching, and brief body scans—into regular group activities. A train-the-trainer approach supported by a structured manual (including session scripts, safety cues, and culturally relevant examples) may facilitate standardized delivery across sites. Importantly, suggestions regarding age-friendly digital interfaces (eg, larger text, simplified navigation, structured screens, and short audio/video materials delivered via familiar platforms) were derived from participants' reports of accessibility barriers (eg, limited reading ability and reliance on family assistance) rather than from formal usability testing; therefore, these design implications should be validated in future work using established usability evaluation methods.

Future research should assess program effectiveness and scalability using adequately powered randomized controlled trials with longer follow-up, objective activity monitoring, more sensitive cognitive measures, standardized protocols, and hybrid effectiveness-implementation designs that assess both outcomes and adoption metrics (eg, reach, fidelity, and cost). Formal usability evaluation (eg, task-based testing and validated usability measures) and objective engagement metrics should also be incorporated to optimize the digital support components.

Conclusion

This study makes a dual contribution: it demonstrates expert consensus on the content validity of a culturally adapted, theory-grounded mindfulness curriculum for community-dwelling older adults in Taiwan, and it provides preliminary evidence of the program's feasibility, acceptability, and beneficial effects across psychological, sleep-related, and aging perception domains. The hybrid delivery format was generally well-received and appeared to support home practice. Importantly, this work extends existing research by showing that mindfulness benefits are not only confined to sleep and mental health but also extend to how older adults perceive and engage with aging. Additional trials are needed to confirm these preliminary effects, refine assessment methods, and establish conditions for scalability.

Acknowledgments

The authors gratefully acknowledge the participation of older adults and the support of staff from the Long-Term Care Service C Stations in Chiayi City, whose contributions made this study possible.

Funding

This research was funded by the National Science and Technology Council, Taiwan (grant number 113-2410-H-255-001-MY1).

Abstract

Background: Mental health help-seeking barriers experienced by female forces veterans result in them being underserved and underrepresented. Efforts are therefore required to adapt interventions for female veterans to enhance acceptability and maximize engagement. Given a smaller number and wider geographical distribution of female veterans, targeting adaptation efforts at a digital mobile phone app based on cognitive behavioral therapy (CBT) has potential for greatest impact to improve access to a scalable evidence-based psychological therapy.

Objective: This study aimed to examine the adaptation of a low-intensity CBT app to support low mood and worry management in female forces veterans and examine acceptability and usability.

Methods: Using a mixed methods methodology, this study comprises a focus group of female forces veterans to inform adaptation with extracted themes used as the basis of an adaptation framework. Following adaptation, a wider sample of female veterans was recruited to use the app and complete the mHealth App Usability Questionnaire to determine acceptability, usability, and usefulness.

Results: Two main areas were identified as requiring adaptation to maximize acceptability and usability. While using imagery and quotes to reflect the armed forces was initially found helpful to initiate engagement, it was considered that continued reference to the armed forces should be dropped when progressing through the app. Most app features were found acceptable; however, adaptations were requested to the content and structure of signposting information, navigation, and the way progress was monitored. No adaptations were required, however, regarding the CBT techniques used, with specific app features motivating engagement. Following the adaptation, there were good levels of acceptability, usability, and usefulness.

Conclusions: Involving female forces veterans as part of an intervention adaptation process has promise to improve acceptability and engagement with a digital CBT mobile phone intervention. Ensuring that the intervention represented the transition from serving to female forces veteran is of particular significance in enhancing acceptability.

Introduction

Increased efforts are being made to recruit females into the UK Armed Forces who currently account for 11.5% of Regular and 16% of Reservists [1]. However, while government policy is seeking to increase this number to 30% by 2030, intake dropped by 1% in 2024 [1]. Despite significant efforts being made to integrate females into active service, female forces veterans remain underserved [2]. Difficulties are experienced because of support systems primarily developed for males with limited tailoring to the distinct needs of female forces veterans [3].

Both male and female forces veterans face barriers accessing mental health support such as stigma, concerns they will not be understood by health care providers, and a culture of stoicism [4]. However, female veterans frequently report additional gendered adversity, such as military sexual trauma and

XSL•FO
RenderX

emotional bullying [5]. Furthermore, they may need to navigate tensions between military culture and their feminine identity [6]. In other words, managing disparities between military culture and feminine norms, discrimination experienced both during and after service, lack of awareness, and particularly branding that reinforces male veteran stereotypes [7] are additional barriers to accessing mental health support faced by female forces veterans.

These barriers can, in turn, shape female forces veterans' help-seeking behavior [8]. Reports indicate that while female forces veterans are more likely to seek statutory adult mental health services than male veterans, they are less likely to access veteran-specific services [9]. Consequently, female veterans' lower engagement with veteran-specific services can limit their access to tailored support addressing areas such as finance, housing, employment, and welfare [10].

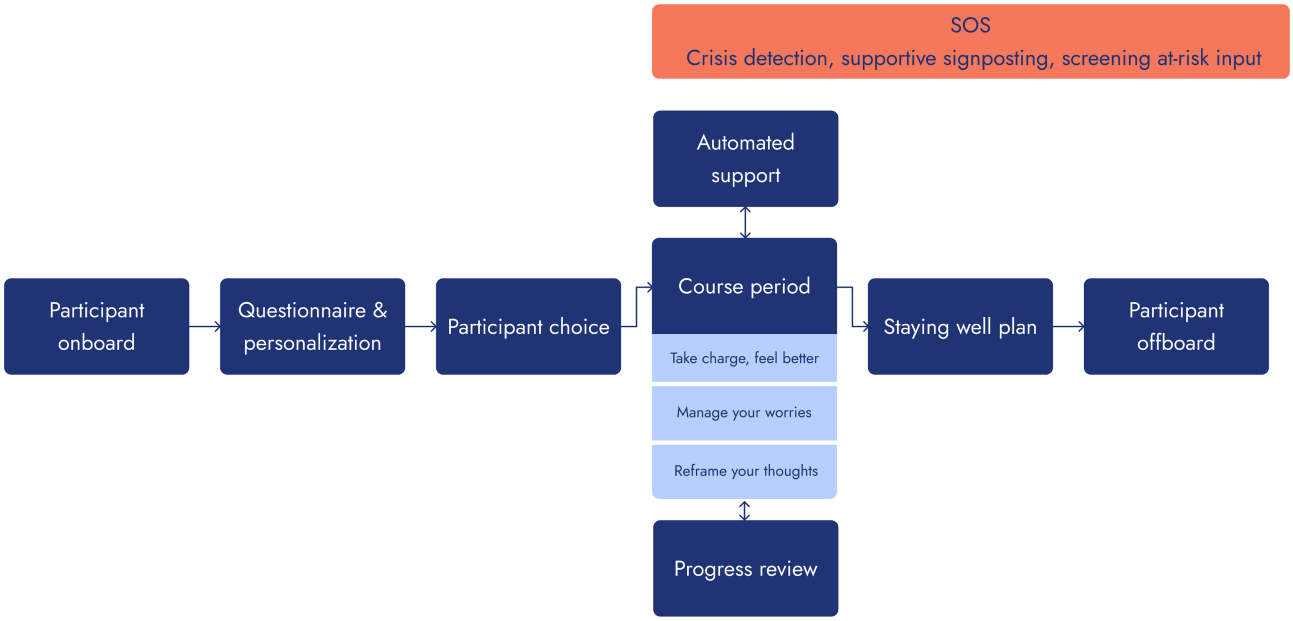
Additionally, compared with male veterans (16.7% and 13.5%), the prevalence of depression and anxiety among female veterans is 25.8% and 25.5%, respectively [11]. Experiencing these stressors during transition into civilian life is of particular concern as this is recognized as a particularly vulnerable period [12]. During this transition, female forces veterans are required to negotiate identity changes, gender-related, and societal expectancies to fit with feminine norms and practical difficulties related to housing and employment [13]. Together, the reduced utilization of veteran-focused mental health services, accompanied by higher rates of depression and anxiety experienced by female forces veterans, may contribute to the existing treatment gap [14]. This is of concern, given a higher prevalence of common mental health difficulties amongst female forces veterans [15].

To reduce the treatment gap, low-intensity cognitive behavioral therapy (CBT) has been implemented in statutory adult mental health services, such as NHS (National Health Service) Talking Therapies for anxiety and depression [16]. Low-intensity CBT improves access via flexible and scalable goal-oriented and time-limited self-help interventions [17]. The approach has already been demonstrated to resonate with values associated with self-management held by the armed forces [18], with flexibility more likely to enhance help-seeking and engagement [19]. Furthermore, acceptability has been demonstrated where intervention adaptations are made to tailor language and imagery to target veterans [20].

Low-intensity CBT also provides greater ability to enhance flexibility through digital delivery [21]. This is particularly important for armed forces veterans, given the growing acceptance of digital mental health support [22]. However, while mobile apps are being developed, for example, to promote recognition of mental health problems and support help-seeking among armed forces veterans [23], they remain largely biased toward male veterans. Challenges to generalizability, therefore, endure, resulting in female forces veterans at risk of remaining underserved [24].

Using a mixed methods methodology [25], this study reports on the adaptation of the Iona app [21] for female forces veterans. Adopting a systematic approach, the Ecological Validity Framework [26] (EVF) serves to guide culturally sensitive adaptations for specific groups by considering 8 dimensions: language, persons, metaphors, content, concepts, goals, methods, and context. Making adaptations to these dimensions offers promise to maximize acceptability to improve engagement and access to a scalable mental health approach [27].

Methods



Intervention

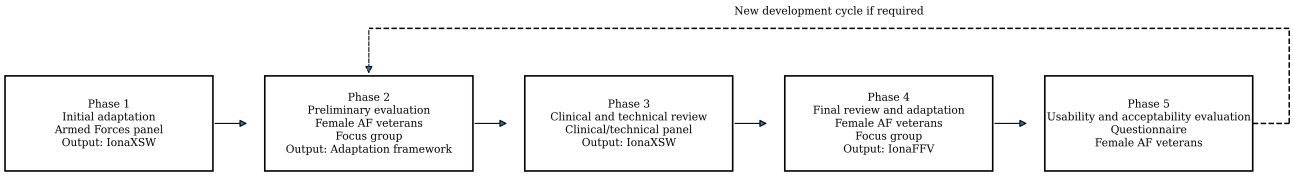
The Iona Mind app (Iona) for the management of mild to moderate low mood [28] or excessive worry [21] informed the intervention adopted for adaptation (see Figure 1 for user flow through Iona).

After onboarding, the user is asked to complete the Patient Health Questionnaire-8 [29] and Generalized Anxiety Disorder-7 Scale [30] patient-reported outcome measures to assess the severity of low mood and worry symptoms, respectively. They then engage with an interactive CBT Five Areas model [31] before progressing through the intervention-specific factor techniques presented as 6 educational modules. Where the user scores mild to moderate symptom severity for both low mood and worry symptoms, they are directed to the technique corresponding with the highest symptom severity. Where symptom severity is identical, however, users are recommended the technique for low mood, although choice still can be exercised. An "SOS" button is available on every screen for users who either score within the severe range during onboarding or show signs of deterioration during use. If the person is seeking immediate help, the "SOS" page contains NHS Emergency contact details.

XSL•FO
RenderX

Figure 1. User flow through the Iona app.

Where treatment for low mood is recommended, the user is introduced to the behavioral activation [32] or cognitive restructuring [33] techniques derived from low-intensity CBT [34]. Alternatively, where symptoms associated with worry are prominent, the Worry Management technique is proposed [21]. To facilitate choice, a description of each technique is available on request. Based on the evidence base, all techniques are informed by protocols recommended by the National Institute for Health and Care Excellence, Behavioral Activation [35,36], alongside Cognitive Restructuring for low mood [37] and Worry Management for excessive worry [38]. All techniques are included within the most commonly adopted written self-help interventions [39], used by NHS Talking Therapies for anxiety and depression services [40]. Engagement with the app is maintained through an omnipresent chatbot to establish a "therapeutic approach" [41]. This promotes collaborative empiricism to encourage the user to explore and reflect upon outcomes arising from engagement for themselves [42].



Intervention Adaptation

The EVF [26] was adopted to systematically inform adaptation from the original Iona app to that specifically for Iona Ex-Servicewomen (IonaXSW). The app was later currently called "Iona Female Forces Veterans" (IonaFFV) based on results from phase 2. To ensure that cultural and contextual factors associated with the female forces veteran's community are represented, the adaptation process focused on dimensions of the EVF [43] related to language, metaphor, context, and content. While dimensions related to concepts and methods were also adapted with respect to language, the theoretical rationale and technique-specific factors maintained high fidelity to the underlying CBT model. These dimensions were used to explicitly inform the focus group topic guide to ensure that structure was provided to ensure adequate coverage.

Adaptation Process

The adaptation process comprised 5 phases to adapt Iona and examine its acceptability for female forces veterans (Figure 2). Across the 5 phases, 4 panels were established to provide different perspectives and contributed in varied ways with each panel building upon the work of the others [44].

Figure 2. Adaptation process. AF: Armed Forces; IonaFFV: Iona Female Forces Veterans; IonaXSW: Iona Ex-Servicewomen.

During the adaptation process, an Armed Forces Panel was established to guide the initial adaptations, focusing on the context and content dimensions of the EVF. Phase 1 aimed to tailor the Iona app for female forces veterans and support the development of IonaXSW. After initial adaptations, a female forces veterans panel used their lived experience to refine the app further in phase 2. Data were analyzed to create an adaptation framework, which confirmed acceptable phase 1 adaptations and identified areas requiring additional modification. The framework was then provided to the clinical or technical panel in phase 3, who made further changes to develop the IonaFFV app. In phase 4, the app was returned to the same female forces veterans panel from phase 2 to assess the acceptability of the adaptations and ensure that changes based on the adaptation framework were effectively implemented. Finally, in phase 5, the IonaFFV app was released online to a wider group of female forces veterans to explore acceptability.

XSL•FO
RenderX

Methodology

Study Design

To adapt the Iona app to maximize acceptability for female forces veterans, an exploratory sequential mixed methods research design comprising focus groups (phases 2 and 4) and a questionnaire to examine acceptability and usability (phase 5) were adopted [45].

Phase 1

Participants

The Armed Forces Panel comprised a male armed forces officer veteran who held senior NHS roles associated with armed forces veterans and study author (AB), a female officer forces veteran holding national roles in veterans' charities, a male NHS Talking Therapies for anxiety and depression [16] armed forces veteran service lead, and a female regional commissioner for armed forces veterans.

Recruitment

Opportunistic sampling [46] based on personal contacts was held by AB. Participants contacted AB with preferences to organize a meeting time. The panel comprised 5 female forces veterans, 3 aged between 45 and 54 years and 2 aged between 35 and 44 years. Members of the panel had served in the Army (n=3), Royal Navy (n=1), and Royal Air Force (n=1).

Methods

Panel members were provided with a link to the unadapted Iona app and asked to review it before the meeting. A 1-hour online meeting, facilitated by AB and recorded for analysis, was held to gather initial feedback on areas requiring adaptation to better meet the needs of female forces veterans. Following the meeting, the recording was transcribed by a researcher (NF), who also made preliminary notes to develop an initial list of suggested adaptations. This list was then reviewed and refined in discussion with another researcher (PF). Once agreed upon, the final list of general adaptations was sent to the Iona app developer (JB) to create IonaXSW.

Phase 2

Participants

The panel comprised 5 female forces veterans, 3 aged between 45 and 54 years and 2 aged between 35 and 44 years. Participants had served in the Army (n=3), Royal Navy (n=1), and Royal Air Force (n=1).

Recruitment

The female forces veterans panel, which served as the focus group, was recruited using snowball nonprobability convenience sampling [47]. Study advertisements, including a link to participant information, were initially posted on social media platforms that engage female forces veterans. Individuals who provided consent and contacted the researcher were invited to share the advertisement on their own social media accounts to further extend recruitment. Interested participants then indicated their availability for the focus group, which was scheduled with the first 5 participants for whom a suitable date could be confirmed. Participants were reimbursed only for travel expenses to attend the focus groups.

Methods

Prior to the focus group, all members were sent a link to IonaXSW and asked to work through it for 4 weeks, with support to download provided by the researcher if requested. Based on the focus group schedule informed by dimensions of the EVF, a 3-hour audio-recorded focus group was held face-to-face facilitated by 2 members of the research team (PF and NF). A reflective journal was used to log the progress, obstacles, and success encountered running the focus group [48]. The topic guide comprised open-ended questions to gain an initial impression of IonaXSW, address each dimension covered by the EVF [43], and explore the ability to use and engage with each app component. Following the focus group, the audio recording was transcribed and analyzed to inform a second adaptation framework.

Analysis

The focus group discussion was transcribed by NF with the transcript uploaded into NVivo (version 12.0; QSR International) to support manifest content analysis [49]. Analysis was based on articulated data [50] where NF read the transcript, coded meaning units using line-by-line inductive coding, and developed a codebook. During coding, concepts and important portions of raw text were recorded with a word or short phrase used to represent the meaning of a specific text segment. To develop a deeper and more nuanced understanding of the findings, the codebook was then discussed with PF with variations in coding discussed and refined until consensus was reached. This resulted in new codes being added until new concepts emerged, or similar concepts were grouped together to form categories and subcategories. To enhance trustworthiness, field notes and audit trails were taken to ensure that preconceived perspectives were not imposed on the data, with a checklist adopted to inform all phases of analysis [51].

Phase 3

The clinical or technical panel comprised a male app developer (JB) for Iona Mind, and a male expert (PF) in low-intensity CBT apps who holds national expert advisory positions in low-intensity CBT and digital technologies. They used the adaptation framework developed in phase 2 to develop IonaFFV. The panel ensured that all adaptations maintained fidelity with the underlying low-intensity CBT clinical protocols, and software remained conformant to appropriate software requirements.

Phase 4

Overview

Once adapted, the same participants who comprised the female forces veterans focus group in phase 2 were sent a link to IonaFFV and asked to engage with it for 4 weeks before participating in a second focus group. The topic guide for this session was designed to gather overall impressions of IonaFFV and to evaluate how effectively the adaptations proposed in phase 2 had been implemented, with reference to each dimension of the EVF. In addition, selected questions from previous topic

XSL•FO
RenderX

guides on low-intensity CBT techniques [52] were incorporated to explore participant perceptions of different app components and their support preferences.

Analysis

Consistent with phase 2, the focus group discussion was transcribed and uploaded into NVivo (version 12.0) to support manifest content analysis [49]. Again, trustworthiness was established through discussions between NF and PF to reach consensus in coding [51].

Phase 5

Participants

A total of 21 participants completed the demographic questionnaire, with a mean age of 49 years. Participants had left the armed forces between 1 and 43 years previously ($\bar{x}$=18.71), although 1 participant did not report their age (Table 1). The majority identified as female (n=20, 95%), White British (n=20, 95%), and as having served as a regular in the Navy (n=11, 52%).

Table . Participant demographics.

Characteristics	Frequency
Age range (years), n (%)	
25 - 34	1 (5)
35 - 44	5 (25)
45 - 54	7 (35)

Recruitment

Permission was obtained to promote a study advertisement on the social media platforms used by charitable and community organizations providing support to British female forces veterans. Additionally, members of the female forces veterans focus group posted the study advertisement through relevant social media platforms they had membership and sent it to personal contacts. The study advertisement stated that they should be female forces veterans aged 18 years or older, not currently receiving mental health support, and had access to a smartphone with internet access. Potential participants consented online and were automatically sent a link to download IonaFFV with onboarding details. To promote recruitment, potential participants were offered the opportunity to enter a prize draw for a £100 (US $133) electronic voucher.

Methods

Following download, participants were asked to trial the app for 2 weeks, after which they were sent a link to complete the stand-alone patient version of the mHealth App Usability Questionnaire (MAUQ) on the Qualtrics platform [53]. This measure adopts 18 items to explore usability and acceptability across 3 subscales: Ease of Use, Interface and Satisfaction, and Usefulness. However, as IonaFFV was used in a research study focused on adapting an app for female forces veterans with participants who did not present with depression or anxiety and developed for use outside of health care services, it was considered that 3 questions were inappropriate. Consequently, "I would use this app again," "The app improved my access to healthcare services," and "The app helped me manage my health effectively" were removed.

Participants also completed a series of Iona-related questions. These included four 7-point Likert scale items, added after phase 4, to assess participants' views on language, signposting information, and the SOS button. In addition, participants responded to a separate 7-point Likert scale question regarding human support. Those who selected Strongly Agree, Agree, Somewhat Agree, or Neither Agree nor Disagree were directed to answer 4 follow-up multiple-choice questions exploring different aspects of receiving human support alongside the app; multiple responses were permitted. At the end of the survey, all participants were invited to provide additional comments.

Analysis

For each subscale of the MAUQ, responses to the relevant items were averaged per participant and reported as median (IQR). All items were rated on a 7-point Likert scale, ranging from 1 (Strongly Agree) to 7 (Strongly Disagree). For analysis of the subscale items, responses of 1-3 were classified as agreement, 4 as neutral, and 5-7 as disagreement [54]. Percentages for each response category are reported for each question.

Additional questions examining attitudes toward specific adaptations to IonaFFV arising from phase 4 were rated using 7-point Likert-scale questions alongside 4 multiple-choice questions regarding preferences regarding type of human support. The Likert-scale questions ranged from 1 (Strongly Agree) to 7 (Strongly Disagree), with means and SDs calculated for each question. Proportions (%) were reported for the multiple-choice questions, with a multiple response frequency analysis conducted to examine the distribution of selected options regarding preferences for different aspects of human support [55]. As participants could select up to 6 responses for 3 questions and up to 5 for 1 question, frequencies and percentages were calculated for each response option.

Ethical Considerations

Ethical approval was obtained for the focus groups (reference: 2611056) and online acceptability (reference: 5930558) studies from the University of Exeter psychology department. To ensure informed consent, all participants were provided with participant information sheets, which included information on the aims of the study, right to withdraw, data storage, and management processes. Participants were informed that their participation was entirely voluntary, and they could withdraw from the study without any negative consequences. No identifying information about participants is included. All data were reviewed to ensure that individuals cannot be identified, and no materials containing identifiable features were used. As all data were anonymized prior to analysis, participant consent for publication of identifying information was not required. Phases 2 and 4 focus group participants were offered compensation for travel costs, and phase 5 questionnaire participants were offered the opportunity to enter a prize draw for a US $133 electronic voucher.

Results

Overview

Overall, feedback provided by the female veterans focus group combined with responses added to the free-text response box included within the MAUQ [53] questionnaire administered in phase 5 highlighted that IonaFFV was well received. Awareness that the app had been adapted for female forces veterans was positively responded to.

> *I'm still using it. It has helped a lot in the last 6 weeks or so. Please don't take it away. I can dip in when I'm finding things tough and knowing it's for female veterans is comforting.*

Adaptations appeared to promote continued engagement with IonaFFV as participants worked through each module.

> *It made me want to continue to see what was coming next and where it was going and all that.*

However, there was 1 disconfirming case reported on the free response text box.

> *The suggested activities are not relevant when you are actually struggling. I doubt anyone who has had an actual mental health episode was consulted. The activities are ok for when feeling a bit low, but not when you can't get out of bed and are struggling to function.*

Phases 2 and 4

Analysis is presented in 2 parts. First, reflecting the attitudes expressed toward IonaXSW by the focus group during phase 2, alongside preferences regarding support. Second, attitudes

XSL•FO
RenderX

expressed in phase 4 regarding the extent to which adaptations have been successfully implemented during phase 3 to create IonaFFV, alongside identifying outstanding areas requiring further adaptation. Categories identified as emerging were associated with "Context," "App features," and "No adaptations needed" (Table 2).

Table . Categories and subcategories associated with adaptation.

Armed forces context	App features	No adaptations required
Label	SOS page	CBT[a] model
Graphics	Navigation	Contextual factors
Quotes	Monitoring progress	Mapping users
Avatar	N/A[b]	N/A

[a]CBT: cognitive behavioral therapy.

[b]N/A: not applicable.

Armed Forces Context

This category captured the attitude of participants toward features of the Iona app that have been adapted to represent female forces veterans. These were grouped into label, graphics, quotes, and avatar.

Label

All participants in the focus group expressed disapproval toward using the "ex-servicewoman" label that was initially proposed by the Armed Forces Panel during intervention adaptation phase 1. They highlighted that this label does not accurately represent who they are and is not consistent with how they identify.

> *I really don't like the term 'ex-servicewoman'. I don't want to be viewed as 'ex' anything, but rather who I am now. I'm a female veteran and that's what I would like to be called.*

While it was agreed that the term "ex-servicewoman" was not appropriate, there was wider discussion among participants regarding a preference for what other labels should be used. While all focus group members preferred the term "veteran" to "ex-servicewomen," further discussion highlighted that some still considered it to be too vague.

> *I don't like veteran because it doesn't stipulate what you're a veteran of. You could be a veteran of working in an ice cream van.*

Participants further discussed using the term "female" versus "women" and armed forces, forces, or military. Consensus was finally reached regarding the term "female forces veteran." Discussions around the language adopted here highlight the importance of this EVF dimension when undertaking adaptations for female forces veterans.

Graphics

Participants expressed a complex set of attitudes toward the use of imagery related to the armed forces. There was general acceptance toward using the triservice colors representing the army, navy, and air force. Participants agreed that having the triservice color enhances the immediate association of the app with the armed forces (Figure 3A).

> *Keep the armed forces colors because people with military connections will pick up on that.*

However, it was considered that using armed forces graphics was justified only when restricted to the start of the app. Participants emphasized that as they progressed through the app, the focus of the content needed to shift toward their identity as female forces' veterans. Several participants also discussed that using these graphics within IonaXSW was extensive and could potentially lead to the app being considered "too official," as this was a military platform. It was considered that this could lead to female forces veterans being reluctant to engage initially or maintain engagement with the IonaXSW app.

> *If I could kind of have the benefit of, like, working through the app but without it feeling like too official, so using the image less so it's like 'this is unofficial', you know, then maybe that.*

Another concern participants expressed regarding overusing armed forces–related graphics was that this could result in the app being seen as developed for male rather than female veterans. That is, participants recognized a lack of female veterans' representation in the app.

> *And I think I just worry that if it's all branded, then it's kind of, it's like a bloke thing.*

XSL•FO
RenderX

Figure 3. Adaptations to Iona Female Forces Veterans.

Quotes

All participants agreed that using quotes from female forces veterans within IonaXSW was a good addition to promote motivation and continued engagement. They also agreed that locating these quotes near the start of the app was effective (Figure 3B). However, participants proposed that using quotes throughout IonaXSW should not be limited to the armed forces only but adapted to recognize the transition from the armed forces to civilians.

> *The idea of using quotes was good, however they should not be military because you are transitioning out of the force and want to blend in.*

One solution suggested by a participant was to facilitate the personalization of quotes by enabling users to add their own.

> *I think it's quite nice [to add your own quotes] and you can go back and then have a look at, and, you know, read over them and think oh, actually yeah.*

Consistent with this solution, one participant suggested adding a tab specifically designed to enable users to add their own quotes and organize them into different categories.

> *The motivational quotes are great. There should be a tab full of them with space to enter your own on a pinboard of gratitude, motivation, inspiration, and positivity.*

However, one participant noted that the user may need to exercise caution when allowing others to see their app with personalized quotes, given the unique armed forces sense of humor which could potentially cause offense to others.

> *What you have to remember is the forces have got their own sick sense of humor and I think sometimes our morbid sense of humor comes, comes through, and it is again a very fine line.*

Avatars

Within phase 2, the female forces veterans were unanimous in their dislike of the avatars chosen to introduce the modules included within IonaXSW. Participants expressed concern that the avatars did not appropriately capture the context dimension of the EVF. Although the appearance and voice adopted for the avatar were initially chosen in phase 1 by members of the Armed Forces Panel to be representative of female forces veterans, this was not considered to be the case in phase 2.

> *You look at them [the avatar] and you think, 'Actually, you don't look like you've ever served'. You know the person that you're looking at has to be believable as well I think.*

However, when the same voice was used without the accompanying avatar to introduce different components of the CBT techniques, only the audio was appreciated.

> *I liked the sound of the audio reading it [technique components] out, but would prefer not to see the face and just listen to it.*

App Features

App features refer to attitudes held regarding general features included within IonaXSW to support help seeking, aid navigation and usability, and motivate continued engagement.

SOS Page

Participants highlighted the importance of having contact details for organizations to manage risk or access wider sources of armed forces–specific support. To aid navigation, attention was directed toward providing a relevant structure. This involved moving the helplines to manage high risk provided at the top, followed by Veterans Welfare and Female Veterans Support. Participants also discussed exclusion of any contact details that may become out-of-date.

> *It's very important to ensure that it [link] works and that those listed don't give users what's termed as the "dockyard run around," where they take your details but ultimately don't help you and pass you on.*

Consequently, links to regional organizations were excluded, and contact details for NHS Op COURAGE provided in the event details for regional support were requested. Some participants also recognized that not all users may be aware of the services offered by included organizations. It was therefore

XSL•FO
RenderX

suggested to "include a brief description of what each charity provides."

Navigation

Overall, participants reported IonaFFV as being easy to engage with and that progress through the educational modules was straightforward.

> *Generally, I found it easy to move through the different parts [of IonaFFV] and get to where I wanted to go.*

However, uncertainty was expressed regarding the ability to navigate between the different low-intensity CBT techniques if they wanted to.

> *Can, I ask, is there a back button? And you know if, if, at the moment, I'm going down one course [low-intensity technique], because that's what I selected, but can you go back to select another one? I haven't quite found that out.*

Monitoring

Features adopted in IonaFFV to support users in recognizing their progress and achievements after completing specific tasks were generally well received by participants in phase 4.

> *I do like having the progress shown, and the praise for completing things.*

While participants appreciated knowing when a module had been completed, the use of graphics representing fireworks and confetti, along with the collection of badges to represent completion, was considered inappropriate for the target audience.

> *Get rid of the fireworks 'pop up'. It's a bit patronizing; but yes, to having something that recognizes your achievement. Likewise, the concept of getting badges is great, but the look is a bit childish and patronizing.*

No Adaptations Needed

Three main screens and interactive functionality were positively responded to by all focus group members in phase 2 and did not need further adaptation. This potentially indicates that initial adaptations in these areas made to accommodate female forces veterans were compatible with the content, methods, and context dimensions of the EVF.

CBT Model

Participants identified the "Here and Now" CBT model as helping the user understand the way in which a mental health difficulty can affect different areas of their life.

> *I liked the diagram [CBT model] where all the different areas associated with a problem were linked together. It helped show how different things are linked and sorting one out by using a treatment [CBT technique] can help the others.*

Additionally, being able to complete the CBT model themselves was also found helpful. This enabled participants to personalize the app to their experience and motivated them to remain engaged.

> *I liked that you filled in the boxes for yourself, so it reflected the problems you were having, and this made it more likely you wanted to carry on using it.*

Enhancing Contextual Factors

All participants agreed that presenting a screen with the names of trusted armed forces veterans' organizations and a university at the start of IonaFFV engagement helped them establish a sense of trust and raised their expectations regarding the app's effectiveness (Figure 3C).

> *Seeing that screen with the armed forces and University logos was good as it made me feel I could trust the app and that it may help.*

Mapping Users

All participants positively evaluated the screen designed to simulate the location of other app users (Figure 3D). One main benefit of this screen was to support an awareness that other female forces veterans were also using the app. This, in turn, led to motivating participants and supporting continued engagement.

> *I didn't realize there was that many people using it around my area. If there's that many people using it, it motivates me to maybe use it more because others are clearly using it as well.*

It was also considered that this screen would enhance engagement by creating a sense of community between female forces veterans. This sense of community helped participants recognize that their difficulties were shared by others, which may have reduced feelings of isolation and encouraged help-seeking behavior.

> *Adds a sense of community. Encourages you to believe you're not the only one [female forces veteran] facing mental health difficulties. In this sense it motivates you.*

The potential benefit of developing a map to enable users to contact each other highlights the importance of peer support in promoting mental health and the need for having this conversation.

> *Would it be possible to contact people who have started using the app? I would be really interested in knowing if I could meet them.*

Support Preferences

All focus group members highlighted the importance of having some form of human support available. They suggested that support could promote and maintain engagement with the app and be beneficial, especially where users are struggling.

> *Some human help might be useful, especially if after two weeks you've stopped engaging with the app as you are having problems.*

While providing face-to-face support was highlighted as a potential opportunity to further enhance and maintain

XSL•FO
RenderX

engagement, it was also considered that some participants may need it to be offered.

> *Face to face is a level of support that people ask for, but they don't actually know how to ask, so being offered it would make it easier, especially when struggling.*

Telephone support also emerged as an acceptable support modality. However, some considerations were raised regarding ways to provide and access it.

> *Regarding telephone calls, many don't answer calls from strangers, so if this were to be offered it might work better if a text was sent prior to a telephone call to advise that it [the call] is imminent.*

Furthermore, providing peer support from other female forces veterans was raised as having considerable potential with good levels of acceptability.

> *...peer to peer support is very underused but has a positive impact for us female veterans if the right person with similar experiences to us was in the role.*

Phase 5 (Acceptability)

Median (IQR) values across each of the MAUQ subscales were as follows: ease of use 1.80 (1.20 - 2.80), interface and satisfaction 2.50 (1.54 - 3.33), and usefulness 2.75 (1.75 - 4.00). Note that the lower values indicate higher agreement. Each subscale was further examined to determine percentage agreement with each statement (Table 3). Responses to some items were missing, resulting in varied sample sizes across items (n=19 - 20). Overall, most participants agreed with each statement, indicating that the app was highly acceptable, except for "I could use the app even when the Internet connection was poor or not available," rated by 63% of participants as neutral or disagreed.

XSL•FO
RenderX

Table . Agreement with each statement.

	Strongly agree/agree	Neutral	Strongly disagree/disagree
Ease of use, n (%)			
The app was easy to use.	17 (85)	0 (0)	3 (15)
It was easy for me to learn and use the app.	19 (95)	1 (5)	0 (0)
The navigation was consistent when moving between screens.	19 (95)	0 (0)	1 (5)
The app interface allowed me to use all the functions offered by the app (such as entering information, responding to reminders, and viewing information).	18 (90)	0 (0)	2 (10)
Whenever I made a mistake using the app, I could recover easily and quickly.	12 (60)	7 (35)	1 (5)
Interface and satisfaction, n (%)			
I like the interface of the app.	17 (85)	2 (10)	1 (5)
The information in the app was well organized, so I could easily find the information I needed.	14 (70)	2 (10)	4 (20)
The app acknowledged and provided information to let me know the progress of my action.	18 (90)	1 (5)	1 (5)
I feel comfortable using this app in social settings.	14 (74)	3 (16)	2 (10)
The amount of time involved in using this app has been fitting (adequate) for me.	13 (69)	1 (5)	5 (26)
Overall, I am satisfied with this app.	12 (60)	1 (5)	7 (35)
Usefulness, n (%)			
The app would be useful for my health and well-being.	11 (58)	2 (10)	6 (32)
This app has all the functions and capabilities I expected it to have.	14 (70)	4 (20)	2 (10)
I could use the app even when the Internet connection was poor or not available.	7 (37)	9 (47)	3 (16)
The app provides an acceptable way to receive mental well-being services and allows me to track my own activities.	15 (75)	2 (10)	3 (15)

Using a 7-point Likert scale (1=Strong Agree to 7=Strongly Disagree) a descriptive analysis was undertaken on questions related to 5 main areas associated with IonaFFV. Participants considered the language engaging (mean 1.85, SD 0.87), SOS button was required in the event of a mental health crisis (mean 1.95, SD 1.47), and the signposting information included within IonaFFV was helpful (mean 2.50, SD 1.38). However, it was considered that signposting details to regional organizations should be provided (mean 2.10, SD 1.15). Participants also indicated a need for human support to engage with the app (mean 1.90, SD 1.18). In follow-up questions about human support, where participants could select more than 1 option, there was a preference for weekly scheduled support provided by a professional or voluntary or community sector staff over the telephone (Table 4).

[b]CBT: cognitive behavioral therapy.

Interestingly, while there was least preference for weekly support to be provided by peers, using peers was identified as the most preferred in the event support was provided on demand. Where support was provided, it was considered that it should be focused on motivating continued engagement and supporting engagement with techniques used within the app as required.

Discussion

Principal Findings

Overall, adopting CBT as the basis of an app to support low mood and worry management in female forces veterans was acceptable. Participants found that the CBT model adapted to reflect female forces veterans both aided understanding of their emotional difficulties and helped tailor the app to them as a distinct group. Furthermore, there was good engagement with techniques used to support low mood and worry management, with initial engagement further enhanced by highlighting use of IonaFFV by other users at the start of engagement and the contextual factors. However, participants differ from most previous research studies with respect to the following characteristics: from the Navy, underwent unplanned discharge, and deployed. Although the average age is consistent with previous research examining access to the Op COURAGE high-intensity service [10].

Applying the EVF [43] to inform the development of an artificial intelligence–supported CBT app for the management of low mood and worry was, however, important to enhance acceptability and usefulness among female forces veterans. Analysis of phases 2 and 4 highlighted the need to make

XSL•FO
RenderX

adaptations to ensure that IonaFFV specifically represented their transition from serving into civilian life. Focusing on the EVF context dimension highlighted the need to redirect adaptations from serving to female forces veterans to adequately capture this transition while maximizing acceptability. This was exemplified by reactions to the term "ex-servicewomen," which was not considered to represent a new civilian identity while acknowledging their past service in the armed forces. This highlights the importance of the language dimension of the EVF when considering adaptations for female forces veterans.

Of interest, "ex-servicewomen" was the term originally proposed during phase 1 of the development process comprising senior members of the armed forces community and service providers. Furthermore, while phase 1 was used to identify the graphics and voices for use by the avatars, these were not considered to represent female forces veterans as a group and therefore removed during development. Adaptations were also required to enhance usability with respect to the structure of the SOS page, enhance navigation through the app where there was a desire to change CBT technique, and enhance the way in which progress was captured.

Comparison With Previous Research

Consistent with previous research, the findings of this study reinforce the significant role that serving in the armed forces plays in shaping the identities of both male and female veterans [56]. The results emphasize the particular challenges faced by female forces veterans in negotiating their identities during the transition to civilian life [6]. This highlights the need for tailored approaches that acknowledge their unique experiences in the armed forces. While female forces veterans are often "hypervisible" during their military careers, they may simultaneously suppress behaviors traditionally considered feminine [7]. Failure to recognize these adaptive strategies supports the need identified in this study for appropriate modifications to IonaFFV. Implementing adaptations was recognized to improve acceptability by better reflecting the experiences of female forces veterans as they transition from life in the armed forces to becoming a civilian [6].

While the initial adaptations to IonaXSW used graphics aligned with the armed forces to enhance engagement, participants emphasized the importance of gradually reducing the focus on the armed forces as they progressed through the app to better reflect civilian life [7]. They also recommended replacing quotes associated with the armed forces context with those drawn from civilian life. A lack of recognition of the transition from military to civilian identity could have hindered the process of "rediscovery" that supports successful reintegration [7]. Furthermore, failing to change the term "ex-servicewomen" [1,7], proposed in adaptation phase 1 to female forces veterans, would have further reflected a transition oversight. However, the preference to maintain "veteran" is not consistent with previous research [57], where it is traditionally considered to reflect previous generations of male veterans [57]. Potentially, these differences have arisen from study demand characteristics, given that recruitment materials adopted the term "veteran" [58].

Features of IonaXSW that did not require adaptation are consistent with those commonly identified as acceptable with CBT [59]. For example, the CBT model both enhanced understanding regarding the nature of the mental health difficulty faced and aided an understanding of the way the low-intensity CBT technique may help [60]. Furthermore, consistent with a metasynthesis of computerized CBT, personalization of CBT-specific factor content enhanced relevance [61], promoting connection and engagement. The screen simulating the location of other female forces veterans also served to normalize mental health support [62] and encouraged lateral social comparisons [63].

While the chatbot successfully maintained user engagement with IonaXSW, consistent with findings from CBT-based self-help interventions more broadly, participants continued to express a preference for human support [64]. Among the various forms of support considered acceptable, the most preferred option was scheduled weekly sessions with a professional from a veteran-specific NHS service. This finding suggests potential benefits of integrating support for IonaFFV through services such as Op COURAGE [10]. However, despite the overall acceptability of this service [10], its evaluation included only male veterans, which limits the generalizability of the findings to female armed forces veterans.

Alternatively, nearly half of the participants preferred on-demand peer support, indicating potential advantages similar to those observed with peer-support groups [65]. Implementing IonaFFV alongside support from female forces veterans within veteran-specific services [9] could serve to enhance help-seeking and address existing barriers to engagement [66]. Moreover, as low-intensity CBT techniques can improve access to care, adoption could enable services to manage increased demand without extending waiting times [67]. While IonaFFV incorporates in-app support to promote engagement [68], incorporating peer support could mitigate low levels of engagement with a stand-alone app following download [69].

Strengths and Limitations

Adopting an approach toward adaptation comprising focus groups to guide initial modifications and using the MAUQ [53] to assess acceptability offers a means to evaluate how well these adaptations are acceptable to a broader group of female forces veterans. This methodology could help address challenges related to the limited generalizability of focus group data [70]. However, the small number of participants completing the MAUQ limited further analysis regarding the acceptability of IonaFFV across different demographic groups. Specifically, only a single participant had served in the Royal Air Force, identified as non-White, or had experience as a reservist. Recruitment challenges for phase 5 may have been influenced by the requirement for participants to engage with IonaFFV for 4 weeks before completing the questionnaire. Therefore, future research should consider strategies to enhance recruitment and questionnaire completion before assessing the acceptability and usability of IonaFFV and generalizing study results [71].

It may also have been of benefit to collect additional information in phase 5 regarding the service experiences of female forces veterans. Female forces veterans experience higher levels of

XSL•FO
RenderX

in-service adversity than their male colleagues, including exposure to military sexual trauma [72]. Although IonaFFV was explicitly designed for female forces veterans experiencing low mood or difficulties with worry management, some questionnaire responses may have been influenced by past service-related adversity. This possibility was suggested by a free-text questionnaire response which indicated that the participant may have been experiencing moderate to severe mental health difficulties. Gathering more comprehensive data on participants' service experiences could have supported a deeper interpretation of the findings and informed further adaptations, such as incorporating broader signposting information.

Conclusions

There is a clear need to recognize female forces veterans as a distinct group from their male peers. While sharing many values and traditions common across the armed forces, they also hold a collective identity that differs from that of male veterans [73]. Addressing the current inequities in access to, and appropriateness of, mental health services for female veterans [8,14] requires a focus on enhancing the acceptability of veteran-specific services. In particular, using dimensions of the EVF to structure the focus group topic guide was valuable to identify the types of adaptations necessary to maximize acceptability. The EVF also helped highlight how these dimensions shift during the transition from serving to armed forces veteran, offering insight into how mental health services can be better tailored for female forces veterans. When applied to the development of a CBT-based mobile phone app for managing low mood and worry, the EVF informed adaptations that produced a digital mental health approach with strong usability, acceptability, and perceived usefulness among female forces veterans.

Acknowledgments

The authors are grateful to members of the Armed Forces Panel, the female forces veterans comprising the focus group and those completing the acceptability questionnaire for participating in this study, and to the female veterans' charities for supporting recruitment into phase 5 of the study.

The authors attest that there was no use of generative artificial intelligence (AI) technology in the generation of text, figures, or other informational content of this manuscript

Funding

This paper has been produced with funding from the Office for Veterans' Affairs in April 2023 as part of an independent research initiative. The views, findings, and conclusions expressed herein are those of the authors and do not reflect the policies or positions of the UK Government.

Data Availability

mHealth App Usability Questionnaire data are available only on request from the authors.

Authors' Contributions

PF conceptualized and designed the study with AB providing theoretical input informing the background of the paper and armed forces context and supporting recruitment. NF, MJ, and ET were involved in data analysis, with JB undertaking adaptations to the Iona app, drafting the section describing the app, and clarifying any uncertainties regarding the app description. PF wrote the initial draft of the paper, with all authors contributing to the development of the paper, interpretation of the analysis, and editing of the final manuscript.

Conflicts of Interest

JB is a full-time employee, and PF is on a paid sabbatical with Iona Mind Inc from the University of Exeter ending October 2025. All other authors have confirmed that they have no conflicts of interest to declare.

Abstract

Background: The widespread use of digital technologies has raised growing concerns about their impact on mental health. While self-regulation has been proposed as a protective factor, little is known about how distinct psychological profiles based on self-regulatory and technology use patterns relate to psychological distress. Person-centered approaches, such as latent profile analysis, may offer deeper insights, particularly in underrepresented populations.

Objective: This study aimed to identify latent psychological profiles based on self-regulation, nomophobia (fear of being without a phone), and problematic use of the internet and social media (defined by behavioral symptoms), to examine their associations with general psychological distress and the presence of emotional symptoms in a Colombian sample. Additionally, the predictive roles of age and gender in class membership were explored.

Methods: Participants were recruited through a convenience sampling strategy aimed at ensuring heterogeneity of the sample in terms of age and gender. A total of 453 participants aged 12 to 57 years (mean 21.03, SD 8.41 years; 257/453, 56.7% female) completed validated measures of self-regulation (Abbreviated Self-Regulation Questionnaire), nomophobia (Nomophobia Questionnaire), internet and social media use (MULTICAGE-TIC, a multidomain screening questionnaire based on the CAGE framework), and psychological distress (General Health Questionnaire-12). Latent profile analysis was conducted using standardized scores of continuous variables. Model fit was assessed using the Bayesian information criterion, entropy, and bootstrapped likelihood ratio test. Differences in psychological distress scores across latent classes were examined through variance analysis (ANOVA) and regression models. A multinomial logistic regression tested the predictive value of age and gender for class membership.

Results: The optimal solution revealed 4 distinct latent profiles (entropy=0.85). Class 1 showed high self-regulation and low problematic technology use, displaying the lowest psychological distress scores. Class 2 presented moderate levels across all indicators but the highest level of psychological distress. Classes 3 and 4 showed mixed patterns. Class 3 (higher information and communication technology [ICT] use and lower self-regulation) exhibited lower distress than class 2, whereas class 4 (younger individuals with low self-regulation and moderately high ICT use) showed higher distress than class 3. Psychological distress differed significantly across profiles (ANOVA, $P<.001$). Age and gender predicted class membership. Older males were more likely to belong to class 1, and younger females were more likely to be classified into classes 3 and 4.

Conclusions: Latent profile analysis identified distinct configurations of digital behavior, self-regulation, and psychological distress. Self-regulation consistently differentiated profiles with lower distress scores, suggesting its relevance for understanding how individuals manage ICT use. These findings support the value of person-centered approaches to characterize heterogeneous patterns of technology-related behaviors. The study provides evidence from a Spanish-speaking sample, offering a novel perspective on psychological distress and problematic technology use in contexts that remain underrepresented in the literature.

Introduction

Background

The global use of information and communication technologies (ICTs) has grown exponentially over the past decade, with more than 67% of the world's population connected as of 2023 [1]. In Latin America, countries, such as Brazil, Argentina, and Colombia, report daily usage exceeding 9 hours, driven by the widespread adoption of mobile devices and the growing popularity of social media platforms [1-3].

In parallel with this digital expansion, studies have reported a rise in problematic behaviors associated with technology use, with documented consequences for both physical and psychological health [4]. Although terms, such as problematic use, digital addiction, and technology dependence, are frequently adopted, there is still no consensus regarding their clinical classification. The literature distinguishes subtypes, including problematic internet use, social media use, smartphone use [5], gaming disorder, and nomophobia [6], which reflect the multidimensional nature of the phenomenon [7]. Some authors argue that problematic technology use shares features with behavioral addictions, social anxiety, and sleep disturbances [8] or compulsive habits [9,10]. However, others suggest that its consequences do not reach the severity of substance addictions and therefore recommend distinguishing among abuse, dependence, and problematic use [11].

Among these, nomophobia has emerged as a relevant subtype of problematic technology use, with direct psychological effects (anxiety, stress, and insomnia). Defined as the irrational fear of being without a mobile phone [6,12], nomophobia is associated with anxiety, insomnia, dependency, and greater psychological vulnerability [13].

This raises the question of which personal protective factors can mitigate the consequences of problematic technology use. Self-regulation, understood as the ability to manage impulses and behaviors, has been studied as a protective factor against both substance-related and behavioral addictions. Evidence suggests that higher self-regulation is associated with greater psychological well-being, healthier digital habits, and reduced procrastination [14-16]. Baumeister and Heatherton [17] proposed that self-regulation failure occurs when individuals are unable to inhibit immediate impulses in favor of long-term goals. In the digital context, this translates to difficulty controlling screen time or compulsive smartphone use, despite the obvious negative consequences.

Empirical evidence supports the notion that deficits in self-regulation are linked to both problematic technology use and broader mental health problems [18-20]. Conversely, higher self-regulation is associated with greater psychological well-being, healthier digital habits, and reduced procrastination [21-24].

Most previous studies have addressed problematic technology use, focusing on average trends and assuming population homogeneity, which obscures subgroup differences. This gap may be explained by the predominant use of variable-centered approaches [25]. In contrast, person-centered approaches, such as latent profile analysis (LPA), enable the identification of specific profiles (subgroups characterized by combinations of self-regulation, ICT use, and nomophobia), thereby revealing differential patterns of psychological distress. For example, it has been demonstrated that self-regulation profiles among students were significantly associated with variations in well-being [26] and personality profiles influenced mental health differently during the pandemic [27].

Aim

This study aimed to identify distinct psychological profiles through LPA, based on the levels of self-regulation, nomophobia, and internet and social media use. By adopting a person-centered approach, the study seeks to uncover subgroups characterized by combined patterns of problematic technology use and self-regulation.

The identified profiles will be examined in relation to age and sex as covariates to determine whether these sociodemographic variables predict membership in specific profiles. In addition, the profiles will be compared in terms of their differential levels of psychological distress, thereby providing a more detailed understanding of whether distinct patterns of problematic technology use and self-regulation have varying impacts on distress scores. This, in turn, provides a basis for designing differentiated and personalized interventions.

Finally, by incorporating a Colombian sample, this study contributes to addressing the scarcity of empirical evidence in Spanish-speaking populations, particularly in Latin America, where digital growth has not been matched by equal progress in preventive and clinical research [28].

Methods

Ethical Considerations

The project was previously approved by the Bioethics Committee of the Konrad Lorenz University Foundation (number: 07-23). This study was conducted in accordance with the ethical principles established in Law 1090 of 2006, particularly Article 13 [29], which states that all professional conduct in psychology must be based on the core principles of the profession, including beneficence and nonmaleficence. In line with these principles, the study used self-report instruments without applying procedures that could pose harm or risk to participants.

This consent process ensured participant autonomy by providing full study information, the opportunity to ask questions, and the option to participate voluntarily. Throughout the research process, participant responses were anonymized, and data were reported in aggregate form to prevent identification of individuals. All identifying data, such as gender, education level, and individual test responses, were replaced with codes. Participation in the study was voluntary and involved no financial compensation, and participants could withdraw at any time without consequences.

Participants

Participants were recruited through a convenience sampling strategy aimed at ensuring heterogeneity of the sample in terms

XSL•FO
RenderX

of age and gender, utilizing both digital and institutional channels. Specifically, the research team distributed the study invitation via social media platforms (Facebook and WhatsApp) and during in-person and virtual classes at 3 universities in Colombia. Individuals interested in participating accessed the study link hosted on Jotform, which included the eligibility criteria and the informed consent form. Recruitment was conducted directly by the research team members. The inclusion and exclusion criteria are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Age between 12 and 60 years
- Colombian nationality
- Possession of a smartphone with internet access
- Ability to provide informed consent

Exclusion criteria

- Diagnosed with a severe condition that limits the ability to answer self-report questionnaires
- Inability to read or understand Spanish
- Lack of internet connectivity that prevents completing an online survey
- Withdrawal of informed consent during participation

Instruments

The MULTICAGE-TIC (a multidomain screening questionnaire based on the CAGE framework) [30] is a questionnaire designed to identify problematic behaviors associated with the use of ICT. Its design is based on the MULTICAGE CAD-4 [31], a screening instrument that assesses compulsive behaviors related to both substance and nonsubstance use and has been widely used to measure behavioral addictions. The MULTICAGE-TIC evaluates 5 areas of ICT use: mobile phones, internet, social media, video games, and instant messaging. A subscale with 4 items represents each area, with each scoring 4 - 8 points. Responses are dichotomous (no=1 point; yes=2 points). According to the suggested interpretation of the authors, usage is classified as nonproblematic (when no response or 1 response is affirmative; 4 - 5 points), at risk (when 2 responses are affirmative; 6 points), and problematic (when 3-4 responses are affirmative; 7 - 8 points). For this study, the areas of internet use and social media use (each with 4 items) were considered representative of overall ICT usage. In previous studies, the instrument has demonstrated adequate reliability levels, with McDonald ω and Cronbach α coefficients above .70 across all subscales. Additionally, its scores have been found to correlate significantly with symptoms of prefrontal dysfunction and psychological distress [32].

The Nomophobia Questionnaire (NMP-Q) [6] measures nomophobia, which is defined as a situational phobia caused by a lack of availability of a smartphone or the thought of not having it, not being able to use it, or losing it. It contains 20 items and 4 dimensions: “communication inability” (6 items), “loss of connection” (5 items), “inability to access information” (4 items), and “renunciation of convenience” (5 items), which can explain 69.5% of the variance. The internal consistency of the factors is between 0.81 and 0.94. Responses are recorded on a 7-point Likert scale, ranging from “1” (strongly disagree) to “7” (strongly agree). The total score ranges from 20 to 140. The Spanish version of the test, which has been validated in a Colombian population [33], was used.

The General Health Questionnaire-12 (GHQ-12) is a brief screening scale designed to detect potential indicators of psychological distress and the risk of mental disorders in the general population [34]. The version used was validated for the Colombian population [35]. It assesses aspects such as emotional symptoms, stress, anxiety, and overall psychological functioning. The scale consists of 12 items with a 4-point Likert response format (range 0 - 3). Higher scores on the GHQ-12 reflect greater psychological distress and poorer mental health. Previous studies have shown a unidimensional structure and significant associations with variables such as experiential avoidance and life satisfaction [35].

The Abbreviated Self-Regulation Questionnaire (CAR-abr) was initially developed by Brown [14]. Its abbreviated Spanish version, which has been validated in a Colombian population [15], was used. It assesses individuals’ general self-regulatory capacity. It comprises 17 items, with Likert-scale response options organized into 4 subscales. The scale has demonstrated solid psychometric performance in terms of both the fit to the Rasch model and the quality of its items and response categories. Previous studies have reported internal consistency values ranging from 0.75 to 0.80, as well as evidence of structural and content validity [15].

Procedure

The project was previously approved by the Bioethics Committee of the Konrad Lorenz University Foundation (number: 07 - 23). The protocol and consent are consistent with the Colombian Code of Ethics [29], which guarantees the anonymous and confidential treatment of the data collected. With institutional authorization, participants were recruited through social networks and public schools in the city. Participants provided informed consent before answering the questionnaires, and guardian assent was obtained for minors.

XSL•FO
RenderX

The instruments were applied virtually and voluntarily, without remuneration.

Data Analysis

All analyses were conducted in RStudio (version 2024.12.1+563; Posit).

To address the possibility of common method bias arising from same-source, same-time self-reports, we planned to conduct 2 complementary tests. First, we applied the Harman single-factor test using a polychoric exploratory factor analysis with all items (self-regulation, nomophobia, internet use, social media use, and GHQ-12 score). Second, we conducted a series of confirmatory factor analyses comparing the following three models: (1) a trait model specifying the 5 latent constructs, (2) a 1-factor model in which all items loaded on a single factor, and (3) an unmeasured latent method construct model that incorporated both the trait factors and a latent method factor. Analyses were performed using the packages psych (for polychoric exploratory factor analysis), lavaan (for confirmatory factor analysis estimation), and semTools (for reliability and method-factor modeling).

All psychological and behavioral indicators were included in an LPA, a person-centered modeling approach designed to identify subgroups of individuals based on similar patterns of responses [36]. The LPA was conducted using 4 continuous indicators: self-regulation, nomophobia, internet use, and social media use. These variables were standardized before analysis to ensure comparability. Models with 1-4 profiles were estimated using the tidyLPA package in R.

Multiple statistical criteria, including the Bayesian information criterion (BIC), Lo-Mendell-Rubin likelihood ratio test (bootstrapped likelihood ratio test [BLRT]), class size, posterior probability, and entropy, guided model selection. The 4-profile model showed the lowest BIC and acceptable entropy (0.85), supporting its selection as the optimal solution. This model yielded 4 distinct psychological profiles based on the interplay between digital behavior and self-regulation.

To evaluate between-group differences in psychological distress across profiles, we first conducted an ANOVA. Pairwise comparisons were examined using Tukey post hoc tests. Then, psychological distress scores were modeled using an ordinary least squares linear regression, with latent classes entered as dummy-coded predictors (class 1 as the reference category). Additionally, a multinomial logistic regression model was estimated, with age and gender as covariates, to predict latent class membership. All visualizations and analyses were performed in R using packages such as ggplot2, nnet, and tidyLPA. Given the exploratory nature of this study and the person-centered approach adopted, no a priori hypotheses were specified regarding the number or structure of latent profiles.

Results

Participant Characteristics

The study recruited 453 participants located in Colombia. Participants were 196 males (43.3%) and 257 females (56.7%), reporting an age between 12 and 57 years, with an average age of 21.03 years (SD 8.41 years). In terms of age distribution, 221 participants were between 12 and 17 years old, 145 were between 18 and 25 years old, and 87 were above 26 years old. Moreover, 70.2% (318/453) of participants were elementary and high school students, while the remaining 29.8% (135/453) had completed technical or professional studies. The majority were single (423/453, 93.4%) and resided in urban areas (417/453, 92.1%). Sociodemographic data are presented in Table 1.

XSL•FO

Postgraduate education	23 (5.1)

[a]Lower income (1) to higher income (5).

[b]Education level indicates the final level of education.

Psychometric Properties

We obtained internal consistency values. For internet use, the McDonald ω coefficient was 0.61, composite reliability (CR) was 0.76, and average variance extracted (AVE) was 0.45. The social media use scale yielded robust psychometric indicators, with a McDonald ω coefficient of 0.75, a CR of 0.86, and an AVE of 0.62, exceeding the recommended threshold.

The NMP-Q showed the strongest indicators among the instruments evaluated. The McDonald ω coefficient and CR were 0.96 and 0.97, respectively, and both were in the excellent range. Additionally, the AVE reached 0.62, indicating adequate convergent validity. Factor loadings were consistently high (0.65-0.91), confirming the internal coherence and explanatory power of the scale.

The total score of the CAR-abr was used as a global indicator of self-regulation, and the values obtained demonstrated high reliability (ω=0.89; CR=0.90), supporting its internal consistency. Nevertheless, the AVE was 0.35, which is below the minimum criterion, suggesting that items do not share enough common variance to ensure strong convergent validity. Despite this, the reliability level suggested that the measure is stable, although it may be multidimensional in its factorial structure.

The GHQ-12 demonstrated adequate internal consistency, with a total McDonald ω coefficient of 0.75 and a CR of 0.76. The AVE was 0.45, which is slightly below the recommended threshold of 0.50, indicating limitations in convergent validity. This pattern indicates that, although the scale is reliable, some items contribute less common variance, which may reflect the multidimensional nature of psychological distress symptoms.

Common Method Bias

The Harman single-factor test showed that the first factor accounted for 25.78% of the variance, which is well below the conservative threshold of 50% - 60%, indicating the absence of a dominant single factor [37]. In the confirmatory factor analyses, the trait model demonstrated good fit (comparative fit index [CFI]=0.959; Tucker-Lewis index [TLI]=0.957), whereas the 1-factor model showed substantially poorer fit (CFI=0.853; TLI=0.847; root mean square error of approximation [RMSEA]=0.181; standardized root mean square residual=0.155). The unmeasured latent method construct model did not yield any meaningful improvement over the trait model (ΔCFI=0.0001; ΔRMSEA=0.0000), and the variance attributable to the method factor was only 3.1% [38]. Taken together, these results suggest that although a small amount of variance may be attributable to method effects, common method bias did not substantively distort the relationships among the study constructs.

Descriptive Statistics of Indicator Variables

The variables used to estimate the latent profiles included self-regulation, nomophobia, internet use, and social media use. Self-regulation showed a mean score of 58.21 (SD 9.58), while the nomophobia score ranged from 20 to 140 points, with a

XSL•FO
RenderX

mean of 61.58 (SD 27.95). For "internet use" and "social media use," usage has been classified as nonproblematic (when no response or 1 response is affirmative; 4 - 5 points), at risk (when 2 responses are affirmative; 6 points), and problematic (when 3-4 responses are affirmative; 7 - 8 points). Details are provided in Table 2.

Table . Descriptive statistics.

Variable	Mean (SD)	Minimum value	Maximum value
Self-regulation	58.21 (9.58)	25	84
Nomophobia	61.58 (27.95)	20	140
Internet use	5.86 (1.30)	4	8
Social media use	5.45 (1.41)	4	8

Associations Between Variables

Following previous guidelines [39], correlations below 0.30 were considered small, those at 0.30-0.50 were considered moderate, and those above 0.50 were considered large. In psychological and health sciences, even small associations may be meaningful at the population level [40]. The results of the associations were in the expected direction. Correlations between variables revealed moderate relationships between nomophobia and internet use (r=0.378) and social media use (r=0.361). There were significant negative correlations between self-regulation and internet use (r=−0.314), and between self-regulation and social media use (r=−0.211). Moreover, higher levels of self-regulation were associated with lower use of these ICTs.

Higher GHQ-12 scores indicated more psychological distress. A negative moderate correlation was found between self-regulation and psychological distress scores (r=−0.506), suggesting that higher self-regulation was associated with lower psychological distress. Nomophobia showed a small positive correlation with psychological distress (r=0.261). Moreover, there were positive correlations between internet use and psychological distress (r=0.327), and between social media use and psychological distress (r=0.188) (Table 3), indicating that more problematic technology use correlates positively with higher distress scores.

Table . Correlation values between variables.

Pair	Correlation	Bootstrapped 95% CI[a]
Self-regulation versus nomophobia	−0.208[b]	−0.301 to −0.113
Self-regulation versus internet use	−0.314[b]	−0.405 to −0.218
Self-regulation versus social media use	−0.211[b]	−0.310 to −0.114
Self-regulation versus psychological distress	−0.506[b]	−0.564 to −0.442
Nomophobia versus internet use	0.378[b]	0.290 to 0.465
Nomophobia versus social media use	0.361[b]	0.270 to 0.445
Nomophobia versus psychological distress	0.261[b]	0.164 to 0.361
Internet use versus social media use	0.592[b]	0.519 to 0.658
Internet use versus psychological distress	0.327[b]	0.238 to 0.411
Social media use versus psychological distress	0.188[b]	0.086 to 0.285

[a]With 1000 iterations in the percentile method.

[b]Correlation is significant (P<.001; 2-tailed).

LPA (Model Without Covariates)

An LPA was conducted to test solutions ranging from 1 to 4 classes. The 4-class model was identified as the best fit based on the BIC. Models with 1 to 4 classes were evaluated using fit indices such as the BIC, entropy, and the BLRT.

The 4-class model showed the lowest BIC (4710), an acceptable entropy (0.85), and a significant improvement over the 3-class model (BLRT P<.01), indicating adequate class separation. Additionally, all classes represented more than 5% of the sample (minimum=17%), suggesting a stable and well-differentiated solution. Details are provided in Table 4.

XSL•FO

Table . Fit statistics and class distribution for competing latent profile analysis models.

Class model[a]	LogLik[b]	AIC[c]	BIC[d]	SABIC[e]	Entropy	BLRT[f] *P* value	n_min (%)[g]	n_max (%)[h]
1	−2569	5154	5187	5161	1.000	—[i]	100	100
2	−2391	4807	4861	4819	0.817	.0099	34.4	65.6
3	−2356	4748	4822	4765	0.745	.0099	26.5	43.0
4[j]	−2285	4615	4710	4637	0.852	.0099	17.2	36.9

[a]Number of latent profiles or classes estimated in the model.
[b]LogLik: log-likelihood.
[c]AIC: Akaike information criterion.
[d]BIC: Bayesian information criterion.
[e]SABIC: sample size–adjusted BIC.
[f]BLRT: bootstrapped likelihood ratio test.
[g]Percentage of the sample assigned to the smallest class.
[h]Percentage of the sample assigned to the largest class.
[i]Not applicable.
[j]Selected model.

The entropy value of the 4-class model was 0.852, indicating good class separation. The BLRT yielded *P*<.01 for model comparisons, supporting the inclusion of additional classes.

Description of the Resulting Profiles or Classes

Figure 1 presents the standardized mean scores (*z* scores) for each latent profile, representing the deviation of each class mean from the overall sample mean. For instance, class 1 scored about 1 SD above the sample mean in self-regulation (+1.0 SD) while remaining nearly 1 SD below the mean in nomophobia and ICT use (–1 SD). In contrast, class 2 showed slightly below-average scores across all variables, including self-regulation, nomophobia, and ICT use (–0.3 to –0.5 SD). Class 3 profiles had self-regulation about 1 SD below the mean (–1 SD), and nomophobia and ICT use more than 1 SD above the mean (+1 to +1.5 SD). Finally, class 4 exhibited moderately low self-regulation (–0.5 SD) in combination with average levels of ICT use and nomophobia (0 SD).

Figure 1. Four-class solution of the latent profile analysis (*z* scores across study variables).

The qualitative interpretation of the latent classes suggested that class 1 was characterized by high self-regulation, low nomophobia, and low ICT use. Class 2 exhibited a more balanced but generally lower profile, characterized by slightly below-average levels of self-regulation, nomophobia, and ICT use. Class 3 was characterized by low self-regulation combined

XSL•FO
RenderX

with high nomophobia and ICT use. Finally, class 4 presented a mixed profile, with moderately low self-regulation and average levels of nomophobia and ICT use. These standardized differences highlight that the most distinctive contrast was present between class 1 (high regulation, low ICT use) and class 3 (low regulation, high ICT use), whereas classes 2 and 4 represented more intermediate or mixed profiles.

Analysis With Predictor Covariates (Age and Sex)

A multinomial model with covariates was also used. Age (as a continuous variable) and sex (1=female; 2=male) were included as latent class membership predictor covariates (class 1 as reference; see Table 5). Age significantly increased the odds of belonging to class 4 (β=−0.70, SE=0.20; *z*=−3.43; *P*<.001; odds ratio [OR] 0.50, 95% CI 0.34-0.74), indicating that younger participants were more likely to belong to this profile. The association with class 3 had a *P* value of .07, and no effect was observed for class 2 (*P*=.55). Regarding gender, males were less likely than females to belong to class 2 (β=−0.68, SE=0.26; *z*=−2.67; *P*=.007; OR 0.51, 95% CI 0.31-0.83). No other gender contrasts reached statistical significance (*P*>.29). Overall, demographic covariates showed selective but meaningful differentiation of latent profiles.

Table . Results of the multinomial model with age and sex as predictors of latent class membership.

Comparison (reference: class 1)	Predictor[a]	β (log-odds, standardized)[b]	SE	*z*	*P* value	OR[c] (95% CI)
Class 2 versus class 1	Age_z	−0.068	0.115	−0.59	.55	0.93 (0.75-1.17)
Class 2 versus class 1	Male versus female	−0.680	0.255	−2.67	.007	0.51 (0.31-0.83)
Class 3 versus class 1	Age_z	−0.252	0.137	−1.84	.07	0.78 (0.59-1.02)
Class 3 versus class 1	Male versus female	−0.277	0.263	−1.06	.29	0.76 (0.45-1.27)
Class 4 versus class 1	Age_z	−0.695	0.203	−3.43	<.001	0.50 (0.34-0.74)
Class 4 versus class 1	Male versus female	0.277	0.280	0.99	.32	1.32 (0.76-2.28)

[a]Age was z-standardized (mean 0, SD 1); sex was coded as 1=female and 2=male.

[b]Coefficients represent multinomial log-odds relative to class 1.

[c]OR: odds ratio.

External Validation Using the Psychological Distress Variable

An ANOVA test was conducted to evaluate whether there were significant differences in psychological distress scores across the latent classes identified in the LPA model (Table 6).

Table . ANOVA results.

Source	Degrees of freedom	Sum of squares	Mean square	*F* test (*df*)	*P* value
Class (factor)	3	2212	737.4	18.32	.001[a]
Residuals	449	18,069	40.2	—[b]	—

[a]Statistically significant differences in psychological distress levels across the latent classes.

[b]Not applicable.

Subsequently, a Tukey post hoc test was performed to examine pairwise differences (Table 7).

XSL•FO
RenderX

Table . Tukey post hoc test results.

Class comparison	Mean difference (est.)	95% CI	Adjusted *P* value[a]
Class 2 versus class 1	5.08	3.09 to 7.06	<.001[b]
Class 3 versus class 1	1.68	−0.43 to 3.79	.17
Class 4 versus class 1	4.62	2.38 to 6.86	<.001[b]
Class 3 versus class 2	−3.40	−5.68 to −1.12	<.001[b]
Class 4 versus class 2	−0.46	−2.86 to 1.95	.96
Class 4 versus class 3	2.94	0.44 to 5.45	.01[c]

[a]*P* values were adjusted using the Tukey method.

[b]*P*<.001.

[c]*P*<.05.

The Tukey test results indicated that class 2 differed from class 1 by an average of 5.08 points in psychological distress scores, suggesting that class 2 experienced more distress. Class 4 showed an average difference of 4.62 points compared with class 1, indicating high psychological distress. Class 3 had lower distress than class 2, with a significant difference of –3.40 points. Additionally, class 4 exhibited more distress than class 3, with a significant difference of 2.94 points. Pairwise comparisons confirmed differences across classes.

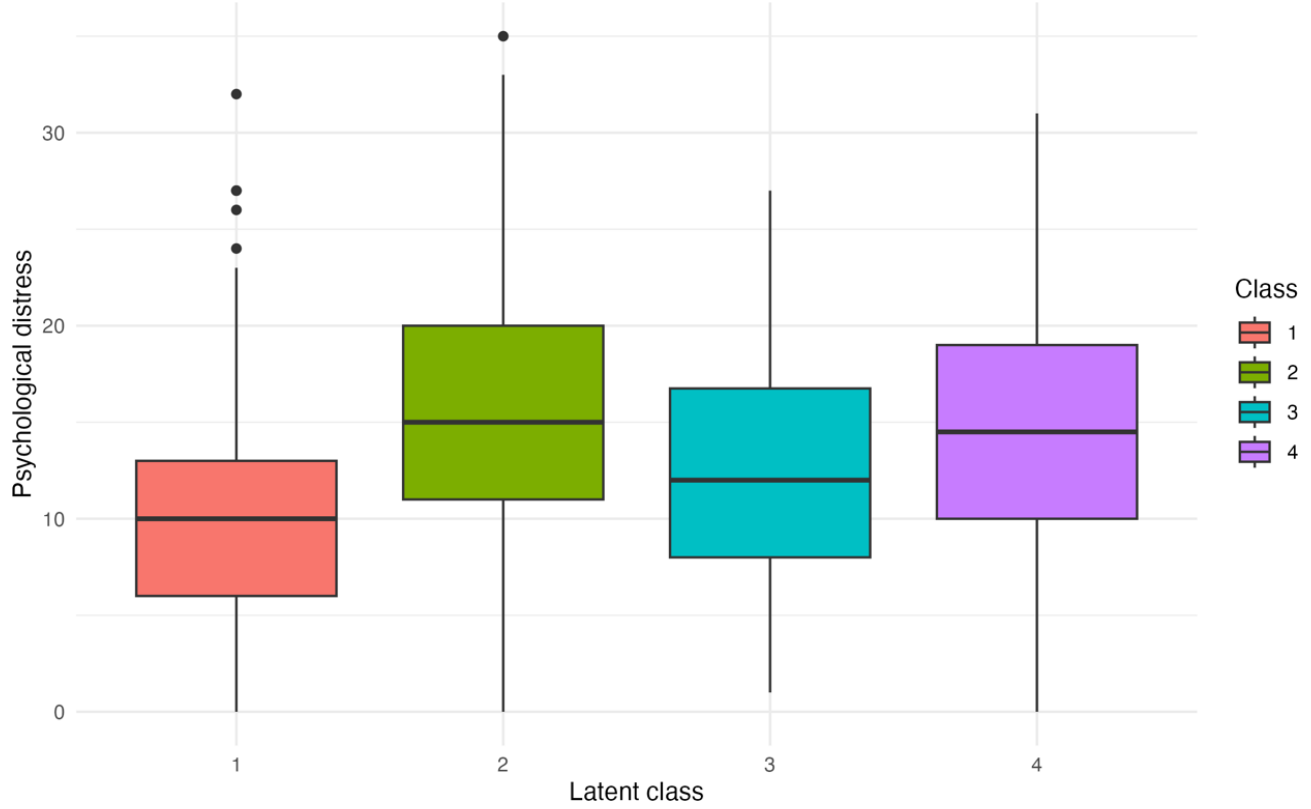
Finally, a regression model was also estimated to predict psychological distress based on latent class membership (Table 8).

Table . Regression model results[a].

Coefficient[b]	Estimate	SE	*t* test (*df*)	*P* value
Intercept (class 1)	10.35	0.49	21.09 (449)	<.001[c]
Class 2	5.08	0.77	6.59 (449)	<.001[c]
Class 3	1.68	0.82	2.05 (449)	.04[d]
Class 4	4.62	0.87	5.31 (449)	<.001[c]

[a]Higher values reflect greater psychological distress (General Health Questionnaire-12).

[b]Adjusted R^2=10.3%. Coefficients indicate mean differences in distress scores relative to class 1.



[c]*P*<.001.

[d]*P*<.05.

Classes 2 and 4 showed higher psychological distress scores than class 1, indicating more average psychological symptoms (since higher scores on this scale reflect increased symptoms or distress). Class 3 showed a slight deterioration, although the effect was more moderate. Details are presented in Figure 2.

XSL•FO
RenderX

Figure 2. Psychological distress comparison across latent profile analysis classes.

The results of combining the 4 classes, along with age, sex, and psychological distress, are shown in Table 9.

Table . Integrated results of profiles (classes 1 - 4), age, sex, and psychological distress.

Class	Nomophobia	Problematic technology use	Self-regulation	Age[a]	Sex[a]	Psychological distress
1	Low (–1 SD)	Low (–1 SD)	High (+1 SD)	Balanced distribution	More men ↑	Lowest psychological distress
2	Below average (–0.3 to –0.5 SD)	Below average (–0.3 to –0.5 SD)	Below average (–0.3 to –0.5 SD)	Balanced distribution	More women ↑	Highest psychological distress
3	High (+1 to +1.5 SD)	High (+1 to +1.5 SD)	Low (–1 SD)	Younger	More women ↑	Significantly lower distress than class 2; not significantly different from class 1
4	Average (0 SD)	Average (0 SD)	Moderately low (–0.5 SD)	Younger ↑↑	More women ↑↑	Significantly higher distress than classes 1 and 3

[a]Arrows indicate relative predominance in group composition based on descriptive comparisons. A single arrow indicates a higher proportion relative to other classes, whereas a double arrow indicates a more pronounced predominance. These symbols are descriptive and do not represent statistical significance or effect size.

Discussion

Principal Results

This study contributes to the field of cyberpsychology by providing empirical evidence on psychological profiles associated with problematic technology use and their relationship with psychological distress. Through a person-centered approach, we identified differentiated profiles characterized by distinct patterns of self-regulation, nomophobia, and ICT use, highlighting both consistent associations and apparent contradictions with prior research.

The LPA identified 4 distinct classes that significantly differed in distress scores. Class 1, which was characterized by high self-regulation and low problematic technology use, showed the lowest psychological distress. In contrast, classes 2 and 4 exhibited higher psychological distress, which was significantly worse than that of class 1. Class 2 was especially relevant because, despite reporting relatively low ICT use and moderate-to-low nomophobia, it exhibited the highest

XSL•FO
RenderX

psychological distress, suggesting that other unmeasured factors may contribute to this vulnerability. Meanwhile, class 4, involving the youngest individuals, showed low self-regulation combined with high ICT use and nomophobia, also resulting in high psychological distress. Interestingly, the distress in class 3 was significantly lower than that in class 2, was comparable to that in class 1, and was lower than that in class 4. These findings indicate that the relationship between problematic technology use and distress is not monotonic, and the interplay of multiple factors must be considered.

Comparison With Prior Work

There are some important aspects to consider. First, the results confirm that self-regulation is a central protective factor for mental health, even in the presence of high ICT use or nomophobia. This is consistent with studies indicating that it is not the absolute amount of use that explains psychological distress, but rather individuals' ability to regulate their digital behaviors [41,42]. Accordingly, class 1, with high self-regulation, showed the lowest psychological distress, while profiles with low self-regulation (classes 3 and 4) experienced greater distress.

Second, class 2 concentrated on individuals with the highest psychological distress despite lower ICT use and lower levels of nomophobia. This apparently counterintuitive finding suggests that other factors not assessed in this study, such as neuroticism, loneliness, low self-esteem, lack of social support, and dysfunctional coping strategies [43-45], may influence the outcomes. The identification of this subgroup underscores the value of LPA, which, unlike variable-centered approaches, can reveal hidden profiles and inform the design of tailored interventions.

Third, the results suggest that age plays a protective role, but it is not linear. While prior research has emphasized adolescents and young adults as especially vulnerable to problematic social media use and nomophobia [46,47], our findings reveal nuances. Class 3, which consisted mainly of young adults with low self-regulation and high ICT use, did not show severe psychological distress, while class 4, which also consisted of younger individuals with a similar usage pattern, showed psychological distress. One possible explanation is that, in class 3, intensive ICT use may have been socially normalized in the age groups, reducing its negative effects [48,49]. In contrast, class 4 combined low self-regulation with more compulsive or maladaptive usage patterns, resulting in significantly more distress.

Fourth, gender showed selective effects. Men were less likely to belong to class 2 compared with class 1, while women were proportionally more represented in classes 3 and 4. These profiles combined higher ICT use and higher nomophobia, which aligns with previous research reporting higher levels of nomophobia and smartphone-related stress among women [49,50].

Finally, the profile comparison reinforces that problematic technology use is a multifactorial phenomenon that cannot be explained solely by usage intensity. A central contribution of this study is the analysis of a Colombian sample, which remains underrepresented in the international literature, thereby expanding evidence from Latin American contexts. A notable finding is that class 2 exhibited the highest psychological distress despite moderate ICT use, suggesting that additional individual or contextual factors—beyond usage frequency—may contribute to psychological outcomes. In addition, young women showed higher levels of nomophobia, greater intensive social media use, and a statistical association with increased psychological distress.

In this context, the role of nomophobia deserves attention. Although initially conceptualized as an emerging phenomenon linked to negative psychological outcomes, the profiles identified in this study suggest that its effects may not operate in a linear manner. For instance, class 3 showed high nomophobia and intensive ICT use combined with only moderate distress levels. This pattern suggests that nomophobia may interact with individual characteristics or contextual factors rather than exerting uniform effects across users. Understanding nomophobia as a component within broader behavioral configurations may help explain why similar levels of ICT engagement are associated with different psychological outcomes across groups.

Limitations

Among the main limitations of this study is the exclusive use of self-report measures, which may have caused bias in the assessment of both technology use and psychological distress. To evaluate common method bias, we conducted the Harman single-factor test and a series of confirmatory factor analyses, which suggested minimal common method bias effects. Nevertheless, future research should incorporate external corroborating measures or social desirability scales to enhance validity.

Although the sample was diverse, a more representative sample of older adults would improve the generalizability of the findings. Additionally, longitudinal designs are necessary to establish causal relationships among the studied variables. Future studies should also incorporate qualitative methodologies to complement quantitative data and evaluate interventions that strengthen self-regulation as a preventive strategy in digital mental health.

Moreover, other psychological and contextual factors, such as resilience, coping strategies, social support, and specific motivations for technology use, should be considered in future analyses, as they may provide valuable insights into psychological vulnerability to problematic technology use [51]. Cross-cultural comparative studies are also recommended, as the dynamics of ICT use and its mental health implications may vary depending on sociocultural contexts. Complementing self-reports with objective indicators (eg, screen time and activity logs) can be considered to enhance measurement accuracy. Ultimately, analyzing the differentiated impact of various ICT types, such as social media, video games, and educational platforms, may provide further insights into their distinct implications for psychological well-being.

XSL•FO
RenderX

Conclusions

The results of this study offer a comprehensive, data-driven perspective on how different patterns of technology use and personal resources shape distinct psychological risk profiles. Strengthening self-regulation has emerged as a promising pathway to promote healthier ICT use, particularly among younger populations and within educational or community contexts.

Our findings underscore the need for differentiated and personalized interventions that enhance self-regulation and promote adaptive technology use, with special attention to vulnerable groups, such as class 2 (individuals with high psychological distress despite low ICT use) and class 4 (young individuals with low self-regulation and high nomophobia). Future studies should expand this framework by incorporating additional psychological and contextual factors, such as social support, neuroticism, and coping strategies, to better explain heterogeneity in the psychological consequences of technology use patterns.

Abstract

Background: Refugees and asylum-seekers commonly experience numerous adverse and traumatic events and are therefore at increased risk of mental health problems. Despite the high need for mental health interventions, services tend to be underused by refugees and asylum-seekers, and various barriers compromise access. Digital, efficient screening, adapted for these groups, could facilitate initial assessment and increase accessibility to mental health services. We developed an internet-based tiered screening procedure (i-TAP) aiming to identify clinically relevant symptoms of major depressive disorder (MDD), anxiety disorder, posttraumatic stress disorder, and insomnia disorder among individuals with a refugee background. The i-TAP is an adaptive procedure with 3 tiers aiming to identify general mental distress in Tier 1, differentiate between symptoms in Tier 2, and assess the severity of symptoms in Tier 3. Each tier additionally functions as a gateway to further assessment, as a negative outcome terminates the procedure.

Objective: The purpose of this study was to evaluate the diagnostic test accuracy of the i-TAP, using structured clinical assessments as the reference standard.

Methods: In this prospective study, 70 adult participants with a refugee background, literate in Arabic, Dari, Farsi, or Swedish, and residing in Sweden, completed the i-TAP on tablets and participated in a subsequent structured diagnostic interview.

Results: It has been shown that the i-TAP could identify 91.7% (33/36) of individuals assessed with any psychiatric disorder, and correctly identified 82.1% of all positive cases of MDD, anxiety disorder, posttraumatic stress disorder, and insomnia disorder, with few false negative assessments. Overall test accuracy of the i-TAP ranged between 77.1% and 84.3%, depending on disorder. The tiered design could reduce item burden while maintaining accuracy. A vast majority of participants rated the user experience as positive. In this sample, 36/70 (51.4%) individuals were assessed with one or more psychiatric disorders and comorbidity was high.

Conclusions: The i-TAP may be a valid, efficient, and feasible screening tool for the identification of common psychiatric disorders among individuals with a refugee background in Sweden. The i-TAP could be implemented as a first screener in various settings, including online and in-person clinical practices. The digital, adaptive, multilingual format could facilitate early assessment and increase the availability of mental health services for refugees and asylum-seekers.

Introduction

Background

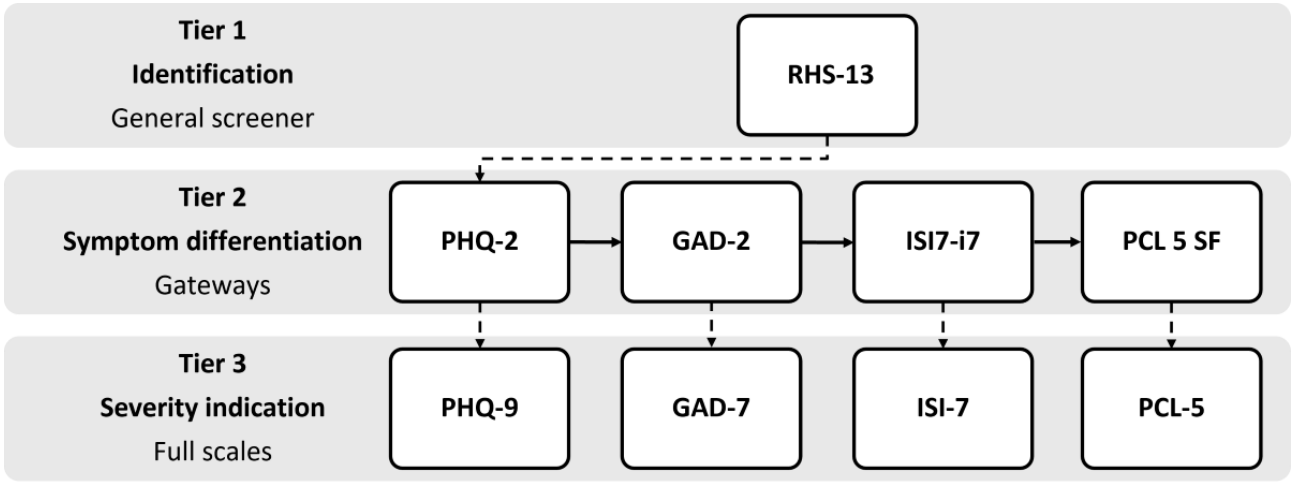
According to the United Nations High Commissioner for Refugees (UNHCR), there were an estimated 123.2 million forcibly displaced people in the world by the end of 2024 [1]. This number is expected to rise due to ongoing conflicts and wars globally. UNHCR reserves the term refugees for forcibly displaced people who, due to violence, war, conflict, or persecution, have crossed international borders to seek safety in another country, and the term asylum-seeker for people who have applied for refugee status and are awaiting a decision [2]. In Sweden, asylum-seekers have come mainly from Syria, Afghanistan, Iraq, Eritrea, Somalia, and Iran in the years 2015-2025 [3]. Since 2022, refugees from Ukraine have been treated under the European Union Temporary Protection Directive.

In addition to having fled their homes, many refugees and asylum-seekers have endured numerous stressful and potentially traumatic events, increasing the risk of psychological distress and various mental disorders [4-6]. When arriving in their host countries, refugees are further exposed to postmigration stressors, such as language barriers, discrimination, long asylum processes, and economic as well as social challenges, all of which are associated with poor mental health [4,6,7].

Posttraumatic stress disorder (PTSD), major depressive disorder (MDD), and anxiety disorders are highly prevalent among refugees [8,9], with even higher rates observed among asylum-seekers [10,11]. Symptoms persist over time [9,12] and often co-occur [11]. Furthermore, insomnia disorder is highly prevalent [13,14] and various sleep disturbances are reported as problematic [15]. Although prevalence rates vary between studies of refugee mental health, consensus in the field establishes significantly elevated levels of psychiatric symptoms and disorders among refugee groups, including asylum-seekers, compared to the general population [8,9,16]. Despite the high prevalence of mental health issues, mental health services tend to be underused [17,18]. This discrepancy, or treatment gap, can be understood through barriers frequently reported by both help-seeking refugees and asylum-seekers, and service providers. These barriers include language obstacles and the need to use interpreters, difficulties navigating the health care system, and fear of stigma [17,19], along with practical issues and financial concerns [20], all of which affect accessibility to relevant services.

Given that the mental health of individuals who have fled their homelands is affected by adversity experienced before, during, and after the flight [6], the increased risk of mental health problems persists over time, also long after resettlement [9,12]. This underscores the importance of identifying those in need of interventions, regardless of the duration of displacement. In a recent review [21], systematic mental health screening with at least 2 screening occasions is recommended for recently resettled refugees and asylum-seekers. Early and repeated mental health screening could increase access to and provision of treatment, ultimately reducing unnecessary suffering from untreated symptoms. This emphasizes the need for validated, efficient, and feasible methods to identify common mental health problems among individuals who have fled their homelands.

Offering internet-based mental health screening could increase accessibility of mental health services by addressing several of the aforementioned barriers. For instance, internet-based and smartphone-assisted options provide flexibility and privacy, can be time-saving, and can easily be offered in multiple languages [22,23]. Although the literature on this topic is limited, digital mental health screening tools have previously been used among refugees and asylum-seekers [24], with evidence supporting their acceptability, feasibility, and validity for these populations [25,26]. Furthermore, a digital format enables the use of adaptive hierarchical screening models, which allow simultaneous screening of multiple psychiatric symptoms and can reduce the overall respondent burden while maintaining high accuracy [27,28].



Recognizing the potential technical as well as social advantages of online mental health screening for refugees and asylum-seekers, we set out to design and evaluate an internet-based tiered assessment procedure (i-TAP). The i-TAP is tailored for refugee groups residing in Sweden, and specifically designed to identify clinically relevant symptoms of depression, anxiety, PTSD, and insomnia.

The i-TAP

In a previous study by Meurling et al [28], the instruments and the procedure constituting the i-TAP were evaluated, yielding a model designed for optimal psychometric performance, along with promising results regarding the efficiency, including a reduced item burden and accuracy of the procedure. The i-TAP is a 3-tiered screening procedure that adapts to the respondent's answers in each tier. The first tier is highly sensitive, aiming to identify general mental distress while preventing further assessment of individuals without psychiatric symptoms. Thus, a negative outcome in Tier 1 terminates the procedure, while a positive outcome forwards the respondent to Tier 2. The second tier comprises brief symptom scales and differentiates between symptoms of depression, anxiety, PTSD, and insomnia. It also serves a gateway function, forwarding individuals with a positive outcome on one or more scales to further assessment in Tier 3, while terminating the procedure for respondents with a negative outcome on all Tier 2 scales. In the third tier, the full scales corresponding to the outcome of Tier 2 are presented to the respondent, with the purpose of indicating severity and identifying clinically relevant symptoms of depression, anxiety, PTSD, and insomnia. The items already answered in Tier 2 have been removed from each full scale in Tier 3. The tiered design of the i-TAP with the included instruments is depicted in Figure 1. In both the initial study [28] and this one, the i-TAP was provided in Arabic, Dari, Farsi, English, and Swedish, based on the largest groups of refugees and asylum-seekers in Sweden at the time the study commenced [29].

XSL•FO

Figure 1. Illustration of the internet-based tiered screening procedure, i-TAP, with the symptom scales used in each tier. GAD-2: Generalized Anxiety Disorder-2; GAD-7: Generalized Anxiety Disorder-7; Insomnia Severity Index-7, item 7; ISI-7: Insomnia Severity Index-7; PCL 5: PTSD (posttraumatic stress disorder) Checklist for DSM-5 (Diagnostic and Statistical Manual of Mental Disorders [Fifth Edition]); PCL-5 SF: PTSD (posttraumatic stress disorder) Checklist for DSM-5 (Diagnostic and Statistical Manual of Mental Disorders [Fifth Edition]) Short Form; PHQ-2: Patient Health Questionnaire-2; PHQ-9: Patient Health Questionnaire-9; RHS-13: Refugee Health Screener-13.

In Meurling et al [28], the Tier 1 and Tier 2 scales were evaluated using the Tier 3 scales as the reference standard. We also applied receiver operating characteristic analysis to identify gateway cutoffs for optimal performance. This resulted in an accurate screening tool (total precision 86%) that could identify most moderate symptoms of PTSD, depression, anxiety, and/or insomnia (96.2%). These results and the fact that only the first 2 tiers of the model were tested prompted further evaluation of the full 3-tiered model. The developmental process of the i-TAP is described in further detail in Meurling et al [28].

Aim

The aim of this study is to test the performance of the full i-TAP. Specifically, we seek to evaluate the criterion validity by assessing diagnostic test accuracy of the full tiered model, using structured clinical assessments of psychiatric disorders as the reference standard. Our objective is to determine the extent to which the i-TAP is able to identify MDD, anxiety disorder, PTSD, and insomnia disorder among individuals with a refugee background, residing in Sweden. We want to emphasize that the heightened risk for these disorders follows experiences of flight and resettlement. The target group for the i-TAP is therefore focused on the refugee experience, irrespective of current legal status. Accordingly, we henceforward use the term individuals with a refugee background to describe our study population.

Methods

Study Context and Design

This study and the development of the i-TAP are part of the SAHA project, a collaboration between Mid Sweden University, Linköping University, and Karolinska Institute, with the overarching aim of developing digital mental health solutions, including tailored interventions, for individuals with a refugee background. We conducted this prospective cross-sectional validation study with individuals with a refugee background residing in Sweden, collecting data from June to October 2022.

Recruitment and Participants

Participants were recruited through convenience sampling in various nonclinical settings (adult education for immigrants, language cafés, nongovernmental organizations, and at an asylum housing facility). Recruitment took place on site with the help of local personnel and interpreters. After being informed about the study orally, interested individuals could approach immediately or later via email or phone. The inclusion criteria were refugee background, aged 18 years or older, literacy in Arabic, Dari, Farsi, Swedish, or English, and currently living in Sweden. Being a refugee or having a refugee background was herein specified as having fled to Sweden due to war, conflict, persecution, threat, or similar reasons, and was self-defined by the participants. This criterion was carefully explained during recruitment and verified before starting each study procedure, to ensure inclusion of participants with a refugee experience. Individuals were thus included regardless of residence status, and we have not differentiated analyses based on that.

Data Collection and Material

Overview

Data collection was carried out by 11 persons trained in clinical psychology and with practical experience of psychiatric assessment, herein referred to as psychologists. The assessments were conducted in each respondent's preferred language. Five of the psychologists were bilingual and 6 psychologists used authorized interpreters via telephone to conduct the assessments. To facilitate translation, the assessment material was sent to interpreters in advance. All psychologists lived in Sweden and were fluent in Swedish. To ensure methodological equivalence, all psychologists received training in the full procedure prior to data collection.

Data collection included digital screening with the i-TAP, followed by a structured clinical interview. The whole procedure was carried out by a psychologist on a single occasion in a private space adjacent to each recruitment site. Each occasion

XSL•FO
RenderX

lasted a maximum of 2 hours and was preceded by oral and written informed consent from the participant.

Digital Screening

Participants completed the i-TAP independently, online via tablets. For this study, we also included background questions and feedback questions regarding the experience of completing the i-TAP. The psychologists (and telephone interpreters) were available to answer any questions but were instructed not to sit next to or help the participants fill in the survey. The results of the i-TAP were blinded to the psychologists.

Structured Diagnostic Interview

The structured diagnostic interview targeted the same disorders as the i-TAP, namely insomnia, PTSD, MDD, and anxiety disorders (panic disorder, agoraphobia, social anxiety disorder, and generalized anxiety disorder [GAD]). Before terminating the clinical interview, the psychologist invited the participant to add any information or raise other topics of their choice. To conclude the procedure, the psychologist summarized the diagnostic interview and gave participants feedback and recommendations based on their assessment. All participants received a brief written summary of the clinical assessment, recommendations (if applicable), a folder with contact information to available local and national health care services, and a SEK 99 (US $9.7) gift card to a supermarket. We offered to guide participants in help-seeking, for example, by showing websites, finding opening hours and contact information, and exploring maps. If an immediate risk was identified, this was handled according to a predefined safety protocol described below. To ensure confidentiality, data were pseudonymized. In cases where the procedure was terminated before completion, participants were also offered the information folder and gift card.

Each clinical interview was discussed at team meetings, referred to as clinical conferences, before determining the final clinical assessment of each participant. The psychologists were still blinded to the results of the i-TAP during these discussions. The clinical conferences promoted both discussion and unanimity in the final assessments.

Index Test

The i-TAP builds on 56 items from 5 validated scales, described in detail below. The symptom scales were selected based on psychometric properties, cross-cultural validity or previous use in refugee populations (or a combination thereof). All scales have previously been evaluated by us for the current population [28,30]. For a detailed description of the scales, translation, and psychometric properties, please see our previous publication from the SAHA project [28]. All scales use Likert response alternatives. For the analyses in this study, responses were dichotomized using cutoffs on each scale. Considering that i-TAP aims for high diagnostic sensitivity yet being an efficient screening procedure, we have applied the sensitivity model proposed in our first study [28] for this study. That is, we have applied cutoffs to identify as many true positives as possible without compromising accuracy.

The following instruments and cutoff values for moderate symptoms were used: for identification of general psychological distress in Tier 1, we used the Refugee Health Screener-13 (RHS-13) [31,32] with cutoff ≥11. For symptoms of MDD, we used the Patient Health Questionnaire-2 (PHQ-2) [33], with cutoff ≥2 in Tier 2 and the Patient Health Questionnaire-9 (PHQ-9) [34] with cutoff ≥10 in Tier 3. Symptoms of anxiety disorders (including panic disorder, social anxiety disorder, and GAD), were measured using the Generalized Anxiety Disorder-2 (GAD-2) [35], with cutoff ≥2 in Tier 2 and the Generalized Anxiety Disorder-7 (GAD-7) [36,37] with cutoff ≥10 in Tier 3. Selection of the anxiety scales was based on very good psychometric properties when screening for GAD, panic disorder, and social anxiety disorder [37], which enables the use of 1 instead of 3 separate anxiety scales, reducing the item burden for the respondents. This aligns with the aim of the i-TAP to efficiently detect clinically relevant symptoms of a range of anxiety disorders. Symptoms of PTSD were measured with the PTSD Checklist for *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [*Fifth Edition*]) Short Form (PCL-5 SF) [38], using cutoff ≥5 in Tier 2 and the PTSD Checklist for *DSM-5* (PCL-5) [39] using cutoff ≥32 in Tier 3. To identify symptoms of insomnia, we used the Insomnia Severity Index-7 (ISI-7) [40], item 7 with cutoff ≥2 in Tier 2 and the full scale in Tier 3. For ISI-7, we previously used a conservative cutoff for detecting moderate to severe symptoms of insomnia (≥14). However, 2 more sensitive cutoffs have been proposed, ≥8 and ≥11 [41,42]. We evaluated the performance of all 3 cutoffs and concluded that cutoff 11 was best suited for the purpose of the i-TAP. Please see Table S1 in Multimedia Appendix 1 for detailed results of this analysis. All Tier 2 instruments are composed of items from the Tier 3 instruments. To avoid posing the same questions twice, these items were not repeated in Tier 3. Instead, we included the item responses from Tier 2 in the analyses of the full scales in Tier 3.

To assess user experience of the i-TAP, we formulated 3 items about answering questions about mental health online. The first assessed if participants had a negative or positive attitude (1-10 with 1=very negative and 10=very positive), the second assessed if the i-TAP was difficult or easy to use (1-10 with 1=very difficult and 10=very easy), and the third assessed if the questions in the i-TAP were difficult or easy to understand (1-5 with 1=very difficult, 2=difficult, 3=neither difficult nor easy, 4=easy, and 5=very easy to understand).

Reference Standard

The reference standard was a clinical diagnosis of MDD, anxiety (panic disorder, agoraphobia, social anxiety disorder, and GAD), PTSD, or insomnia according to the clinical assessment. The assessment of clinical diagnoses relied on a structured diagnostic interview, including sections investigating insomnia disorder, trauma experience, PTSD, MDD, panic disorder, agoraphobia, social anxiety disorder, and GAD, in the presented order. Structured diagnostic interviews are generally accepted as the gold, or reference standard in clinical research [43].

The principal instrument of the structured diagnostic interview was the Mini International Neuropsychiatric Interview 7.0.0 (M.I.N.I.) [44]. M.I.N.I. is a short, structured psychiatric

XSL•FO
RenderX

interview based on *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*) and *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) diagnostic criteria and has demonstrated excellent test and interrater reliability [45]. It was originally designed for epidemiological and multicenter studies and is now used extensively in both research and clinical settings, as well as in global mental health settings [46] and with refugee populations [16,47]. The M.I.N.I. is designed to be sensitive [44] and has repeatedly been proven so in comparison with expert clinical diagnoses [43,46]. In this study, we used the diagnostic sections for PTSD, major depressive episode, panic disorder, agoraphobia, social anxiety disorder, and GAD. No official validated translations of the M.I.N.I. were available. For Arabic, we used a previously evaluated translation [46], and the bilingual psychologists made translations to Dari and Farsi. As insomnia is not included in the M.I.N.I., we designed a module for this specific diagnosis comprising 6 questions responding to the diagnostic criteria in *DSM-5* [48], matching the format in the M.I.N.I. to facilitate administration. We formulated brief questions to simplify interpreter-assisted assessments. The complete insomnia assessment is depicted in Multimedia Appendix 1. Furthermore, we adapted the M.I.N.I. to the target population by replacing the suicidality module and the criterion A assessment for PTSD (see details below).

To investigate potentially traumatic events (PTEs), we used the Refugee Trauma History Checklist (RTHC), a measure developed for adult refugees and previously validated in a sample of Syrian refugees in Sweden [49]. The RTHC is designed to assess the most common refugee-related PTEs, before, during, and after flight, in a nonintrusive way. The checklist is composed of 2 questions, where the respondent is asked if they have experienced any of 7 or other PTEs before and after they left their home (war at close quarters, forced separation from family or close friends, loss or disappearance of family members or loved ones, physical violence or assault, witnessing physical violence or assault, torture, sexual violence, and other frightening situation where you felt your life was in danger). Participants were not asked to elaborate or describe reported events further. We used the RTHC as a replacement for item H1 in the M.I.N.I., which corresponds to the criterion A assessment for PTSD in *DSM-5*; thus, a positive RTHC outcome regarding any traumatic life event was followed by continued PTSD assessment with the M.I.N.I. This adaptation was made against previous research pointing toward the importance of broadening the trauma criterion and description in *DSM-5* for individuals with a nonwestern background [50].

To assess suicidality, we used the Columbia Suicide Severity Rating Scale Screening Version (C-SSRS Screen) [51,52] as a structured interview. The C-SSRS Screen has 6 items with a similar structure to the M.I.N.I., is validated as an initial step to identify individuals with short-term suicide risk [51], and has previously been used in refugee populations [53]. A positive outcome was handled according to a predefined safety protocol, including immediate consultation with relevant health services, together with participants, for thorough suicide risk evaluation. If suggested, we offered to accompany the participant to the care facility. We included suicidality as part of the clinical assessment to identify any individuals in need of immediate clinical attention; however, suicidality was not part of this validation study. Against this, and to further adapt the structured assessment to the target group, we decided to replace the extensive and sometimes linguistically complicated suicidality module in the M.I.N.I. with a shorter, more comprehensible screener.

Data Treatment and Analysis

Sample size requirements were estimated based on expected prevalence and desired sensitivity. Based on previous studies of refugee mental health [8,9,16], we expected a high prevalence (>30%) of moderate symptoms of each disorder and an even higher prevalence based on total outcomes from the i-TAP. According to Bujang and Adnan [54], a sample size of 67 is adequate to determine accuracy (80% power and significance level <.05) based on a minimum prevalence of 30%, and the aim of 80% sensitivity we set for the i-TAP.

The structured diagnostic interview was assessed and summarized as positive (“diagnosis”) or negative (“no diagnosis”) for each diagnosis. A diagnosis is herein defined as fulfilling diagnostic criteria for a psychiatric disorder according to clinical assessment with M.I.N.I. and the structured clinical interview for insomnia. Panic disorder, agoraphobia, social anxiety disorder, and GAD in M.I.N.I. were collapsed into one variable, anxiety disorder, for the analysis.

Descriptive measures were summarized as frequencies and proportions or means and SDs depending on variable type. Internal consistency was calculated for the full scales included in the i-TAP using Cronbach alpha. Intercorrelations were assessed using Pearson *r*.

We tested the criterion validity of the i-TAP by comparing the outcome of the complete i-TAP procedure for each symptom category (depression, anxiety, PTSD, and insomnia) with the corresponding clinical diagnoses according to the reference standard. We used Cohen κ as a statistically adjusted measure of concordance between 2 measures [55]. Interpretation of κ values was guided by Landis and Koch [56] suggested labels: <0 no agreement, 0-0.20 slight, 0.21-0.40 fair, 0.41-0.60 moderate, 0.61-0.80 substantial, and 0.81-1.0 perfect agreement. Diagnostic test accuracy, including sensitivity, specificity, positive and negative predictive values [57], and the number of false negatives and false positives, was calculated for each tier and symptom category, using clinical diagnosis from the structured clinical interview as the reference standard.

All individuals had complete data on all scales and were included in the analysis. Analyses were performed using IBM SPSS (version 29).

Ethical Considerations

The study protocol has been approved by the Swedish Ethical Review Authority (2020-00214). This study was planned and performed in accordance with the ethical standards of the 1975 Helsinki declaration and its amendments (World Medical Association, 2001). Written informed consent was obtained from all participants, in their preferred language, prior to study participation. Participants were carefully informed that

XSL•FO
RenderX

participation was voluntary and data confidential, that they could terminate their participation at any time, and that participation could not affect the asylum process. To protect the privacy of participants, data are presented at the group level, and potentially identifying details regarding participants or data collection have been omitted.

Results

Sample

In total, 85 individuals registered interest to participate in the study; however, 6 were lost due to nonattendance. Out of the 79 that initiated assessments, 7 did not complete for reasons such as low literacy, not having a refugee background, or practical circumstances. We completed assessments with 72 participants. Due to technical issues, data were incomplete for 2 respondents, rendering a final sample of 70 participants. Against the power calculation, our sample size of 70 was deemed sufficient.

Clinical and Sociodemographic Characteristics

Out of the 70 analyzed assessments, 31 were conducted in Arabic, 14 in Dari, 15 in Farsi, and 10 in Swedish. Participants were 31 females and 39 males, between 19 and 69 years old (mean 39.1, SD 13.16), and 31.4% (22/70) lived at an asylum facility, 50% (35/70) had their own housing, and 18.6% (13/70) lived together with family or friends, see Table 1 for sociodemographic characteristics of the sample.

[a]Iraq, Eritrea, Tajikistan, Somalia, Sudan, and Kurdistan.

Each scale in the i-TAP demonstrated excellent internal consistency, with Cronbach α of 0.93 for RHS-13, 0.92 for PHQ-9, 0.92 for GAD-7, 0.96 for PCL-5, and 0.92 for ISI-7. All scales were intercorrelated, *r* ranging from 0.70 to 0.89 (all *P*<.001). Regarding symptom assessment, the mean for RHS-13 was 21.61 (SD 13.95; 95% CI 18.29-24.92), for PHQ-9, 9.86 (SD 7.20; 95% CI 8.14-11.57), for GAD-7, 8.33 (SD 6.43; 95% CI 6.79-9.86), for PCL-5, 29.99 (SD 22.74; 95% CI 24.56-35.41), and the mean for ISI-7 was 11.64 (SD 7.96; 95% CI 9.75-13.54).

Prevalence of clinical diagnoses of MDD, anxiety disorder, PTSD, and insomnia disorder was high in the sample, see Table 2 for prevalence estimates for each disorder by the i-TAP and the clinical assessment, respectively. All participants reported experiencing at least one potentially traumatic event. According to the structured diagnostic interview, 51.4% (36/70) met diagnostic criteria for one or more disorders.

Insomnia disorder	26 (37.1)	32 (45.7)
Any[f]	36 (51.4)	41 (58.6)

[a]i-TAP: internet-based tiered screening procedure.

[b]Multiple diagnoses per individual are possible. Clinical assessment=assessment results of the structured diagnostic interview, i-TAP=individuals who scored positive in Tier 1, Tier 2, and above the cutoff for moderate symptoms in Tier 3.

[c]Positive case for any anxiety disorder.

[d]Not applicable.

[e]PTSD: posttraumatic stress disorder.

[f]Positive case for any disorder.

Comorbidity was generally high. The clinical assessment showed that 23 individuals (32.9%) fulfilled criteria for 2 or more diagnoses, of which 8 individuals met criteria for 3 diagnoses, and 8 for all 4 diagnoses. Comorbidity rates per identified disorder are depicted in Table 3. Among the 13 individuals who fulfilled criteria for one diagnosis only, insomnia was most prevalent (n=7).

Table 3. Comorbidity of disorders diagnosed with the structured diagnostic interview (N=70)[a].

Diagnosis	Number of participants	Comorbid MDD[b], n (%)	Comorbid anxiety disorder, n (%)	Comorbid PTSD[c], n (%)	Comorbid insomnia disorder, n (%)
MDD	20	—[d]	—	—	—
Anxiety disorder	17	12 (17.1)	—	—	—

Concordance of the i-TAP and the Structured Diagnostic Interview

The i-TAP identified 33 of the 36 (91.7%) individuals with a clinical diagnosis according to the structured diagnostic interview. The i-TAP correctly identified 19/20 cases of MDD, 13/17 cases of anxiety, 16/20 cases of PTSD, and 21/27 cases of insomnia disorder (ie, true positives) in the current sample. κ values indicated moderate concordance between the i-TAP and the clinical assessment for the specific disorders, and diagnostic test accuracy was between 77.1% and 78.6% for all 4 diagnoses. Regarding overall concordance, accuracy was 84.3% for the identification of any disorder and the overall concordance was substantial, see Table 4 for detailed results.

[d]NPV: negative predictive value.

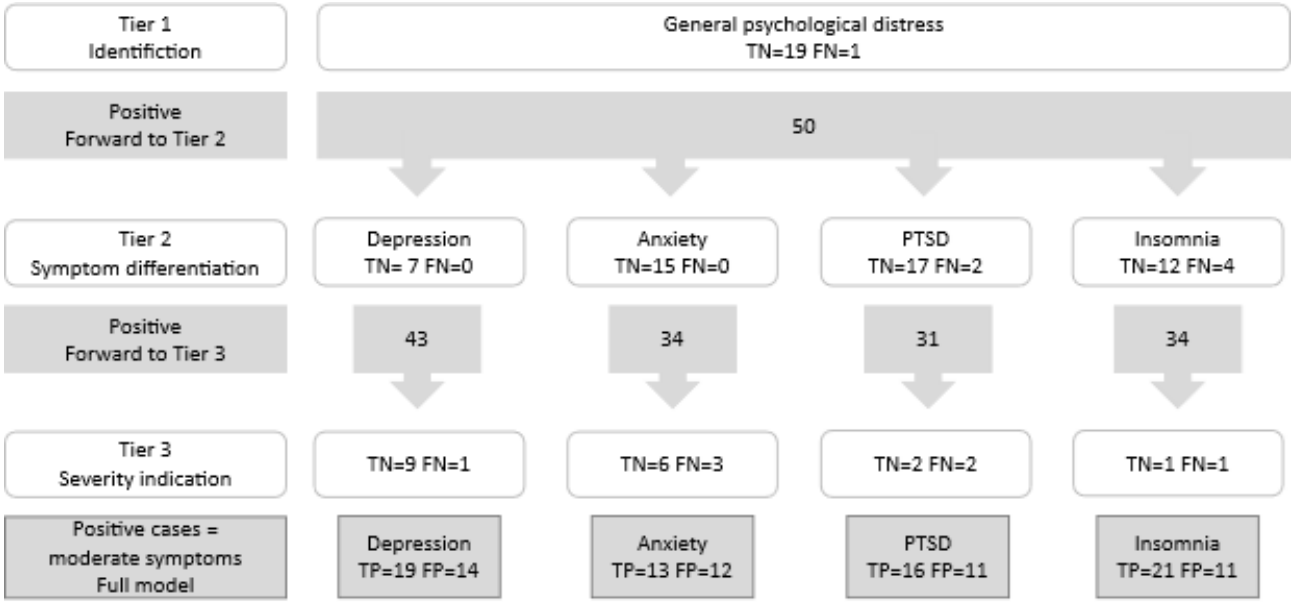
[e]PTSD: posttraumatic stress disorder.

[f]Positive case for any diagnosis.

Precision of the i-TAP

To investigate to what level the i-TAP was able to correctly assess the prevalence of disorders on an individual level, we have calculated the number of correct assessments (ie, true positives and true negatives) performed by the i-TAP over all 4 disorders and within each individual. That is, each participant could have 0 to 4 correct assessments of diagnosis or no diagnosis.

The i-TAP could correctly assess 54.3% (n=38) of all participants. These individuals were thus correctly positively or negatively assessed on all 4 disorders. Fourteen (20.0%) individuals were correctly assessed on 3 of the 4 disorders, of which 11 (78.6%) of the failed assessments were false positives. The remaining 18 participants had 2 or less correctly identified assessments. Equally for these individuals, a vast majority of the failed assessments were false positives (77.1%). A total of 8 individuals were assessed as false positives by the i-TAP without any diagnosis.



Regarding false negative assessments, a total of 11 individuals were affected as the i-TAP failed to identify 1 case of MDD, 4 cases of GAD, 4 cases of PTSD, and 5 cases of insomnia disorder. However, only 3 individuals with a diagnosis according to the reference standard were entirely missed, as the other 8 false negative cases were identified as positive on another diagnosis.

A Tiered Model

To calculate the tiered model, we used all data (all respondents answered all scales) to simulate the effects of the tiers in the i-TAP. In Tier 1, identification of symptoms, 50 individuals screened positive, indicating psychological distress in 71.4% (50/70) of the participants. Tier 1 showed very high sensitivity (97.2%), low specificity (55.9%), and correctly excluded 19 individuals (ie, true negatives) from further assessment; however, 1 individual with clinical anxiety diagnosis was falsely excluded (ie, a false negative). Tier 2, differentiation between symptoms, also exhibited high sensitivity (range 78.6%-100%) and specificity ranging between 54.0% and 74.0% for the 4 disorders. See Figure 2 for an illustration of the culling effects of the hierarchical design. Detailed results of the psychometric evaluation of each tier and disorder are depicted in Table S1 in Multimedia Appendix 2.

XSL•FO
RenderX

Figure 2. The culling effects of the hierarchical design of the internet-based tiered screening procedure (i-TAP). FN: false negatives (incorrectly excluded cases); FP: false positives (incorrectly identified cases); PTSD: posttraumatic stress disorder; TN: true negatives (correctly excluded cases); TP: true positives (correctly identified cases).

User Experience

A majority of the sample had a positive attitude toward answering questions about mental health online, with 51% (36/70) scoring 10/10 (very positive; mean 8.41, SD 2.08; range 3-10) and only 4.3% (3/70) scoring in the negative range (ie, <5). Moreover, the method was perceived as easy (mean 8.47, SD 1.98; range 3-10), with 50% (35/70) scoring 10/10 (very easy), whereas 5.7% (4/70) scored it somewhat difficult (ie, <5). Participants scored the questions as easy to understand, with 61.4% (43/70) scoring 5/5 (very easy; mean 4.37, SD 0.90; range 1-5) and only 1 (1.4%) participant answered that it was very difficult (<3). There were no significant differences between language groups.

Discussion

Principal Findings

The results from this study show that the i-TAP was very efficient in detecting individuals assessed as having a clinical diagnosis (91.7%) and could correctly identify a total of 82.1% of all positive cases of MDD, anxiety disorder, PTSD, and insomnia disorder, while keeping a low rate of false negatives. The overall accuracy of the i-TAP, ranging between 77.1% and 78.6% for the specific diagnoses and rising to 84.3% for any diagnosis, could be considered commendable, considering the multisymptom screening function and the emphasis on sensitivity. Furthermore, the psychometric performance of the i-TAP is comparable to the performance of the individual instruments included [41,50,58,59], showing that a hierarchical design does not compromise accuracy. In line with previous findings [9,15], our results show a sample with high prevalence of MDD, anxiety disorders, PTSD, and insomnia disorder, as well as a high rate of comorbid disorders. The higher prevalence rates found by the i-TAP compared to the clinical assessment were expected, since the use of self-rating instruments is known to overestimate prevalence [60-62] as they identify symptoms, not disorders. Since the i-TAP is a screening tool, we have prioritized sensitivity over specificity in this validation study. This comes at the cost of a higher number of false positives, which have affected the overall diagnostic test accuracy negatively, and which contribute to the overestimation of prevalence. However, prioritizing specificity would increase the risk of overlooking individuals in need. Weighing sensitivity against specificity for the i-TAP is based on the aim to identify as many individuals as possible, and is built upon the standpoint that, in this case, false positives are less harmful than missing someone in need of mental health services. Against this aim, the i-TAP performed very well. However, the relationship between sensitivity and specificity must be considered for each setting and context, with regard to the purpose and resources for implementation of the i-TAP.

Using a tiered hierarchical model for screening enables the reduction of the number of items an individual responds to, referred to as item burden. Reducing the item burden reduces the time and effort required to complete a screening, thereby increasing the probability of both initiating and completing a screening. Using the i-TAP, an individual with no symptoms would have a reduction in item burden with 69.8% compared to a screening using the full scales, and an individual with, for example, clinically relevant symptoms of anxiety would have 37.2% reduction in item burden. However, for the individuals with comorbid symptoms of all disorders, there is, in fact, an increased item burden, adding the RHS-13 [32] in Tier 1. Despite this, we have weighed the benefits of including the RHS-13 as higher than the costs, in this case, in item burden for individuals with symptoms of all 4 diagnoses. The RHS-13 is a suitable first screener, with culturally sensitive items including somatic symptoms, designed for the general refugee population [31]. In this study, it was shown to be highly sensitive, detecting all but one individual and case of clinical diagnosis, thus serving the purpose of the first tier superbly.

XSL•FO
RenderX

The high prevalence of comorbid diagnoses observed in this sample, as evidenced in several prior studies, for example [11,13], underscores the importance of broad initial screening for refugees. Moreover, the high comorbidity might affect the accuracy of the i-TAP for the specific disorders. Several items and symptoms are similar or shared between instruments and diagnoses, making differential diagnosis difficult in early screening. Regarding anxiety specifically, a positive outcome on the i-TAP can imply any, as well as comorbid, anxiety disorders. Furthermore, the i-TAP falsely identified 8 individuals without any disorder. Hence, the i-TAP cannot be used as a diagnostic tool. Nevertheless, the i-TAP could correctly identify a clear majority of the positive cases for each diagnosis, and all but 3 individuals with a clinical diagnosis. Thus, even if not always precise, the i-TAP can be considered a reliable screening tool for the identification of individuals in need of mental health services.

Regarding the user experience of the i-TAP, results were promising, with a vast majority reporting being positive toward the format and finding the questions easy to complete, indicating acceptability of the i-TAP; however, this needs further investigation.

Clinical Implications

The results from this study show that the i-TAP could be implemented as a first screener in various clinical settings, such as primary and psychiatric care, schools, health programs, and online mental health services, for individuals with a refugee background in Sweden. In practice, the i-TAP could be useful as a guide to assessment, for symptom-specific interventions, or to tailor support and treatment. For example, combining the i-TAP with a tailored internet-based cognitive behavioral therapy intervention [63], where treatment module provision is based on symptoms, would facilitate automatic adaptation without requiring help-seeking individuals to answer lengthy questionnaires unnecessarily.

In a setting where differentiation of symptoms is less important, the i-TAP could serve as a general screener to identify individuals with any clinically relevant symptoms, and would do so with higher specificity and efficiency compared to using the RHS-13 or full scales only. Applying either approach, the i-TAP's tiered design could prove especially beneficial in settings with resource and time constraints [25,27]; however, unsuitable in settings where complete data on measures are essential (eg, clinical trials).

Concerning implementation, it is critical to emphasize that the i-TAP is not designed to be a diagnostic instrument and should not be used as such in any context. It is intended as a screening tool, requiring further clinical assessment by a mental health professional in the case of a positive outcome. Moreover, the i-TAP is highly sensitive, and acknowledging the stigma around mental health reported by refugees, we want to highlight the risk of false positive results causing unnecessary distress. Thus, when reporting results back to a patient or participant, it should be done with both cultural and psychometric sensitivity in mind.

Finally, completing the i-TAP requires reading proficiency and digital literacy, and would thus not be a suitable option for all help-seeking individuals with a refugee background; however, adding audio files could be considered to increase applicability. Against this, and the fact that the i-TAP missed 3 individuals with a disorder, we emphasize the need for flexibility and individual adaptation of assessment procedures to promote equity in care.

Limitations

Some methodological limitations need consideration. The selection of participants was neither randomized nor consecutive, resulting in a convenience sample, which raises questions about bias, representativeness, and generalization. Given the sampling method and self-selection, there is a risk that individuals with mental health problems were more likely to participate, potentially resulting in a higher prevalence compared with the broader population of individuals with a refugee background in Sweden. However, relative to this population, our sample included a higher proportion of asylum-seekers (no residence permit) and individuals residing in asylum facilities—established risk factors for mental ill health [10,11]—which likely contributed to the high prevalence found in this study. The literacy requirement excluded illiterate individuals, who thus are not represented in the sample. Nevertheless, regarding the distribution of sex, age, and countries of origin, the sample was found representative of the Swedish adult population of refugees and asylum-seekers at the time of data collection [29]. While the sample mainly comprised individuals from South West Asia, thereby limiting the generalizability of the findings to these groups, it is likely that the i-TAP could be applicable to other refugee populations currently residing in Sweden, such as Ukrainians, as well as in other contexts. However, this warrants future studies.

Another limitation regards language proficiency as we did not control for literacy. However, the results point to a general understanding of the questions, indicating sufficient language proficiency in the sample. Furthermore, about half of the structured diagnostic interviews were conducted with telephone interpreters, the most common interpretation modality within health care in Sweden [64]. Although clinicians, patients, and interpreters have been found to prefer in-person interpretation for building rapport and trust [65,66], a systematic review found no differences in patient satisfaction between modes of interpretation [67]. Validated translations of the M.I.N.I. would have increased reliability and validity, but were not available. This is the common reality in both research and practice with linguistically diverse groups, and interpreters have assisted M.I.N.I. assessments in previous studies [68,69]. Sharing the Swedish and Arabic translations with interpreters did facilitate the interview, but it was not always possible. Nevertheless, the use of interpreters should not, but always can, influence communication quality and ultimately the clinical assessment [9], and thus pose a limitation in this study.

We did not conduct an interrater reliability check as it was not deemed ethically justifiable to film or ask participants to partake twice, given the vulnerability of the population and study settings [70,71]. It would also pose a risk to recruitment. Measures taken to counter this limitation were: psychologists with previous experience of the M.I.N.I., training, authorized

XSL•FO
RenderX

interpreters, assessment conferences, and using structured and validated material. We argue that the range of psychologists and interpreters is a strength in this study, reducing the risk of individual bias in assessments.

Using the M.I.N.I. as the reference standard comes with some limitations. Previous studies show that standardized diagnostic interviews result in more diagnoses when compared to clinical psychiatric assessments [43], thus, the results on prevalence should be interpreted with some caution. Regarding the validation of the i-TAP, we however argue that the sensitivity of the M.I.N.I. [43,44] is suitable, as the objective was to develop and evaluate a sensitive screening tool with the aim of identifying clinically relevant symptoms.

Conclusion

Our results suggest that the online tiered assessment procedure, i-TAP, can identify clinical depression, anxiety, PTSD, and insomnia efficiently and with high accuracy among individuals with a refugee background residing in Sweden. Implementation of the i-TAP would enable simultaneous screening of the most common psychiatric disorders among refugees and asylum-seekers, reduce the item burden for symptom-free individuals and circumvent decisions on what to screen for. This, together with the digital, multilingual format of the i-TAP, underlines its potential as a feasible, accessible screening tool, with the potential to bridge several of the reported barriers to mental health care.

Acknowledgments

The authors are grateful to all participants for their time and engagement in the study. We thank Karin Christiansen and her team, as well as Lina Andersson for valuable collaborations and assistance with recruitment. We also acknowledge the contributions of the psychologists Helen Ahmadpourian, Olivia Erling, Tove Forsström, Hania Kutabi, Agnes Lorenz, Hajar Mohammadi, and Thilda Persson. For translations of the material, we thank Amjad AbuLeil, Farzaneh Sianpour, and Sohrab Soltani. Finally, we thank George Vlaescu for providing technical support.

Abstract

Background: Lived experience stories are often used on formal help sites as a support resource for individuals who self-harm. While self-harm–related internet use provides an alternative for individuals who are not yet ready or are unwilling or unable to access support offline, it has also been shown to unintentionally reinforce self-harm behavior. There are several components that might influence whether a lived experience story is perceived as helpful, unhelpful, or potentially harmful, and the evidence supporting that these encourage help-seeking in the reader is limited.

Objective: This study is part of a mixed methods project that aimed to investigate how variations in help-seeking messages contained within online lived experience stories are interpreted by and psychologically impact those with a history of self-harm.

Methods: Individuals with a recent history of self-harm were recruited via newsletters, social media, and websites run by the university and mental health charities to take part in an online experiment. During the experiment, participants were randomized to read stories that either mentioned (1) self-help strategies, (2) seeking help from informal and formal sources, or (3) did not mention help-seeking. Help-seeking intentions, mood, entrapment, and expectations of future self-harm were measured, and participants provided feedback on the stories.

Results: There was limited evidence for an effect of story type on help-seeking intentions ($F_{2, 230}$=4.2; P=.02; η^2=0.25), and clearer evidence for an effect of story type on negative affect ($F_{2, 230}$=4.02; P=.02; η^2=0.10; adjustment for age, gender, and help-seeking history included). Participants in the “self-help” condition (n=83) reported lower negative affect after reading the stories compared to participants in the “no help” condition (n=80; mean difference=–3.97, 95% CI –7.72 to –0.22; P=.04) and the “informal/formal” help condition (n=75; mean difference=–3.70, 95% CI –7.55 to 0.14; P=.06). A key criticism of the stories was that they were unrelatable, but this sentiment was less prevalent among those in the “no help” condition. Key positives were that the stories included a realistic but hopeful outlook of recovery (less prevalent in the “informal/formal help” condition) and were supportive (less prevalent in the “no help” condition).

Conclusions: While the inclusion of self-help strategies in a lived experience story reduced its impact on negative affect, the inclusion of self-help strategies or seeking help from others did not encourage help-seeking intentions. Making stories relatable, authentic, and providing multiple strategies for support might be key to encouraging help-seeking, but more research is needed.

Introduction

Individuals experiencing self-harm or suicidal thoughts often seek support via the internet. Self-harm–related internet use can be both helpful and harmful [1,2]. Self-harm–related internet content can foster a sense of community, thereby reducing feelings of loneliness and isolation [3-6], and provide practical advice and moral support on how to manage self-harm [4,7-10]. In addition, self-harm–related internet use provides an alternative for individuals who are not yet ready, or may be unwilling, or unable to access support offline [11-14].

However, there is also a link between self-harm–related internet use and higher levels of suicidal intent [12,15,16], although the direction of effects is not clear. Due to a lack of regulation, content encouraging self-harm is easily accessible online [2,17,18]. In addition, content or environments intended to discourage self-harm could unintentionally reinforce self-harm behavior, for example, via normalization or competition [18,19]. Further, the categorization of self-harm content as either harmful or helpful is not straightforward. A recent systematic review illustrates the complex nature of engagement with self-harm content. Whether the content negatively or positively affects the individual engaging with it depends on the content, the individual, and the time and space in which it is encountered [2].

The internet provides a wide range of self-harm content, including information about self-harm behavior, self-help strategies, lived experience stories, images of self-harm, signposting to help, and dialogue [2,13,18,20,21]. They all come with limitations; for example, research suggests that information-giving can often be impersonal, disengaging, and "insufficient in moments of crisis" and that signposting can often be redundant, as many searching for help online are doing so because of barriers to engaging with signposted services [13]. The impact of self-harm images, such as scars, can be mixed, reminding some of recovery while triggering others [2]. Among those who access self-harm–related internet content, there seems to be a preference for real-time help (eg, "live chat"), self-help tools, and interaction with others, particularly via lived experience content [13,22].

Lived experience stories are often used on formal help sites. They are viewed as personal and engaging and can validate the crisis for readers, while also offering reassurance that they are not alone in their struggle and that recovery is possible [13,22,23]. However, there are several components that might influence whether a lived experience story is perceived as helpful, unhelpful, or potentially harmful. Stories appearing on forums, even those that are run by trained moderators, might be triggering for some people, for example, by including details of methods, injury, or graphic imagery. Stories appearing on websites run by charities and health care organizations usually include a personal narrative of help-seeking and recovery. However, the evidence supporting that these encourage help-seeking in the reader is limited [22,23]. Further, the careful regulation of content might be perceived as overly censored and lead some to search for unrefined content in covert and riskier spaces [2]. Even unregulated content posted by a lay individual is curated in a different respect, for example, on social media platforms where users are often presenting themselves in an idealized way [24,25].

This study is part of a mixed methods project that aimed to investigate how variations in help-seeking messages contained within online lived experience stories are interpreted by and psychologically impact those with a history of self-harm. This study used an experimental design to investigate the psychological impact of stories with different types of help-seeking messages, including those mentioning self-help strategies, informal/formal help-seeking (ie, friends, family, or professionals), and no help-seeking. We sought to assess if the type of help-seeking referenced in a lived experience story had an impact on help-seeking intentions, mood, expectations of future self-harm behaviors, as well as psychological factors implicated within the suicidal pathway, such as sense of entrapment (ie, lack of escape from unbearable thoughts, feelings, or situations) [26,27]. It also incorporated an exploratory, qualitative component in which participants provided open-ended feedback on the stories to assess their acceptability as potential interventions. The other study in this mixed methods project conducted focus groups with a subset of the participant sample used in this study (after they took part in the online experiment) to further explore this topic. The results from the focus group, published before this paper was written, demonstrated that although it is a complex relationship, individuals with recent self-harm experience could positively engage with lived experiences stories, for example, if they reflected a wide range of personal journeys and avoided the use of stigmatizing language [23].

Methods

Overview

This paper presents the quantitative and qualitative results of a self-administered online experiment [23] which explored how people with self-harm experience and interpret lived experience accounts as a means of support. The protocol [28] was preregistered ahead of data collection [29]. For results of the follow-up focus groups, see Winstone et al [23] for further discussion.

Ethical Considerations

Ethical approval was granted by the University of Bristol School of Psychological Science Research Ethics Committee (reference number 10504). Before beginning the online experiment, participants were presented with the participant information sheet, which included researcher contact details. Participants were invited to contact the researcher with any questions

XSL•FO
RenderX

regarding the study, before providing informed consent. Participants were able to navigate away from the survey while awaiting researcher response and resume participation once ready. Participants were then asked to confirm (via tick boxes) that they met the eligibility criteria and that they were providing informed consent to take part in the online study. Participants who completed the online survey were offered the option to enter a prize draw to win one of four £50 (US $67.50) Love2shop vouchers. All aspects of the General Data Protection Regulation and the Data Protection Act 2018 were adhered to. Anonymous study data have been backed up on a secured University of Bristol network drive and transferred to a designated University of Bristol Research Data Storage Facility for long-term archiving. The study data will be kept for a minimum of 15 years. The data sheet has been made open using the University of Bristol Research Data Repository.

Recruitment

The study was advertised by the research team and mental health charities on their web pages, social media accounts, and in newsletters sent out to individuals who signed up to hear about regular research/charity activity. The study was also advertised on self-harm/mental health-specific forums, on Reddit, RecoverYourLife, and the National Self-Harm Network website. The advertisements contained a link to the experiment, which was programmed and hosted online using Gorilla Experiment Builder [30]. Participants needed access to a device and an internet connection, but could access the task from any device that allowed them to access any web browser. After confirming eligibility and providing consent, and completing a self-administered baseline questionnaire, participants were randomly assigned (using Gorilla's balanced randomization feature) to one of the following three story conditions: (1) self-help strategies, (2) informal/formal help-seeking, (3) no help-seeking.

We conducted an a priori power analysis using G*Power (version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) [31], which determined that a sample of 246 participants would provide adequate (80%) power for our main analysis (1-way ANOVA) to detect a small to medium effect size (f=0.2) for our primary outcome (differences in help-seeking intentions) among the 3 story groups.

The study was conducted according to the revised Declaration of Helsinki (2013) and the 1996 International Council for Harmonisation Guidelines for Good Clinical Practice E6(R2). Further details about anticipated risks and our strategy to mitigate any risks can be found under "Ethical Considerations and Informed Consent" and "Safety" in the study protocol [28]. To be eligible for the study, participants had to be aged 16 years or older, fluent in English, currently resident in the United Kingdom, have engaged in self-harm within the past year, and be able to provide informed consent. Before beginning the study, participants had to provide informed written consent. Safeguarding resources were signposted to participants at the start and at the end of the study. Participants were asked to download a copy (or make note of) the safeguarding resources before beginning the study to ensure that all participants had access to the resources regardless of how far they progressed in the study. Participants were informed that it would take approximately 30 minutes to complete the survey. It was mandatory to answer all questions during the experiment, but participants were reminded that they could stop taking part at any time. Participants were also informed that the study was anonymous and that all data from participants who completed the study would be made public at the end of the study. After taking part, participants were debriefed (and again presented with safeguarding resources) and were offered the opportunity to enter a prize draw to win one of four £50 (US $67.50) Love2shop vouchers.

Materials

A total of 3 template stories were used in this study (Multimedia Appendix 1). The same 3 templates were presented to all participants, but a portion of text was modified (removed and/or inserted) to reflect the different experimental conditions: self-help strategies, informal/formal help-seeking, and no help-seeking. The template stories were chosen from an initial shortlist of 10 real-life stories curated by BM. These were selected from a variety of online sources, including the websites of third-sector organizations, health care organizations, web-based forums, and personal blogs. This approach was used to ensure that they were not solely representative of the more polished stories that often appear on formal help sites. For ethical reasons, stories were excluded if they encouraged self-harm, described self-harm methods in detail, or did not have a recovery-oriented/hopeful outlook. Each of the 10 stories was independently ranked (in order of preference) and discussed by BM and 3 of the study authors (JF, IP-V, and LB). The 3 lived experience stories were then chosen following the ranking and discussion to be used as the template stories. The only key difference across the experimental conditions was whether text concerning self-help strategies, informal/formal help-seeking, or no help-seeking (but a positive/hopeful message) was inserted into the stories. These inserts were drawn from the original 10 stories selected by BM.

Measures

Participant Characteristics (Assessed at Baseline)

Participants reported their age in years, their gender, sexual orientation, and ethnicity. They also answered questions on self-harm thoughts (past year frequency), passive and active suicidal thoughts (in lifetime and recency), nonsuicidal self-harm (in lifetime, recency, and past year frequency), and suicide attempts (in lifetime and recency). To measure help-seeking history, participants completed a modified version of the Actual Help-Seeking Questionnaire (AHSQ) [32,33]. For further details, please refer to the protocol [28].

Outcome Measures (Assessed Post Randomization)

Primary Outcome: Help-Seeking Intentions

To measure help-seeking intentions, participants completed a modified version of the General Help Seeking Questionnaire (GHSQ) [34]. A total GHSQ score was computed by summing responses across all help-source items, excluding the "I would not seek help from anyone" item, in line with prior research [35,36]

XSL•FO
RenderX

Secondary Outcomes: Affect, Entrapment, and Future Self-Harm

Participants completed the Positive and Negative Affect Schedule (PANAS) [37]. They completed the 4-item Entrapment Scale Short Form (E-SF) [38]. They also answered 2 questions about future self-harm, rated on a 5-point scale. First, how likely they would be to hurt themselves on purpose in the future after reading the stories, and second, how likely it was that they could see a time in the future without self-harm.

Open-Ended Feedback on the Lived Experience Stories

Participants were asked to provide open-ended feedback on the lived experience stories presented to them during the study. Specifically, they were asked, "Was there anything you found helpful/unhelpful about the stories? If so, please explain."

Attention Check

To ensure that only data from participants who were paying attention during the study were included in the analysis, one of the items among the outcome measures asked participants to select 1 on a scale from 0 to 4. Participants who selected a number other than 1 had their data removed prior to the analysis [39].

Procedure

Participants completed the questionnaires on demographics, current/past self-harm thoughts and behaviors, and help-seeking history. They were then randomized, using Gorilla's balanced randomization feature, to 1 of the 3 conditions (ie, self-help, informal/formal help-seeking, or no help-seeking). Participants were presented with and asked to read the 3 lived experience stories, with amended text based on the condition that they were assigned to. Participants were not aware of the condition they had been assigned to, nor were they informed that there were different variations of the stories. The stories were presented in the same fixed order for all participants. They then completed the outcome measures in the following order: (1) free text opinions of the lived experience stories, (2) mood, (3) entrapment, (4) thoughts of self-harm/suicide, and (5) help-seeking intentions.

Analysis Plan

Data Screening

To maintain data quality, each participant's data were screened against the following criteria prior to analysis: (1) each participant must have completed the entire study and (2) must have correctly answered the eligibility questions and the attention check question within the experiment. The data were assessed for normality using skewness and kurtosis statistics, and were assessed to ensure that they met the assumptions for ANOVA testing.

Data Analysis

Descriptive statistics were used to summarize the participant characteristics and outcome measures in each group. An ANOVA was used to test if the type of help-seeking mentioned in the lived experience story influenced the primary outcome of interest (ie, total score on the GHSQ). A series of ANOVAs was used to test if the type of help-seeking mentioned in the lived experience story influenced the secondary outcome measures (ie, total scores on PANAS, E-SF, and the 2 items assessing future self-harm). Where the type of help-seeking mentioned in the stories impacted any of the outcomes, post hoc pairwise comparisons were conducted using Tukey's Honestly Significant Difference (HSD) test to control for multiple comparisons.

This study was powered to detect a main effect of the type of lived experience story; therefore, any interactions were exploratory. Where any of the analyses indicated a main effect of type of lived experience story on the outcome measures, then "story type × self-harm history" analyses of covariance (ANCOVAs) were used to assess if the influence of type of lived experience story on the outcome measures differed by self-harm history. The self-harm history variable was defined as the recency of self-harm behavior in the past year. In cases where a participant had a history of both nonsuicidal self-harm and attempting suicide, the recency score (indicating "either in the past week" or "more than a week ago, but in the past year") for whichever behavior was more recent was used. Where any interactions existed, they were explored in post hoc analyses using 2-tailed *t* tests. As prior research demonstrates that gender [40,41], age [40], and prior help-seeking experience [42] impact future help-seeking, all analyses were run both unadjusted and adjusted for age, gender, and a continuous variable of help-seeking history (ie, total score on the AHSQ).

In the protocol, we had specified that exploratory analyses would be guided by the qualitative results. Findings from focus groups suggested that lived experience stories can have a positive impact on readers, but that this effect may be moderated by age; for example, older participants struggled emotionally when reading about someone else's recovery that occurred by a certain age [23]. Therefore, we have included a tertiary analysis, exploring interactions between story type and age on any primary and secondary outcomes where main effects were found.

Participant opinions on the lived experience stories were analyzed using content analysis. After reviewing the data, specifically noting that many responses were brief and lacked richness, it was decided that instead of conducting thematic analysis (as originally specified in the protocol), it would be more appropriate to conduct content analysis. Established guidelines for conducting a conventional concept analysis were followed [43]. No preconceived categories were imposed; instead, key concepts were allowed to emerge inductively from the data. The data were imported into NVivo (version 14; QSR International) [44] for coding. Initial open coding was conducted independently by JF and JS (see Acknowledgments section), who identified salient thoughts and concepts within participants' responses. JF then refined the coding scheme by examining conceptual relationships and consolidating codes where responses reflected similar underlying ideas. LW subsequently coded 10% of the responses, adding additional codes when deemed appropriate. Intercoder reliability was then assessed and calculated to be around 99%. JF reviewed any amendments, and any disagreements were discussed and resolved. Finally, JF refined and renamed codes to ensure that each label accurately captured the underlying concept.

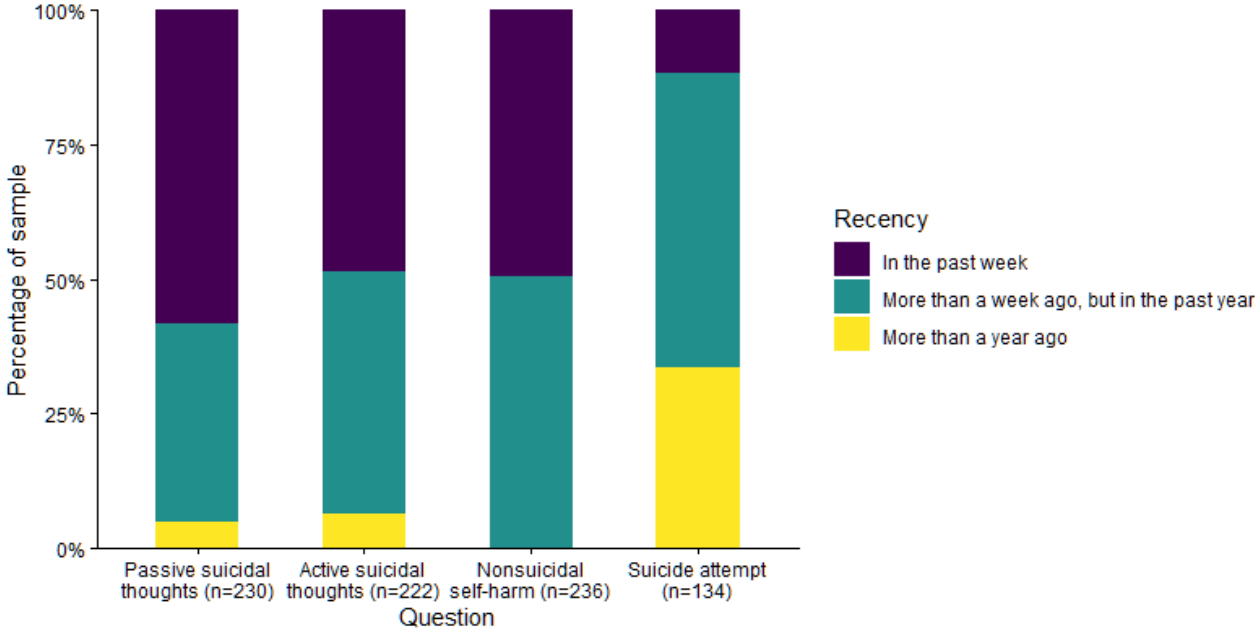
Results

The data that form the basis of the results presented here are available from the University of Bristol's Research Data Repository [45].

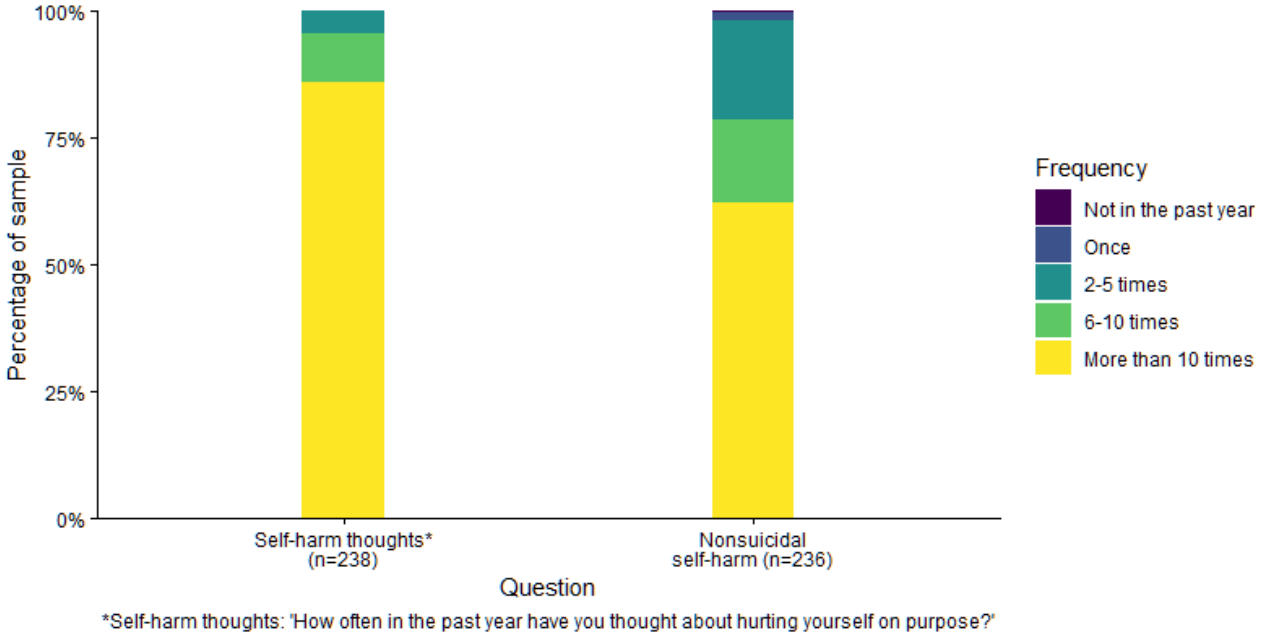
Participant Characteristics (Assessed at Baseline)



Demographics

Data collection ceased when there were complete datasets from 246 participants. One participant was identified as completing the study twice (based on IP address) and was removed from the dataset. Of the remaining 244 participants, data cleaning procedures identified 2 participants who failed the attention check and 6 who did not meet the eligibility criterion of having hurt themselves on purpose in the past year. Therefore, data from 238 (97.5% of our target sample size) participants were included in the analysis. Participants were primarily female (188/238, 78.9%), White (207/238, 86.9%), and were aged between 16 and 59 (mean 23.2, SD 9.4) years. Table S1 in Multimedia Appendix 2 provides further details on participant demographics across the experimental conditions, as well as a breakdown by experimental condition. The experiment ran for 28 weeks (from late March to early October 2022). In total, 381 individuals visited the link for the experiment, 379 provided informed consent, 361 passed the screening, and 340 were randomized.

Self-Harm Thoughts and Behaviors



Out of 238 participants, 236 (99.2%) had engaged in nonsuicidal self-harm, 230 (96.6%) had thoughts that life was not worth living (ie, passive suicidal thoughts), and 222 (93.3%) had experienced suicidal ideations (ie, active suicidal thoughts) during their lifetime. Just over half the sample (n=134, 56.3%) had made a suicide attempt. Figures 1 and 2 display information about the recency and past-year frequency of self-harm thoughts and behaviors in the sample.

Figure 1. Recency of suicidal thoughts and self-harm behavior.

XSL•FO
RenderX

Figure 2. Frequency of self-harm thoughts and behavior (in the past year).

In terms of the type of self-harm methods used, 105 (44.1%) out of 238 participants reported swallowing pills or something poisonous, 109 (45.8%) reported burning themselves, and 226 (94.9%) reported cutting themselves. Using another method not listed was reported by 109 (45.8%) participants. These were screened by JF and BM and then categorized (for full details, please refer to Table S2 in Multimedia Appendix 2). Behaviors not considered to be self-harm (eg, tattooing, eating behaviors, or indirect self-harm such as unsafe sex) were removed; however, all participants reporting these behaviors also reported at least one other self-harm method, and so no participants were removed from the analysis. In terms of the number of self-harm methods used, 100 (42%) out of 238 participants reported having used 2 self-harm methods during their lifetime, with 45 (18.9%), 62 (26.1%), and 31 (13%) reporting 1, 3, and 4 or more methods, respectively.

Help-Seeking History

When reflecting on help-seeking over their lifetime, not seeking help from anyone was reported by 39 (16.4%) out of 238 participants. While some of these participants responded affirmatively to other items on the scale, 30 (12.6%) of those participants did not report any form of help-seeking. For a breakdown of the prevalence of accessing each source of informal and formal help, please refer to Table S3 in Multimedia Appendix 2.

Outcome Measures (Assessed Post Randomization)

Overview

Descriptive statistics are reported for the 5 outcome measures by experimental condition in Table 1.

Table 1. Descriptive statistics for outcomes.

	Self-help	Informal/formal help	No help
Primary outcomes, mean (SD; range)			
Help-seeking intentions (higher scores indicate greater intention to seek help),	34.3 (12.2; 13-73)	34.3 (12.3; 13-76)	38.6 (12.4; 13-73)
Secondary outcomes, mean (SD; range)			
Positive affect	18.4 (6.0; 10-36)	18.0 (6.5; 10-43)	18.8 (6.0; 10-35)
Negative affect	24.8 (10.4; 10-48)	28.5 (10.6; 11-49)	28.7 (9.5; 10-49)
Entrapment	15.1 (4.9; 4-20)	15.0 (4.4; 4-20)	15.6 (4.1; 5-20)
Future self-harm, median (IQR)			
"After reading these stories, how likely is it that you will hurt yourself on purpose in the future?" (0=much less likely; 4=much more likely)	2 (2-2)	2 (2-2)	2 (2-3)
"Can you see a time in the future without self-harm?" (0=not at all likely; 4=very likely)	2 (1-3)	1 (0-3)	1 (1-3)

XSL•FO
RenderX

Help-Seeking Intentions

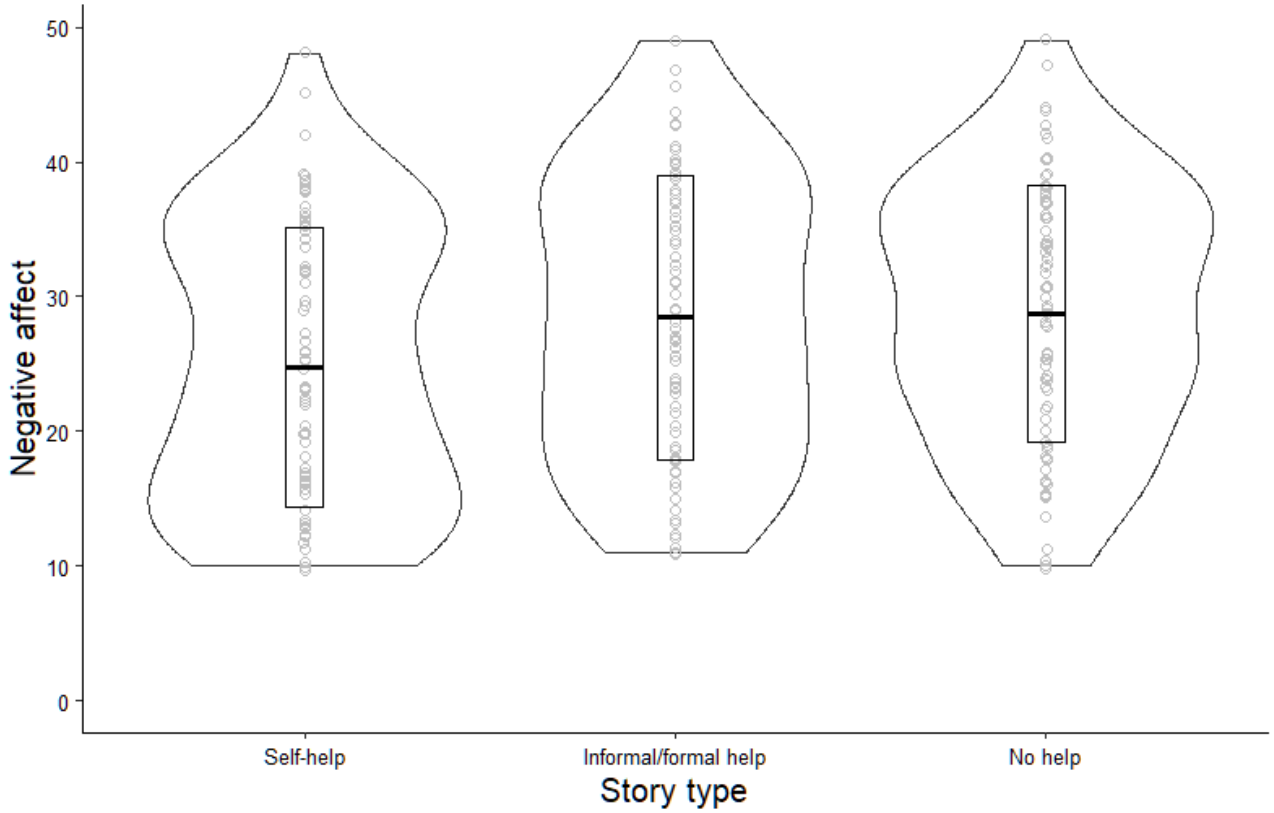
Due to the skewed nature of the data, the variable for help-seeking intentions was transformed using a square-root transformation. There was moderate evidence for an effect of story type on help-seeking intentions ($F_{2,\ 235}$=3.3; P=.04; η^2=0.03). Adjusting for age, gender, and help-seeking history provided stronger evidence for an effect of story type on help-seeking intentions ($F_{2,\ 230}$=4.2; P=.02; η^2=0.25; the full results of the model using transformed and untransformed data can be found in Tables S1 and S2 in Multimedia Appendix 3). None of the pairwise comparisons (Tukey's HSD on the unadjusted means) reached the conventional significance threshold. However, 2 comparisons approached significance, suggesting a trend toward group differences that were consistent with the overall effect. Participants in the "no help" condition reported marginally higher levels of help-seeking intentions after reading the stories compared to participants in the "self-help" condition (mean difference=–0.36, 95% CI –0.75 to –0.03; P=.08) and the "informal/formal help" condition (mean difference=–.36, 95% CI –0.74 to –0.02; P=.07). The impact of story type on help-seeking intentions is illustrated in Figure 3 (using untransformed data to aid interpretability).

Figure 3. Impact of story type on help-seeking intentions.

An ANCOVA was conducted to determine whether self-harm history (recency of self-harm) interacted with story type to influence help-seeking intentions. Evidence for this interaction was not found ($F_{2,\ 232}$=0.28; P=.76). An ANCOVA was conducted to explore if age interacted with story type to influence help-seeking intentions. Evidence for this interaction was also not found ($F_{2,\ 232}$=1.25; P=.29). However, the former only achieved 15% power, and the latter 41% power.

Affect, Entrapment, Future Self-Harm

Due to the skewed nature of the data, attempts to normalize the distribution of all secondary outcomes, using square-root and cube transformations, were made. Despite these efforts, visual inspection of residuals and formal tests of normality indicated that the residuals remained nonnormal. Therefore, the following analyses were conducted using untransformed data.



We found no evidence for an effect of story type on positive affect ($F_{2,\ 235}$=0.32; P=.73; η^2=0.002) or entrapment ($F_{2,\ 235}$=0.33; P=.72; η^2=0.003). There was also no evidence for an effect of story type on future self-harm (likelihood of self-harm after reading stories: $F_{2,\ 235}$=2.40; P=.09; η^2=0.02; likelihood of a future without self-harm: $F_{2,\ 235}$=0.94; P=.39; η^2=0.008). The pattern of results was unchanged following adjustment for age, gender, and help-seeking history (the full results of the model can be found in Tables S3 and S5-S7 in Multimedia Appendix 3).

There was evidence for an effect of story type on negative affect ($F_{2,\ 235}$=3.83; P=.02; η^2=0.03). Adjusting for age, gender, and help-seeking history increased the strength of association between story type and negative affect ($F_{2,\ 230}$=4.02; P=.02; η^2=0.10; the full results of the model can be found in Table S4 in Multimedia Appendix 3). Pairwise comparisons (Tukey's HSD on the unadjusted means) demonstrated that participants in the "self-help" condition reported lower levels of negative affect after reading the stories compared to participants in the

XSL•FO
RenderX

"no help" condition (mean difference=–3.97, 95% CI –7.72 to –0.22; *P*=.04) and the "informal/formal help" condition (mean difference=–3.70, 95% CI –7.55 to 0.14; *P*=.06). Figure 4 presents the impact of story type on negative affect.

Figure 4. Impact of story type on negative affect.

An ANCOVA was conducted to explore whether self-harm history interacted with story type to influence negative affect. Although there was strong evidence for an effect of self-harm history on negative affect ($F_{1, 232}$=28.94; *P*<.001), evidence for an interaction with story type was not found ($F_{2, 232}$=0.94; *P*=.39). An ANCOVA was also conducted to explore if age interacted with story type to influence negative affect. Although there was strong evidence for an effect of age on negative affect ($F_{1, 232}$=16.85; *P*<.001), evidence for an interaction was not found ($F_{2, 232}$=1.06; *P*=.35). However, the former only achieved 22% power, and the latter 26% power.

Open-Ended Feedback on the Lived Experience Stories

Approximately 87.8% (209/238) of the sample provided written feedback on the stories. Limitations and advantages of the lived experience stories, categorized by the type of story, are reported in Tables S1 and S2 in Multimedia Appendix 4. Below, we have reported noticeable differences in the themes across conditions.

Differences in Perceived Limitations of the Stories Across Conditions

The Recovery Messaging Was Problematic

Within the comments, messages of hope, positivity, and recovery were described as annoying, frustrating, and overwhelming. Some participants expressed dislike toward references to counting the number of days without self-harm. Other comments referred to the difficulty in looking to the future, as that felt dismissive and more challenging than taking it day by day. A participant explained,

> *I don't care if I'm fine by the time I'm 21. I've ruined my teenage years with this, and I can't get that back. Yeah, I hope for a happier future, but when people say that everything is fine because they recovered (...) they're ignoring how horrific the emotions were when they were struggling. Recovery doesn't magically erase the past.* [Participant in "informal/formal help" condition]

Another participant expressed frustration that the narrators in the stories seemed to be working toward recovery due to feeling stigmatized and pressured to conform, rather than of their own accord. The "no help" condition stands out in that more participants appeared to struggle with the inclusion of recovery messaging compared to the other story conditions. This may be because the recovery message appeared without a clear indication of how recovery occurred, as comments reflected the following sentiments,

> *Sometimes words can get lost, eg, "things get better." The term has been used so many times that I have almost become desensitized to it and what it means.* [Participant in "no help" condition]
>
> *Doesn't say how to get better.* [Participant in "no help" condition]

XSL•FO
RenderX

The Stories Were Unrelatable

While some participants in all conditions commented on the stories being unrelatable, this was less pronounced in the "no help" condition. This is plausibly a result of the stories in this condition providing less concrete detail about the narrator's experience, and thus, there being less to be able to relate to. Stories in the "self-help" condition were criticized more than stories in the other conditions for neglecting to acknowledge that "one size does not fit all." This was mostly reflected in the criticism that the stories were too specific, usually because of a focus on younger ages. However, some participants in the "self-help" condition agreed with the sentiment that "the people in the stories seemed to have a better idea of why they started self-harming and why they continued to do it, which I don't have."

The most prevalent reasons why the stories were unrelatable referred to the stories having unrealistic portrayals of self-harm, and instilling feelings of competition and thus feelings of isolation in readers. They also commented that they felt pressure to have "stronger urges" and "scars" as the narrators had. Participants in all conditions found the stories unrealistic to a similar degree; however, more references about the stories seeming sanitized or inauthentic were made by participants in the "self-help" condition. Participants in the "self-help" and "informal/formal help" conditions commented on the stories, making them feel isolated much more than those in the "no help" condition. Several participants emphasized that there is a very competitive nature to self-harm at both extremes:

> *It can sometimes make you feel as if you are not bad enough to deserve help.* [Participant in "self-help" condition]

> *All people who seemed to be able to stop with help. It made me feel bad for still struggling.* [Participant in "informal/formal help" condition]

The Specific Support Mentioned in the Stories (or Lack Thereof) Was Problematic

The stories in the "self-help" condition were criticized for not mentioning professional or medical support. All conditions were criticized for offering nonpractical advice. This was more predominant in the "self-help" condition, followed by the "informal/formal help" condition, and much less in the "no help" condition. The type of self-help methods mentioned were mainly criticized for being methods that readers had already tried and found unsuccessful in aiding recovery; there were also a couple of comments criticizing the focus on short-term coping mechanisms, instead of long-term recovery.

> *After trying the methods they said helped them, I eventually slipped back to self harming. I don't know what else to do.* [Participant in "self-help" condition]

> *They didn't give much detail on what actually helped them other than immediate coping mechanisms.* [Participant in "self-help" condition]

The type of informal/formal help methods mentioned were mainly criticized, as participants felt the stories made accessing those kinds of support sound much easier than it is. For example, a participant stated,

> *Sometimes it may not be as easy to access support services, whilst barriers to access are likely to vary, it felt like the people in the stories were able to somewhat easily access support - the way it should be I guess.* [Participant in "informal/formal help" condition]

Another stated,

> *I'm a first-generation immigrant, mental health was never something to talk about in my household because of cultural reasons. If I had gone to my parents, I know I wouldn't get the same sympathy just frustration.* [Participant in "informal/formal help" condition]

This made readers who did not have supportive friends/family or who had struggled to access formal support feel isolated and distressed,

> *I guess it makes me sad to hear about people having their boyfriend, friends and family around to help them when I feel like I have no one.* [Participant in "informal/formal help" condition]

Differences in Perceived Advantages of the Stories Across Conditions

While the "informal/formal help" condition did not stand out in the number of criticisms received, participants in this condition did seem to have fewer positive things to say about the stories. This was apparent in relation to comments about the stories having a realistic but hopeful outlook of recovery and comments about the authenticity of the stories.

The Stories Included a Realistic But Hopeful Outlook on Recovery

Participants in all conditions appreciated hearing the stories from those who recovered, and particularly the emphasis on recovery being a nonlinear process that takes time. Only the "self-help" stories were praised for highlighting that the path to recovery is not a one-size-fits-all approach, and that readers will find different coping mechanisms and recovery strategies helpful. As mentioned earlier, participants in the "self-help" condition were also more likely to criticize the stories for failing to do exactly this. Only the stories in the "self-help" and "no help" conditions were praised for the discussion of relapses, despite these themes appearing in all conditions.

The Stories Were Relatable

The number of positive comments about the relatability of the stories was similar across conditions. However, there were some differences among the conditions when looking at the subthemes of relatability. Although positive comments about the authenticity of the stories were made about all of the stories, this was more prevalent in the "self-help" and "no help" conditions. All of the stories were commended for accurately portraying the emotions experienced in self-harm, but the stories in the "self-help" and "no help" conditions were further

XSL•FO
RenderX

commended for relaying "lived experience" and seeming "honest and truthful." One participant explained that,

> *It can be hard to accept advice from people that don't fully understand or appreciate just how dark the thoughts can be and how strong these urges and negative thoughts can take over your mind.* [Participant in "no help" condition]

We note that there are inconsistencies between the unrelatable and relatable themes, which we will elaborate on in the discussion.

The Stories Were Supportive

Unsurprisingly, participants in the "no help" condition had fewer positive remarks about the theme of support compared to participants in the conditions that focused on help-seeking. However, this difference was not as substantial, as some participants in this condition felt that hearing others' stories reminded them that they were not alone. It is also worth noting that this feeling of "camaraderie" was reported a similar number of times across conditions. Other aspects that fell under the theme of support seen in the other conditions were: participants in the "self-help" condition appreciated hearing what specific methods worked for others, as it gave them hope, generally, but also ideas about new coping mechanisms to try. Participants in the "informal/formal help" condition appreciated the emphasis on the importance of accessing support for recovery. The stories highlighted to them how helpful it was to have both informal and formal help at the start, but also throughout recovery. The stories could help to instill hope and confidence,

> *It does get better once you find the right support. There are people who do care about you, you just don't know it.* [Participant in "informal/formal help" condition]

While some participants who had negative or no help-seeking experiences in the past found it difficult to read about others having success, some participants found it reassuring to hear about other people successfully accessing support, as there is concern that accessibility can be restricted.

Discussion

Main Findings

In this study of individuals with recent self-harm experience, we were unable to find clear evidence of an association between the type of content of lived experience stories and help-seeking intentions, entrapment, or positive affect. However, we did find evidence that reading stories about self-help strategies led to a lower prevalence of negative emotions, compared to reading stories about seeking help from others, or stories that made no mention of help-seeking.

One potential explanation for why we did not see an increase in help-seeking intentions after reading a story that emphasizes help-seeking might be due to the relatability of the stories. The open-ended feedback suggested that the stories that mentioned help-seeking were seen as less relatable than the stories that did not mention help-seeking. This demonstrates that it is not only the characteristics of the narrator (eg, age and gender) that the reader might not relate to. They might also struggle to relate to the actions and consequences of help-seeking experienced by the narrator. First, about 12.6% (30/238) of participants reported no history of help-seeking. Others who recounted negative experiences when they sought help (eg, ineffective self-help strategies, negative reactions from family and friends, and inaccessible formal support) reported feeling distressed (ie, feeling like a failure, alone, and hopeless) when they read about others' positive experiences. Further, only the stories that mentioned help-seeking seemed to evoke a feeling that the reader's situation was less serious than the narrator's. As perceived need is an important component of help-seeking decision-making [46], it is feasible that the stories that mentioned help-seeking set a benchmark for when help-seeking is needed. In our focus group study, we similarly found that being able to identify with the narrator of a lived experience story—made more challenging by including specific details of age or circumstances—was "an important factor in encouraging help-seeking through the recognition of need in others and thus oneself" [23].

Findings need to be interpreted in light of some limitations. First, the sample was self-selecting, so it is possible it may not be representative of the wider population; further, there was a considerable degree of attrition, and the reasons for this are unknown. Second, we did not measure help-seeking intentions before and after the exposure, so we cannot determine if there was an overall increase across all participants. Third, the study was powered to detect a main effect of the type of lived experience story, and tests of interactions were exploratory and underpowered. These post hoc findings therefore need to be interpreted with caution, and larger-scale research is needed to understand the role of moderators, such as self-harm history and age. Fourth, as we only measured help-seeking intentions, we do not know if these intentions would manifest into help-seeking behavior. Therefore, future research would benefit from recruiting a larger sample, capturing reasons for deciding not to participate or withdrawing from the study, and including a follow-up assessment to measure whether intentions translated into behavior.

It is worth noting that some of the themes that emerged from the open-ended feedback questions contradicted one another. For example, the self-help stories seemed to arouse thoughts about self-harm and recovery being very individualistic experiences, but they were both praised for doing this well and critiqued for doing it poorly. Similarly, the same aspect of a story could be a positive that made the story more relatable for one participant, and a negative addition that made the story less relatable for another. While some attempts were made to reconcile contradictions like this when interpreting the data, we were conservative in our approach. First, because we felt that the contradictions were the result of a broad focus. Feedback was collected from a large number of individuals, and that feedback could be directed toward various aspects of the stories. Second, the contradictions in themselves may be meaningful, as they indicate how individualistic the experience of self-harm and recovery can be, and emphasize that a delicate balance needs to be found in these stories if hoping to apply them broadly.

XSL•FO

Overall, there was broad consistency between the themes that emerged from the open-ended feedback collected in this study and those that emerged during the focus group discussions with 5.5% (13/238) of the original sample [23]. Both studies highlighted the importance of lived experience stories to be relatable, but that a careful balance had to be struck between specificity and ambiguity. Both studies also highlighted the importance of lived experience stories to feel authentic (avoiding both dramatization and sanitization) and that authenticity is a key factor in how relatable a story is to the reader. Previous research on mental health recovery narratives also emphasizes the importance of authenticity to readers [47,48]. A systematic review on peer support for self-harm found that shared experience was an important component in making the support they received feel genuine [49]. While the template stories were written by those with lived experience, it was up to the research team's discretion about how to modify them for the purpose of this study, and this might have impacted the relatability or other aspects of the stories. Therefore, we suggest using a co-design approach in future work.

In line with the findings of Winstone et al [23], this study also highlighted the importance of lived experience stories to offer practical advice and to portray the journey to recovery realistically. This finding might be specific to self-harm recovery, as another study, which more broadly focused on participants with any mental health concern and excluded narratives that described harmful behavior (eg, self-harm), found participants reported a preference for narratives about upward trajectories toward recovery over narratives that focused on only snapshots of the journey or nonlinear journeys [47].

Results from the focus groups suggest that reading the stories had a generally positive impact on mood [23]. We did not measure baseline mood in this study, and we cannot assume that if we did that the results would support the qualitative findings, as the focus group sample may have been subject to sampling bias, as participants who felt the stories negatively impacted their mood might have been less likely to enroll in the follow-up qualitative study. Nonetheless, this study did demonstrate that participants who read stories about self-help strategies reported lower levels of negative emotions, compared to the other two groups. The open-ended feedback suggested that reading about self-help strategies that were successful for others left some readers feeling hopeful that recovery might be possible for them too. It also gave them ideas of new strategies to try, inspiring them to act toward achieving their own recovery. It is possible that these positives may have increased their self-efficacy [50] to recover, thereby increasing their mood and decreasing feelings of needing to rely on others for help. While this interpretation is speculative, further investigation is warranted since an unintended negative consequence may be a decreased likelihood of seeking help from others.

The results from this study suggest that readers might react more negatively to themes of recovery in the absence of practical advice on how to recover. The results from this study also add the caveat that it would be beneficial to mention various help-seeking strategies within the same story. This might prevent the reader from feeling demoralized (and avoid seeking help) after reading about someone else successfully obtaining help via a strategy that was unsuccessful for the reader or is a strategy that they are unwilling to try.

Our findings, consistent with the findings of Winstone et al [23], demonstrate that lived experience stories can help readers to "feel validated and help them to better understand their own feelings and experiences" and manage "feelings of isolation, knowing that others are experiencing similar feelings, and engaging in self-harm as a coping mechanism" [23]. However, the results from both studies also highlight that reading about others' experiences can sometimes foster a sense of competition and thereby increase feelings of isolation. Previous research has also highlighted the competitive element of self-harm [19,42,49] and found that individuals sometimes purposefully seek out material that instills feelings of competition when experiencing self-harm urges [42].

One way to prevent lived experience stories from triggering a sense of competition in readers is by avoiding words such as "clean" or other language that might cause readers to feel stigmatized or under pressure to recover. Focus group participants in the follow-up study further explained that stigma can arise when using these terms, because they can unfairly attach moralistic judgments to a medical issue [23]. In addition, it might be helpful to explicitly refer, in lived experience stories, to the competitive nature of self-harm. For example, narrators can emphasize that they are relaying only one out of many stories (that not everyone's self-harm will have the same causes, that not everyone will experience it in the same way, and that not everyone will recover in the same way), but that everyone's experience is valid. Winstone et al [23] further concluded that avoiding numeric references within a story, such as the number of days without self-harm, might help to reduce competition.

The lived experience stories under study were carefully selected to be recovery-oriented and exclude details that might be triggering for someone who self-harms (eg, detailed descriptions of self-harm methods). While this was an important consideration to mitigate risk in this study, it does mean that the results may not generalize to lived experience stories that include more triggering content that one might find on unregulated forums. This will need to be kept in mind if using the results of this study to inform practice.

Further, despite attempts to exclude triggering content from the stories, the results demonstrated that some participants (across all conditions) reported emotional distress as a result of reading the stories. Some participants were negatively impacted by the mention of the specific self-harm method used (ie, cutting). While lived experience stories on forums often include descriptive detail about methods and injuries [51], those hosted on more formal websites (eg, run by charities and health care organizations) usually exclude these kinds of details [22]. However, some participants were negatively impacted by other details that might be found in stories hosted on formal websites, such as hearing about others struggling with self-harm, being reminded of how they harm themselves, or how one's self-harm might impact their loved ones. It was also reported that reading about others still struggling with self-harm made readers feel hopeless that their situation would ever meaningfully improve.

XSL•FO
RenderX

Therefore, future research, using a co-design approach, is needed to identify elements that make a story harmful.

Conclusions

Lived experience stories of self-harm are commonly found on the internet, including on formal help sites, blog posts, and forums. The results of this study provide guidance for those posting or moderating such content. The findings taken together illustrate that the impact of lived experience stories on individuals with a recent history of self-harm is complicated. While the inclusion of help-seeking in a story can help readers to feel validated, less isolated, less helpless, and more hopeful that recovery is possible for them, there is a fine line to tread. The results indicate that the experience of self-harm and the pathway to recovery are very personal, so too many personal details about either experience can make the stories feel unrelatable. However, there are certain shared experiences of self-harm that can be included to ensure a lived experience story feels authentic. Therefore, the results suggest that stories should aim to foster both a sense of individuality as well as community. For example, stories should focus less on the characteristics of narrators, but more on their emotions and experience of self-harm, to which readers can more easily relate. Stories should also propose multiple strategies for achieving recovery, and emphasize that recovery will take time and that there may be setbacks along the way. Future experimental work is needed to confirm whether these adaptations to lived experience stories about help-seeking can motivate individuals to seek help for their self-harm. Future experimental work should also incorporate suggestions on how to limit bias and improve the methodology used in this study. Lived experience stories of self-harm that find the right balance of many of these nuances have the potential to encourage those struggling with self-harm urges to engage in self-help practices or reach out to others for support.

Acknowledgments

This study was funded by the National Institute for Health and Care Research (NIHR) Biomedical Research Centre at the University Hospitals Bristol and Weston National Health Service Foundation Trust and the University of Bristol. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care. BM is funded by a Medical Research Foundation fellowship (MRF-058-0017-F-MARS-C0869). LW is supported by the NIHR School for Public Health Research (SPHR) (NIHR204000). Abstract

Background: Anonymous, 24/7 digital peer support (DPS) offers a scalable solution to support employees' emotional well-being. Understanding sociobehavioral factors, such as timing of engagement and the impact of shared resources, can help employers and employee assistance programs (EAPs) integrate digital tools to better support workforce well-being.

Objective: This study examines (1) outcomes via overall sentiment changes among DPS users; (2) sociobehavioral differences between employees who accessed real-time, anonymous DPS during versus outside business hours; (3) differences in sentiment outcomes based on time of use; and (4) the impact of in-session resource sharing on sentiment improvement.

Methods: Using OpenAI's large language model (LLM) GPT-4o-mini with a few-shot learning approach, 24,818 anonymous chat conversations from 13,879 employees at 5 large employers were evaluated for subclinical sentiment variables, including loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism.

Results: Distinct activity patterns were observed between employees during and outside business hours, with a median user age of 36 years. During business hours, employees reported higher baseline stress (Δ1.6%), whereas outside business hours, baseline depression (Δ1.7%) and loneliness (Δ1.2%) were higher. After DPS use, LLM-derived negative sentiment scores decreased (loneliness 46% reduced, sadness 45%, stress 46%, anxiety ~39%, depression ~40%, despair ~40%, and helplessness ~38%), and optimism increased (~77%). Outside business hours, users engaged more (~68% of all sessions), remained in sessions 19% longer, and discussed 13% more topics, whereas users during business hours reported greater improvements in depression (Δ2.3%), helplessness (Δ1.9%), and loneliness (Δ0.5%). Resource sharing was associated with greater improvements in loneliness (Δ2.9%), stress (Δ1.3%), anxiety (Δ1.9%), depression (Δ7.3%), despair (Δ3.0%), helplessness (Δ2.8%), and optimism (Δ8.8%), but not sadness.

Conclusions: DPS complements employers' EAPs by addressing employee engagement gaps, reducing barriers to mental health care, and promoting emotional well-being among the workforce.

KEYWORDS

digital peer support; employee benefits; employee wellness; workforce well-being; employee assistance programs

Introduction

Background

Workplace emotional well-being is a pressing concern, as increasing numbers of employees suffer from burnout and chronic stress [1,2]. These issues lead to additional workplace problems, including absenteeism, reduced productivity, and mental health concerns [3]. Current mental health tools and employee assistance programs (EAPs) have expanded significantly in scope, evolving from a focus on mental health and substance use to include broader aspects of emotional well-being, such as family health and workplace stress [4]. However, the effectiveness of EAPs has been mixed. A 2017 systematic review concluded that EAPs benefit functioning and presenteeism but have mixed effects on absenteeism and

XSL•FO
RenderX

engagement [5]. Due to the continued shortage of mental health workers, novel strategies are necessary to meet the growing demand for employee emotional support [6].

The integration of digital technology has enabled more immediate, cost-effective, and accessible forms of employee support, such as digital peer support (DPS), to be incorporated into traditional counseling-focused EAP infrastructures [7]. DPS offers an innovative approach to complement traditional EAPs, providing support on demand, in real time, by peers with shared experiences rather than clinicians, thereby promoting social connectedness, significant sentiment improvements, and emotional regulation [7,8]. However, how employees engage with DPS has yet to be studied.

Sociobehavioral Factors

Demographic variables such as age, gender, culture, technology use, and internet access significantly affect the engagement and effectiveness of digital interventions [9-12]. Barriers such as limited technological proficiency, especially among older adults or individuals with low digital abilities, may reduce user engagement and limit program success [13]. Prior research indicates that women are more likely than men to seek mental health support and use digital mental health tools [14-17]. These differences highlight the importance of tailoring support strategies to the needs of different groups. While mobile apps and chatbots using cognitive behavioral techniques are effective in reducing symptoms of depression and anxiety, evidence shows that digital tools are more effective when supplemented with human interaction, whether through peer support or moderated participation [9].

Additionally, promoting awareness of and trust in EAP resources through culturally sensitive education has been linked to enhanced utilization among diverse employee populations [13,18]. Addressing these sociobehavioral challenges through user-centered design, sensitive outreach, and anonymous technology can improve accessibility and inclusivity across demographic groups [13,19].

Digital Peer Support

Research shows that DPS improves emotional well-being, self-efficacy, and social connection and empathy, all of which contribute to positive organizational outcomes [14]. DPS has emerged as a critical modality for delivering emotional health and wellness services through technological platforms [7,20]. It encompasses both synchronous and asynchronous support delivered via chat, forums, video, mobile apps, and other digital communication tools, allowing users to flexibly seek mental health support [20,21]. It offers higher accessibility than more traditional services, as most individuals own a smartphone, including those from lower socioeconomic backgrounds or with serious mental illness [22-24]. Additionally, DPS has fewer barriers than in-person services, which may involve scheduling, transportation, mobility, or discomfort with face-to-face interactions [19,25], as well as tele- or mobile clinical mental health services that may require insurance, appointments, and delays due to formal clinical assessments before care can begin. As a result, DPS facilitates broader participation, particularly among populations that are underserved or less likely to engage in typical care [19,25].

In addition to accessibility, DPS services can be available 24/7, allowing continuity of care and reinforcing self-efficacy and emotional regulation, thereby filling temporal gaps left by typical mental health services [7]. Peer-delivered digital interventions have been shown to improve both psychiatric and medical self-management by empowering individuals to actively participate in their care within a supportive, nonclinical environment [20,21,25]. Reviews of DPS programs, including those for public safety workers, highlight reductions in stress and trauma [26-28], while workplace-based engagement is associated with increased belonging, accountability, and a sense of community [20,21,25]. DPS is also unique in its ability to integrate lived experience into its design, development, and delivery [21,29,30]. The involvement of peers and their lived experiences increases the relevance and acceptability of interventions [31].

The timing of user engagement is affected by a variety of sociobehavioral factors. Users who seek DPS after work hours may experience heightened levels of emotional distress, loneliness, insomnia, or anxiety, and may engage in more spontaneous or emotionally charged exchanges, whereas interactions during business hours tend to be more structured [7,20,32]. Additional barriers such as privacy concerns, stigma, and work-hour constraints can also reduce engagement during regular business hours, highlighting the need for after-hours availability of support [18,33]. Engagement patterns are also affected by demographic variables such as age, gender, employment status, education level, and housing conditions [34,35]. Preferences for specific technologies, such as text-based versus visual platforms, may vary depending on users' mental health conditions and comfort levels [36]. For instance, some individuals may avoid video-based support and prefer text-only interactions, seeking privacy, cultural alignment, or emotional safety [37].

DPS has also demonstrated measurable improvements in emotional well-being. Services report rapid reductions in sadness (57.5%) and loneliness (55.0%), with sentiment changes emerging within minutes of engagement [8]. These benefits may be understood through relational frameworks such as social penetration theory, which suggests that trust and intimacy in relationships deepen over time, especially when individuals feel secure in their anonymity and in control over self-presentation [38]. These dynamics are often heightened during after-hours use, when users may feel more emotionally vulnerable and open, forming meaningful peer connections [32,38]. Taken together, these findings point to the critical role of timing, sociobehavioral context, and technological preferences in shaping DPS engagement.

Role of Resource Sharing in DPS

A central mechanism of DPS effectiveness is resource sharing, which promotes mental health literacy, reduces stigma, and encourages help-seeking behaviors [27,28]. Sharing success stories and testimonials has been shown to increase employee engagement within EAPs, supporting a workplace culture that values mental health and well-being [27]. Workplace-related

XSL•FO
RenderX

resource sharing also enhances coping, particularly in managing remote work, and reduces isolation [26-28]. DPS also offers timely, subclinical support during a shortage of behavioral health clinicians, helping users access resources when needed without waitlists [6,27]. Access to tailored resources may be especially valuable for underserved or marginalized populations, helping to reduce equity gaps in mental health care [13].

This study examines how sociobehavioral factors, such as the timing of support access, levels of perceived emotional distress, and in-session resource sharing, shape employee engagement and sentiment outcomes within a DPS environment. By analyzing user data across 5 large employers, we aim to identify key trends that can inform the design and implementation of digital emotional support services within workplace well-being programs.

Study Objectives

This study examines how timing and in-session support influence sentiment outcomes within an anonymous, synchronous DPS service, Supportiv. Specifically, we investigate (1) overall sentiment changes across users of DPS; (2) sociobehavioral differences between users who accessed DPS during versus outside business hours; (3) differences in sentiment outcomes based on the timing of service use (during vs outside business hours); and (4) the impact of targeted in-session resources on users' sentiment changes.

Methods

Supportiv DPS Service Model

Supportiv is an anonymous, synchronous, small-group, live-chat DPS service that is available on demand, 24/7. Employees can access the service through links from their employer portals, health plans, EAPs, or related channels. This study analyzes data from employees whose organizations offered Supportiv in addition to their existing EAP programs.

Users voluntarily access Supportiv's anonymous peer-to-peer support service through an informed self-selection process. Engagement begins with a user-initiated response to the free-text prompt, "What's your struggle?" Before accessing services, individuals are required to review and actively consent to the Terms of Service and Privacy Policy, which include consent for the use of their inherently anonymous data—anonymous from the point of collection—for research and service improvement purposes. No personally identifiable information, personal health information, or Health Insurance Portability and Accountability Act (HIPAA)–protected health information is collected.

To reduce the risk of indirect user identification through free-text content, all transcripts were audited using automated methods followed by manual processing before analysis. Potential personal identifiers, including names, locations, or contact information, as well as contextual details that could allow for identification, were omitted from the text. Data were stored and analyzed in deidentified form, and access was limited to authorized personnel. All data handling complies with General Data Protection Regulation (GDPR) and California Consumer Privacy Act (CCPA) requirements, including lawfulness, fairness, transparency, data minimization, purpose limitation, and integrity and confidentiality.

The platform is designed according to data protection by design and by default principles. To mitigate the risk of indirect identification in free-text content, all chats are continuously processed through automated filtering systems that remove explicit identifiers such as names, contact information, social media handles, websites, and physical addresses. In addition, trained human moderators review chats in real time and remove any remaining potentially identifying or narrowing contextual information as needed. These safeguards are applied universally across all chats as part of routine platform operations, not solely for research purposes. Access to research data is restricted to authorized personnel. Together, these safeguards reduce the risk of direct or indirect identification and ensure compliance with applicable privacy regulations.

Supportiv uses artificial intelligence (AI)–driven natural language processing (NLP) to match users with other concurrent users experiencing similar life challenges, forming small, synchronous groups of no more than 5 peers. Each group is facilitated in real time by a trained subclinical human moderator. Users are automatically placed into a chat session that may include other participants and the moderator. Moderators facilitate peer-to-peer discussion, maintain psychological safety by enforcing community guidelines, and share contextually relevant, useful resources identified through AI to match users' expressed needs. Moderators also guide collaborative problem-solving and, in cases of crisis, promptly refer users to professional crisis services, ensuring comprehensive support.

Study Design and Participant Enrollment

During the study period, 40,431 total chat sessions were recorded between January 2023 and December 2024. This retrospective observational study analyzed 24,818 anonymous, live user chat sessions from 13,879 employees after excluding sessions with fewer than 3 messages. Data were securely stored in the Supportiv database. Users consisted of employees from 5 large companies that implemented Supportiv's digital peer-to-peer support service to complement their existing EAPs. The main objective was to evaluate the service's impact on employee well-being through sentiment outcomes derived from chat session transcript analysis. The primary outcomes were within-session sentiment changes across 8 key dimensions: loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism. Secondary descriptive outcomes included engagement metrics, use patterns, and resource-sharing outcomes. In addition to anonymous chat content, limited metadata, such as user location at the city level, derived from nonidentifying technical data, were available to support contextual analysis and geographic segmentation. No personally identifiable information or personal health information was collected.

Ethical Considerations

As this study used a large language model (LLM) to identify sentiment scores associated with user language in DPS live chats, several ethical considerations must be addressed [39]. Concerns related to privacy are mitigated by the use of

XSL•FO
RenderX

anonymous text data and the absence of user data collection. Additionally, sentiment scores were used to assess within-session emotional benefits rather than to make clinical diagnoses. All chats were facilitated by trained subclinical human moderators to support accurate sentiment interpretation and constructive DPS sessions. This retrospective study utilized operational data and did not involve direct human participant research. It was determined to be exempt from human participant research review by the Alpha Institutional Review Board (protocol IRBEMP042025).

Conversation Setting

Each participant was matched to a chat within approximately 30 seconds of responding in free text to a single prompt: "What's your struggle?" This response, referred to as the "user-chat-session struggle," determined whether the user was placed into a live, ongoing small-group chat discussion on the same topic or into a 1-on-1 session with a moderator, to which others with similar struggles could later be added. Each chat could include up to 5 users and a trained subclinical professional moderator.

Moderators facilitated discussions using motivational interviewing–based OARS (open-ended questions, affirmations, reflective listening, and summaries) techniques, including open-ended questions, affirmations, reflective statements, summarizations, and structured information sharing [40]. These strategies supported conversation flow, encouraged engagement, and promoted collaborative problem-solving. To maintain continuity, moderators provided a summary for new participants joining mid-session. Moderators played a key role not only in guiding discussions and fostering a psychologically safe environment but also in reviewing AI-recommended resources, such as practical articles and informational materials tailored to users' expressed needs, to ensure contextual sensitivity before sharing them with users.

Sentiment Analysis

Each user chat was analyzed independently, even if the same user participated in multiple sessions. These individual sessions were referred to as "user-chat sessions." Although some users returned for multiple sessions, the service's anonymous nature required that each chat experience be analyzed independently, without linking sessions to the same individual. This approach ensured that each interaction was assessed in isolation, providing a clearer and more user-focused analysis of sentiment changes per intervention.

To analyze the target sentiments (loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism), OpenAI's LLM model, GPT-4o-mini, was leveraged using a few-shot learning technique. This method involves presenting the model with a limited number of labeled examples within the prompt to guide its outputs [41]. Previous research has demonstrated that this approach matches or exceeds the performance of state-of-the-art models [8]. Despite agreement with expert human ratings established in previous work, the LLM-derived sentiment scores should not be regarded as psychometric instruments for clinical diagnoses. These scores are indicators of expressed emotional content rather than measures of clinical symptom severity.

A user session was defined by the initial "user-chat-session struggle," consisting of a brief free-text response of up to 300 characters, along with all subsequent messages exchanged during the chat. When a user joined a new chat session at a later time, they submitted a new struggle prompt, initiating a separate and independent session that was analyzed separately. Sentiment changes were tracked for each user within a session. Every message was assessed for sentiment intensity on a 1-10 scale, where a score of "1" indicated low intensity, "5" indicated moderate intensity, and "10" indicated high intensity for the relevant sentiment. This scale provided sufficient granularity to detect subtle variations while maintaining interpretability. The use of sentiment scoring with this model has been previously validated and reported in a prior study [8] (Multimedia Appendix 1), demonstrating strong agreement with expert human assessments. The model's performance is continuously monitored for false positives and false negatives, and flagged misclassifications are reviewed to iteratively fine-tune the model. Importance sampling is employed to prioritize messages with high uncertainty and those near the model's decision boundary. This strategy allows human experts to review and further refine the model's detection of language that may involve linguistic nuances, such as indirect, metaphorical, or sarcastic expressions.

Examples illustrating scores of 1, 5, and 10 are provided in Multimedia Appendix 1. Messages not suitable for sentiment analysis, such as clarifying or irrelevant statements, were excluded (eg, "Or a skill," "What do you mean," "At what time?"). To reduce misclassification, the model was instructed to refrain from assigning scores when insufficient information was available to infer sentiment content.

Due to the DPS service's voluntary live chat model, validated multiitem self-report instruments such as the 9-item Patient Health Questionnaire (PHQ-9), 7-item Generalized Anxiety Disorder (GAD-7), or 10-item Perceived Stress Scale (PSS-10) were not administered to users. Although ecological momentary assessments and visual analog scales can support in-the-moment measurement, they are typically used in structured research protocols and rely on repeated prompts and user incentives. By contrast, peer support environments prioritize user autonomy and natural conversational flow; therefore, repeated prompts may be disruptive. Additionally, many symptom instruments rely on self-report, which is prone to bias, social pressure, reduced introspection, distortion, and response fatigue. In this context, LLM-assigned sentiment scores were used as conversationally embedded measures rather than validated instruments. These scores were based on the language used by participants. Our previous study demonstrated that this approach is comparable to state-of-the-art models [8]. Additionally, rather than indicating diagnostic severity, sentiment scores were used to assess within-session changes. This is consistent with prior research using NLP to evaluate digital interventions at scale [42-44]. These scores were not intended to represent diagnostic severity; instead, they provide scalable indicators of expressed emotional content to assess within-session sentiment changes. Future validation work may assess how NLP-derived indicators

XSL•FO
RenderX

align with standardized measures (such as PHQ-9, GAD-7, and PSS-10).

Inclusion and Exclusion Criteria

To ensure a meaningful assessment of sentiment trends, specific criteria were applied when selecting chat sessions for analysis. Only conversations in which users engaged beyond a single message were included, as single-message interactions did not provide sufficient data to track sentiment changes over time.

For each user chat session, 8 emotions were screened to determine whether the session contained an interpretable sentiment change. To ensure the analysis focused on sessions with meaningful sentiment expression, a threshold score of 5 was established. For negative emotions (loneliness, sadness, stress, anxiety, depression, helplessness, or despair), sessions were included if the initial score was greater than 5, whereas for the positive emotion (optimism), a score below 5 was required. The initial emotional state was defined using the highest sentiment score from the user's first 3 messages, recognizing that individuals often begin conversations with brief or casual exchanges before revealing more meaningful emotional content and underlying struggles. This approach captured users who eventually expressed their emotional concerns while filtering out sessions lacking sufficient sentiment depth for analysis.

Sentiment Analysis Across All User Chat Conversations

To evaluate sentiment states over time across user chat sessions, the sentiment data were standardized to allow comparison despite variation in conversation duration. Each conversation was normalized to a relative scale (from 0 to 1) using bins of size 0.01. If a message with a sentiment score was present within a bin, the score was assigned to that bin. This normalization process allowed sentiment trends to be compared across conversations.

After aggregating the binned data for each sentiment, a linear trend line was fitted. The slope of this line indicated the direction and magnitude of sentiment change, reflecting the service's effectiveness in supporting well-being. The goodness of fit was evaluated using the coefficient of determination (R^2). Finally, CIs were calculated to represent the standard error of the data, indicating variability around the mean for each conversation duration bin.

Propensity Matching

Propensity matching was used to create comparable cohorts for each research question. Users within the cohorts were matched by training a logistic regression classifier using the following features: user-chat-session topic, device type, user country, number of users in the chat, conversation duration, engagement rate (number of characters typed by the user per unit of conversation time), and initial sentiment score. This matching ensured a high level of alignment between users in the 2 cohorts at the start of the chat by incorporating both demographic and behavioral metrics.

To ensure meaningful matching, conversation duration and engagement rate were transformed into categorical bins using predefined ranges. For conversation duration, conversations in each cohort were divided into the following bins based on length (in minutes): "0-5," "5-10," "10-20," "20-45," "45-60," and ">60." Similarly, for engagement rate (measured as the number of characters typed by the primary user per unit of time), bins were created to categorize conversations based on characters typed per unit time: "0-10," "10-20," "20-30," "30-40," "40-50," and ">50."

The logistic regression model produced a propensity score for each user chat session, representing the likelihood of assignment to one cohort. We used 25% of the SD of all propensity scores as the caliper (radius of search) for matching. For each user chat in 1 cohort, the closest match in the other cohort was identified using a k-nearest neighbor classifier within the caliper. Propensity matching was conducted separately for each trend analyzed.

The topics for user chat struggles were categorized into the following themes (alphabetically): anxiety, caregiving/parenting, depression, financial/social determinants of health, identity, loneliness, mental health conditions, physical health/medical, relationship issues, social connection and belonging, stress, suicide/self-harm, trauma, and work/productivity/burnout. These categories were identified through manual inspection of chats to determine common themes across the population.

Analyzing Employee User Experiences

To gain a comprehensive understanding of employee users and characterize their engagement with the service, several key components were analyzed. First, although the service is anonymous, users may voluntarily provide demographic information and optional feedback at the end of a chat session. Analysis of these data offers valuable insights into the study population.

The primary target group consisted of employees from 5 large employers across varied industry sectors, including retail, media, and health care. As these organizations differed in job roles and workforce structure, engagement patterns were analyzed across heterogeneous contexts, enhancing ecological validity and reducing bias. User engagement patterns were examined throughout the day to determine whether usage varied between business and nonbusiness hours. For this analysis, business hours were defined as Monday through Friday from 8:00 AM to 5:00 PM local time, while all other periods, including evenings, nights, and weekends, were categorized as nonbusiness hours.

A core advantage of the Supportiv service is its ability to deliver highly personalized resources tailored to users' stated struggles and needs. Supportiv enables moderators to share coping tools, self-help materials, and other resources, as well as links to relevant employee benefits or community resources, specifically tailored to a user's needs based on context. These resources include various formats such as articles, videos, audio files, tools, worksheets, exercises, community resources, and client-specific materials. Resource sharing is driven by a 2-stage AI recommendation system. The AI model retrieves relevant items that match users' expressed needs from a resource library and then ranks the retrieved items to ensure that the most

XSL•FO
RenderX

appropriate and valuable options are prioritized. Moderators review and select from this AI-curated list before sharing resources with users. The analysis examined the types of resources recommended by AI and shared by moderators, as well as how users interacted with them.

Lastly, although all target users were employees utilizing Supportiv through sponsored links (via their EAPs, employee benefits portals, or other employer-specific URLs), moderators may refer employees to additional relevant EAP services based on their expressed needs. These EAP-related metrics were analyzed to better understand how employees used integrated support services and how DPS functioned within the organizational benefits system.

Sentiment Trends

Variables Analyzed

Two primary variables were independently analyzed for their influence on user sentiment trends: (1) time of engagement and (2) in-session resource sharing.

Time of Engagement

We hypothesized that users engaging with the service outside business hours would exhibit different sentiment outcomes compared to those using it during business hours. To evaluate this, chat sessions initiated during business hours were compared with those started outside business hours, with the user's time zone used to convert the system's default time to local time for cohort classification.

Resource Sharing

We also hypothesized that receiving a shared resource would promote positive sentiment trends, regardless of the type of resource or the extent of user interaction with it.

For both variables, sentiment evolution throughout each chat session was analyzed, and propensity matching was employed to create 2 comparable cohorts for each target variable. This matching procedure ensured a fair comparison between groups to effectively assess how the effects of time of engagement and in-session resource sharing shape sentiment outcomes.

Statistical Analysis

Statistical analyses were conducted to (1) compare differences between groups for specific features, (2) evaluate the significance of predicted sentiment trends, and (3) compare sentiment improvement metrics (slopes) between target cohorts. Statistical significance was defined as $P<.05$, and all tests were 2-tailed. Independent contractors were engaged to develop the analysis plan and conduct statistical analyses to minimize commercial bias. Effect sizes for pairwise comparisons were computed using Cohen *d*.

All analyses were performed using Python 3.9.6 (Python Foundation) with the following libraries: pandas 2.3.3, NumPy 2.0.2, SciPy 1.13.1, scikit-learn 1.6.1, statsmodels 0.14.6, matplotlib 3.9.4, and seaborn 0.13.2.

Topic Modeling

We utilized a topic-modeling framework based on LLM-driven categorization to assign topics and subtopics to text data. After reviewing the conversations, a list of topics was manually defined. All texts were then processed using GPT-4o-mini with a structured prompt to categorize them into the predefined categories. Classification accuracy was manually verified, and, when necessary, categories were corrected manually.

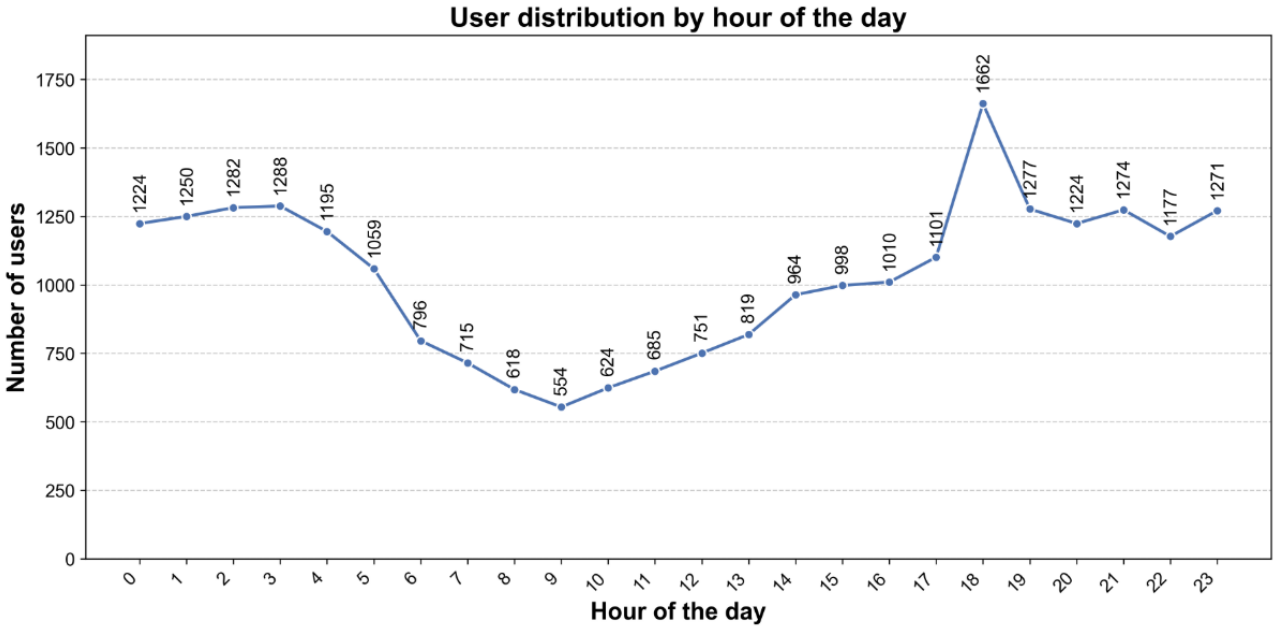
Results

Chat Statistics

A total of 40,431 chat sessions were recorded during the study period. Sessions containing only 1 or 2 messages were excluded, as they lacked sufficient context to evaluate sentiment trends or changes over time. After applying these criteria, 24,818 chat sessions from 13,879 employees with at least three messages were included in the analysis.

User Reported Struggle Topics

Users often reported more than 1 concern during their chat sessions. The most common struggles were relationship issues (7531/24,818, 30.34%), trauma (2663/24,818, 10.73%), workplace concerns (2650/24,818, 10.68%), stress (2074/24,818, 8.36%), loneliness (1757/24,818, 7.08%), depression (1570/24,818, 6.33%), and financial/social determinants of health (1565/24,818, 6.31%). Additional struggles included support system challenges (1160/24,818, 4.67%), anxiety (1098/24,818, 4.42%), mental health conditions (723/24,818, 2.91%), identity concerns (638/24,818, 2.57%), caregiving/parenting (617/24,818, 2.49%), physical health/medical concerns (399/24,818, 1.61%), and suicide/self-harm (373/24,818, 1.50%).



User Activity

On average, users spent 37.97 (SD 35.51) minutes in peer group chats. The average number of messages sent by the primary user was 24.42 (SD 29.45). Variation in chat duration, as reflected by time spent and number of messages, indicates that the analysis includes both users who engaged in extended conversations and those who participated for shorter periods but met the minimum inclusion criteria. To better capture user participation intensity, a metric termed "characters per chat duration" was calculated, with an average of 70.65 (SD 1394.24) characters per minute. The high SD in this metric may be attributed to differences in users' communication styles. While some users type long, paragraph-style messages, others send multiple short messages consisting of only a few words at a time.

Figure 1 illustrates the number of users throughout the day. User activity decreases during late-night hours, increases steadily as business hours begin, and peaks toward the end of the day before declining at night. Notably, user engagement was higher outside business hours, suggesting that employees may be more likely to use DPS during their personal time, when they are away from job responsibilities and have more space to share their thoughts and concerns without distraction.

XSL•FO
RenderX

Figure 1. Distribution of conversation start times based on local time over a 24-hour period. The graph shows the frequency of user chat sessions throughout the day.

Study Population

Demographics

Employees from all global regions accessed the DPS service, with the majority of conversations (16,720/20,976, 79.71%, chats with reported location information) located in the United States. Most users accessed the service via mobile devices (19,854/24,817, 80%), followed by desktop (4467/24,817, 18%) and tablets (496/24,817, 2%). Although the service is anonymous, users have the option to voluntarily share demographic information, including age, race, and gender. Out of 24,818 anonymous chat conversations, 8647 (34.84%) users disclosed demographic information, which is a relatively high response rate compared with similar digital mental health services [45]. While demographic data were not available for all users, the information that was voluntarily provided offered valuable insights and was incorporated into the propensity matching algorithm to enhance comparative sentiment analyses among similar users.

Table 1 presents the distribution of user ages, grouped into 3-year increments. Overall, the median age of the users is 36 years, with a mean of ~45 years, indicating that DPS attracts a broad adult population. Individuals aged 37-57 generally access psychological services less frequently [46]. However, the accessibility and anonymity of Supportiv's DPS model may make it a more viable option for this group by offering an easier point of entry to mental health support.

In conversations with users who disclosed their gender, 5738 (66.36%) identified as female, 2538 (29.35%) as male, and 371 (4.29%) as nonbinary. This distribution aligns with the literature showing that, despite using digital services more frequently [47], men are significantly less likely to seek mental health support than women [48]. The use of DPS by nonbinary users may reflect its inclusive and anonymous design, which can reduce barriers often encountered in traditional clinical settings. This inclusivity highlights the potential for DPS services to foster psychological safety.

In terms of race and ethnicity among conversations with those who provided their ethnicity/race demographic information (n=8914), 4759 (53.39%) identified as White, followed by African American (n=1469, 16.48%), Hispanic (n=1290, 14.47%), and Asian (n=810, 9.09%) users, with the remainder reporting other minority groups (n=309, 3.47%, American Indian or Alaska Native; n=171, 1.92%, Native Hawaiian or Other Pacific Islander; and n=106, 1.19%, Middle Eastern or North African). This diversity suggests that DPS services are effective in reaching historically underrepresented groups. Anonymous access and culturally neutral peer interaction may help reduce barriers to accessing support services.

Table 1. Distribution of users by age.[a]

User age (years)	Count, n
13-15	239
16-18	954
19-21	833
22-24	691
25-27	616
28-30	630
31-33	582
34-36	640
37-39	275
40-42	484
43-45	238
46-48	266
49-51	466
52-54	194
55-57	367
58-60	169
61-63	172
64-66	106
67-69	149
70-72	91
73-75	85
76-78	139

[a]Demographic data were obtained from users who voluntarily disclosed age information (8386/24,818, 33.79%).

EAP Inflows and Outflows

Tables 2 and 3 provide perspectives on the relationship between DPS and EAP utilization, reflecting users referred to DPS through their EAP programs (inflow) and those referred to EAP programs after using DPS (outflow). These sessions were initiated by employees with varying job roles from 5 large employers representing multiple industries, including retail, media, and health care. Table 2 (EAP inflows) presents the distribution of users who accessed the service through their organization's EAP, categorized by struggle topic. This table shows how employees are reaching DPS and aims to identify the most common concerns prompting employees with existing EAP benefits to use DPS services. Of 24,818 total user chat sessions, 5482 (22.09%) were initiated through users' EAP programs. Table 3 (EAP outflows) illustrates the distribution of users who were referred to their organization's EAP services through DPS sessions, also categorized by struggle topic. This reflects continuity of care from DPS chat sessions—based on moderator assessment or users expressing need—to additional employer-provided services. Of 24,818 user chat sessions, 2720 (10.96%) were referred to EAP services after DPS sessions.

Notably, the proportions of inflow and outflow vary across topics, suggesting that certain concerns may be more likely to drive employees to seek support through DPS, while others necessitate referrals to EAP resources. These insights can help refine targeted support strategies across both DPS and EAP services, ensuring that users receive effective care that bridges gaps in traditional care. For example, topics such as relationship issues, loneliness, stress, and trauma are among the most common concerns and may show higher referral rates, indicating opportunities to strengthen collaboration between DPS and EAPs for these specific issues.

Shared Resources

A key feature of the Supportiv service is its ability to share contextually relevant, tailored resources with users seeking emotional support, enhancing the user experience and the effectiveness of the DPS service on sentiment outcomes. In total, 33,632 resources were shared across 24,818 chat sessions, averaging 1.36 resources per session, indicating that at least one relevant resource was shared per session. Among these resources, 16,157 were articles, 8813 were videos, 5269 were employer-specific benefits, 2581 were worksheets, 810 were inspirational quotes, and 2 were audio files. Table 4 shows the distribution of resource types across various struggle topics, with an average of 2402 resources shared per topic.

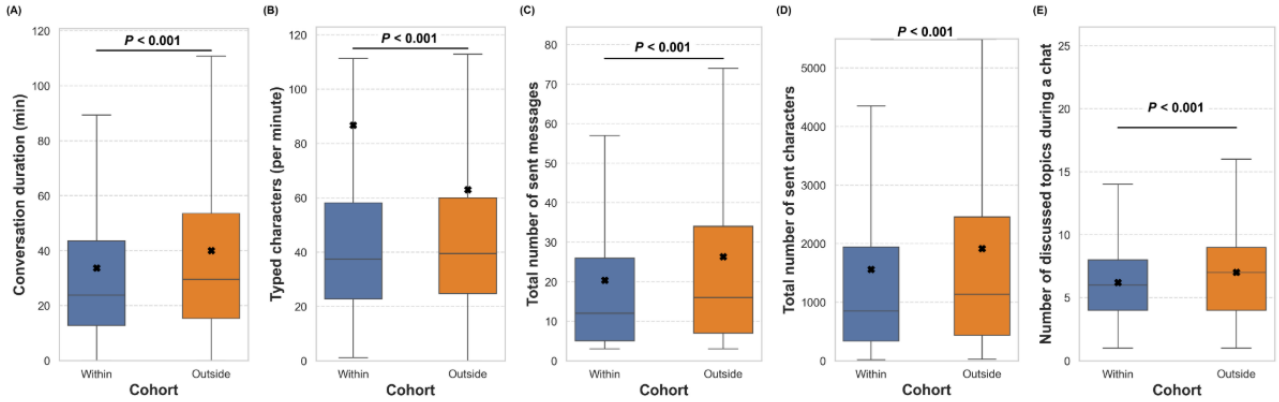
User Struggles

The 5 most common struggle topics expressed by users during business hours (total chats n=7995) were relationship issues (n=2249, 28.13%), workplace concerns (n=1029, 12.87%), financial or Social Determinants of Health (n=744, 9.31%), trauma (n=734, 9.18%), and stress (n=732, 9.16%). By contrast, outside business hours (total chats n=16,823), users most frequently reported relationship issues (n=5282, 31.40%), trauma (n=1929, 11.47%), workplace concerns (n=1621, 9.64%), stress (n=1342, 7.98%), and loneliness (n=1313, 7.80%). These patterns suggest that, while some concerns are consistently reported throughout the day, workplace and financial concerns are more prevalent during business hours, when work-related stressors affect users. Outside business hours, loneliness and trauma are more commonly reported, indicating that users are more open to engaging in personal discussions during nonworking hours.

User Activity

Several user activity metrics were analyzed for the 2 cohorts in the business-hour study. These included conversation duration (time from chat initiation to exit), typing activity (number of typed characters per minute as an indicator of engagement), total messages and characters sent, and the number of topics discussed during the chat.

As shown in Figure 2A, a significant difference (P<.001) was observed in conversation duration between user chat sessions. The mean conversation duration was 33.63 (SD 32.72) minutes for the “within-business-hours” cohort and 40.03 (SD 36.59) minutes for the “outside-business-hours” cohort, indicating that users in the “outside-business-hours” group stayed on the service 19% longer than those in the “within-business-hours” group.



User participation, measured by typing activity, also differed significantly between groups (P<.001; Figure 2B). During business hours, users typed an average of 86.75 (SD 2316.61) characters per minute, compared with 63.00 (SD 563.27) characters per minute outside business hours. This suggests that users during business hours typed 38% faster.

Another key engagement metric is the number of messages and characters sent. Users in the “within-business-hours” group sent an average of 20.36 (SD 25.55) messages and 1559.61 (SD 2084.01) characters, whereas those in the “outside-business-hours” group sent 26.35 (SD 30.95) messages and 1917.05 (SD 2406.78) characters, representing increases of 29% and 23%, respectively. These differences were significant between the 2 groups (both P<.001; Figures 2C and 2D).

Users discussed an average of 6.21 (SD 3.28) topics in chat sessions during business hours, compared with 7.01 (SD 3.53) topics outside business hours, representing a 13% increase outside business hours (P<.001; Figure 2E). Taken together, these findings indicate differences in user engagement patterns between the 2 cohorts. Users who used DPS outside business hours remained in chats longer, exchanged more messages, and covered more topics, suggesting that they were more likely to engage at a deeper and more personal level when work-related stressors, distractions, or time constraints were not present.

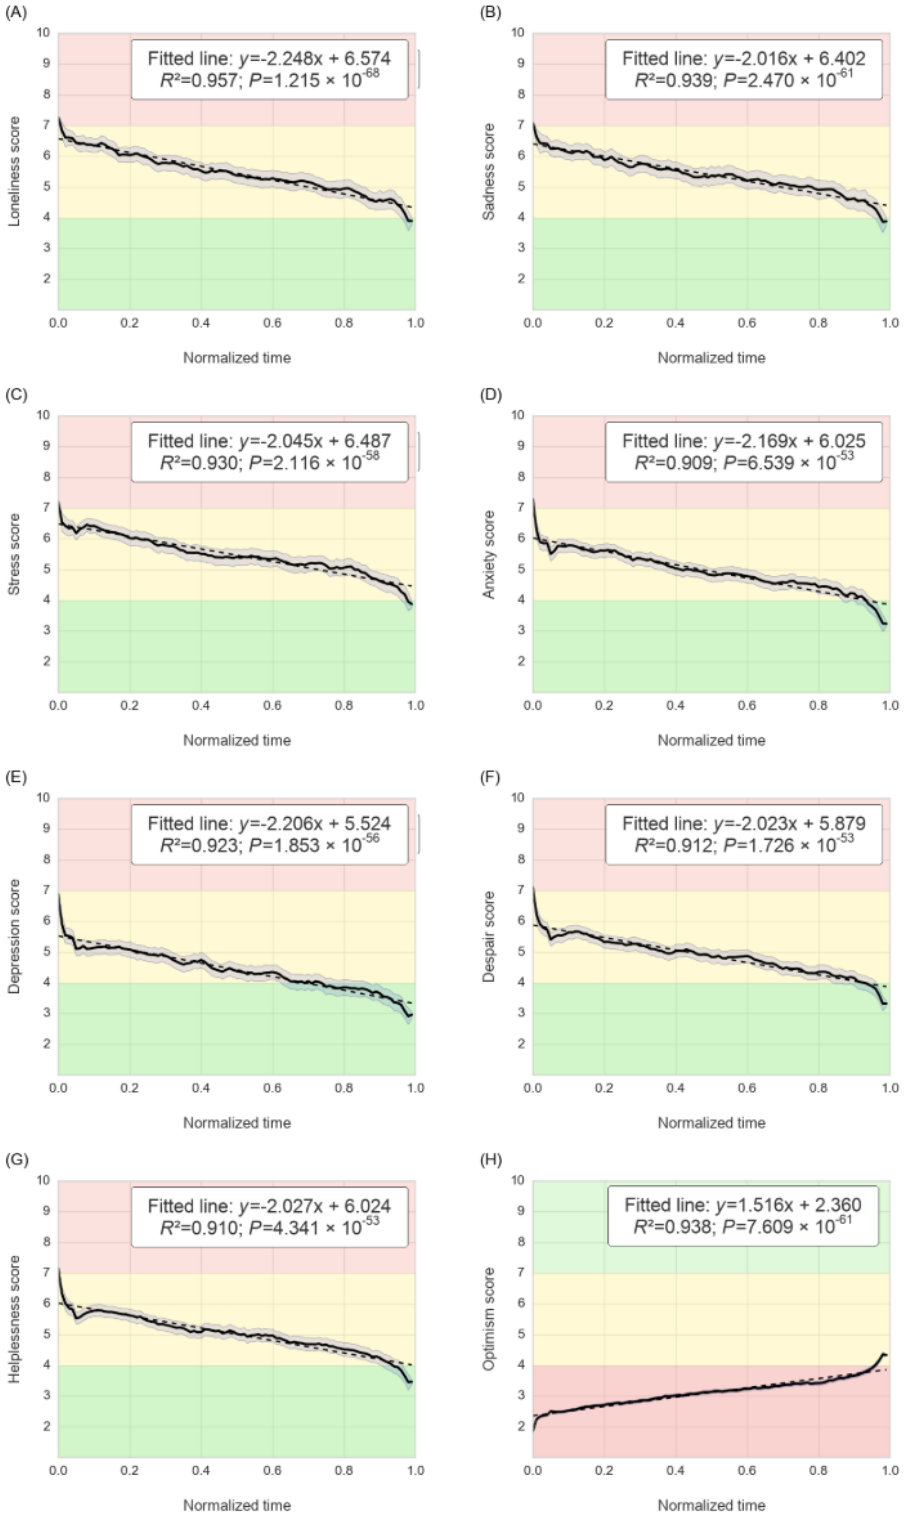
XSL•FO
RenderX

Figure 2. User activity in the "within" versus the "Outside" business hours groups are separated based on (A) conversation duration, (B) characters sent per minute, (C) number of sent messages, (D) number of sent characters, and (E) number of discussed topics, by the user. The value denoted by "x" is the mean.

Sentiment Outcomes and Trends

Within-Session Sentiment Trajectories Across DPS Engagement

Changes in users' sentiment outcomes for loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism were analyzed from the beginning to the end of each moderated, peer-to-peer live chat session to assess whether engaging with DPS was associated with improved sentiment scores. These trends provide an overview of the service's general sentiment support and serve as a reference point for interpreting more targeted results in subsequent sections.



As shown in Figure 3, the 8 time-series graphs illustrate how users' sentiment states evolved throughout the course of the live chat sessions. Each graph displays one of the key dimensions (loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism) with a fitted linear regression line, where the x-axis represents normalized session time and the y-axis represents the respective sentiment scores on a 10-point scale. These plots capture trends across all users, offering a holistic picture of Supportiv's influence on sentiment change, independent of contextual factors such as session timing or receipt of a resource.

The results reveal consistently improved sentiment states across all 8 dimensions. Notably, all negative sentiments (loneliness, sadness, stress, anxiety, depression, despair, and helplessness) declined steadily over the course of a session, while the positive sentiment of optimism increased. The negative sentiments showed strong, pronounced downward trends. As not all conversations included all sentiments, the number of conversations per sentiment analysis differed. The greatest changes were observed in loneliness, which was reduced by 46% (n=11,492; R^2=0.957; P<.001; Figure 3A); sadness, by 45% (n=10,741; R^2=0.939; P<.001; Figure 3B); and stress, by 46% (n=13,928; R^2=0.93; P<.001; Figure 3C). These were followed by anxiety, which was reduced by about 39% (n=9654; R^2=0.909; P<.001; Figure 3D); depression, by about 40% (n=5585; R^2=0.923; P<.001; Figure 3E); despair, by about 40% (n=6197; R^2=0.912; P<.001; Figure 3F); and helplessness, by about 38% (n=7742; R^2=0.910; P<.001; Figure 3G), highlighting the consistency of sentiment relief across users. The downward trends in negative sentiment scores suggest that users' expressed emotional language became less indicative of negative affect over DPS chats. By contrast, optimism increased by about 77% (Figure 3H). This sustained upward trend (n=23,491; R^2=0.938; P<.001) suggests that users not only experienced relief from distress during DPS conversations but also left sessions feeling more hopeful and supported. Notably, these changes occurred smoothly over time, with minimal noise or volatility, as shown by the narrow CIs in most graphs.

Taken together, these findings indicate that DPS use was consistently associated with improvements in within-session sentiment scores. The strength and stability of the observed trends confirm improved sentiments following DPS use. Overall, users began sessions with high-intensity negative affect and concluded within the neutral-to-positive range by the end of the sessions, illustrating that engagement with DPS is associated with favorable shifts in sentiment scores.

XSL•FO
RenderX

Figure 3. Sentiment outcomes trends throughout live chat peer-to-peer conversation progression. Sentiment changes were observed as conversations progressed. The solid black line shows the emotion score across the conversation, the dashed line represents the fitted line, and the shaded area represents the SEM. The fitted line information is provided in the box, which includes the slope (how fast the emotion is reduced per normalized conversation time), the intercept (the approximate initial emotion score), and the goodness of fit. (A–G) The green area (1-4) represents "low" levels of emotion, yellow (4-7) signifies "moderate" levels, and red (7-10) indicates "high" momentary emotion. (H) The red area represents low optimism (1-4), the yellow area represents neutral optimism (4-7), and the green area represents positive optimism (7-10).

Business Hour Effect

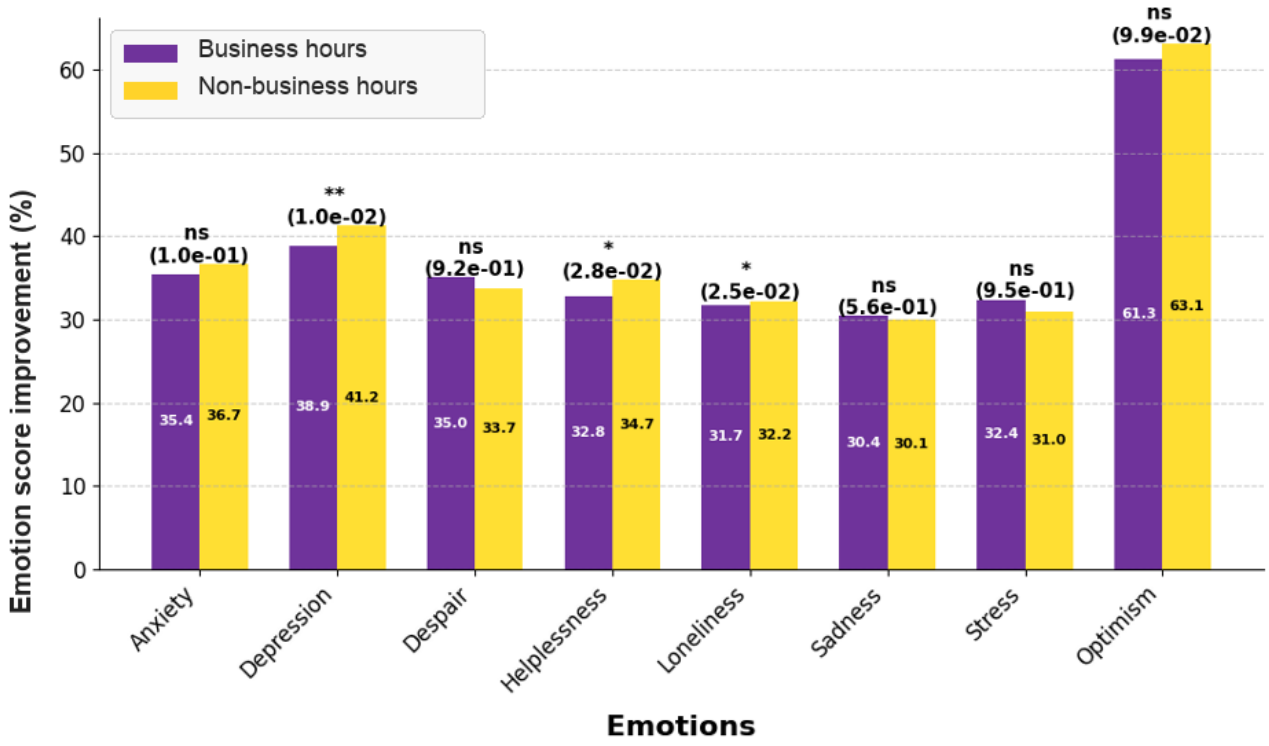
Consistent with previous research [7], user engagement revealed that nearly two-thirds of sessions occurred outside business hours, with 16,823 chats outside business hours and 7995 during local business hours (Figure 1). Table 5 presents the initial baseline sentiment states of users who accessed the service during business hours compared with those who did so outside business hours. Baseline scores were similar for most sentiments, although a few showed differences. Users who

XSL•FO
RenderX

accessed the DPS service during business hours reported slightly higher stress levels (P<.001), suggesting that work-related stressors may contribute to increased distress during business hours. Conversely, users who accessed DPS after business hours reported higher levels of loneliness (P=7.63 × 10^{-3}), possibly due to increased isolation during evening and nighttime hours. No significant differences were found in anxiety (P=.54), despair (P=.23), helplessness (P=.58), sadness (P=.26), or optimism (P=.15) scores. These results suggest that employees may seek support with different baseline sentiment states depending on the time of engagement.

Figure 4 compares sentiment score improvements between users who initiated chat sessions during local business hours (within) and those who did so outside business hours (outside) across 8 sentiment domains: anxiety, depression, despair, helplessness, loneliness, sadness, stress, and optimism. Users who utilized DPS outside business hours showed significantly greater reductions in depression (41.2% vs 38.9%; P=1.0 × 10^{-2}; d=0.0197), helplessness (34.7% vs 32.8%; P=2.8 × 10^{-2}; d=0.0058), and loneliness (32.2% vs 31.7%; P=2.5 × 10^{-2}; d=0.0166), suggesting that support outside work hours was associated with greater changes in sentiment scores, although the effect sizes were small. No statistically significant differences were observed for anxiety (P=.10), despair (P=.92), sadness (P=.45), stress (P=.62), or optimism (P=.10), and changes in sentiment scores were similar for users during and after business hours. These results also suggest that engagement during business hours may serve as an important source of immediate support and validation for employees, allowing them to process their thoughts and feelings while helping sustain concentration during the workday.

Table 5. Comparison of baseline sentiment scores between business hours and nonbusiness hours users.



Factor	Anxiety	Depression	Despair	Helplessness	Loneliness	Sadness	Stress	Optimism
Within business hours, mean (SD)	6.24 (2.40)	5.17 (2.29)	5.82 (2.31)	6.17 (2.33)	6.66 (1.99)	6.62 (1.82)	6.96 (1.85)	3.12 (1.64)
Outside business hours, mean (SD)	6.25 (2.29)	5.26 (2.16)	5.88 (2.19)	6.17 (2.27)	6.74 (2.00)	6.58 (1.83)	6.85 (1.86)	3.10 (1.65)
P value	.54[a]	.04[b]	.23[a]	.58[a]	7.63 × 10^{-3}[c]	.28[a]	<.001	.15[a]

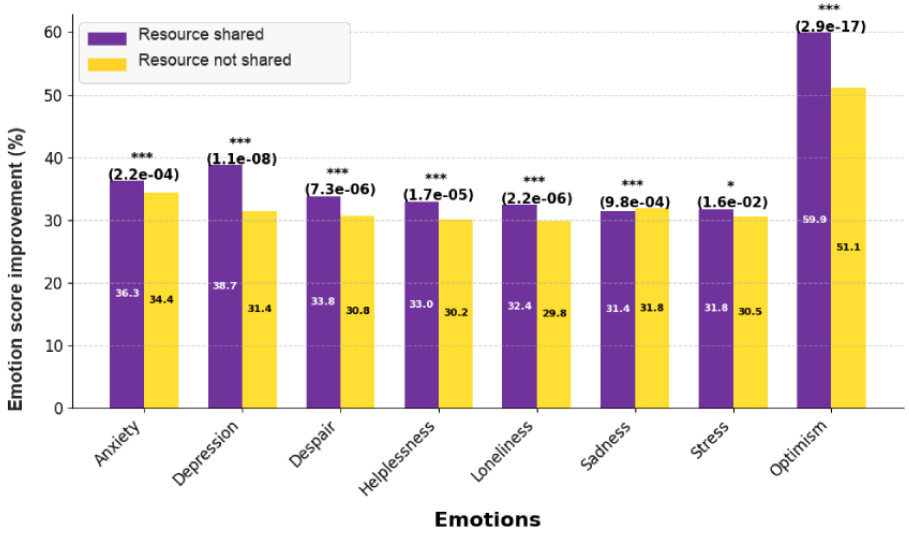
[c]P<.01.

Figure 4. Emotion score improvements by time-of-service use: users engaged during business hours experienced greater reductions in depression, helplessness, and loneliness. No significant differences were found for anxiety, despair, sadness, stress, or optimism. The improvement percentages were calculated based on the slope of the fitted trend line. P values are indicated in brackets. *P<.05. **P<.01.



XSL•FO
RenderX

Resource Sharing Effect

Figure 5 compares sentiment score improvements between users who received at least one resource during their chat session (with) and those who did not (without) across 8 dimensions: anxiety, depression, despair, helplessness, loneliness, sadness, stress, and optimism. Users who received a resource showed significantly greater changes in almost all sentiment states: anxiety (36.3% vs 34.4%; P<.001; d=−0.0003), depression (38.7% vs 31.4%; P<.001; d=−0.0830), despair (33.8% vs 30.8%; P<.001; d=−0.0468), helplessness (33.0% vs 30.2%; P<.001; d=−0.0752), loneliness (32.7% vs 29.8%; P<.001; d=−0.0789), stress (31.8% vs 30.5%; $P=1.6\times10^{-2}$; d=−0.0342), and optimism (59.9% vs 51.1%; P<.001; d=−0.0145). Interestingly, users who did not receive a resource showed a slightly greater reduction in sadness (31.8% vs 31.4%; P<.001; d=−0.0287), although the difference was negligible. Overall, these findings highlight an association between resource sharing and improved sentiment scores, particularly in alleviating negative sentiment states and enhancing optimism. Therefore, resource provision serves as a supportive tool when incorporated into DPS services.

Figure 5. Comparison of emotion score improvements between users who received at least one resource and those who did not. Resource sharing was associated with significantly greater reductions in anxiety, depression, despair, helplessness, loneliness, and stress, and gains in optimism, while sadness slightly favored the nonreceiving group. The improvement percentages were calculated based on the slope of the fitted trend line. *P* values are indicated in brackets. *P<.05; ***P<.001.

Discussion

Principal Findings

This study offers novel insights into the role of timing, in-chat behaviors, and structural barriers in shaping user engagement and sentiment outcomes in a DPS service offered as a stand-alone service or integrated into EAPs. The findings advance understanding of when and how employees use DPS services, how these interactions guide sentiment trajectories, and which factors affect access to mental health support.

Barriers to EAP Utilization

Despite the potential of DPS to fill critical gaps in care, broader EAP engagement remains limited due to persistent systemic barriers. The most pressing among these is a widespread lack of awareness about the scope and availability of EAP services, leading to underutilization even in organizations with robust offerings [49]. Research shows that, without sustained promotional efforts, EAP usage rates remain below 10%, while programs with active education and engagement campaigns have reported utilization rates closer to 30% [50,51]. Additionally, internalized stigma may deter individuals from seeking help [52]. Employees may interpret help-seeking as a signal of personal failure or professional inadequacy, especially in high-performance cultures. National surveys indicate declining employee comfort with employer-sponsored mental health services, with only 52% of employees reporting comfort accessing EAP resources in 2022, down from 64% in 2021 and 67% in 2020 [53]. Addressing these gaps requires shifts at the organizational level, including visible leadership endorsement of mental health resources, normalization of mental health care, and integration of DPS into wellness initiatives. These strategies can help develop EAPs from crisis tools into preventive support systems and increase their perceived legitimacy [54].

Sociobehavioral Factors Influencing Use

Beyond timing, additional sociobehavioral factors also influenced engagement with DPS. Although many users identified as female and reported White ethnicity, as expected for mental health services [55], DPS attracted a larger proportion of male and Black, Indigenous, and People of Color users than is typically observed in such services. The age distribution also reflected a broad user base, with a median age of 36 years and a mean of approximately 45 years. The accessibility and anonymity of DPS may offer a solution for adults who are underserved by traditional mental health care. These patterns highlight the broader demographic reach of DPS compared with typical services. The flexible, anonymous nature of DPS mitigates certain barriers associated with traditional mental health care, such as time constraints, privacy concerns, and stigma. Users were more likely to engage outside work hours,

XSL•FO
RenderX

likely due to an increased sense of psychological safety for vulnerable self-disclosure when outside of work environments. This pattern supports theories of readiness to disclose, which suggest that individuals are more likely to seek help in environments they perceive as emotionally and socially safe [56,57]. Therefore, timing is not only an operational variable but also a sociobehavioral signal of trust, readiness, and psychological safety. Designing digital services that accommodate different levels of readiness would better enable users to engage based on their comfort and needs.

Discussion Topics

The most commonly discussed topic, by a clear margin, was relationship issues, which appeared in nearly one-third of all live chat sessions. However, differences in topic prevalence emerged when inflows from and outflows to EAP sources were examined. Most frequently, users accessed DPS services through their EAP (inflows) to discuss anxiety, loneliness, physical or mental health, and suicide or self-harm (Table 2). By contrast, users who sought DPS services and were subsequently referred to their EAP programs (outflows) most frequently discussed anxiety, depression, and caregiving or parenting (Table 3). Resource distribution across discussion topics showed that sessions centered on relationship issues received the greatest number of resources, reflecting the high volume of conversations on this topic (Table 4). Trauma, workplace concerns, and stress followed, aligning with their discussion frequency.

Sentiment Outcomes

Significant improvements in sentiment scores were observed across all investigated sentiment states. The trajectories for loneliness, sadness, stress, anxiety, depression, despair, helplessness, and optimism revealed consistent and statistically significant improvements across all 8 dimensions (Figure 3). Notably, optimism showed the most pronounced change (n=23,491, ~77%; R^2=0.938; P<.001), indicating that DPS use was associated with increased feelings of hopefulness and support. The greatest reductions in negative sentiment states were observed in loneliness (n=11,492, 46%; P<.001), stress (n=13,928, 46%; P<.001), and sadness (n=10,741, 45%; P<.001), suggesting that DPS use was associated with nearly halving users' initial distress.

Impact of Timing of Use

Consistent with previous research [7], user engagement revealed that nearly two-thirds of sessions occurred outside business hours. This high level of engagement after hours may reflect limited access to traditional in-person or typical tele-mental health support, as well as employees' greater openness to sharing personal struggles during periods of privacy or reduced work-related stressors.

Users discussed different topics during business hours compared with outside work hours. During business hours, the most common topics were relationship issues, workplace concerns, financial or social determinants of health, trauma, and stress, whereas outside work hours, relationship issues were discussed most frequently, followed by trauma, workplace concerns, stress, and loneliness. Although concerns such as relationship issues were prevalent throughout the day, these differences suggest that users tend to focus more on workplace concerns and social determinants of health during the business day, while outside work hours they are more likely to explore more personal issues such as trauma, stress, and loneliness.

Differences in user activity based on time of use also emerged. Users were more likely to engage for longer periods (Figure 2A), send a higher number of messages and typed characters (Figures 3C and 3D), and discuss more topics (Figure 2E) outside business hours. By contrast, users typed faster during work hours (Figure 2B), suggesting that time constraints related to work responsibilities may limit engagement. Overall, users were able to participate in deeper conversations outside work hours, indicating the need for services that are accessible beyond the typical 9-to-5 window.

Baseline sentiment states differed by time of engagement between the 2 cohorts (Table 5). Users who engaged during business hours reported significantly higher baseline stress, potentially due to situational demands (eg, work or other daytime stressors) [58,59]. By contrast, users who accessed DPS after business hours reported higher baseline levels of depression and loneliness, aligning with research suggesting increased social isolation during evening and nighttime hours, when there are fewer opportunities for social interaction [60,61]. Meanwhile, other sentiment outcomes did not differ by time of day, suggesting that they may be more stable and less influenced by situational factors [62].

These findings suggest 2 distinct sentiment profiles: engagement during business hours is characterized by acute, reactive distress, whereas after-hours engagement reflects more chronic vulnerability. Improvements in sentiment states support these profiles. Depression, helplessness, and loneliness were reduced at higher rates with DPS use outside work hours, suggesting deeper personal engagement (Figure 4). Comparable reductions in anxiety, despair, sadness, stress, and optimism across the 2 groups indicate that these dimensions may be less affected by timing [58-61]. Furthermore, DPS supported psychological relief independent of timing, reinforcing the need for around-the-clock accessibility.

Impact of In-Session Resource Sharing

Another significant factor influencing sentiment improvements was resource sharing within DPS sessions. Sessions that included at least one resource, such as coping strategies or other psychoeducational materials, were associated with greater positive sentiment changes in anxiety, depression, despair, helplessness, loneliness, stress, and optimism (Figure 5). This finding aligns with the peer support literature, which emphasizes the therapeutic value of shared knowledge and validation of distress [63]. Peer support has been described as "a system of giving and receiving help founded on key principles of respect, shared responsibility, and an agreement of what is helpful" [64]. In digital formats, where users may initially feel disconnected or skeptical, resource sharing may help deepen engagement, enhance perceived value, and reinforce feelings of self-efficacy.

Interestingly, users who did not receive a resource showed slightly greater improvements in sadness, although this difference was minimal. This pattern may suggest that

XSL•FO
RenderX

individuals with higher sadness were less likely to seek additional support materials, or that focusing on problem-solving interventions may temporarily heighten awareness of one's struggles. These nuances highlight the importance of tailoring support strategies to individuals, suggesting that resource sharing may be most impactful for those navigating more acute sentiment states, while others may benefit more from affirmation and increased social connection.

Limitations and Future Research

While the study provides valuable insights, several limitations should be noted. The observational design prevents causal inference regarding the relationship between session characteristics and sentiment outcomes. An important limitation is that the primary outcome—sentiment change—was based on LLM-derived sentiment scores rather than clinical psychometric instruments. Although prior work and post hoc analyses have shown alignment between LLM-derived sentiment scores and expert human ratings, this study did not examine the psychometric properties of the sentiment scoring approach used. Given the large dataset, human annotation and validation were not conducted. However, post hoc analyses on a subgroup of conversational transcripts confirmed alignment between the model and expert human interpretation. Therefore, the reported sentiment score changes are not diagnostic or absolute measures of emotional change, but rather model-estimated shifts in sentiment within DPS sessions. Despite their relevance in understanding how DPS may support users and potentially encourage engagement with additional clinical care, these results should not be interpreted as indicators of absolute sentiment severity and are not equivalent to self-reported or clinician-scored outcomes. They do not reflect psychiatric symptom severity.

Additionally, limited demographic data restrict analyses of how variables such as age, gender, cultural background, or job role may shape engagement patterns or session efficacy. Although more than half of the users who reported demographic information identified as female and White—a pattern common across digital mental health platforms—DPS attracted a higher proportion of male and Black, Indigenous, and People of Color users than is typically observed. However, the limited demographic data prevented detailed subgroup analyses of sentiment outcomes. Future research should adopt randomized controlled trials or mixed methods designs to identify causal mechanisms underlying DPS effectiveness, while also prioritizing more comprehensive demographic reporting to better capture the service's impact across diverse populations.

Demographic variables were analyzed for only 8647 out of 24,818 (34.84%) conversations with users who voluntarily disclosed their information. The optional disclosure of personal information introduced selection bias, limiting generalizability to a broader population. A large proportion of individuals may have preferred to withhold information due to privacy, stigma, or other vulnerability-related concerns, and individuals from certain demographic backgrounds may be more likely to face stigma or distrust the health care system, potentially skewing the findings. Therefore, these results may not fully represent the demographic distribution of the broader population; however, they provide valuable insight into user characteristics. The analyzed subset remains sizable and informative regarding the distribution of users in real-world digital mental health settings.

Longitudinal tracking could also reveal whether sentiment improvements persist over time and whether early engagement predicts long-term EAP utilization or mental health outcomes. Moreover, segmenting user data by demographic and occupational variables could clarify subgroup differences, such as among shift workers, caregivers, parents, or underrepresented racial and ethnic groups. Further investigation of digital literacy and privacy preferences as moderating factors could help guide the design of more inclusive digital support systems. Finally, further exploration of resource sharing is warranted. Examining resource types, relevance, and user feedback could help refine the resources provided. Such analyses could also inform best practices for moderator facilitation and content curation within DPS, optimizing its function as a bridge between nonclinical and clinical support systems.

Practical Implications

The implications of these findings for workplace mental health strategy are substantial. Organizations can benefit from prioritizing awareness-raising efforts for EAP offerings through multimodal, repeated communications, especially during employee onboarding and at moments of organizational stress [54]. Embedding DPS as a core EAP component could expand reach and reduce barriers to support. Leadership endorsement, testimonials, and peer ambassador programs may help reduce stigma and foster a culture of openness [54]. Moreover, training moderators in sentiment attunement and evidence-based resource sharing may enhance user engagement and, in turn, increase the perceived benefits of DPS in improving sentiment state changes [9]. Integrating DPS within EAPs is a scalable approach that could reduce stigma associated with mental health care and improve employee well-being. This approach aligns well with a modern workforce that requires immediate, accessible, and flexible support tools.

Conclusions

This study underscores the importance of 24/7 access to mental health support, especially for employees who experience emotional distress outside standard business hours. However, because the primary measures were based on LLM-derived sentiment scores, conclusions about effectiveness remain exploratory. Around-the-clock DPS can bridge gaps in care when traditional services are unavailable, helping prevent crisis escalation and demonstrating organizational commitment to employee well-being. To improve EAP utilization, organizations should invest in consistent awareness efforts and destigmatize help-seeking. Leadership endorsement, integration of mental health into everyday communications, and collaboration with employee resource groups can broaden reach and foster a culture of support.

In-session resource sharing demonstrates the value of a hybrid approach that combines AI recommendations with trained peer support moderators to deliver targeted, practical tools. Incorporating psychoeducational resources within sessions may

XSL•FO
RenderX

increase user engagement, emotional regulation, and self-efficacy. Furthermore, tailoring resources to users' expressed needs in real time influences their effectiveness.

Finally, effective mental health strategies must be inclusive and flexible, adapting to diverse schedules, privacy needs, and digital comfort levels. By aligning accessibility with flexibility, employers can offer effective digital mental health interventions to employees. Overall, this study contributes to the growing evidence positioning DPS as an effective, scalable, and equitable tool for mental health across a diverse user base.

Acknowledgments

This work was sponsored by Supportiv. The authors thank Alejandro Martinez of Stanford University for providing the original peer support training for Supportiv moderators and Dylan Dudek, MS, for assistance in completing this manuscript.

Funding

Abstract

Background: Blended therapy (BT) combines digital applications with face-to-face treatment and has become an increasingly important component of psychiatric care. Evidence indicates that BT can achieve outcomes comparable to or even superior to those of traditional face-to-face therapy. Despite certain advantages, routine implementation of BT remains challenging, and clinical practice suggests that while some inpatients engage with BT, many either discontinue early or do not initiate its use at all. To better understand these patterns, this multicentric, retrospective observational study investigates factors associated with noninitiation and dropout among inpatients who are offered BT.

Objective: In this study, data from 278 inpatients were analyzed to examine the influence of sociodemographic variables, comorbidities, and symptom severity on the uptake and continued use of BT. The objective was to identify predictors of noninitiation and dropout.

Methods: Multivariable logistic regression models were conducted to identify significant predictors of noninitiation and dropout among inpatients using the transdiagnostic, cognitive behavioral therapy–based electronic mental health platform Minddistrict, which offers modules targeting psychoeducation, cognitive restructuring, and behavioral activation. Data were collected from 2 psychiatric hospitals between January 2020 and May 2024. The sample consisted predominantly of patients diagnosed with depression (182/278, 65.7%) and posttraumatic stress disorder (61/278, 21.9%), alongside various comorbid conditions.

Results: The findings indicate distinct patterns of association for noninitiation and dropout. Of the 278 patients, only 5 (1.8%) completed all the assigned modules, and one-third of the patients never initiated the platform at all. Specifically, increasing age was linked to a lower risk of noninitiation (odds ratio [per year age difference] 0.98, 95% CI 0.96-1.00; *P*=.01), while the presence of a comorbid anxiety disorder was associated with a reduced risk of dropout (odds ratio 0.23, 95% CI 0.08-0.66; *P*=.007). Several variables showed no association with either noninitiation or dropout across all analyses, including sex, overall symptom severity, and certain comorbidities such as personality disorders and depression.

Conclusions: In this preselected inpatient sample, uptake of BT was very limited. Older age was associated with lower noninitiation, and comorbid anxiety disorders were associated with a lower likelihood of dropout. These findings may help inform future prospective studies on how BT can be introduced and supported more effectively in inpatient psychiatric care. As access to BT was granted selectively by therapists, the results should be interpreted as predictors of engagement within a selected sample rather than general predictors of BT uptake among all psychiatric inpatients.

Introduction

Blended therapy (BT) is defined as the combination of digital applications, such as computer-based or internet-based programs, with face-to-face therapy. This combination of therapy modalities can be implemented in various forms. A substantial body of literature indicates that BT can achieve outcomes comparable or even superior to those of traditional standalone face-to-face therapy [1,2].

Despite its numerous advantages, implementing BT in routine practice remains challenging. This is due to various factors, including the high resource demands associated with the use of BT [3,4].

Online interventions are often characterized by high dropout and low adherence rates [5,6], highlighting the need to systematically investigate the underlying mechanisms behind it, as adherence can be a relevant factor for therapeutic success in prior research on treatment outcomes [7,8]. Understanding these factors is essential for building a comprehensive knowledge of how to optimize and implement this BT effectively. Evidence suggests that dropout is not a random phenomenon but is influenced by specific factors, particularly sociodemographic characteristics and symptom severity [9,10]. For example, Wu et al [10] examined predictors of noninitiation and dropout in blended cognitive behavioral therapy and found that both sociodemographic and clinical variables, such as depression severity and early digital engagement, significantly influenced adherence. Similarly, a meta-analysis by Karyotaki et al [9] and earlier findings by Christensen et al [11] confirmed that younger age, limited knowledge about psychological treatments, and greater symptom severity are associated with lower adherence in internet-based interventions. It should be noted that there is limited scientific literature specifically addressing BT, as most of the existing literature focuses on the area of unguided and guided self-help. Nonetheless, it is reasonable to assume that the use of BT also involves diverse patient-specific and diagnosis-specific influencing factors.

In the real-life implementation of BT at the psychiatric hospital *Clienia Schlössli AG*, many patients were offered blended treatment, but only a few actually started and completed the modules. This showed a relevant gap between initial setup and active participation in the treatment. This discrepancy is noteworthy, especially because a prior qualitative study conducted at the same hospital suggested that patients who engaged with BT were generally satisfied with its implementation [4]. This may indicate that acceptability among users does not necessarily translate into broad uptake or sustained use in routine inpatient care. Identifying risk factors for a low uptake of BT and/or low adherence could be therefore crucial to optimize the selection of suitable patients for this therapeutic approach. Adherence, defined as the completion of assigned modules on the platform, is associated with better treatment outcomes for depression [12]. In contrast, metrics such as the number of log ins or the total time spent on the platform have shown no correlation with improved outcomes [13]. Therefore, this study emphasizes module completion as a key indicator of engagement and its potential association with improved therapeutic outcomes. A distinctive feature of this study is its examination of therapy noninitiation, a phenomenon of clinical relevance that is exemplified by the case discussed earlier. While most studies on adherence primarily address dropout, referring to participants who begin but do not complete therapy, patients who never appropriately start therapy are often excluded from analysis. This exclusion may result in the loss of valuable information about a potentially important subgroup of patients.

A more targeted and personalized application of BT in selected patient groups may promote more efficient use of clinical resources. This is particularly relevant given that previous studies have reported that the implementation of BT can require additional time, effort, and resources [3,4,14]. Therefore, a part of optimizing resources should be the careful selection of patients who can truly benefit from its application.

The population examined in this study consists of patients receiving inpatient treatment. This is particularly relevant because the evidence base for BT in inpatient settings remains limited. Although only a few studies have examined its use in this context, the implementation of BT in inpatient care represents a valuable extension of this therapeutic approach.

The primary objective is to examine potential links between the noninitiation and dropout of BT and various influencing factors, building on findings from previous studies investigating similar phenomena.

Methods

BT Intervention

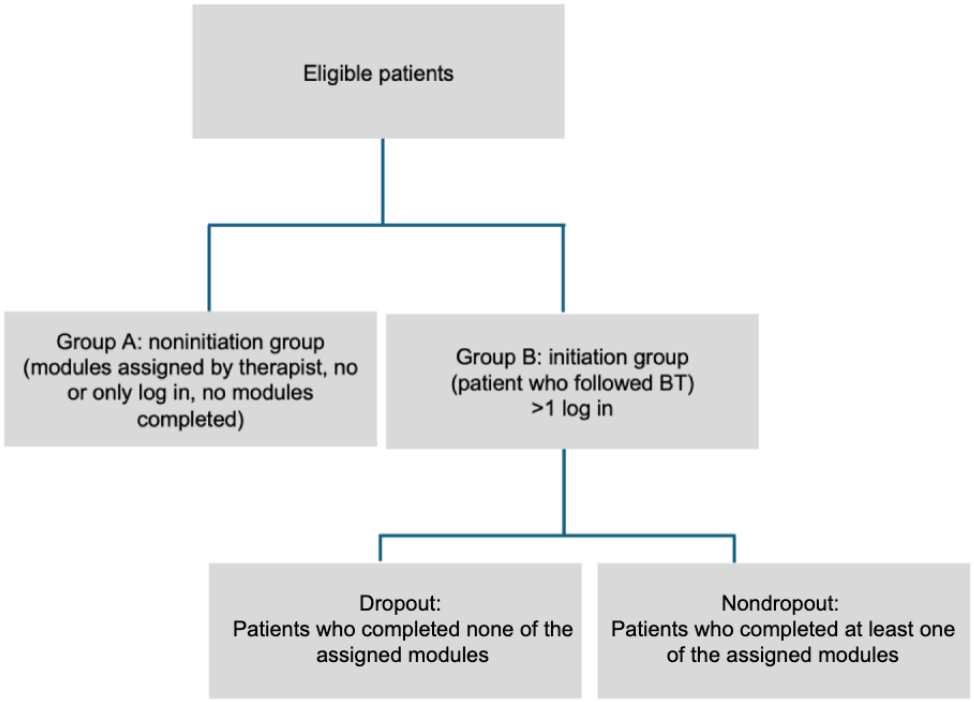
The study is a multicentric, retrospective observational study. We analyzed data from patients who used the electronic mental health platform *Minddistrict* at 2 psychiatric hospitals during their inpatient treatment. *Minddistrict* is a platform founded in the Netherlands in 2008, and it provides a transdiagnostic catalog structured into modules, self-help training, and diaries, drawing on cognitive behavioral therapy principles. The platform's modules primarily target psychoeducation, cognitive restructuring, and behavioral activation. It allows for individualized treatment by assigning suitable interventions tailored to each patient's needs. Patients can monitor behavioral patterns and track therapy progress through diaries or independently select interventions from the self-help catalog. *Minddistrict* additionally offers various communication channels, including video calls and chat functions. Access to *Minddistrict* was granted to selected and interested patients by their therapists, who created user accounts on their behalf. After the account creation, patients could engage with the platform

XSL•FO
RenderX

through therapist-guided modules, which required therapists to unlock new content after certain steps were completed. Additionally, patients had the option to use diaries, where they could document and reflect on their experiences independently and without therapist involvement. *Minddistrict* additionally offers various communication channels, including video calls and chat functions. The use of the video calls and diary features was excluded from this study because these components do not involve structured BT interventions.

Inclusion and Exclusion Criteria

The analysis includes inpatients from 2 psychiatric hospitals: *Clienia Schlössli* and *Clienia Littenheid*, which accessed the electronic mental health platform between January 2020 and May 2024. Platform use was reassessed in August 2024 to capture a comprehensive overview of module engagement and log in frequency. Although it is possible that some patients completed additional modules or increased use after this cutoff, such cases are considered unlikely. Patients were excluded if no modules had been assigned by their therapists. Patient accounts with multiple log ins and without module assignments were excluded, as we assumed that the platform was only used for video calls rather than for structured BT in these cases.



Division of Patient Groups

As outlined in the Introduction section, this study investigates noninitiation, defined as the failure to begin the intervention, and dropout, defined as the failure to complete any of the assigned therapeutic modules after platform initiation. To enable this analysis, patients were categorized into the following groups:

- Group A: patients who never logged in or only logged in once while not completing any modules
- Group B: patients who logged in once and completed one or more modules
- Dropout: patients who completed none of their assigned modules
- Nondropout: patients who completed at least one of their assigned modules

A schematic overview of the patient categorization process is presented in Figure 1.

Figure 1. Flowchart of patient classification into noninitiation and initiation groups. BT: blended therapy.

Outcome Measures

Overview

The data sources for this study included electronic medical records containing routinely collected datasets at the time of patient admission. Additionally, data on user activity on the platform are obtained directly from the *Minddistrict*'s database. An overview of all collected data is presented in Textbox 1.

Assessments for symptom severity

- Brief Symptom Checklist
- Health of the Nation Outcome Scales

Diagnosis

- Main diagnosis
- Comorbid diagnoses

Platform use

- Number of log ins to the platform
- Number of modules assigned by the therapist
- Number of modules completed by the patient

Assessment of Symptom Severity

Brief Symptom Checklist

The Brief Symptom Inventory is a standardized self-report questionnaire used as a psychometric instrument to assess psychological distress. It consists of 53 items rated on a 5-point Likert scale and covers 9 symptom dimensions, including somatization, obsessiveness, interpersonal insecurity, depressiveness, anxiety, aggressiveness or hostility, phobic anxiety, paranoid thinking, and psychoticism. The Brief Symptom Checklist (BSCL) is the licensed German adaptation of the Brief Symptom Inventory. In the clinical setting, assessment is based on the total score of the BSCL, which was documented at admission and discharge. This allows the evaluation of symptom change over the course of inpatient treatment. Internal consistency (Cronbach α) ranged from satisfactory to very good across subscales, with the highest values for depressiveness and the Global Severity Index. Test-retest reliability after 1 week has been satisfactory to good across most dimensions [15].

Health of the Nation Outcome Scales

The Health of the Nation Outcome Scales (HoNOS) is a clinician-rated scale used to assess 12 items covering behavior, impairment, symptoms, and social functioning, including work and daily life. Each item is rated from 0 to 4, with a maximum score of 48, with higher scores indicating higher problem burden. The scale is routinely completed at hospital admission and discharge to track symptom changes. HoNOS is considered a practical tool for assessing the severity of mental health problems in inpatient settings. Existing literature supports its good interrater and test-retest reliability [16].

Ethical Considerations

This study (project ID: 2024-00768) has been reviewed and approved by the Zurich Ethics Committee. This research was conducted as a retrospective cohort study; therefore, active informed consent was not required by the ethics committee. Patient data were pseudonymized prior to analysis. Identifying information was stored separately from the analytic dataset and accessible only to authorized study personnel.

Data Analysis

Descriptive statistics include means and SDs for continuous variables, as well as numbers and percentages for categorical variables. Multivariable logistic regression models were used to identify factors associated with the extent of platform tool use based on a predefined set of variables, including age, sex, education, employment, civil status, disease severity (HoNOS or BSCL), treatment setting, and main diagnosis. Missing values were handled using multiple imputation by chained equations with the *mice* package in R [17]. Appropriate imputation methods were applied depending on the variable type, including logistic, polytomous, proportional odds regressions, and predictive mean matching. A total of 70 datasets were imputed for the whole dataset with 30 iterations, and 45 datasets were imputed for the stationary setting subset with 15 iterations. All analyses were carried out with R (version 4.4.3; R Foundation for Statistical Computing), and RMarkdown (Posit Software) was used for dynamic reporting.

Results

Descriptive Analysis

Distribution of Patient Characteristics

Descriptive statistics for the full inpatient sample (N=278) are presented in Table 1. The mean age was 45.45 (SD 15.14) years, and the sample consisted of 112 (40.3%) patients who were male. Regarding civil status, most patients were either single (96/236, 40.7%) or married or cohabiting (92/236, 38.9%). In terms of educational background, the largest proportion had completed an apprenticeship or vocational school (114/263, 43.3%), followed by university or higher education (54/263, 20.5%). Employment status varied considerably, with 94 (34.4%) out of 273 patients unemployed, 67 (24.5%) patients employed full-time, and 60 (21.9%) patients receiving disability or retirement benefits.

Most patients were diagnosed with depression (182/278, 65.7%) or posttraumatic stress disorder (61/278, 21.9%). Comorbidity was common, with a mean of 2.56 (SD 1.34) diagnoses per patient. The most frequent comorbid conditions were posttraumatic stress disorder (82/278, 29.6%), substance use disorder (65/278, 23.5%), and personality disorder (55/278, 19.9%).

Disease severity decreased substantially over the course of inpatient treatment. Mean HoNOS scores improved from 18.04 (SD 4.54) at admission to 9.22 (SD 4.42) at discharge, and BSCL scores decreased from 78.36 (SD 33.57) to 42.79 (SD 31.64).

Distribution of Platform Use Parameters

On average, patients logged into the system 5.9 (SD 14.4; median 2.0, IQR 1.0-5.8) times. The mean number of modules assigned was 3.8 (SD 3.4; median 3.0, IQR 1.0-5.0), while the mean number of completed modules was 0.9 (SD 2.0; median 0.0, IQR 0.0-1.0), corresponding to a mean module completion rate of 24% (0.9/3.8). Notably, only 5 (1.8%) out of 278 patients completed all assigned modules. In terms of group distribution, 94 (33.8%) patients were in group A (noninitiation group), and 184 (66.2%) patients initiated the platform. Among those who initiated the platform, 94 (51.1%) completed none of their assigned modules (dropout), while 90 (48.9%) completed at least one assigned module (nondropout).

Regression Models With Imputed Data

Logistic Regression Model on Factors Potentially Associated With Noninitiation

In the logistic regression model assessing factors associated with noninitiation of the online platform among inpatients (N=278), age was the only variable significantly associated with noninitiation. Specifically, increasing age was linked to a lower likelihood of noninitiation (odds ratio [OR]=0.98, 95% CI 0.96-1.00; *P*=.01). While the OR is presented as 1, the significant *P* value indicates an actual effect, with the actual OR likely being marginally below 1 but not captured due to rounding. The odds decreased by 2% for each 1-year increase in age, suggesting that older patients were more likely to engage with the platform. For an age difference of 10 years, this would indicate an OR of 0.8. All other variables were not significantly associated with noninitiation (Table 2).

Table 2. Logistic regression model of factors potentially associated with noninitiation.

Parameter	Odds ratio (95% CI)	*P* value
Sex (male)	1.05 (0.60-1.84)	.86
Age (difference per year)	0.98 (0.96-1.00)	.01
Depression	1.24 (0.51-3.03)	.63
Personality disorder	0.68 (0.34-1.37)	.28
Substance use disorder	1.34 (0.73-2.46)	.35
Posttraumatic stress disorder	1.22 (0.66-2.26)	.52
Anxiety disorder	1.12 (0.52-2.40)	.77
HoNOS[a] entry	0.98 (0.93-1.05)	.59
BSCL[b] entry	1.04 (0.94-1.15)	.41

Logistic Regression Model on Factors Potentially Associated With Dropout

In the logistic regression model assessing factors associated with dropout, anxiety disorder emerged as a statistically significant predictor. Patients diagnosed with an anxiety disorder had significantly lower odds of dropping out (OR 0.23, 95% CI 0.08-0.66; *P*=.007), indicating a higher likelihood of continued engagement with the platform. In addition, 2 nonsignificant trends were observed. First, patients with a personality disorder showed a tendency toward lower dropout rates (OR 0.50, 95% CI 0.21-1.19; *P*=.11), suggesting a potential association that may need further investigation. Second, there was a weak trend indicating that higher symptom severity at admission, as measured by the HoNOS score, might be associated with increased dropout risk (OR 1.07, 95% CI 0.99-1.15; *P*=.08), though this finding did not reach statistical significance (Table 3).

Discussion

Summary and Interpretation of Findings

This study identified 2 significant predictors of engagement with BT among inpatients: increasing age was associated with a lower risk of noninitiation, while comorbid anxiety disorder was associated with a lower risk of dropout. These findings are particularly noteworthy as they differ depending on whether noninitiation or dropout is examined, and these associations were observed in a heterogeneous patient population encompassing a broader range of diagnoses than that included in a previous study [10], which was limited to patients with anxiety disorders and depression. In contrast, our study examines a more heterogeneous patient population with a wider range of diagnoses, allowing a more comprehensive analysis of the BT's applicability across different conditions. The statistical analysis reveals significant findings, which interestingly differ depending on whether we examine the issue of noninitiation or dropout.

Previous studies have demonstrated that nonparticipation in general psychotherapy does not occur at random over time. The risk is particularly high at the beginning of the therapeutic process, often even before the first therapy session [18]. This finding is consistent with our study, where approximately one-third of the participants (94/278, 33.8%) were classified as belonging to the noninitiation group. This pattern suggests that not initiating a therapy may be driven not by the intervention itself but by other underlying factors. Therefore, it is essential to monitor this vulnerable phase closely and provide enhanced support precisely at this critical phase.

A striking finding of this study is the overall low uptake of the intervention. Despite being offered to a preselected group of interested patients, only 5 (1.8%) out of 278 patients completed all the assigned modules. One-third of patients never initiated the platform at all, and of those who did, most did not complete their assigned modules, resulting in a mean module completion rate of approximately 24% (mean 0.9, SD 2.0 out of 3.8, SD 3.4 assigned modules). These findings are consistent with the broader literature on digital interventions, which has repeatedly documented high rates of nonuse and early disengagement [5,6].

Several factors may help explain this low overall uptake. First, the absence of standardized follow-up procedures likely played a relevant role. Without systematic monitoring of patient engagement, low levels of platform use may have gone unnoticed or unaddressed by therapists [4]. Second, the lack of standardized criteria for module assignment may have contributed to low completion rates. Therapists in a qualitative study conducted at the same institution reported uncertainty about which modules were suitable for which patients and emphasized that active integration and follow-up are essential for meaningful engagement and that module assignment alone is insufficient unless supported by structured guidance [4].

Furthermore, the findings suggest that increasing age has a protective effect against noninitiation, indicating that older patients may be more likely to begin the intervention after modules have been assigned by the therapist. Previous research investigating internet-based cognitive behavioral therapy has shown that older adults tend to complete more modules and remain engaged over longer periods compared to younger users [19-22]. These studies suggest that older individuals may benefit from greater persistence, show more stable use patterns, and show potentially higher motivation, resulting in better adherence and lower dropout rates in digital interventions. One hypothesis could be that older individuals may adhere slightly better to digital interventions because they are more likely to be retired and therefore may have more time available to engage with therapy. However, this explanation does not apply to this study, as all participants were treated under inpatient conditions and therefore had access to comparable time resources. This suggests that factors other than time availability may underlie the higher adherence observed among older patients. A possible explanation is that younger users may approach digital interventions in a more exploratory way while lacking a strong initial commitment to the intervention. If immediate benefits are not apparent, they may disengage quickly. In contrast, older adults may begin treatment with more realistic expectations and greater persistence. Their decision to engage with digital therapy, despite potential barriers such as unfamiliarity with technology or initial skepticism, may be due to a high baseline level of intrinsic motivation. Younger individuals, for whom

XSL•FO
RenderX

digital tools are more embedded in daily life, may face lower entry thresholds, resulting in a more heterogeneous group with varying levels of motivation, including those with only low therapeutic interest. Additionally, older adults who agree to participate in digital treatment may possess other characteristics associated with treatment success, such as higher education, more cognitive resources, or greater health-related self-efficacy.

Our findings indicate that patients with comorbid anxiety disorders in inpatient settings have a lower likelihood of discontinuing therapy. Anxiety disorders frequently cooccur with other psychiatric conditions, making it important to investigate their potential influence on the chance of dropouts. The prior evidence regarding the relationship between comorbid anxiety and psychotherapy dropout has been mixed and inconsistent. Studies have examined anxiety as a predictor of dropout both in general psychotherapy settings and specifically in the context of internet-based interventions. Some studies suggest that comorbid anxiety is associated with lower dropout rates [23], while others report the opposite, indicating a higher likelihood of early termination [24]. The evidence remains inconclusive. This raises the question of why patients with anxiety disorders in our study were less likely to drop out. One possible hypothesis relates to personality characteristics. Evidence suggests that individuals with anxiety disorders more frequently display cluster C personality traits [25]. These traits are associated with high conscientiousness, and a strong sense of duty can have a link to improved treatment adherence. Such individuals may be more willing to follow therapeutic guidance and continue engaging with assigned modules due to their conscientious traits. Another possible explanation for the lower dropout rate among patients with comorbid anxiety is that the structured and predictable nature of BT aligns well with their needs. The clear framework and guidance of online modules may support adherence by complementing traits commonly associated with anxiety. Additionally, the platform's transdiagnostic content may target essential mechanisms of anxiety, such as rumination and avoidance, which may increase the perceived personal relevance of the material. In addition, anxious patients also tend to closely monitor their own progress, which may support ongoing participation, particularly in digital formats that involve self-tracking or structured exercises. It is also possible that individuals with anxiety disorders require additional effort to engage in social situations, including those encountered during face-to-face psychotherapy. psychotherapy. Working on a digital platform may reduce the potentially distressing effects of direct interpersonal interaction, which could make digital therapy a more appealing and manageable option for them. Finally, the higher frequency of contact points in BT may lead to a sense of safety and continuity that helps reduce uncertainty.

Implications of the Findings

The results of this study could lead to 2 possible approaches. On the one hand, it might be beneficial to provide additional support to patients with a high risk of dropout or noninitiation to ensure successful completion of the therapy, for instance, by giving special attention to these patients. On the other hand, one could argue that these patients may not benefit from this therapy form and that alternative therapeutic approaches should be prioritized for them. Considering the wide range of available therapy options, certain approaches may simply be better suited for specific conditions. Wentzer et al [26] aimed to develop a tool to systematically assess factors critical for successful outcomes in BT, focusing on aspects such as computer access, internet skills, acute crises, and patient motivation. Similarly, Karyotaki et al [27] applied a personalized medicine approach in a systematic review to improve therapy allocation for patients with depression. Using sociodemographic characteristics and baseline symptom severity as predictors, the authors developed an interactive decision-support tool to guide treatment allocation among guided digital therapy, unguided digital therapy, and treatment as usual. While these studies concentrated on either practical barriers or depression-specific treatment optimization, this study extends this approach by including a broader patient population across multiple diagnoses. Such efforts are essential to optimize both treatment outcomes and resource use. In the future, standardized tools could help predict dropout risk, thereby enabling more targeted and effective implementation of BT. Accurate identification of suitable patients may enhance therapeutic efficiency and reduce health care costs. However, the findings of this study should be interpreted within their specific context. Our analysis focuses exclusively on adherence to BT, without assessing treatment outcomes. It is conceivable that some patients completed modules without having any clinical benefit, for example, to meet expectations from their therapists. Nevertheless, previous research has shown that homework adherence is positively associated with therapeutic success [28]. In line with this, we assume that module completion in BT also contributes to improved outcomes. By identifying risk factors for noninitiation and dropout, this study offers valuable insights into an underexplored area of digital mental health. It supports a more personalized and cost-efficient approach to psychiatric care by helping to match BT more precisely to patients who are likely to benefit. It expands the existing evidence base and contributes to the advancement of targeted, evidence-based treatment strategies.

Limitations

Our findings must be interpreted considering several limitations. A limitation is the heterogeneity of the data, collected over an extended period (January 2020 to May 2024), with considerable variability in therapist training, application methods, and patient selection. No standardized procedures were applied, and information on selection criteria is missing. Importantly, as access to the Minddistrict platform was granted selectively by therapists to interested patients, no systematic data were collected on patients who were not offered BT during the study period. This precludes any formal comparison between included and nonincluded patients, and the extent and direction of the resulting selection bias therefore remains unknown. Future prospective studies should consider collecting data on all potentially eligible patients, regardless of whether they are ultimately offered BT, to allow for such comparisons.

Moreover, therapist-related variables are incomplete. Prior research shows that the extent and consistency of guidance significantly affect adherence [29,30] and that therapists' attitudes toward digital tools play a role in patient engagement. The therapeutic relationship is also a known protective factor

XSL•FO
RenderX

against dropout [31]. The absence of standardized training and varying application strategies may have contributed to differences in adherence. Additional influencing factors such as self-efficacy, expectations, digital affinity, and therapeutic alliance were not assessed. Finally, while the study reveals associations between predictors and dropout or noninitiation, it does not clarify underlying mechanisms. Qualitative studies could offer further insights, and future prospective studies with standardized protocols and more homogeneous samples are recommended. These limitations should be considered when interpreting the findings.

Abstract

Background: In recent years, the global prevalence of myopia among children has continued to rise. The preschool years represent a critical period for visual development, and the widespread adoption of electronic screens among young children has brought increasing attention to pediatric visual health. However, the association between visual environmental exposures related to screen use—such as screen brightness and ambient illuminance—and the risk of myopia in preschool children has not been thoroughly investigated.

Objective: This monitoring study aimed to investigate the association between electronic screen brightness, ambient illuminance, and axial length in preschool children to provide evidence-based support for developing screen brightness usage recommendations for this population.

Methods: This cross-sectional monitoring study was conducted between March and July 2023 in Shanghai, China, involving 2 representative samples of kindergarten children aged 3 to 6 years. Each participant was provided with a tablet preinstalled with intelligent monitoring software, which continuously and objectively recorded real-time data on screen time and screen brightness over a consecutive 7-day period. In addition, comprehensive data collection encompassed standardized ophthalmic assessments, high-precision ambient illuminance measurements, simulated laboratory lighting evaluations, and parental questionnaires. Associations between ambient illuminance, screen brightness, and axial length were analyzed using multivariable linear regression and restricted cubic spline models.

Results: Of the 199 children included in the total sample, 124 (62.3%) were boys, and 75 (37.7%) were girls. After adjustment for demographic characteristics, parental myopia, and screen use behaviors, the median ambient illuminance during tablet use was significantly inversely associated with axial length (β=–0.13, 95% CI –0.22 to –0.04; P=.006). A nonlinear dose-response relationship was identified between median screen brightness and axial length ($P_{nonlinearity}$=.004), with axial elongation accelerating beyond approximately 27 cd/m² and peaking around 56 cd/m². Boys (P<.001) and greater height (P=.33) were also significantly associated with longer axial length.

Conclusions: Higher ambient illuminance during tablet use is associated with shorter axial length in preschoolers, whereas screen brightness exhibits a nonlinear effect on axial elongation. This study highlights the importance of optimizing both environmental lighting and device settings to protect visual health in young children, providing empirical support for guidelines on safe digital device use and ambient lighting conditions in early childhood.

Introduction

The rising global prevalence of myopia among children and adolescents has become a significant public health challenge [1]. Early intervention is critical, as a younger age of onset is strongly associated with a higher risk of developing high myopia [2,3]. Axial length represents a key biomarker for evaluating myopia severity and predicting disease progression, with abnormal elongation being strongly associated with myopia advancement [4]. The preschool stage (age 3 - 5 y) is a critical period for refractive development. During this time, the characteristics of visual environmental exposure can profoundly influence the onset and progression of myopia.

In our digitalized society, electronic screens have become a dominant component of children's visual environment. A large-scale epidemiological study conducted across 38 countries on 6 continents revealed that 60% to 93% of children and adolescents are exposed to screens for more than 2 hours daily [5], with preschool children showing a trend of earlier initial screen exposure and higher usage frequency [6,7]. This underscores the urgent need to evaluate the potential impact of screen exposure on visual health and myopia risk in preschoolers. Population-based studies have preliminarily demonstrated the association between screen time and myopia. A systematic review and meta-analysis published in *The Lancet Digital Health* confirmed that the independent duration of smartphone and tablet use as well as the cumulative effect of screen time from computers were significantly associated with an increased risk of myopia [8]. A study from Japan further identified a relationship between prolonged screen time and abnormal axial length elongation in young children [9]. A cross-sectional study from the Netherlands revealed a significant positive correlation between the increased frequency of uninterrupted smartphone usage lasting over 20 minutes and increased scleral elasticity ratio as well as the anterior chamber depth-to-lens thickness ratio [10]. Although existing studies have investigated the association between screen time and visual development, research on the impact of screen brightness, a critical optical parameter, on visual health remains absent and warrants further exploration.

Modern mobile devices are commonly equipped with ambient light sensors that enable automatic screen brightness adjustment, a dynamic feature that may influence the visual system through two mechanisms: first, the adaptation of screen brightness to ambient light levels may affect visual function; and second, excessively high ambient light levels may induce dry eye symptoms, while abnormally elevated screen brightness could increase the burden of glare perception [11-13]. Evidence from animal models indicates that low illumination levels can induce myopia, whereas increased light exposure may activate retinal dopaminergic activity (primarily via the D2 receptor pathway), thereby regulating retinal gene expression and suppressing the biological signaling pathways that promote axial elongation [14]. Furthermore, ergonomic research has identified an inverted U-shaped relationship between display brightness and visual performance, fatigue, and discomfort, suggesting that both excessively low and high brightness levels compromise visual comfort and performance [15]. Benedetto et al [11] demonstrated that increased screen brightness significantly exacerbates visual fatigue. However, epidemiological evidence regarding the impact of screen brightness on eye axial elongation in children remains lacking.

Therefore, the primary aim of this study was to collect real-time objective exposure data through intelligent monitoring technology and then examine the association between electronic screen brightness, ambient illuminance, and axial length in preschool children. These findings may contribute to the development of evidence-based guidelines regarding screen use and myopia prevention in young children.

Methods

Study Design and Population

This cross-sectional monitoring study was conducted in two districts of Shanghai, China: Xuhui District (urban) and Pudong New Area (suburban), from March to July 2023. A random sampling method was used to select a kindergarten from each of the 2 districts. For each kindergarten, a cluster sampling method was used to select 5 classes, in which the average number of children in each class was 30, from the junior, middle, and senior grades. A total of 199 preschool children participated in the study, each of whom was provided with a tablet for a 1-week period. Before participation, parental consent was obtained during the eligibility screening phase. During the monitoring period, participants were instructed to maintain their typical screen usage habits, with the provided tablets being strictly limited to use by child participants only, thereby ensuring the integrity of exposure data collection. The study enrollment criteria were established as follows. Inclusion criteria were as follows: (1) preschool children currently registered in the kindergarten; (2) aged 3 to 6 years at the time of recruitment; and (3) whose parents or other caregivers have allowed them to use screen devices, such as televisions, mobile phones, tablets, and computers. Exclusion criteria were as follows: (1) presence of diagnosed organic ocular pathologies, (2) demonstrated inability to complete refractive error assessments, and (3) absence of legally authorized guardian consent.

Measures

Vision Screening

Axial length, corneal curvature, and refractive errors were measured using standardized ophthalmic instruments. Spherical and cylindrical refractive errors were assessed with the KR-800 auto-refractor (Topcon Corporation), while axial length and corneal curvature were measured using the IOL Master 700 (Carl Zeiss Meditec AG). To ensure measurement accuracy, examinations were conducted sequentially, starting with the right eye, followed by the left eye. If children demonstrated poor cooperation, measurements were repeated. All examiners received prior training, and instruments were regularly calibrated to maintain precision.

Screen Exposure Monitoring Technology

The *Healthy Screen Viewing for Children (HSVC)* application, developed in collaboration with Huawei Corporation, was installed on dedicated tablets provided to participants [16]. This

XSL•FO
RenderX

software automatically recorded screen usage data, including application type, screen brightness, and duration of use, at 1-minute intervals over a 7-day monitoring period. Equipped with built-in ambient light sensors, the tablets dynamically adjusted screen brightness according to real-time ambient lighting conditions. The HSVC application concurrently recorded the corresponding screen luminance values (in cd/m²) along with precise time stamps for each measurement. All collected data were securely transmitted to a cloud server for subsequent analysis.

Simulated Lighting Environment Setup

To convert the recorded screen brightness values into corresponding ambient illuminance levels for each child, we established a response model between screen brightness and horizontal illuminance under controlled laboratory conditions. This model allowed us to estimate the ambient illuminance during each child's tablet use based on the screen brightness data captured by the HSVC application. A controlled experiment was conducted in a professional lighting laboratory equipped with blackout conditions, where a response model between horizontal illuminance and screen brightness was constructed. The lighting environment was simulated using a warm-white light source with a correlated color temperature of 3000 K and a color rendering index (Ra) >80, to reflect typical nontask lighting conditions found in residential settings. The relative spectral power distribution of the light source is provided in Multimedia Appendix 1. This setup was designed to ensure both environmental realism and comfort.

The self-luminous device was operated under its default automatic brightness adjustment mode and fixed on a standard platform, with the screen center positioned at a height of 75 cm above the ground. A CL-500A spectroradiometer (KONICA MINOLTA) was used to record illuminance levels, with the sensor placed horizontally at the center of the desktop, approximately 30 cm in front of the screen. In accordance with the BS ISO/CIE 8995-1:2025 standard, horizontal illuminance was adopted as the primary photometric parameter due to its experimental stability and representativeness in evaluating screen-based visual environments. A total of 32 paired measurements of screen brightness and horizontal illuminance were collected by systematically adjusting ambient light intensity. A significant nonlinear relationship was observed between screen brightness and horizontal illuminance. As illustrated in Multimedia Appendix 2, the fitted quadratic regression model was as follows:

$$E=0.199x2-11.862x+177.930$$

where x denotes the screen brightness (unit: cd/m²) and E represents the corresponding horizontal illuminance (unit: lux). The model exhibited a high goodness of fit (R^2=0.988).

On the basis of the illuminance requirements specified in BS ISO/CIE 8995-1:2025 for *computer work only and young children* (300 lux) and *general classroom activities* (500 lux), the experimental data were classified into three ambient lighting categories: low illuminance (<300 lux), representing relaxed or recreational settings; moderate illuminance (300 - 500 lux), suitable for light visual tasks or display-based activities; and high illuminance (>500 lux), corresponding to functionally enhanced or brightly lit environments.

Covariates

A self-administered online questionnaire was distributed to parents to collect demographic information, including the child's age, sex, caregiver characteristics, only-child status, parental education levels, and household income. Additionally, the questionnaire collected relevant covariates based on existing literature, such as parental myopia status and children's daily behaviors (eg, duration of indoor and outdoor activities and sedentary time). Furthermore, the questionnaire assessed screen time across all media types, addressing the limitations of the HSVC in capturing data from television, personal computers, and other nontablet devices.

Statistical Analysis

Categorical variables were analyzed through frequency distributions (%), whereas continuous variables were presented according to their distribution. The normality of all continuous variables was assessed using the Shapiro-Wilk test. The Shapiro-Wilk test indicated that axial length and height were normally distributed (P>.05), whereas the other continuous variables deviated significantly from normality. Normally distributed data were presented as mean (SD), and nonnormally distributed data were presented as median (25th percentile and 75th percentile). Univariate analyses used independent *t* tests for binary comparisons (eg, sex differences) and 1-way ANOVA for multigroup comparisons (eg, age category). To evaluate monotonic relationships between variables, the Spearman rank correlation coefficient (ρ) was used. Spearman correlation coefficients quantified bivariate associations between axial length and continuous physiological or behavioral measures (eg, height, weight, and activity durations). Before model fitting, key regression assumptions were verified. The homoscedasticity assumption was evaluated using a Breusch-Pagan test, and the normality of residuals was formally assessed using the Shapiro-Wilk test; no substantial violations were detected (P>.05). Multivariable linear regression models adjusted for covariates (eg, age, sex, parental myopia, screen time, and activity levels) to assess independent effects of ambient illuminance and tablet brightness on axial length. Restricted cubic spline (RCS) models with 3 knots explored nonlinear dose-response relationships. Statistical significance was set at P<.05 (2 tailed), and analyses were performed using R software (version 4.3.2; R Foundation for Statistical Computing).

Ethical Considerations

Before the participants underwent screen exposure monitoring and questionnaire surveys, we informed their parents (legal guardians) of the entire process of participation in the surveys as well as the benefits and risks involved, and the legal guardians signed the informed consent. As a participation acknowledgment, children received art supply kits valued at US $15 per set. This study conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the Ethics Committee for Medical Research at the School of Public Health, Fudan University (IRB#2023-11-1088). When extracting data from the Huawei Research Platform and the online

XSL•FO
RenderX

questionnaire library for analysis, all data were deidentified, and an anonymous study ID was used as an identifier for each participant.

Results

Participant Characteristics

Complete demographic and axial length data were available for all 199 participants. As presented in Table 1, 62.3% (n=124) of the participants were boys, and the majority (n=144, 72.4%) were aged between 4 years 9 months and 5 years 6 months. The participants' caregivers were predominantly their mothers (n=106, 53.3%), and more than half of the parents held a bachelor's degree (fathers: n=113, 56.8%; and mothers: n=113, 56.8%). The prevalence of maternal myopia was significantly higher (n=113, 56.8%) compared to paternal myopia (n=108, 54.3%), and maternal myopia was found to be significantly associated with a longer axial length (*P*=.01).

Variable	Values, n (%)	Axial length (mm), mean (SD)	*T* test/*F* test[a] (*df*)	*P* value[b]
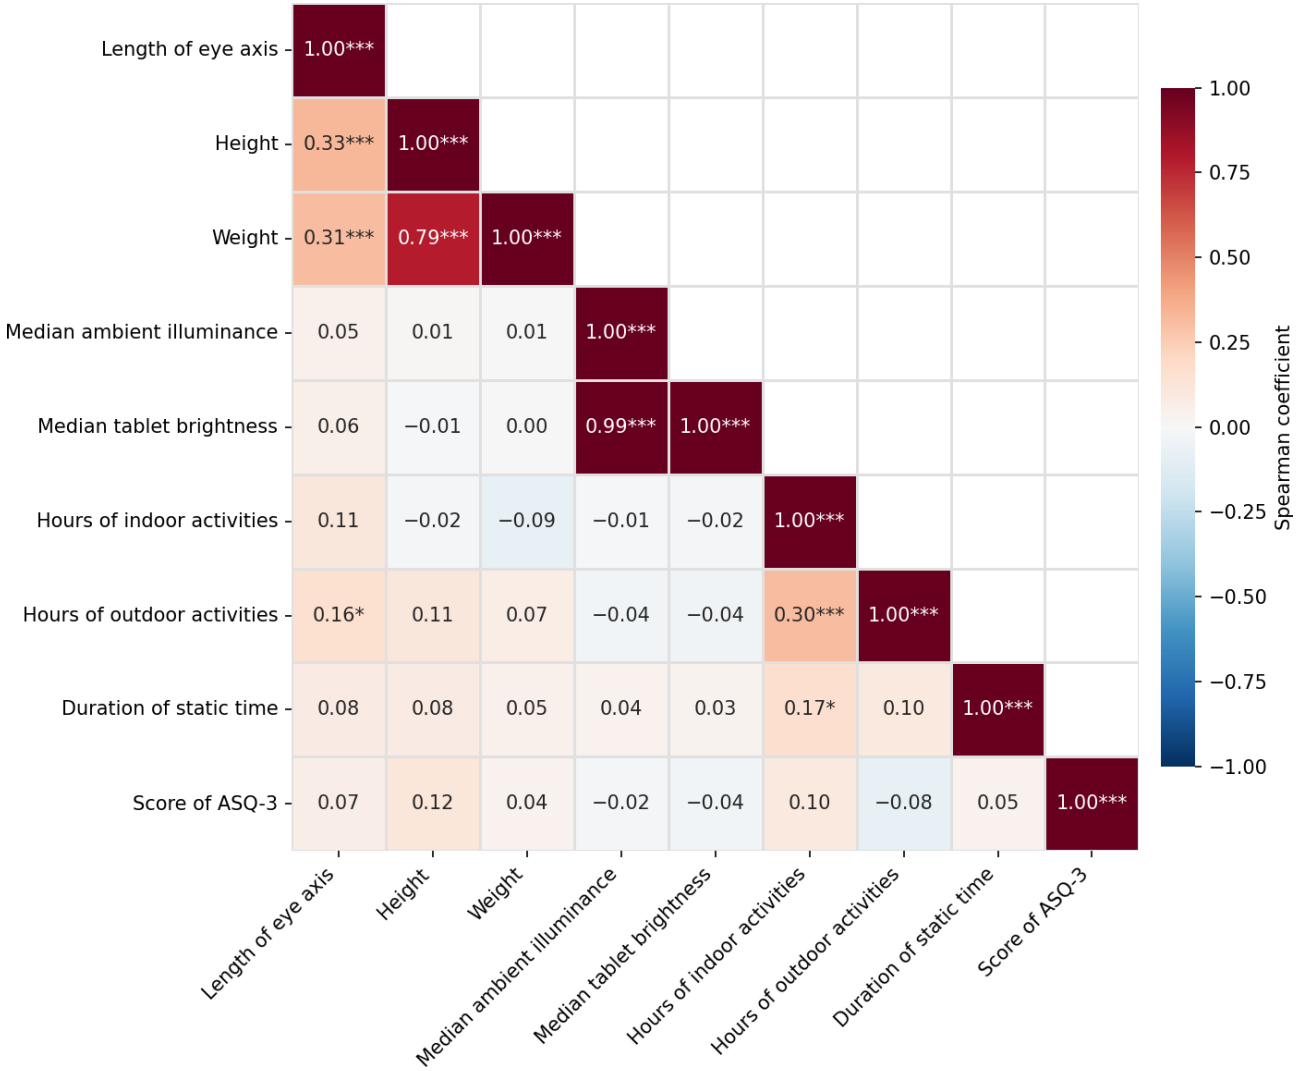
Yes	113 (56.8)	22.56 (0.713)		
Whether the child was ill in the past year			–1.167 (197)	.24
Yes	173 (86.9)	22.42 (0.740)		
No	26 (13.1)	22.61 (0.721)		

[a]*T* tests were used for binary comparisons, and the *F* statistic from a 1-way ANOVA was used for multigroup comparisons.



[b]*P* values were derived from independent *t* tests (for binary variables such as sex) or 1-way ANOVA (for multicategory variables such as age group). *P*<.05 was considered statistically significant.

Univariate analyses revealed significant differences in axial length based on sex, with boys having a greater mean axial length (22.68, SD 0.653 mm) compared to girls (22.07, SD 0.717 mm; *P*<.001). Additionally, significant differences in axial length were observed across different age groups (*P*=.04). However, no significant associations were found between axial length and variables, such as caregiver type, parental education level, household income, or only-child status (*P*>.05).

Correlation Analyses

The Spearman rank correlation analysis revealed several significant associations between certain demographic and behavioral factors and axial length. Specifically, height (ρ=0.33; *P*<.001), weight (ρ=0.31; *P*<.001), and outdoor activity duration (ρ=0.16; *P*=.03), all demonstrated statistically significant positive correlations with axial length (Figure 1). Notably, these relationships persisted even after adjusting for potential confounders, including parental myopia status and digital device exposure parameters.

Figure 1. Spearman rank correlation heatmap of key variables and axial length (N=199). Note: **P*<.05, ***P*<.01, ****P*<.001. ASQ-3: Ages and Stages Questionnaires, Third Edition.

Associations Between Ambient Illuminance or Tablet Brightness and Axial Length

As presented in Tables 2 and 3, multivariable linear regression demonstrated that higher median ambient illuminance during tablet use was inversely associated with axial length (β=–0.13, 95% CI –0.22 to –0.04; *P*=.006), after adjusting for sex, age, height, parental myopia, total screen time, and behavioral factors (Table 2). Specifically, the median ambient illuminance was 134.77 lux (P25=67.74 lux and P75=221.65 lux). Boy sex (*P*<.001) and greater height (*P*=.33) also significantly predicted axial length. However, there was no significant association between tablet brightness and axial length (Table 3). Although the median tablet brightness was 55 cd/m^2 (P25=47 cd/m^2 and P75=63.25 cd/m^2), it did not exhibit a linear association with axial length (Table 3).

Dose-Response Relationships Between Ambient Illuminance or Tablet Brightness and Axial Length

The dose-response relationships of tablet brightness and ambient illuminance with axial length were examined using RCS, as shown in Figures 2 and 3. Multivariable linear regression models incorporating RCS were fitted with 3 knots placed at the 10th, 50th, and 90th percentiles of the exposure distribution [17]. All models were adjusted for sociodemographic factors (eg, boy or girl, age, height, weight, and parental myopia), behavioral factors (indoor and outdoor activity duration, and sedentary time), and developmental characteristics (score from Ages and Stages Questionnaires, Third Edition). A significant nonlinear association was identified between median tablet brightness and axial length ($P_{\text{nonlinearity}}$=.004). The coefficient β represents the marginal change in axial length (in mm) per unit increase in exposure. The fitted curve indicated a negative slope at brightness levels below 27 cd/m², suggesting a reduction in the rate of axial elongation. This was followed by a transitional phase (27 - 56 cd/m²) where the curve became positive and increased, peaking at approximately 56 cd/m². Beyond this point, the fitted curve gradually decreased. In contrast, no significant nonlinear relationship was found between ambient illuminance and axial length ($P_{\text{nonlinearity}}$=.17), with the curve remaining approximately flat across the measured range (Figure 3).

Discussion

Principal Findings

On the basis of continuous 7-day real-time monitoring data collected via the HSVC application from 199 preschool children aged 3 to 6 years in 2 kindergartens in Shanghai, this study investigated the associations among screen luminance, ambient illuminance during device use, and axial length in early childhood, addressing a critical gap in the existing literature regarding the impact of dynamic screen optical parameters on visual development in children. Our findings reveal a significant inverse association between higher ambient illuminance during tablet use and shorter axial length, as well as a nonlinear dose-response relationship between tablet luminance and axial length. These results elucidate the link between digital device optical exposure and axial elongation, providing robust empirical evidence to inform public health recommendations on screen use practices and ambient lighting standards in preschool children.

Relationship Between Ambient Illuminance and Axial Length

Our study identified a significant inverse association between ambient illuminance during tablet use and axial length in preschool children, aligning with findings from animal models [14]. Experimental studies in chicks and rhesus monkeys have established that light intensity modulates myopic progression [18-21]. Multiple investigations further demonstrate that increased light exposure may exert its effect by activating retinal dopaminergic activity—primarily through D2 receptor pathways—thereby regulating retinal gene expression and suppressing pro-axial elongation signaling [22-25]. The retinal

XSL•FO
RenderX

dopamine system is thus considered a potent inhibitor of ocular growth [26].

The present results align with several domestic studies investigating the role of light environment in myopia prevention. For instance, a study on elevated classroom lighting found that increasing illuminance significantly slowed axial elongation and reduced the incidence of myopia among school-aged children [27]. Similarly, a cluster randomized trial in Shanghai using objective monitoring showed that increased outdoor time and sustained high-intensity light exposure delayed axial elongation [28]. Together, these studies support a protective role of light exposure against axial growth. Our study extends this evidence from "macroenvironmental" settings to "microenvironments during screen use," refining the understanding of light exposure effects.

Complementing this mechanistic context, it is important to recognize that not all studies of indoor optical environments have detected an effect on refractive development. For instance, a school-based comparison of high-daylight versus low-daylight classrooms reported no overall difference in 6-month changes in refractive error or axial length, with effects limited only to a baseline subgroup characterized by short axial length [29]. Similarly, an independent population-based analysis found no association between exposure to ambient nighttime lighting during infancy and later myopia [30]. These inconsistent outcomes may be attributable to methodological and contextual differences. The former study used classroom-level daylight factors—a distal and nonspecific metric—which may not accurately capture retinal light exposure during near-device use. Furthermore, the study was conducted in a specific ethnic and educational setting (Korean schoolchildren), where genetic predispositions and academic pressures may modulate the effects of light exposure. The latter study examined nighttime lighting exposure in infancy. This differs fundamentally from daytime ambient light during visual tasks in its spectral composition, exposure timing, and biological mechanisms. Furthermore, the cohort primarily comprised White participants, who have a distinct genetic background from Asian populations. These methodological and demographic differences may collectively account for the heterogeneity observed regarding the association between light exposure and myopia.

It is noteworthy that typical indoor illuminance experienced by humans rarely exceeds 1000 lux and is usually much lower, often within the range of 100 to 500 lux [31]. According to standards set by the International Organization for Standardization and the International Commission on Illumination, as well as China's national guidelines (GB 7793 - 2010) on classroom lighting, the recommended threshold for children's indoor ambient illuminance is 300 lux [32,33]. In our findings, the median ambient illuminance during tablet use for 174 children was below 300 lux, with an overall median of 134.77 (IQR 67.74-221.65) lux, indicating that the ambient lighting conditions when participants used electronic devices were generally lower than internationally recommended standards. Nevertheless, we still observed a robust association between ambient illuminance and axial length, underscoring the critical role of environmental lighting in ocular development. Suboptimal lighting may fail to provide adequate visual comfort and could contribute to visual fatigue or other adverse effects on visual development. The widespread prevalence of insufficient ambient lighting during device use is concerning, as it represents a potentially modifiable environmental risk factor for myopia in children. Given the increasing reliance on digital devices in early childhood, our findings highlight the urgent need for evidence-based guidelines on ambient lighting for children to mitigate potential risks to visual health and development.

However, our results diverge from some previous reports, suggesting that ambient illuminance has no significant effect on visual fatigue [34]. This discrepancy suggests that the mechanisms underlying short-term visual discomfort and long-term regulation of axial growth may differ and warrant separate investigation. While short-term visual fatigue is likely associated with transient visual stimuli and ocular muscle strain, long-term axial elongation is influenced by a complex interplay of factors, including light-mediated regulation of ocular signaling pathways. From the perspective of long-term axial development, our study provides novel evidence for the impact of ambient illuminance on children's visual health.

Relationship Between Tablet Brightness and Axial Length

Using RCS with knots at the 10th, 50th, and 90th percentiles of the exposure distribution, we identified a significant nonlinear association between median tablet brightness and axial length after adjustment for sociodemographic, behavioral, and developmental covariates ($P_{\text{nonlinearity}}$=.004). At lower levels of tablet brightness (with a median tablet brightness <27 cd/m²), increases in brightness are accompanied by a deceleration in axial length growth ($\beta<0$), suggesting that very dim screens may accelerate eye growth, whereas moderate brightness increases could help mitigate excessively rapid axial elongation. When tablet brightness exceeds a certain threshold (median tablet brightness >27 cd/m²), further increases in brightness result in an acceleration of axial elongation, with excessively high screen brightness stimulating abnormal axial growth. When tablet brightness reaches a critical threshold (median tablet brightness=56 cd/m²), the rate of axial elongation peaks. Excessive brightness can cause glare or strong light stimuli, disrupting normal physiological eye development and accelerating axial elongation, which may worsen myopia progression [13]. In this study, the median tablet brightness was 56 cd/m² (P25=47 cd/m² and P75=63.25 cd/m²), falling within the critical range that may influence ocular growth.

These findings align with the "parabolic or inverted U-shaped dose-response curve" described in previous ergonomic studies regarding screen brightness, visual performance, and discomfort symptoms [15]. At very low brightness, children may reduce viewing distance to maintain visibility, increasing accommodative demand and potentially stimulating axial elongation. Moderately increased brightness may improve legibility and allow for more comfortable viewing distances, corresponding to the observed negative marginal effect below 27 cd/m² [35,36]. Within the midrange, heightened brightness during sustained near-work may provide stronger visual signals associated with axial elongation, resulting in a positive marginal

XSL•FO
RenderX

effect that peaks near 56 cd/m² [35,37]. At even higher brightness, discomfort and incipient glare may prompt self-regulatory behaviors—such as microbreaks, blinking, or adjustment of posture or gaze—that could attenuate the marginal effect, consistent with the decline in the fitted curve at high brightness levels [37-39]. This nonmonotonic pattern aligns with ergonomic literature in which display brightness often exhibits nonlinear relationships with both performance and discomfort [15,40]. To our knowledge, this is the first study to quantitatively characterize a nonlinear dose-response relationship between objectively measured tablet brightness and axial length in children, addressing a significant evidence gap in this field. This finding is also consistent with the "light dose-axial plasticity" effect reported in domestic studies on optical interventions. For instance, a randomized clinical trial in 10 primary schools in Shanghai demonstrated that repeated low-level red light therapy reduced the annual axial elongation rate in children from 0.47 mm to 0.30 mm over 12 months, alongside a significant decrease in new-onset myopia [41]. Although repeated low-level red light represents a therapeutic intervention fundamentally distinct from daily screen-based illuminance, its outcomes clearly indicate that the mode and dosage of light stimulation can structurally influence axial elongation. This lends biological plausibility to the nonlinear association between screen brightness and axial length observed under naturalistic conditions in our study and further supports the notion that optical parameters play a modifiable and nonlinear role in axial eye growth.

More importantly, the study identifies a relatively "safe" brightness range for children's use of mobile devices, within which axial elongation remains stable and the impact on myopia progression is minimal. To translate these key findings into practical application, device manufacturers should implement child-specific brightness-limiting features that cap maximum screen luminance below 56 cd/m², incorporating ambient-adaptive safeguards to prevent exceedance of this threshold and thus reduce the risk of excessive axial elongation. Caregivers should be advised to maintain screen brightness within the empirically derived safe range identified in this study and to encourage regular, timed breaks during prolonged use to minimize potential adverse effects on visual development. These results provide robust scientific evidence to support public health guidelines for optimal screen brightness settings in both educational and household environments.

Limitations

Several limitations of this study should be acknowledged. First, the cross-sectional nature of this study precludes any causal inferences. Future prospective studies are needed to determine whether reduced ambient illuminance directly accelerates axial elongation and to clarify causal relationships among relevant factors. Second, our sample was limited to children in Shanghai, potentially restricting the generalizability of our findings to populations with different screen usage habits. Future research should extend to larger and more diverse cohorts across various regions and populations to enhance external validity. Additionally, although we attempted to control for covariates, such as the duration of outdoor activities and unmeasured confounders—including genetic predisposition and dietary factors—may partially account for the observed associations. Future research should address these factors to comprehensively elucidate the determinants affecting axial eye development in children. Finally, as cycloplegic refraction was not performed in this study, the accuracy of refractive error measurements was limited. Therefore, axial length was selected as the primary outcome. In future research, we will refine the methodology by incorporating cycloplegic refraction to enable a more comprehensive evaluation of the effects of ambient illuminance on children's visual health.

Conclusions

This monitoring study demonstrates a significant association between both ambient illuminance and tablet screen brightness with ocular axial length in preschool children, with a nonlinear dose-response relationship observed for screen brightness. These findings underscore the importance of optimizing both environmental lighting and device settings to safeguard early childhood visual development and inform evidence-based guidelines for digital device use in preschool children.

Acknowledgments

The authors would like to extend our sincere appreciation to Huawei for developing the intelligent monitoring software used to assess children's screen exposure in this study. The authors are also deeply grateful to the kindergarten teachers from Pudong New District and Xuhui District for their invaluable assistance, as well as to all the participants and their families for their contributions to this research.

Abstract

Background: There is an unmet need for reliable medication stability information to avoid suboptimal administration of intravenous medications, which may lead to reduced efficacy of therapy and potential patient harm through medication degradation or incompatibilities that cause vascular access issues.

Objective: This study aimed to develop evidence-informed guidance for pharmacists and nurses on the use of administration line materials, in-line filtration, and light protection during storage and intravenous administration of medications commonly used in critical care and oncology.

Methods: An initial list of 181 medications was compiled in consultation with pharmacist stakeholders from critical care and oncology specialties. A modified Delphi study was conducted over 3 rounds with a panel of 8 expert pharmacists selected for their clinical expertise, professional experience, and geographic location to ensure representation of diverse health care settings and medication administration practices. Panelists anonymously ranked statements on a 5-point Likert scale developed from a review of the literature with respect to the requirement for a specific administration line material for each medication; the need for, and type of, filtration required during administration; and the need for light protection during storage and administration of medications. After each round, items achieving 80% consensus were finalized. Those that did not achieve consensus were carried forward to the next round. This iterative approach allowed panelists to reconsider their ratings based on emerging group consensus and additional evidence shared by panelists between rounds.

Results: A total of 1044 administration and storage requirements were assessed for a final list of 174 medications. In round 1, consensus was reached for 613 (58.7%) statements, with every statement being addressed and scored by the panelists. Panelists provided additional evidence sources for their decisions, and these were distributed to all panel members for round 2. All items were addressed and scored by the panelists. By the conclusion of round 3, consensus had been achieved for 697 (66.8%) statements, with all items being addressed and scored by the panelists.

XSL•FO
RenderX

Conclusions: This study developed consensus-based recommendations for the selection of administration line materials, the use of in-line filtration, and light protection for the administration and storage of a range of medications administered intravenously. The guidance will aid medication stability and efficacy and promote good clinical practice; it currently underpins a prototype bedside app for correct intravenous administration line selection for nursing and pharmacy staff in critical care and oncology units.

administration; consensus; panels; reviews; protection; panelists

Introduction

Pharmacists are considered, by both medical and nursing staff, to be the arbiters of administration knowledge for intravenous (IV) medications. Knowledge of administration line material types and their associated requirements, including light protection and filtration, has been reported to be poor, even among nurses working in specialist disciplines [1]. This is despite approximately 40% of nursing time being devoted to medication administration [2]. In a survey of Spanish nurses, 80.8% of respondents reported having "a good level of knowledge on the preparation and administration of IV medicine," although 88.1% also reacted positively to statements on the need to improve their skills [3].

While pharmaceutical manufacturers provide guidance on the storage and protection of parental medications, there is generally much less information available to the end user after reconstitution or following compounding processes. Furthermore, preparation of IV medicines takes place in many locations across facilities, and information should be provided for their mixing and administration across many medical specialties. Some health systems provide medications compounded in the pharmacy or by a commercial compounder, in which cases, the package inserts may be unavailable for consultation by the nursing staff who administer the medication. Conversely, in many health systems, most IV medication preparation is undertaken by nurses in the clinical area without direct pharmacist support [4], and often package inserts or supporting guidelines do not offer information on storage and handling after reconstitution. For example, there may be an assumption that medicines prepared on the ward will be administered immediately, but this is not always the case.

An extensive survey of sterile compounding errors in American hospital pharmacies indicated that wrong preparation techniques, including the attachment of an incorrect administration line, were identified in 26% of compounding errors [5]. A key contributory factor to these findings was the lack of standardized processes. The need for systems-focused interventions, including standardized pathways, has been recognized as a key concept in driving efficiency and sustainability in cancer care [6]. A substantial component of such tools would be dedicated to improved compounding processes, final-product preparation, labeling, and the provision of information [7].

There are many variables to consider when developing standard practice guidelines for medication preparation and administration, and these differ depending on where and how the medication is prepared for administration. However, with the assumption that most preparation occurs at the bedside and that, once a medication is reconstituted or diluted, members of the health care team need a practical reference guide for IV medication stability, the requirements for such a clinical reference fall broadly into the following 3 categories: the need for filtration, the need for protection from light during storage and administration, and the material composition of administration systems—syringes, bags, and lines. These factors are essential for maintaining medication stability and effectiveness, yet this information is often missing from standard drug references.

Additionally, there are 3 potential medication-material interactions: absorption into the administration line, adsorption onto the administration line, and leaching or migration of materials into medication solutions. Reduced efficacy of medications due to product degradation is a concern because it has the potential to directly impact patient care and management and affect treatment outcomes associated with regimens and individual medications. Vascular access issues, patient condition, or delayed laboratory results can cause delays in medication administration in both critical care and oncology treatment centers [8].

Such delays may be important in terms of the integrity of the compounded solution if it is sensitive to light exposure or affected by contact with administration line material.

The deleterious effect of light on some compounds, such as parenteral nutrition, is well known [9], but the effect of light on other medications is less well established. Approximately 30% of the degradation of clear medication solutions due to light may occur in the line or tubing of the infusion set [10], and this would logically increase at very low flow rates.

There is also an aspect of pharmaceutical waste in these circumstances, whereby medications that are not administered may be discarded because of uncertainty regarding their stability outside the controlled environments in which they are stored and prepared.

There is an unmet need for reliable and unambiguous medication stability information to support clinical decision-making at the bedside. This study aimed to develop guidance for different types of administration lines, in-line filtration, and light protection during storage and administration through a review by subject matter experts of available evidence for 181 IV medications commonly used in critical care and oncology.

Methods

Overview

The stability of IV admixtures is fairly well studied; however, the literature on this topic is vast and often contradictory. Therefore, we sought expert consensus to inform pragmatic information for clinicians and conducted a 3-round Delphi study. The Delphi approach is considered a powerful method that can deliver agreement in areas of uncertainty or where definitive evidence is lacking, and it allows expert opinion to emerge through consensus [11-13].

We formed a panel of 8 subject matter experts, identified for their professional experience, geographic location, patient population served, and compounding processes and workflows used in practice. The panel represented practice and expertise from Europe, the United Kingdom, and Australia, and practice in hospitals, manufacturing units, and academia. The panel also represented pediatric practice, critical care, oncology and palliative care. The panel members were selected by the lead author (AD) and study facilitator (JW), but the panel was otherwise anonymous. Initial agreement to participate was secured by email exchange and a formal letter of commitment. AD acted as chair of the panel and oversaw data analysis and the mitigation of disagreements in later stages.

Our modified Delphi process ran over 3 rounds. After 2 rounds, a further review was conducted by panel members who were considered outliers with respect to consensus. They were shown the anonymized scores of other panel members who had reached consensus. In addition, the panel chairperson (AD) and cochairperson (PT) reviewed these results and had casting votes. The reason for this approach was that, while local practice was actively sought as a constructive contribution to the Delphi panel, it might also act as an anomaly if practitioners had not been exposed to recent evidence regarding an individual medication. In this way, it was hoped that the Delphi panel process would itself facilitate consensus by sharing knowledge and challenging assumptions. Outlier selections by only one panel member were subject to the casting votes of the chair and cochair, but, as noted later, this only extended to exposing the panel member to the scores of other (still anonymized) Delphi panel members and encouraging further review of their selection. This modification of the Delphi technique is in line with current thinking on the process, which advocates “controlled feedback” [14].

Panel members were presented with an evidence dossier of 181 IV medications (presented by their recommended international nonproprietary names) and a library of literature to support assessment and opinion development. The following references were used to build the dossier:

1. Stabilis.org (independent pharmacy advice system) [15]
2. Medicines and Light, Oslo University [10]
3. University of Illinois at Chicago College of Pharmacy, Drug Information Group, with the 2023 update used upon publication [16,17]
4. Manufacturer package inserts
5. Individual independent scientific studies addressing specific medications and research on material compatibility, filtration, and light protection requirements

Sources 1 to 3 were selected because they were either recently published or updated frequently. Source 4 was selected as these are the evidence presented to and accepted by regulatory bodies. The independent scientific studies (n=5) were obtained via individual medication name searches undertaken in PubMed, Google Scholar, and under searches using specific search terms related to administration line materials. Evidence sources were evaluated according to time since publication and the strength of their conclusions. Where multiple sources were available, literature that most closely met the above criteria was selected. A sample of the evidence dossier is given in Multimedia Appendix 1.

Delphi panel members were instructed to work independently to determine their own opinions regarding the administration requirements of each medication with regard to material selection of the administration line, the need for protection from light during storage and administration, and the need for filtration of the product during administration. They were advised to use real-world assumptions to guide their deliberations: there may be delays between compounding and administration due to compounding processes, such as batching and preparation ahead of time, and patient-related factors (such as vascular access issues) could lead to an extended period during which the infusion would be exposed to light and possible administration line material interactions.

The threshold for consensus across the 8 panel members was set at 80% for each question asked. After each round of questions, those medications and their administration characteristics that reached 80% consensus were removed from further rounds. In the third (and final) round, the chair approached those panelists who were outliers in their responses. These panelists were shown the anonymized decisions of other panel members and asked whether they wished to reconsider their responses. Four medication profiles were resolved using this process, with 1 panelist per medication (3 individual panelists overall) being identified as an outlier.

The role of the chairperson was to oversee data analysis, identify and remove items that had reached consensus at each round, and field comments, questions, and queries from panel members. Panel members were also encouraged to identify and present new evidence if, within their scope of experience, they felt it was relevant, but the chairperson made decisions on the inclusion of this new data.

Ethical Considerations

Given the absence of human participants or their data and the noncontentious nature of the questions being asked, the study was undertaken as a service evaluation. All variables in the worksheets were vendor-neutral. Panel members received reimbursement for their time. Individual participation by panel members was undertaken under the supervision of the Ethics and Compliance Department of Becton, Dickinson and Company and according to the Becton Dickinson Global Standards for Interactions with Healthcare Professionals, Healthcare

XSL•FO
RenderX

Organizations, and Government Officials (effective March 1, 2022) and the Becton Dickinson Global Interactions with Healthcare Professionals Policy (effective October 1, 2019). Reimbursement and the expected duration of the work involved were agreed upon through four standard operating procedures for engagement of health care professionals according to this policy:

1. Calculation of a reimbursement fair market value (hourly rate) according to profession, qualification, standing, and geography
2. Cosigning of a master services agreement stating the fair market value and general conditions of engagement
3. A cosigned statement of work stating the task to be undertaken and the expected duration of the activity
4. A cosigned privacy agreement stating the rights of panelists regarding data protection under the General Data Protection Regulation: Regulation (European Union) 2016-679 of the European Parliament and of the Council of April 27, 2016

Delphi Procedure

Panelists were provided with 3 worksheets created in Microsoft Excel (version 17). Each worksheet considered a different aspect of the administration or storage of the medication—material of the final administration line, protection from light, or the need for terminal filtration at the point of administration. Panelists were presented with recommendations from the evidence dossier. Because there was likely to be variation in practice and experience, and because for many medicines, answers to the questions could be ambiguous (eg, morphine could be refrigerated or not with no impact on the stability of the end product), a binary "Yes/No" response would not have captured those medicines for which storage or administration materials were critical and those for which these factors were less important. Therefore, panelists were asked to rate the strength of their decision on a 5-point Likert-type scale. This scale ranged from 1 ("strongly disagree") to 5 ("strongly agree"). A score of 3 indicated no strong opinion. We chose a 5-point Likert scale because there is no absolute definition for the tools a Delphi panel should use, and we were interested in identifying disagreement as much as consensus. However, it was important to give panelists distinct and clear statements for evaluation [11,17,18].

Definition of Consensus

Classically, Delphi panel methods accept consensus at ≥70% for individual-item removal from subsequent rounds [18]. This is commonly because there is a dearth of empirical evidence in areas where the technique is applied [19]. Given the importance of appropriate administration practice, the accepted threshold for consensus in this study was set at 80%. Likert weighting was used as the first point of assessment of the overall panel response. This required median scores of 1 to 2 (negative) or 4 to 5 (positive) on the Likert scale to be considered a collectively valid response to the statement being reviewed. The degree of consensus was calculated using the SD of the panel members' scores. Percentage consensus was then derived using the Excel formula:

Consensus percentage=(1–SD/2)×100

In practice, it was found that, for items where the median did not reflect a strong opinion (median >2 and median <4), the SD was also always >0.4, giving a consensus score of less than 80%.

After the first round, items with ≥80% consensus were removed from review. Comments from panel members in round 1 were reviewed by the chairperson and cochairperson, which led to the removal of several medications. For example, moxetumomab was deleted based on its removal from the European market in 2021 and from the US market in 2023 [20].

Panel members also offered further evidence sources for their score selection in round 1. The chairperson and cochairperson added these to the second-round review. Therefore, the evidence base grew and could alter opinions and gain more consensus through subsequent rounds. For the remaining items, each member's scores were returned to them in a workbook with instructions to review them as in round 1, and to apply any change they felt was appropriate to their score.

After round 2, items with ≥80% consensus were removed from further analysis. Items were identified for which a maximum of 2 panel members' determinations were outside the consensus (ie, outliers). Mini-review sheets were created for individual panel members whose scores for individual medications were outliers, and all panel members' scores (aggregated while maintaining anonymity) were revealed to the outlier panel member. The chairperson and cochairperson also rated these medications, effectively using their casting votes for these medications only.

After this final round of review, the process was closed, with items with >80% consensus being carried forward as clinical end-user guidance.

Results

Following the removal of medications no longer marketed, 174 medications were assessed. Of the 1044 IV medication administration requirements assessed, there was ≥80% consensus for 613 (58.71%) items after round 1, rising to 697 (66.76%) items after 3 rounds. The number of definitive and nondefinitive recommendations achieving ≥80% consensus for each attribute assessed is shown in Table 1.

XSL•FO
RenderX

Table 1. Number of definitive and nondefinitive recommendations (N=1044)[a].

Recommendation category	Definitive recommendations (≥80% consensus; n=697), n (%)	Nondefinitive recommendations (<80% consensus; n=347), n (%)
Di(2-ethylhexyl) phthalate–free polyvinyl chloride administration set	132 (75.86)	42 (24.14)
Polyethylene administration set	123 (70.69)	51 (29.31)
Polypropylene administration set	93 (53.45)	81 (46.55)
In-line filtration		
0.2-µm filter	16 (9.20)	10 (5.75)
1.2-µm filter	2 (1.15)	1 (0.57)
0.2- to 1.2-µm filter	1 (0.57)	2 (1.15)
0.2- to 5-µm filter	1 (0.57)	0 (0)
15-µm filter	0 (0)	2 (1.15)
No filter required	131 (75.29)	8 (4.60)
Light protection during storage		
Yes	76 (43.68)	41 (23.57)
Not required	26 (14.94)	31 (17.81)
Light protection during administration		
Yes	8 (4.60)	62 (35.64)
Not required	88 (50.59)	16 (9.17)

[a]For full output by each assessed medication, refer to Multimedia Appendix 2.

Table 2 illustrates how consensus and no-consensus conditions were determined. Some consensus issues were due to highly conflicting (and sometimes emerging) evidence. This highlighted how the final consensus opinion could diverge strongly from the initial evidence statement presented to the panelists for review. This was most commonly seen in the sections related to light protection during administration and filtration.

Discussion

Principal Findings

We have generated an extensive list of medications, with recommended administration sets and storage and handling requirements, that can be applied at the bedside to potentially improve access to high-quality medication information. The Delphi panel method proved to be a useful tool for creating consensus-based guidance for clinicians administering IV medications, many of which might be considered specialized therapies. The study goal was achieved by creating a distilled and easy-to-understand guide. The guidance is comprehensive for the parameters reviewed, and its basis in published evidence and professional expertise should provide clinicians with confidence in any tool within which it is subsequently deployed. Furthermore, by distilling a diverse range of sources into a single output, we potentially mitigate some of the idiosyncrasies commonly present in localized clinician assessments.

There is potential for this tool to reduce avoidable medication waste and unnecessary storage, which supports health care initiatives aimed at improving sustainability and efficiency. This is additionally important given the financial burden of medication waste on health care systems and patients [19].

The panel made a collaborative decision during a final open meeting on the required frequency of review of the medication list, based on likely changes in the evidence base, new administration line materials, and new medications entering the market. This was set at 24 months, which is within the review timing of other medication review sites, such as the National Injectable Medicines Guide in the United Kingdom [21]. The assessment of new medications, either requiring an interim decision between formal reviews or addition to the "pending" list for future panel review, is possible based on local experience and the review of dashboard sites, such as the UK National Institute for Health Research Innovation Observatory [22].

Limitations

There are limitations to the study. Only the most common administration line materials and those most readily available to clinicians were considered to ensure real-world guidance. New medications may be introduced, while established medications may be withdrawn, and the evidence base for their administration requirements is changing. Line material is also

XSL•FO
RenderX

evolving. For example, thermoplastic polyurethane is expected to replace polyvinyl chloride (manufactured without di(2-ethylhexyl) phthalate). No study can be exhaustive, but a review period of 24 months was considered by the panel to be sufficient to cover these changes in the environment. It is also difficult to cover, in any study or review, all regions and countries. There was no panel member from North America, but there was a strong reliance on evidence presented to the Food and Drug Administration.

There was no consensus for just over one-third of the medications assessed. Therefore, the global nature of the panel highlighted a diversity of opinion and reflects the issues faced by compounding pharmacists and nursing staff. These unresolved medications can be prioritized in the planning of the next Delphi panel (ie, at the 24-month review period). The potential for machine learning to assist in synthesizing evidence dossiers for these medications could include incorporating evidence from languages other than English. A wider catchment of generic manufacturers' package inserts and extracts from industry publications could also aid in the creation of consensus for these medications. Our general advice for these medications is to follow a conservative approach for light protection during storage, and to consider the duration of infusion when determining whether light protection is needed during administration. For filtration, there is emerging evidence that higher-concentration infusions used at lower rates [23], and the use of 1-lumen for multiple infusions may contribute to vascular access occlusion, and that the use of 0.2-µm filters may reduce this risk [24,25]. Reviewing medications at high and low concentrations, and the effect of concentration on the need for specific line materials, filtration, and light protection, could be included in subsequent reviews.

The dossier of evidence was prepared by JW and AD. Given the extent and variety of the evidence reviewed, it is inevitable that omissions were made. This was evident in the panelists' recommendations to incorporate new medications or remove those that were no longer actively marketed. In the future, these dossiers should be coproduced by a broader panel of experts, independent of the Delphi panel.

A further important limitation lies in the Delphi process. Delphi exercises are labor-intensive, and there is evidence that cycles of consensus reach diminishing returns once they extend beyond 3 cycles [26,27]. There is also the potential for bias within the panel; however, its members are selected, and it is impossible to ensure that the outcome would be the same if panel membership were different. Therefore, we must reiterate that this tool is not a universal consensus but is representative of the views of the 8 subject matter experts who took part.

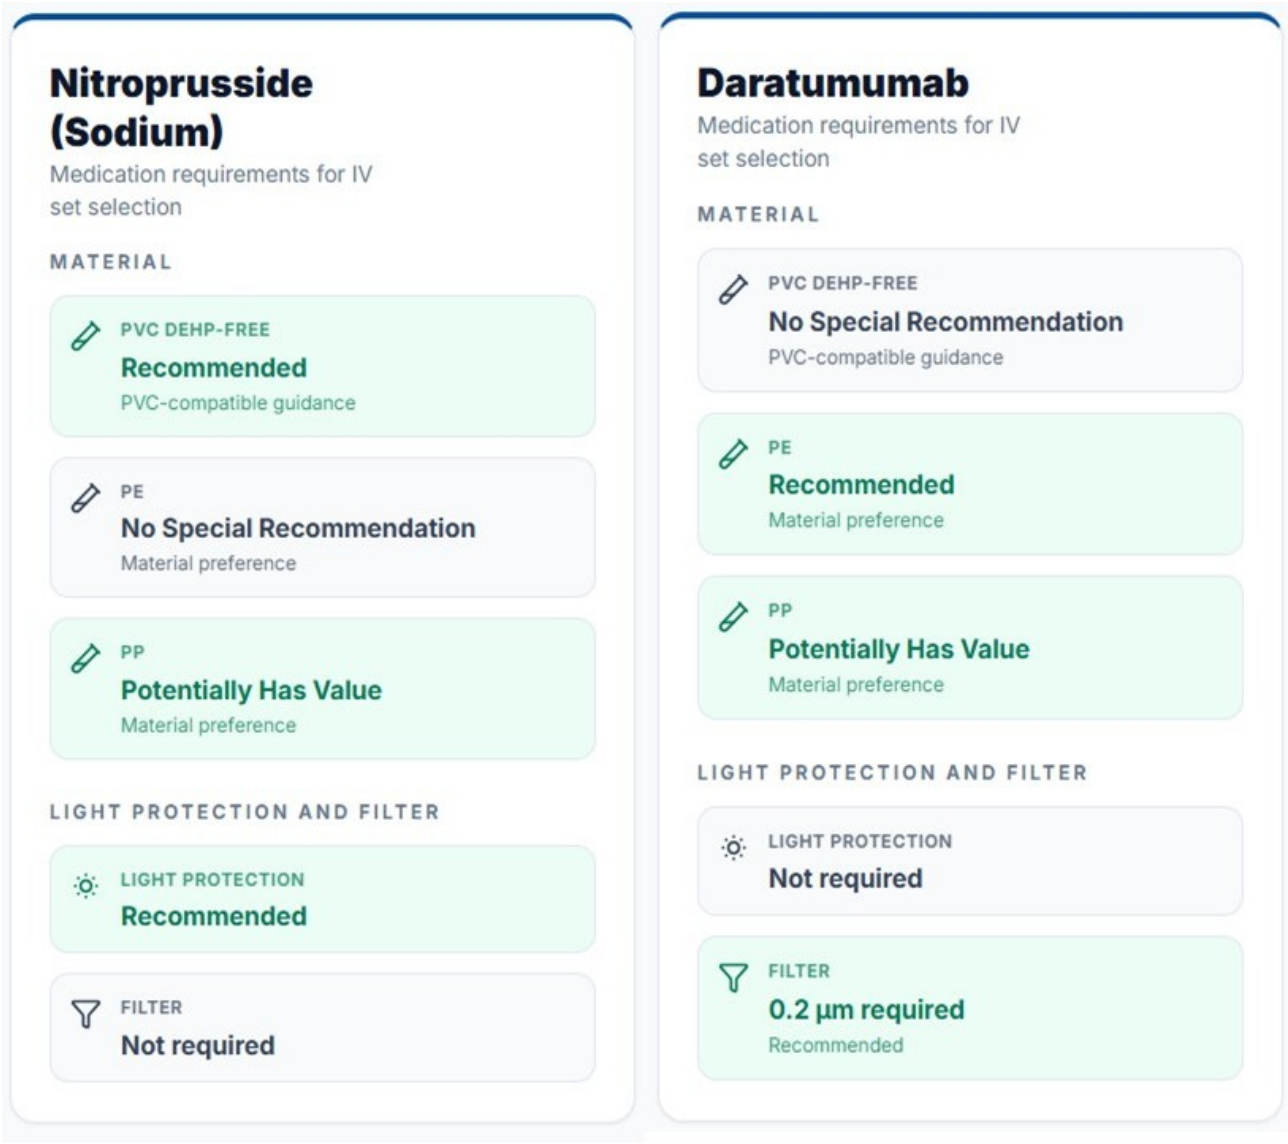
Generic manufacturers are allowed—and often do use—different inactive excipients in their formulations. Excipients can influence properties, such as solubility, pH, particulate formation, adsorption to plastic, or light sensitivity. Therefore, 2 generics labeled as "the same drug" may behave differently. The ultimate goal would be to consult each generic's prescribing information or stability study, as uniform performance across all brands cannot be expected. In this work, we had to narrow down the scope of validity to the sources we have used in our dossier.

Recommendations for Future Research

While we have produced an outline framework for decision support for these medications, it has not been tested for utility in real-world settings. Therefore, we recommend a program of study evaluating the utility of this tool in health care practice environments. There are also myriad ways in which this can be deployed, either as simple lookup tables in low-resource settings or through integration into electronic patient records and prescribing systems.

Conclusions

We feel that our approach of restricting ourselves to the fundamental information required by bedside clinicians was vindicated, as casting the net wider to include other parameters, such as concentration and solvent, would arguably overcomplicate the output we were seeking from the study and any tools derived from it. Our experience here matched that of other authors who found that the "temptation to be comprehensive by including every theoretically possible scenario may be counterproductive. Also, being selective allows larger numbers of cues to be considered explicitly, which should be an advantage in terms of reliability" [17]. As noted previously under the "working assumptions" in the Methods section, panel members were instructed to use the most conservative scenarios for each medication being assessed; for example, higher-concentration solutions would be assessed as part of the requirements for filtration, administration line material, and light protection.



One immediate step that could use the results of the consensus study would be to label sterile compounded products with information for the end user, such as "protect from light during storage and administration."

The output of the study is also being used to underpin algorithms for a Python-based prototype bedside app through which clinicians can identify the correct administration line characteristics required for both primary and secondary administration after entering the medication name into the app. Such a tool could also help address the perennial problems of clinicians spending considerable amounts of time looking for information and guidance or addressing knowledge and information deficits with recalled facts gathered from past experience, including informal and formal teaching, interactions with colleagues, and the traditions of care within the unit where they work [28]. This was one reason we prioritized simplicity in our project plan and method, as we aimed to ensure that the results could be simply disseminated to the point of care. Given the 2022 study's findings that knowledge of administration line material type and characteristic requirements (light protection and filtration), even among specialist nurses, was poor [1]; the immense (and well-established) challenges associated with cascading information through organizations [29]; and the fact that end users would be predominantly nurses (the largest component of the tertiary health care workforce), such a point-of-care line selection tool could be very valuable [30].

XSL•FO
RenderX

We hope to fully evaluate this bedside tool in a study within the next year. In its current unreleased form, a medication can be selected on a smartphone app from a drop-down list of the medications on which consensus was secured, and the required properties of the line in terms of material, light protection, and filtration are displayed (Figure 1). This will need to be extended to the inventory of administration lines and IV infusion pumps available to the end user to direct them to the most appropriate options for the administration of the medication.

Figure 1. Screenshots of a prototype app to be used bedside for selecting administration line characteristics.

Acknowledgments

The authors acknowledge the contribution of Dr Eng Khalil Rafiq Al-Battat to the development of the initial prototype administration line selection tool shown in Figure 1.

Funding

The study was sponsored by Becton, Dickinson and Company. The study did not specifically address any product manufactured or distributed by Becton, Dickinson and Company, and was undertaken as a clinical and quality-of-care improvement exercise. The evidence dossiers were compiled by the Medical Affairs Department of Becton, Dickinson and Company. The dossiers, as noted previously, were compiled from the scientific literature, pharmaceutical manufacturers' package inserts, and independent pharmacy advice systems. No evidence was drawn from Becton, Dickinson and Company internal sources. The Medical Affairs Department operates as a distinct arm outside the commercial operations of the company.

Authors' Contributions

Study planning, conception, and design were undertaken by AD, PT, and JW. Data acquisition and dissemination were undertaken by JW. Initial manuscript drafting was undertaken by AD, PT, JW, RT, and AS. A Delphi panel review of each evidence monograph was undertaken by PT, AS, RT, RA-J, ME-H, JS, and IT-S. Review of the final manuscript and revisions in response to peer review were undertaken by AD, JW, PT, AS, RT, RA-J, ME-H, JS, and IT-S.

Conflicts of Interest

JW declares no conflicts of interest other than his employment in the Medical Affairs Department of Becton, Dickinson and Company. All other authors declare no other conflicts of interest.

Abstract

Background: Insufficient engagement in moderate to vigorous physical activity (MVPA) is a significant risk factor for major noncommunicable diseases, including cardiovascular diseases (eg, coronary heart disease and stroke), type 2 diabetes, and several cancers. Physical inactivity accounts for an estimated 3.2 million deaths annually. Office employees, due to their sedentary and desk-based work patterns, are particularly vulnerable to low MVPA levels, which negatively affect health and work productivity. The COVID-19 pandemic exacerbated these issues, further reducing MVPA levels due to lockdowns and work-from-home policies. Although numerous interventions have aimed to promote MVPA, many lack theoretical grounding, stakeholder involvement, or systematic development frameworks. A theory- and evidence-informed approach is warranted to target modifiable determinants and mechanisms, improve coherence and replicability, and enhance effectiveness and scalability.

Objective: This study aimed to design an evidence-based blended intervention to improve MVPA, health, and productivity among office employees, guided by the intervention mapping (IM) framework.

Methods: Following the first 4 steps of the IM framework, we developed a 12-week blended intervention and created a website named “Smartly Active for Health and Life.” Step 1 involved a needs assessment through a literature review and focus group discussions (n=12 office employees) to identify barriers, facilitators, and determinants of MVPA. Step 2 defined intervention

XSL•FO
RenderX

outcomes, performance objectives, and change objectives based on the social ecological model. Step 3 integrated theory- and evidence-based behavior change techniques with delivery methods, resulting in a 3-group randomized controlled trial design: (1) a blended intervention group (web-based sessions and e-workshops), (2) a web-only intervention group, and (3) an active control group. Step 4 developed and refined intervention materials and protocols through a pilot study (n=18). Key behavior change techniques included problem-solving, goal setting, self-monitoring, and habit formation.

Results: The pilot study demonstrated the intervention's acceptability, feasibility, and adaptability. Participants reported increased motivation, improved knowledge of MVPA benefits, and greater confidence in goal setting and self-regulation. Feedback led to refinements such as improved website navigation and interactive content. The intervention is expected to enhance MVPA levels, health, and work productivity by addressing both motivational and volitional phases of behavior change while supporting habitual behaviors.

Conclusions: The IM framework offered a systematic and iterative approach for developing a blended MVPA intervention tailored to the needs of office employees. This study highlights the importance of theory-driven and stakeholder-informed approaches in designing scalable and sustainable health promotion programs. The intervention has the potential to address the critical public health challenge of physical inactivity in office settings and serves as a model for future behavior change interventions.

KEYWORDS

physical activity; intervention mapping; behavior change; theory and evidence-based; intervention development; intervention design

Introduction

Physical inactivity is a leading risk factor for global mortality, contributing significantly to common noncommunicable diseases and increased health care burdens [1]. Regular moderate to vigorous physical activity (MVPA) mitigates such risks, improving physical and mental health, work productivity, and overall well-being [2-4]. World Health Organization (WHO) guidelines recommend that adults aged 18 to 64 years engage in 150 to 300 minutes of MVPA per week, but approximately 1.8 billion adults (31% of the global adult population) do not achieve this recommendation [5,6]. A systematic review revealed that working adults engage in an average of 14.7 minutes of MVPA daily, with office employees exhibiting the most sedentary behavior due to their desk-based work and daily tasks [7]. In the COVID-19 pandemic (2020 to 2022), there was a marked decrease in adults' MVPA levels due to lockdowns, closures, and limited mobility, with office employees particularly affected by work-from-home setups, leading to reductions in commuting and leisure activities [8-10].

Many theory-based and non–theory-based interventions have been developed to increase MVPA levels among adults. However, the effectiveness of such interventions remains unclear due to the substantial heterogeneity in their designs and components [11]. Furthermore, many interventions have been developed without reference to sufficient empirical evidence and have frequently failed to include key stakeholders' perspectives [12]. There is evidence that behavioral change interventions based on theoretical frameworks, empirical evidence, and stakeholder engagement are potentially more effective than those lacking a theoretical basis [13-15]. Nevertheless, few well-designed theory-based interventions have been conclusively demonstrated to be effective.

Intervention mapping (IM) is regarded as a systematic framework that guides effective decision-making throughout the development, implementation, and evaluation of evidence-based health promotion and disease prevention programs. It is a stepwise process that uses theory, empirical evidence, and community feedback to develop interventions that are effective, feasible, sustainable, and customized to the needs of the target population [16]. The six steps of IM comprise (1) conducting a needs assessment; (2) specification of intervention outcomes, objectives, and change objectives; (3) selection of theory- and evidence-based change methods and practical modes of delivery; (4) creation and refining of materials and a protocol; (5) development of an implementation plan; and (6) design of an evaluation plan.

There is an urgent need for interventions to increase MVPA levels using the IM framework to bridge existing research gaps and enrich the evidence base. While the protocol and results of the main randomized controlled trial (RCT) examining the effectiveness of the intervention have been published elsewhere [17,18], this paper focuses on the development process of the blended intervention. Specifically, it describes the application of IM steps 1 to 4 (needs assessment, intervention outcomes and objectives, intervention design, and intervention production). The final stages of the IM framework, intervention implementation and evaluation, will be detailed in separate publications.

Methods

Overview

Steps 1 to 4 in this paper involved developing and refining the intervention protocol and materials, with each step building on the results of the previous step. A book on the IM approach [16], which outlines the planning of health promotion programs, served as the foundation for the development of the intervention.

XSL•FO
RenderX

The methodology and tasks of steps 1 to 4 are detailed in Multimedia Appendix 1.

Step 1: Needs Assessment

The first step of the IM framework involved a needs assessment to identify the health problem, justify the promotion of MVPA, and determine the underlying determinants in the target population. This provided a solid foundation for designing an evidence-based and culturally appropriate intervention [16].

Planning Group

A planning group was formed at the start of the process, comprising researchers with expertise in epidemiology, statistics, health promotion, psychology, and sports science, as well as office employees from local companies. These stakeholders ensured all steps of the intervention were well aligned with workplace realities. Weekly meetings focused on planning and brainstorming, transitioning to biweekly sessions for progress tracking. However, due to challenges presented by the COVID-19 pandemic restrictions, managers had to be excluded from the group.

Literature Review

A comprehensive literature review was conducted to better understand the prevalence and effects of insufficient MVPA on health and workplace productivity, as well as the most common barriers and facilitators identified in working adults. The review also explored the evidence on theory- and evidence-based change methods and delivery modes for intervention design, which has been published elsewhere [19]. Six academic databases (Scopus, PsycInfo, PubMed, Embase, Web of Science, and SPORTDiscus) were searched for original studies and systematic reviews published in English before July 30, 2022. Search terms included topics like “physical activity,” “working populations,” “health outcomes,” and “theory-based interventions.” Governmental reports from organizations such as the WHO were also consulted to provide global context. Detailed search strategies can be found in Multimedia Appendix 2.

Focus Group Discussions

Focus group discussions were conducted to complement findings from the literature review and gain detailed insights into the barriers, facilitators, and preferences for interventions specific to insufficiently active office employees. This group was intentionally selected to ensure the study directly addressed the needs of individuals likely to benefit most from tailored interventions. Two focus groups (n=12) were conducted to explore gender-specific barriers and facilitators to MVPA [20,21]. Participants were intentionally recruited via online surveys. Of the 12 participants, 6 (50%) were female, with a mean age of 29 (SD 3.08) years. A total of 9 (75%) held a bachelor’s degree or higher, and 3 (25%) had a diploma or lower educational qualification. The participants provided informed consent to be video recorded during discussions. The focus groups, moderated via Zoom (Zoom Video Communications, Inc) due to COVID-19 pandemic restrictions, lasted 60 to 100 minutes and were facilitated by a trained qualitative researcher, with a second researcher present for note-taking and follow-up questions. The video recordings were transcribed verbatim by 2 trained investigators (AYTO and YS). The transcripts were cross-checked with the video recordings to ensure accuracy. The transcripts were reviewed and analyzed, and the research questions were used as a framework to categorize codes and derive themes from the narrative data [22]. Any discrepancies in interpretation were collaboratively discussed until a consensus was reached.

Step 2: Intervention Outcomes and Objectives

Step 2 focused on defining the desired intervention outcomes and specifying performance objectives (POs) based on the needs assessment conducted in step 1. The planning group developed a matrix of behavioral change objectives by linking these POs with the underlying determinants of MVPA identified earlier, ensuring that the intervention addressed the key factors influencing MVPA behavior.

Step 3: Intervention Design

The purpose of step 3 was to design theory- and evidence-based interventions to promote MVPA, addressing the determinants and objectives identified in step 2. This step involved selecting behavior change methods, linking them to practical applications, and specifying their implementation. The effective theories, behavior change techniques (BCTs; eg, goal setting and self-monitoring), and delivery modes (eg, web-based platforms) were identified from the literature review [19,23,24]. These findings informed the intervention’s design to ensure alignment with evidence-based practices. The planning group held additional meetings to finalize the intervention’s structure, components, and sequence, ensuring feasibility and cultural relevance within workplace settings.

Step 4: Intervention Production

Step 4 focused on preparing the intervention materials, messages, and activities, followed by a 12-week pilot study with 18 participants (6 per group, excluded from the main study) to evaluate the readability of the materials, message execution, and acceptability, feasibility, and adaptability of the intervention. The pilot study also assessed participant recruitment and outcome measures, while collecting feedback from participants and implementers. On the basis of the pilot results, the intervention materials, protocols, and implementation plans were refined to optimize delivery and ensure smooth execution.

The original study protocol [17], developed before the COVID-19 pandemic, had to be revised due to challenges caused by the pandemic. Between June and August 2022, despite reaching out to approximately 2000 companies, none agreed to participate, mainly due to concerns about COVID-19 transmission and disruptions in work routines. As a result, the original cluster-RCT design was replaced with an individualized RCT. Key changes to the study design are summarized in Multimedia Appendix 3.

Ethical Considerations

This study received ethics approval from the Research Ethics Committee of Hong Kong Baptist University (HASC/17-18/0529). Electronic informed consent was obtained from the 18 participants included in the pilot study after they were informed of the study objectives, procedures, potential

XSL•FO
RenderX

risks and benefits, data use, confidentiality protections, and their right to withdraw. Identifiable information was stored separately from research data and will be destroyed after study completion. Deidentified datasets will be retained for research purposes and may be available from the corresponding author upon reasonable request. No identifiable participant information or images are included in this manuscript or supplementary materials. Participants received HK $50 (HK $1=US $0.13 as of June 17, 2026) coupons for each completed evaluation session and a personalized physical activity and health tracking report as part of the study benefits.

Results

Step 1: Needs Assessment

The literature review analyzed 183 articles spanning observational, intervention-based, and systematic review studies. Key themes identified barriers and facilitators to MVPA participation, categorized into personal, interpersonal, and environmental levels following the social ecological model [16]. These insights, outlined in Table 1, were enriched by focus group discussions to create a tailored intervention addressing the needs of inactive office employees.

Table 1. Facilitators of and barriers to moderate to vigorous physical activity (MVPA) participation identified from literature reviews and focus groups.

	Facilitators of MVPA participation	Barriers to MVPA participation
Personal level [25-30]	• Knowledge of the benefits of MVPA (physical and mental health and disease prevention) • Self-monitoring (eg, track progress and record workouts) • Time availability (time management) • Self-efficacy and confidence • Improve sleep quality • Improve self-esteem and sense of achievement • Workplace well-being and quality of life • Being active with children	• Lack of knowledge and awareness (importance of participating in MVPA) • Lack of time or competing demands on time • Lack of motivation (eg, lack of interest and low self-efficacy) • Lack self-monitoring and goal setting • Health limitations or concerns (eg, health conditions, physical limitations, and injuries) • Psychological barriers (eg, mental health concerns, perceived lack of energy, fatigue, and concerns about sweating) • Safety concerns • Minimize exposure to infection during the COVID-19 pandemic • Unpredictable breaks and shifts (eg, certain life changes or events)
Interpersonal level [25-27,31]	• Body image and societal beauty standards • Religious and cultural norms • Mentoring and coaching (professional supervision) • Social ties • Positive support (social, emotional, and psychological)	• Lack of social support • Negative social influences (eg, peer pressure and lack of positive role models)
Environmental level [25,26,28,32]	• Accessibility of resources (eg, facilities, supportive environments, and professional supervision) • Leadership and institutional support • Supportive policies (eg, reminders for work breaks)	• Limited access to facilities, environment, and space • Lack of professional-development opportunities • Lack of institutional support • Lack of financial resources • Inclement weather (eg, rain and extreme heat) • COVID-19 pandemic policy restrictions (eg, closure of sports venues and exercise facilities to reduce infection risk)
Additional findings from focus groups	• Young, energetic, and confident • Improve work productivity • Master motor and athletic skills • Interesting and engaging • Incentives • Policies and flexible work arrangements • Environmental modifications	• No additional information was added from focus groups.

Step 2: Intervention Outcomes and Objectives

In step 2, outcomes and POs were defined, leading to the creation of a matrix of change objectives. The primary outcome was expected to be an increase in MVPA levels. The secondary outcomes were expected to be improvements in health and work productivity. The POs developed in Table 2 were aligned with the determinants identified in step 1 to construct a matrix of change objectives (Multimedia Appendix 4). For example, PO5 (Table 3) focuses on action planning and highlights determinants such as knowledge, self-efficacy, and social support.

XSL•FO
RenderX

Table 2. Performance objectives (POs) for promoting moderate to vigorous physical activity (MVPA) levels among inactive office employees.

Code	Performance objective
PO1	Possess knowledge of MVPA and its impacts
PO2	Generate motivation to promote MVPA
PO3	Monitor personal MVPA levels
PO4	Set long-term and short-term MVPA goals
PO5	Make specific action plans
PO6	Develop self-monitoring skills and capabilities (eg, progress feedback)
PO7	Evaluate goals and revise action plans
PO8	Address identified barriers with coping plans
PO9	Identify prompts and cues for being active
PO10	Prevent habit reversal (relapse prevention)
PO11	Engage in and maintain sufficient MVPA in daily life
PO12	Serve as positive role models and leaders
PO13	Seek support and motivation from family, friends, and colleagues to engage in MVPA

Table 3. Example of change objectives for performance objective PO5.

Determinant	Change objective
Knowledge	Provide employees with tools and strategies for effective time management, and training and guidance on setting specific, measurable, achievable, relevant, and time-bound goals aligned with their desired outcomes
Self-efficacy	Enhance employees' belief in their ability to create and execute action plans by enhancing confidence and providing support through skill-building exercises and positive reinforcement
Self-monitoring	Assist individuals in developing self-monitoring strategies to track their progress and adherence to action plans, such as using activity trackers, journals, or digital apps
Social support	Enhance peer interaction, foster a more supportive and collaborative environment, and encourage action planning with peers, colleagues, and family

Step 3: Intervention Design

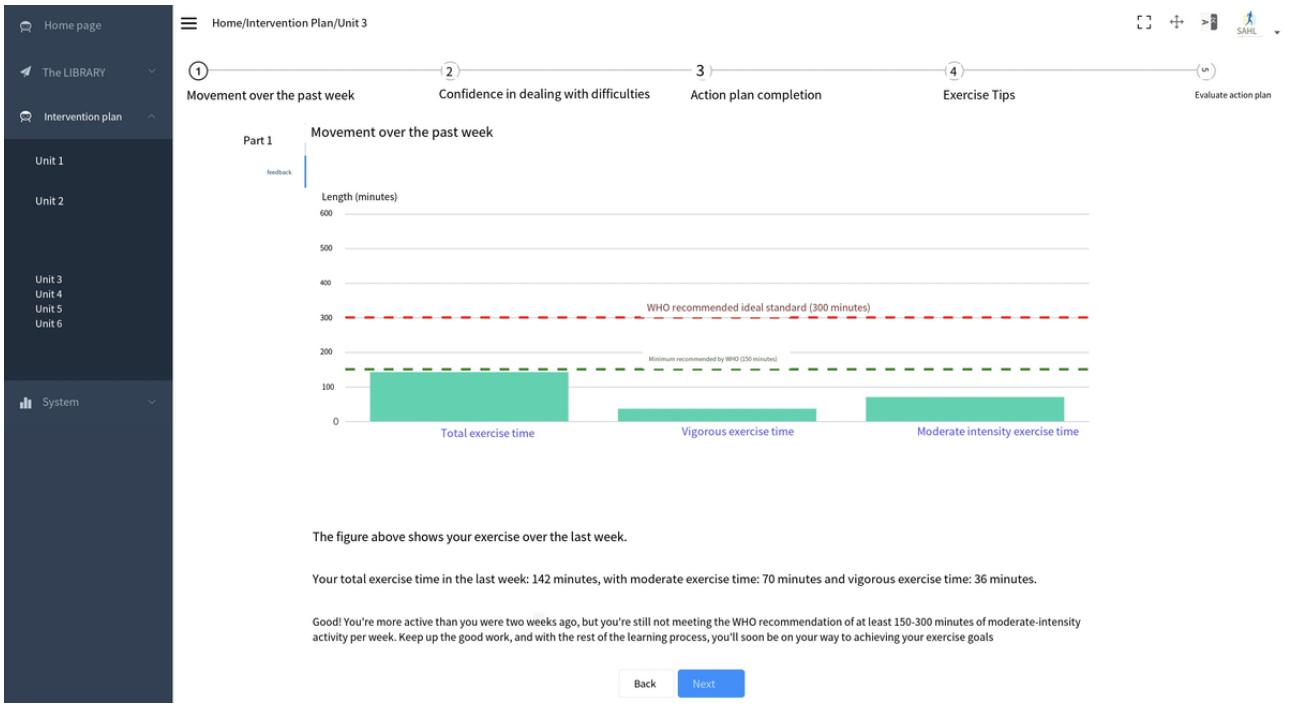
We designed a 3-group RCT consisting of a web-based intervention group, a blended intervention (web-based intervention combined with e-workshops) group, and an active control group. Web-based interventions are widely adopted for their accessibility, convenience, and ability to provide personalized content; however, these interventions are often hindered by high dropout rates and limited interactivity, which may reduce user engagement and effectiveness [33]. In contrast, workplace-based live workshops offer direct knowledge transfer, support, and interaction, which can enhance motivation and engagement [34-37]. By integrating these methods, the blended intervention aimed to combine the strengths of both approaches, improving its overall effectiveness. Additionally, insights from focus group discussions were considered when designing the intervention. Participants expressed a preference for textual content supported by a few simple and essential images, which informed the design of the web-based materials.

After specifying the change objectives, appropriate theoretical change methods were selected from the literature review [19]. To address the intention-behavior gap, our intervention incorporated dual-process theories, combining reflective (eg, deliberate self-regulation) and automatic (eg, habit formation) components [38,39]. Three complementary strategies, motivation, self-regulation, and habit formation, were integrated to enhance MVPA levels and sustained engagement. These strategies were operationalized using BCTs to ensure coherence, usability, and effectiveness [40,41]. Regarding the web-based intervention content, a detailed breakdown of the 6 sessions, including the timelines, questions asked, personalized feedback, and BCTs used, was provided (Multimedia Appendix 5). For example, in session 3 (week 5), action planning (1.4) was implemented by encouraging participants to articulate their MVPA goals by answering specific prompts, such as "What activity will you do?", "Where will you do it?", and "When will you do it?" Participants were further instructed to document their plans and place them in a visible location as regular reminders. Additionally, feedback on the evaluation and adjustment of action plans (eg, reviewing goal progress and refining prompts) helped reinforce participants' motivation and habit development.

The control group was designed as an active control, incorporating 3 BCTs: information about health consequences (5.1), social and environmental consequences (5.3), and emotional consequences (5.6) [42]. A total of 18 essays containing general, nonpersonalized information were provided to participants. Three essays were delivered every 2 weeks across 6 sessions. The essays covered a variety of topics, such as the recommended MVPA levels, the health and productivity

XSL•FO
RenderX

benefits of MVPA, the importance of time management for staying active, strategies for injury prevention, and the advantages of leading an active and healthy lifestyle. The content was factual and designed to be informative, focusing on general knowledge rather than individualized guidance.



The topics in the e-workshops for the blended intervention included understanding MVPA, building self-efficacy, establishing habits, setting goals, developing action plans, identifying barriers, creating coping strategies, using prompts, and fostering social support. Each topic was carefully designed to address participants' needs and challenges, providing a comprehensive framework to encourage long-term engagement in MVPA. To enhance the effectiveness of these workshops, 4 additional BCTs were applied: problem-solving (1.2), instruction on how to perform the behavior (4.1), reattribution (4.3), and mental rehearsal of successful performance (15.2) [42]. For instance, problem-solving was integrated into sessions focused on identifying barriers and creating coping strategies, helping participants develop "if-then" plans (eg, "If I have only 15 minutes during lunch, then I will take a brisk walk around the office building"). Similarly, mental rehearsal was used to support participants in visualizing success when setting goals or enacting action plans, boosting their confidence and motivation. By embedding these BCTs within the core topics, the intervention ensured that theoretical strategies were effectively applied to practical, real-life situations. This design not only reinforced behavioral changes but also provided interactive and personalized elements to address participants' unique challenges.

A 12-week intervention period was selected, as it aligns with durations commonly used in prior web-based physical activity studies. This timeframe is generally considered sufficient for participants to adapt to new exercise routines and form habits, which research suggests may take a median of 66 days [43,44]. A 12-week follow-up period was included to assess the maintenance of behavioral changes and monitor any health outcomes resulting from the intervention. These collaborative design efforts enhanced the practicality of the intervention and participants' motivation to sustain their plans.

Step 4: Intervention Production

We developed materials and messages for the web-based intervention that were informed by the outcomes of the first 3 steps and organized them into 6 distinct sessions. These sessions were deployed every 2 weeks via the website named "Smartly Active for Health and Life." For reference, a screenshot of session 3 from the "Intervention" subsection has been translated from Traditional Chinese using YouDao Translate (NetEase Youdao; Figure 1). The website was structured into 2 main subsections: an "Intervention" subsection and a "Library" subsection. The participants in the blended intervention group and the web-based intervention group were able to access both subsections, whereas the participants in the control group were only able to access the "Library" subsection. Eighteen essays were included in the "Library" subsection, with 3 essays available in each session. The e-workshops were delivered in weeks 2, 4, and 8.

Figure 1. A screenshot of session 3 in the "Intervention" subsection on the website (translated from Traditional Chinese by "YouDao" translator).

The planning group scrutinized and refined all materials before launching the pilot study. Recruitment posters were disseminated on social media platforms, including WeChat (Tencent Holdings Ltd), Instagram (Meta Platforms, Inc), and Facebook (Meta Platforms, Inc). A total of 18 participants were recruited for the pilot, of whom 15 (83.3%) completed the study and provided feedback. The retention and engagement rates were 83.3% (15/18) and 73% (92/126), respectively, demonstrating the intervention's feasibility and acceptability. Participants rated the intervention highly in terms of usefulness (13/15, 86.7%),

XSL•FO
RenderX

enjoyability (13/15, 86.7%), and time acceptability (14/15, 93.3%).

Participant feedback led to minor improvements, such as adding navigation aids to the website and redesigning the "Library" section by replacing long text blocks with clickable links to enhance usability and engagement. Observations during trial implementation also captured implementers' perceptions, focusing on trialability, observability, and potential challenges under COVID-19 pandemic conditions. On the basis of these findings, strategies such as implementer training plans were developed to improve the intervention's acceptability, implementation, and sustainability.

Discussion

Principal Findings

In this study, we developed a blended intervention to increase MVPA among physically inactive office employees using IM steps 1 to 4. The main outputs were (1) a logic model of the problem and a set of key determinants identified through the needs assessment, (2) POs and change objectives mapped to these determinants, (3) a set of theory- and evidence-informed intervention components and materials delivered in a blended format, and (4) feedback during the optimization and pilot phase used to refine the content and delivery of the intervention.

Our selection of IM as our guiding framework significantly influenced our findings and led us to gain critical insights into the final outcomes and the development of our interventions [16]. In step 1, we conducted a needs assessment primarily using a literature review and focus group discussions. We also formed a planning group comprising professionals from various disciplines and key stakeholders. This led to the generation of a comprehensive, acceptable, and resource-effective intervention plan. It also promoted consensus among the members, leading to a unified approach to the implementation of the intervention. Moreover, the needs assessment revealed knowledge gaps about MVPA and attitudes that could potentially hinder engagement in MVPA, which shaped the educational and motivational components of our intervention. The information gathered was vital in tailoring the intervention to meet the unique needs of our target population, thereby enhancing its relevance and value. In step 2, we ensured that the change objectives aligned closely with the identified determinants and intervention goals. This alignment was crucial to the success of the intervention as it ensured that the approach was focused on achieving meaningful outcomes while meeting specific needs. In step 3, we translated the broad goals and objectives identified in the previous steps into concrete strategies for change. These strategies formed the backbone of our intervention, providing a clear road map for its implementation. In step 4, intervention components and materials were produced and subjected to several rounds of feedback and revision. This iterative process ensured the quality and appropriateness of our intervention. Additionally, the pilot study results indicated high levels of acceptance and satisfaction among the participants, suggesting that our intervention was well received and had achieved their intended goals. Our study aligns with a growing body of research that has used the IM framework for developing disease prevention interventions [15]. For instance, a previous study used IM to create a workplace health promotion intervention targeting enhanced presenteeism. It was found that the systematic nature of IM enabled the unique needs and preferences of workers to be addressed, which resonates with our own results [45]. Nevertheless, although IM is a systematic process for intervention development, outcomes can vary widely depending on numerous factors. This reinforces the need for continued research to refine and optimize health interventions in diverse settings.

The strengths of this study lie in its systematic and theory-driven approach. Using the IM framework, we integrated stakeholder insights and behavioral theories to design an intervention supporting both the initiation and maintenance of MVPA. The flexibility of the framework during the COVID-19 pandemic allowed adaptations to online sessions and home-based exercise, ensuring feasibility and relevance in dynamic conditions.

However, despite these strengths, several limitations should be noted. First, the IM framework, while robust and comprehensive, is highly resource-intensive, requiring significant time, expertise, and financial resources, making it challenging to replicate in resource-limited settings [12,46,47]. Second, the needs assessment relied on a small focus group sample (n=12), limiting the representativeness of findings and potentially overlooking diverse perspectives [45]. Additionally, since participants were individuals who did not meet WHO's MVPA guidelines, the findings may not generalize to populations already achieving recommended activity levels. Third, COVID-19 pandemic–related adaptations, while ensuring feasibility, altered the original intervention design, limiting its generalizability to nonpandemic contexts. For instance, workplace-level components could not be implemented due to restrictions.

Our findings have important implications for advancing health behavior change interventions in both research and practice. From a research perspective, applying the IM framework strengthened the rigor and transparency of our study while facilitating replication and exploration of mechanisms that contribute to intervention efficacy. From a practical perspective, the blended intervention outlined in this study offers a feasible road map for office employees to incorporate more MVPA into their routines, thereby improving health, productivity, and organizational outcomes. Additionally, these insights could guide policymakers in creating supportive environments that encourage MVPA in workplace settings.

Future research should address the broader applicability of IM-designed interventions across diverse populations and health behaviors. Specifically, studies should explore whether such interventions are more effective than other approaches in areas like disease management, mental health, and among vulnerable groups, such as children and older adults. Incorporating multilevel strategies that address organizational and environmental components, alongside individual-level approaches, could improve ecological validity. For instance, school-based interventions could benefit from engaging stakeholders, such as parents and teachers, to scale and adapt programs effectively. Similarly, implementing cluster RCTs in real-world settings is crucial to assessing the relevance, scalability, and sustainable impact of such interventions.

XSL•FO
RenderX

Conclusions

This study demonstrates the value of the IM framework as a systematic, stepwise tool for designing blended interventions to promote MVPA among office employees. The framework's ability to integrate evidence and stakeholder insights while adapting to dynamic contexts, such as the COVID-19 pandemic, highlights its versatility and practical relevance. These findings underscore the framework's potential for developing scalable, long-term health promotion programs to improve both individual well-being and workplace productivity.

Future research should expand on this work by testing IM-based interventions in diverse populations and real-world contexts to assess scalability and broader applicability. By maintaining a continuously updated evidence base, the IM framework could enhance the design and impact of interventions across changing circumstances.

Funding

This study received support from the General Research Fund, University Grants Committee of Hong Kong (project number 12609919). The funding body had no role in study design, collection, management, analysis, and interpretation of data, writing of the manuscript, or the decision to submit the manuscript for publication. The funding body had no ultimate authority over any of these activities.

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Abstract

Background: Virtual reality (VR) offers immersive, interactive environments, with growing evidence supporting its use in mental health diagnostics and therapy. Despite the increasing availability of VR equipment in clinical settings, integration into routine mental health care remains limited. Understanding health care workers' attitudes, knowledge, and perceived barriers is essential for bridging the gap between technological availability and clinical implementation.

Objective: This study aimed to investigate health care workers' attitudes toward VR in mental health treatment and identify factors influencing its adoption in settings where VR equipment is already available.

Methods: A qualitative study design was used, combining structured one-to-one interviews with a supporting narrative literature review. The narrative review informed the interview design and contextualized findings within the existing evidence base. Structured interviews were conducted with 16 mental health professionals (n=12, 75% women; n=4, 25% men) working in psychiatric and mental health settings in one city in southern Poland where VR equipment was available for patient care. Descriptive statistics summarized closed-ended question responses, and thematic analysis was applied to open-ended questions.

Results: Of the 16 participants, 10 (62.5%) had heard of VR technology before and held a favourable view of it, but only 6 (37.5%) were aware of its applications in mental health care. Participants aged under 35 years (6/16) rated the value of VR in therapy more positively than those aged over 50 years (3/16). Among those with prior VR exposure, 85.7% (6/7) expressed confidence in its effectiveness compared with 44.4% (4/9) of those without prior exposure. The most frequently mentioned benefits included interactivity, the ability to individualize therapeutic activities to patient needs, isolated visual and auditory interactions, and an increased sense of patient involvement and control. High costs were identified as the primary barrier by 75% (12/16), and 68.8% (11/16) expressed a need for comprehensive training. Women rated their subjective VR knowledge lower than men despite demonstrating comparable objective knowledge during interviews. VR equipment was described as being restricted within certain service areas. Legal and insurance constraints limited the use of home-based VR.

Conclusions: Access to VR equipment alone is insufficient to drive adoption in mental health services. Effective integration requires targeted education, comprehensive training, clear institutional guidelines on equipment responsibility and insurance, and supportive infrastructure. Addressing barriers and knowledge gaps identified in this study is essential for realizing VR's therapeutic potential in routine clinical practice.

virtual reality; mental health; health care workers; qualitative research; technology adoption; barriers; attitudes

Introduction

Virtual Reality Applications in Mental Health

Virtual reality (VR) technology has evolved substantially over the past 2 decades, offering immersive, interactive environments with growing applications in mental health diagnostics and therapy [1-3]. VR enables clinicians to create controlled, reproducible therapeutic scenarios that would be difficult or impossible to replicate in traditional clinical settings. Clinical VR tools have advanced the prevention, assessment, and treatment of conditions including posttraumatic stress disorder [4], anxiety disorders [5-7], and depression [3,8].

The therapeutic potential of VR extends across a broad range of mental health conditions. VR-based interventions have demonstrated efficacy for anxiety disorders through VR exposure therapy, which allows patients to confront fear-inducing stimuli in a safe, controlled environment [6,9,10]. Meta-analyses have confirmed that VR interventions produce

XSL•FO
RenderX

significant reductions in symptoms of anxiety and depression [3,8]. Beyond exposure therapy, VR has shown promise for social skill training in schizophrenia [11], pain management [12], and broader psychotherapeutic applications [13].

One factor in assessing the viability of VR therapy is treatment adherence. A meta-analysis of 46 studies on VR therapy for anxiety disorders found an overall dropout rate of 16%, lower than estimated rates for in vivo therapy and cognitive behavioral therapy (CBT) [14]. Similarly, a review of CBT in VR treatments found no significant difference in dropout likelihood between VR and traditional modalities [15], suggesting that VR-based approaches are at least as acceptable to patients as conventional treatments.

Accessibility remains a critical consideration. Digital mental health tools, including VR, must be designed to accommodate diverse populations, including those with disabilities and limited technological literacy [16,17]. The digital divide—unequal access to digital mental health resources—disproportionately affects people with serious mental illness in community settings [18]. Addressing these accessibility concerns is essential for the equitable implementation of VR in mental health services.

Research on Health Care Workers' Attitudes and Barriers Conducted to Date

A growing body of research has examined health care professionals' perspectives on VR in clinical practice. Recent years have seen a substantial increase in studies investigating clinician attitudes, acceptance, and implementation barriers [19-23]. A systematic review by Bin et al [24] synthesized evidence on mental health professionals' attitudes toward VR therapies, whereas Felnhofer et al [25] identified key barriers to adoption from the perspective of clinical psychologists and psychotherapists, including concerns about technical complexity, insufficient evidence, and lack of training. Recent reviews [26,27] of VR interventions for psychosis demonstrated the expanding scope of VR applications in severe mental illness and the corresponding need to understand clinician readiness.

Studies focused on cognitive behavioral therapists have provided important insights. Lindner et al [19] conducted a cross-sectional survey and found generally positive attitudes toward VR therapy, with therapists recognizing its potential not only for anxiety disorders but also for other conditions. However, therapists' decisions about future VR use were more strongly influenced by negative attitudes—concerns and fears—than by positive attitudes, suggesting that addressing clinician apprehensions may be more effective than simply promoting benefits [19,28,29]. Therapists' main concerns included doubts about the real-world transfer of therapeutic gains, worries about the quality of the virtual environment, and practical issues such as the potential impact of VR goggles on the therapeutic relationship and eye contact [20,30].

The successful integration of new technologies into health care depends substantially on the knowledge and training of health care workers. Adequate training enhances acceptance and effective use [31]. Designated champions—personnel with specific training and a clear institutional mandate—can significantly facilitate technology adoption within services [32,33]. Wray et al [20] identified that, despite the unambiguous success of VR treatments for anxiety disorders, few therapists use them in practice, pointing to a gap between evidence and implementation driven by barriers at multiple levels: individual (lack of training and unfamiliarity), institutional (cost and infrastructure), and systemic (lack of guidelines and insurance coverage).

Health care professionals' attitudes toward adopting technological innovations are influenced by factors including perceived usefulness, ease of use, and potential to enhance patient care [34]. Positive attitudes are often linked to the technology's perceived benefits and alignment with clinical workflows [35]. However, resistance can occur due to concerns about disrupting established practices or skepticism about effectiveness. Engaging health care workers in development and implementation processes can lead to more favorable attitudes [36]. Health care providers have reported generally favorable attitudes toward VR despite limited previous clinical use and perceived barriers to implementation [21]. Clinician-focused research further highlights the importance of practical guidance and institutional support for successful VR adoption [22].

Despite the potential benefits, several barriers hinder widespread VR adoption in mental health care. Cost is a significant factor as acquiring and maintaining VR equipment can be expensive. Safety concerns arise regarding the potential for cybersickness or exacerbation of symptoms in vulnerable populations. Ethical considerations include ensuring patient privacy, obtaining informed consent, and addressing the risk of overreliance on technology at the expense of human interaction [37,38]. Addressing these barriers requires comprehensive strategies encompassing policy development, training, and ongoing evaluation.

Aims of This Study

The present study was conducted in mental health settings in Poland where VR equipment was already available for patient care. This unique context—investigating staff who have physical access to VR but may not use it routinely—enabled examination of whether access alone is sufficient to drive adoption. We aimed to (1) explore health care workers' attitudes, knowledge, and perceptions regarding VR in mental health care; (2) identify barriers to and facilitators of VR adoption in settings where equipment is already available; and (3) examine how demographic factors such as age, gender, and professional experience relate to attitudes toward VR. We hypothesized that mere availability of VR equipment would be insufficient to ensure its integration into clinical practice and that training, institutional support, and prior personal experience with VR would be key factors shaping adoption.

Methods

Study Design

This study used a qualitative design combining structured one-to-one interviews with a supporting narrative literature review to examine health care workers' attitudes and knowledge regarding VR in mental health care. The narrative review

XSL•FO
RenderX

informed the interview design and contextualized findings within the existing evidence base. The structured interview guide was developed based on themes identified in the literature, including VR awareness, perceived benefits and barriers, training needs, and attitudes toward technology adoption in clinical settings.

Participants

This study targeted health care workers actively engaged in mental health services. A total of 16 participants were recruited, comprising psychiatrists (n=7, 43.8%), mental health nurses (n=3, 18.8%), psychologists (n=2, 12.5%), CBT psychotherapists (n=2, 12.5%), physical therapists (n=1, 6.3%), and social workers (n=1, 6.3%). Of the 16 participants, 12 (75%) were women, and 4 (25%) were men. Most (n=11, 68.8%) had experience working only with adult patients. Participants were recruited across mental health care settings in one city in southern Poland, including a general psychiatry hospital unit, ambulatory care, and a community mental health center. All selected participants worked in services that offered patients the opportunity to participate in VR-based therapy and were involved in the care of patients taking part in a therapeutic program using VR.

Of 22 interview invitations, 6 (27.3%) individuals declined due to conflicting work commitments. The sample included individuals with diverse experience levels, from newly trained professionals to senior practitioners, to capture a range of perspectives. Demographically, efforts were made to ensure representation across gender and age groups to account for cultural and systemic influences on attitudes toward VR. .

Data Collection

The structured interview collected responses from professionals in therapeutic fields about their experiences, perceptions, and knowledge regarding VR tools in therapy. The interview guide (Multimedia Appendix 1) covered the following domains: (1) VR familiarity—participants' prior exposure to and subjective knowledge of VR technology, (2) perceived advantages and limitations—benefits and drawbacks of VR in therapeutic settings, (3) barriers and support needs—factors hindering VR adoption and resources required for implementation, and (4) future use—likelihood of integrating VR tools into regular clinical practice.

The interview comprised both closed-ended questions (eg, rated on Likert-type scales) and open-ended questions designed to elicit detailed perspectives. Each interview lasted approximately 20 to 30 minutes and was conducted entirely by a single researcher (AS) to ensure consistency and reduce potential interviewer bias. Interview themes and sample questions are shown in Textbox 1.

Textbox 1. Interview questions regarding virtual reality (VR) use in clinical practice.

VR familiarity

- How would you rate your knowledge of VR technology in general?
- Have you previously used VR tools in other settings (eg, entertainment, games)?
- Have you previously used VR tools in your patient care practices?

VR in a therapeutic context

- In your opinion, which disorder group, out of the following, could VR tools be used successfully?
- In your opinion, which disorder group, out of the following, should VR tools not be used at all?
- In your opinion, what is the biggest strength of the VR environment in a therapeutic context?

Barriers and support needs

- Do you have concerns regarding data security, patient privacy, and the storage of personally identifiable information within VR platforms?
- Would marketing resources or patient orientation materials be helpful in addressing potential patient resistance or reluctance to try VR?
- Would the provision of dedicated IT support personnel be a critical enabler for implementing VR in your workflow?

Future use

- How likely do you believe it is that VR technology will become a routinely implemented tool in your clinical environment within the next 1 to 5 years?
- How likely are you to begin using VR tools in your patient work within the next year?
- What support do you need to implement VR tools into your regular work?

Data Analysis

With participants' consent, face-to-face interviews were transcribed verbatim. At the beginning of each interview, participants were informed about the study's purpose, data security measures, and their right to withdraw at any time without providing a reason. The authors identified and discussed data saturation; after reaching this point, no additional interviews were scheduled.

Data from closed-ended questions were analyzed using descriptive statistical methods to identify patterns and trends across demographic subgroups. Given the small sample size (N=16), all analyses were exploratory and descriptive; no formal

XSL•FO
RenderX

inferential statistical tests were performed. Percentages are reported alongside absolute numbers throughout.

Open-ended question transcripts were analyzed using thematic analysis following the 6-phase approach described by Braun and Clarke [39]. Each transcript was carefully examined, and relevant passages were categorized during an initial, primarily deductive coding process based on the interview domains. Subcategories were then developed inductively from the data, and significant text passages were assigned to these subcategories in a second coding process.

The narrative literature review was conducted separately to inform interview design and provide context for findings. Relevant literature was sourced from PubMed, PsycInfo, and Scopus using search terms related to VR, mental health, and health care workers' attitudes (publications up to March 2026). Inclusion criteria focused on peer-reviewed studies examining VR use in mental health care, with emphasis on adoption, clinician perspectives, and implementation barriers.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki. It is part of a larger project titled "An attempt to identify factors influencing the effectiveness of physical activity in virtual reality conditions in the treatment of anxiety and depressive disorders" approved by the Bioethics Committee of the Medical University of Silesia in Katowice under the number PCN/CBN/0052/KBI/106/22. This study involved voluntary, structured interviews with health care professionals about their professional opinions on VR technology. All participants provided informed verbal consent before taking part, including consent to audio recording and transcription. Participants were assured of anonymity and informed of their right to withdraw at any time without consequence. All data were stored securely, and identifying information was removed during transcription.

Results

Participant Characteristics

Sixteen mental health professionals participated in the structured interviews. Table 1 summarizes participant demographics. The detailed recruitment process is presented in Figure 1.

Table . Participant demographics (N=16).

Profession	Frequency, n (%)	Gender[a]	Experience (y)[b]
Psychiatrists	7 (43.8)	5 women; 2 men	5 - 25
Mental health nurses	3 (18.8)	3 women	10 - 30
Psychologists	2 (12.5)	1 woman; 1 man	3 - 15
CBT[c] psychotherapists	2 (12.5)	2 women	5 - 10
Physical therapists	1 (6.3)	1 woman	20
Social workers	1 (6.3)	1 man	8

[a]Total: 12 women; 4 men.

[b]Mean experience was 14.70 (SD 11.91) years.

[c]CBT: cognitive behavioral therapy.

XSL•FO
RenderX

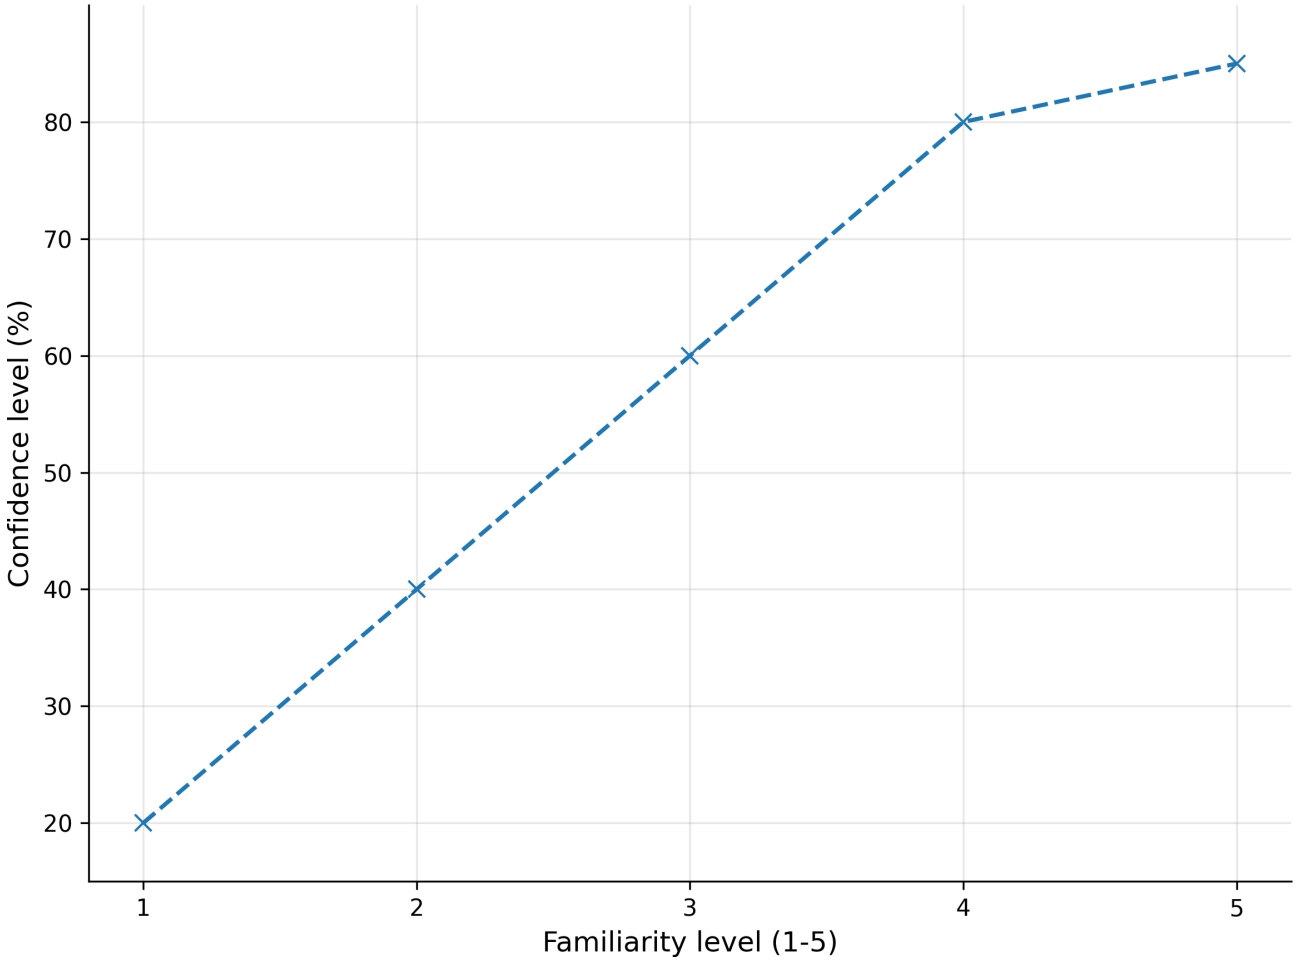
Figure 1. Flow diagram of participant recruitment. CBT: cognitive behavioral therapy; VR: virtual reality.

XSL•FO
RenderX

VR Awareness and Knowledge

Participants rated their subjective VR knowledge with a mean of 2.44 (SD 1.26) out of 5 (where 1 indicated complete unfamiliarity with VR technology and 5 indicated extensive knowledge), suggesting moderate self-assessed familiarity. No clear patterns were observed between VR knowledge ratings and demographic factors such as age or years of experience.

A gender-based pattern was noted: women rated their subjective VR knowledge lower than men despite demonstrating comparable objective knowledge when asked factual questions about VR functionality during interviews. When women were asked general questions about VR equipment appearance and use (assessing objective knowledge), their responses were at the same level as those of men. This mismatch between subjective self-assessment and objective knowledge among women may reflect broader gendered patterns in technology confidence and warrants further investigation.



A positive relationship was observed between personal use of VR outside the workplace (eg, for gaming or entertainment) and self-rated VR knowledge, suggesting that personal familiarity enhances confidence (Figure 2). Higher self-rated VR knowledge was associated with a greater expressed likelihood of adopting VR tools in clinical practice, underscoring the importance of exposure and training.

One participant, a nurse aged 56 years, offered an illustrative example. Although she had never used VR herself, her son had. After hearing about his experiences, she concluded that VR could be a valuable relaxation tool for patients in a hospital ward, especially those with limited opportunities to go for walks or connect with nature. This suggests that even indirect exposure—through family members or peers—can shape positive attitudes toward VR.

Notably, mainly younger participants reported having had nonclinical contact with VR. Participants also mentioned that even when using VR outside clinical settings, it was typically done under supervision. They expressed concerns about the equipment being expensive and requiring oversight, which contributed to a feeling of limited independence with the technology. None of the 16 participants owned VR equipment for personal entertainment or gaming at home.

Overall, 87.5% (14/16) had heard about the VR project operating in their institution. However, a smaller proportion, 25.0% (4/16), had actively used VR tools in a clinical setting. These findings indicate high awareness of the internal institutional initiative, which contrasts sharply with the staff's limited pre-existing knowledge of psychiatric VR applications and their minimal hands-on clinical experience. When asked about practical applications, most respondents pointed to relaxation aspects of VR—nature scenes, breathing exercises, and guided mindfulness. In total, 31.3% (5/16) of the participants specifically mentioned exposure therapy in the context of phobias.

Figure 2. Correlation between virtual reality (VR) familiarity and confidence, emphasizing the role of exposure in shaping attitudes toward VR adoption.

XSL•FO
RenderX

VR in the Therapeutic Context

Participants noted that VR's ability to provide interactive, personalized, and engaging therapy was a strong motivator for its potential adoption. VR was seen as particularly promising for patient groups with conditions such as anxiety or depression but less applicable for those with severe cognitive impairments.

One participant, a psychiatrist aged 32 years, stated that nearly all patients, regardless of diagnosis, could benefit from individually tailored VR therapy. She noted the following:

> *My experience is that patients are eager to participate in "novelty" classes. They are drawn to technological solutions and enjoy engaging in games that can assist with cognitive rehabilitation, even if they don't always recognize it as therapy.*

Another participant, a physiotherapist aged 51 years, emphasized the importance of VR tools for individuals with psychiatric conditions:

> *VR can help eliminate barriers to physical activity, especially for patients with mental health disorders who often engage in low levels of physical exercise. This lack of activity can lead to chronic conditions and more pronounced side effects from medication, ultimately affecting their quality of life and increasing mortality rates. VR-based activities could provide an opportunity to integrate physical activity into their lives beyond the gym or sports, which are often inaccessible to these patients.*

Among all participants, 31.3% (5/16)—3 psychiatrists, 1 psychologist, and 1 physiotherapist, all with prior VR experience—stated that no group of patients should be excluded from potential VR use. The remaining 68.8% (11/16) identified schizophrenia (during acute episodes), psychotic disorders, and advanced dementia as conditions for which VR should be avoided, citing concerns about exacerbating psychotic symptoms or causing confusion.

Practitioners expressed largely positive attitudes toward VR's potential to enhance mental health treatment. The most frequently mentioned benefits included interactivity, the possibility of individualizing therapeutic activities according to patient needs, isolated interactions in visual and auditory perception, and an increased sense of patient involvement and control. A total of 68.8% (11/16) believed that VR could complement traditional therapies, and 62.5% (10/16) identified its adaptability as a strength.

Despite this optimism, notable knowledge gaps were evident. In total, 43.8% (7/16) of participants perceived VR primarily as a gaming tool, reflecting misconceptions about its clinical applications. A lack of understanding of VR safety protocols and evidence-based effectiveness also contributed to hesitancy among some participants.

Barriers to VR Adoption

Several barriers to VR adoption in therapeutic settings were identified. Financial constraints emerged as the most prominent obstacle, with 75% (12/16) identifying the cost of purchasing and upgrading VR equipment as the greatest disadvantage. Notably, none of these participants could specify the actual cost of a single headset available at their institution; their estimates were, on average, €500 to €1000 higher than the actual cost (€1=US $1.15 as of August 5, 2026). This discrepancy suggests that perceptions of cost may be inflated relative to reality.

A particularly striking finding concerned the sense that VR equipment was "locked" or restricted within certain service areas. Participants reported that even when VR equipment was technically accessible, there was often no clear information regarding who was responsible in the event of damage. This ambiguity about responsibility created anxiety among staff and limited their willingness to use the equipment freely. A female psychiatrist aged 30 years highlighted a specific issue: for legal reasons surrounding equipment insurance, patients could not take VR goggles home. This limited the ability to maintain the positive therapeutic effects observed during ward-based VR sessions and reduced the likelihood of VR being incorporated into ongoing therapeutic programs.

Staff described wanting more independence with the equipment—the ability to use it during individual therapy sessions or bring it to patients' rooms (eg, for bedridden individuals)—but felt constrained by institutional rules, unclear protocols, and insufficient guidance. Several participants noted that although written materials about the VR program were provided, participants lacked the time to seek answers independently. Joint training sessions had been limited: only 2 were held over a 6-month period during working hours, making it difficult for many staff members to participate.

Consequently, comprehensive training emerged as the secondary barrier, with 68.8% (11/16) of participants expressing a need for thorough education. Other significant obstacles included ethical and safety concerns, raised by 37.5% (6/16), such as patient privacy, risk of retraumatization, and potential overreliance on VR technology; infrastructure limitations, including limited access to dedicated space and technical support; and digital literacy concerns, noted by 25% (4/16), who observed that without proper digital education, some patients may struggle to use VR independently.

Most participants (12/16, 75%) reported that access to VR equipment at work and involvement in caring for patients in a VR-based therapeutic program had not substantially changed their attitudes toward VR. They explained that the information provided about available therapeutic options had been superficial, lacking the full range of activities offered to patients. There was no information on whether the therapeutic protocol could be modified or whether the equipment could be used in patients' rooms or during one-on-one therapy sessions.

Facilitators of VR Adoption

When asked about the likelihood of starting to use VR tools in patient work over the following year, participants rated their chances at a mean of 3.25 out of 5 (where 1 was "very likely" and 5 was "definitely not"). Only 6.3% (1/16) selected "very likely," citing positive experiences during an ongoing ward-based VR therapeutic program.

Exploratory subgroup analysis indicated that participants aged under 35 years (6/16) rated the value of VR in therapy more

XSL•FO
RenderX

positively than those aged over 50 years (n=3; mean 3.83, SD 0.75 vs 3.00, SD 0.00 on a 5-point scale, with higher scores reflecting more favorable attitudes). Professionals with fewer than 5 years of experience (5/16) also reported a somewhat greater likelihood of starting to use VR within the next year than those with more than 15 years of experience (6/16; mean 2.80, SD 1.10 vs 3.33, SD 1.21, respectively, with lower scores indicating greater likelihood). The latter group more often cited concerns about disrupting established practices. Among those with prior VR exposure (whether personal or professional), approximately 85.7% (6/7) expressed strong confidence in its effectiveness, compared with approximately 44.4% (4/9) of those without such exposure. This pattern underscores the potential importance of hands-on experience in shaping positive perceptions.

These subgroup patterns should be interpreted cautiously given the small sample size (N=16) and are presented as exploratory, descriptive observations rather than statistically significant differences.

In response to the question "What support do you need to implement VR tools into your regular work?" participants highlighted several priorities: support from institutional leadership, education for all department staff to encourage active participation, adequate administrative and logistical support, and high-quality visualization programs enabling immersion. A total of 18.8% (3/16) of the participants specifically indicated the need for funding covering not only a one-time equipment purchase but also the systematic development and evaluation of therapeutic programs.

A female physiotherapist aged 51 years suggested that VR-based therapeutic activities should be presented to patients as additional relaxation options rather than strict treatments, emphasizing the importance of making the experience enjoyable. Other participants recommended organizing more afternoon activities, allowing patients to engage independently without staff oversight to help them feel more comfortable. They also highlighted the need to inform patients about VR's therapeutic mechanisms and evidence base.

Discussion

Principal Results

This qualitative study of 16 mental health professionals working in settings where VR equipment was available for patient care revealed a consistent pattern: physical access to VR technology alone was insufficient to drive its integration into routine clinical practice. While most participants (10/16, 62.5%) had heard of VR before the project and expressed broadly positive attitudes toward its therapeutic potential, only 37.5% (6/16) were aware of VR's mental health applications, and only 25.0% (4/16) had actively engaged with VR in a clinical capacity. This study identified a constellation of barriers—including knowledge gaps, financial concerns, insufficient training, unclear institutional guidelines, and legal and insurance constraints—that collectively prevented adoption despite equipment availability.

Several qualitative observations were particularly noteworthy. Staff described VR equipment as being "locked" within certain areas of the service, with no clear framework for independent clinical use. Anxiety about responsibility for expensive equipment deterred staff from allowing patients to use it freely. A gender-based pattern in VR knowledge self-assessment was observed, with women rating their knowledge lower than men despite demonstrating comparable factual understanding, suggesting that confidence rather than competence may be a barrier for some professionals. Younger and less experienced professionals were descriptively more open to VR, whereas those with prior personal VR exposure—even outside clinical settings—expressed markedly greater confidence in its effectiveness.

Comparison With Prior Research

Our findings are broadly consistent with the growing literature on clinician perspectives on VR in mental health care. Felnhofer et al [25] identified similar barriers among clinical psychologists and psychotherapists, including concerns about technical complexity, insufficient evidence, and lack of training. Lindner et al [19] found that CBT therapists held generally positive attitudes toward VR but that negative concerns—particularly about real-world transfer of therapeutic gains—more strongly predicted future use intentions than positive attitudes. This aligns with our finding that even staff with access to VR and generally favorable views hesitated to adopt it in the face of unresolved practical concerns.

The importance of prior exposure and familiarity identified in our study is consistent with findings by Wray et al [20], who noted that despite the unambiguous success of VR anxiety treatments, very few therapists use VR in practice, largely due to unfamiliarity and lack of training opportunities. Cushnan et al [22] similarly found that clinicians' perspectives on immersive tools were shaped by hands-on experience and institutional support. Our finding that 85.7% (6/7) of participants with prior VR exposure expressed confidence in its effectiveness compared with 44.4% (4/9) without exposure reinforces the critical role of experiential learning in technology acceptance.

The misconception that VR is primarily a gaming tool, expressed by 43.8% (7/16) of our participants, is consistent with findings that clinicians often lack awareness of VR's clinical applications [40]. At the same time, participants in our study suggested that framing VR as entertaining might paradoxically encourage patients to engage with therapeutic tools. This tension between clinical credibility and patient engagement represents an important consideration for implementation strategies.

Our study extends existing research by focusing specifically on staff working in settings where VR is already physically present but not integrated into routine practice. Previous studies have generally examined attitudes in the abstract or in settings where VR is being newly introduced. The finding that access alone is insufficient—and that institutional, legal, and training frameworks are necessary to translate access into use—adds a new dimension to the implementation literature. This is consistent with the work by Berardi et al [31], who identified systemic barriers to digital technology implementation in mental health, and by Chung et al [41], who emphasized the importance of clinician and service manager engagement.

XSL•FO
RenderX

Recent research highlights familiarity and exposure as key factors in mental health professionals' adoption of VR. Prior experience with VR and greater knowledge of VR-based therapy have been associated with a greater likelihood of future clinical use [20,42]. Moreover, recent findings similarly indicate greater interest in therapeutic VR among professionals with prior VR experience [25,43]. Structured VR training has also been shown to improve therapists' knowledge, skills, and confidence in using VR [43]. Furthermore, younger mental health professionals may show greater interest in therapeutic VR than older professionals. By contrast, a large recent study [25] found that years of professional experience were not significantly associated with interest in VR. In the exploratory sample under consideration, younger and less experienced professionals appeared more receptive to the use of VR. We should interpret these findings with caution, given the small subgroup sizes.

Limitations

This study has several limitations. First, the sample of 16 participants was drawn from mental health services in a single city in southern Poland, limiting generalizability to other geographic, cultural, or health care system contexts. Second, the use of structured interviews, while ensuring consistency, may have limited the depth of qualitative exploration compared with semistructured or in-depth interview approaches. Third, the small sample size precludes formal statistical inference; all quantitative findings are descriptive and exploratory, and subgroup patterns (by age, gender, and years of experience) should not be interpreted as statistically significant differences. Fourth, potential selection bias may have influenced participation: staff with a preexisting interest in technology may have been more inclined to take part, potentially inflating positive attitudes relative to the broader workforce. Fifth, the rapidly evolving nature of VR technology means that findings may become outdated as new, more affordable and user-friendly VR systems enter the market, necessitating ongoing research. Finally, despite individual studies showing positive effects of VR therapies, there remains insufficient scientific evidence regarding the optimal use and target populations for these tools [44], which may influence clinicians' willingness to adopt VR even when it is available.

Conclusions

There was a broadly positive outlook on VR use in mental health care among the health care professionals interviewed in this study. However, significant barriers related to knowledge, cost, training, institutional guidelines, and legal constraints must be addressed before VR can be effectively integrated into routine clinical practice. Free access to VR equipment may foster more positive attitudes, but a lack of knowledge about how to use it—combined with anxiety about equipment responsibility and the absence of clear protocols—decreases willingness to implement VR in daily therapeutic routines and may hinder its introduction as a permanent tool in mental health services.

Financial constraints extend beyond initial equipment purchase. It is equally important to establish clear rules for equipment use, create appropriate insurance conditions, and ensure systemic access to training and evaluation of therapeutic programs. Targeted education, comprehensive training, and supportive institutional infrastructure are essential to overcome the barriers identified in this study and fully realize VR's potential as a therapeutic tool. Future research should include larger, multisite samples; use semistructured interview methods to capture richer qualitative data; and investigate the effectiveness of specific implementation strategies—such as VR champion programs, structured training curricula, and institutional policy frameworks—in translating equipment access into routine clinical use.

A visual abstract summarizing the main study findings, implementation barriers, and integration requirements is presented in Multimedia Appendix 2.

Abstract

Background: The introduction of STARA (smart technology, AI, robotics, and algorithms) changes work processes and the application of skills, depending on specific task design within a given context.

Objective: From a Human Factors perspective, this study uses empirical data from a case study to demonstrate how different task designs influence the application of theater nurses' skills during robot-assisted surgeries. Moreover, from a transdisciplinary perspective, the data elucidate that STARA-related task design extends beyond Human Factors' perspectives, encompassing cross-level effects between task configurations of different surgical units and individual evaluations regarding career motives. Finally, the study aims to integrate interdisciplinary perspectives by outlining theoretical, methodological, and practical implications for both STARA-related Human Factors task design in health care and Sustainable Career Research.

Methods: Empirical data derive from an embedded single-case study design within a hospital. The case study illustrates field experiences from a focus group interview (n=5) and postsurgery surveys (n=36) on Human Factors–related variables (objective task variety, perceived workload, perceived application of professional skills), and variables from Career Research (perceived career sustainability, growth needs).

Results: Higher task variety and skill application during surgeries correlate with long-term career sustainability evaluations. Moreover, career-related growth needs relate to interindividual differences in STARA task evaluations. Interdisciplinary perspectives with respect to theoretical models, practical implications, and methodological challenges are discussed.

Conclusions: The introduction of STARA (smart technology, AI, robotics, and algorithms) changes work processes and the application of skills, depending on specific task design within a given context.

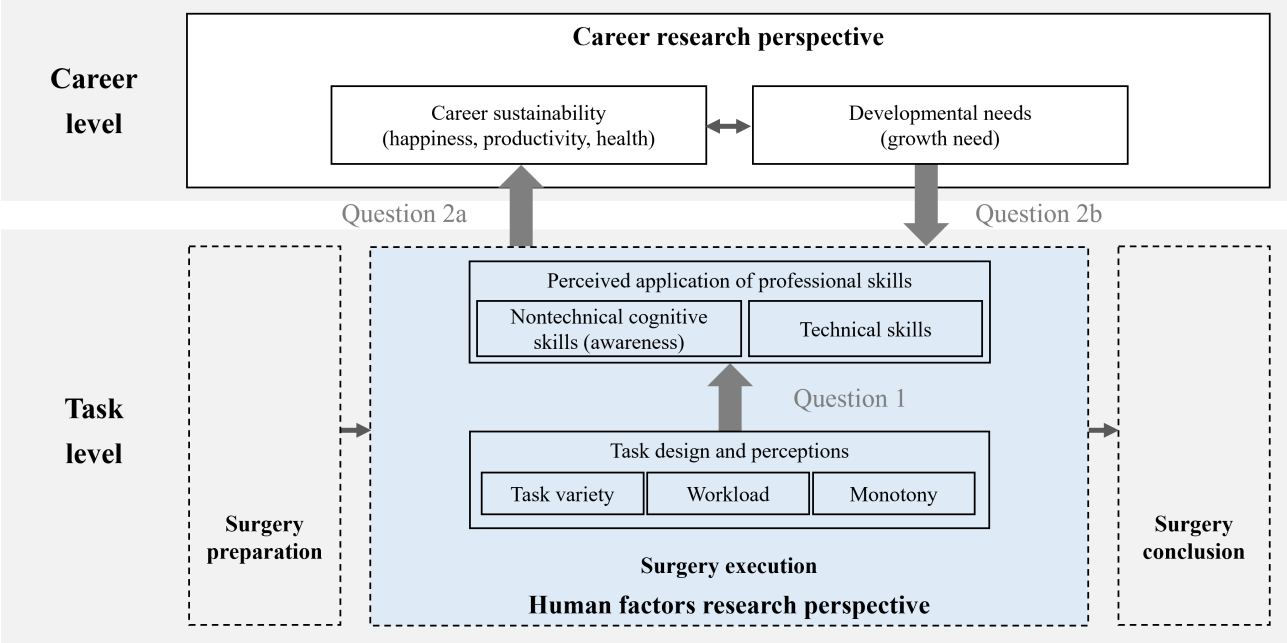
Introduction

Background



The implementation of smart technologies, AI, robotics, and algorithms (smart technology, AI, robotics, and algorithms; STARA) has substantial interdisciplinary implications in the health care sector. In Human Factors, the focus lies on designing work systems that are human-centered, efficient, effective, and resilient. In the field of human resource management, the emphasis is, for example, on questions of sustainable career development. One prominent example, among many, is the da Vinci Surgical System (Intuitive Surgical Inc), which has significantly transformed the landscape of surgery and, in particular, the role of operating room nurses who assist surgeons during procedures [1]. During surgical execution, the surgeon operates the robotic system from a console, using hand controls to manipulate instruments while viewing the surgical field in detail. However, the surgeon no longer stands face-to-face at the table with the theater nurse and does not interact directly. As a result, nurses' tasks are modified, and task designs can differ across units within a hospital. This results in a varying number of tasks that nurses perform during robot-assisted surgery (RAS), thereby impacting workload, monotony, and the application of professional skills during these tasks. In that respect, the project underpinning the case study focused on a Human Factors perspective to elaborate on the following research question: "How are different task-specific demands in surgical workflows related to perceived skill application?" (see Question 1 in Figure 1). Specifically, nontechnical cognitive skills were investigated to predict safety and resilience of the work-system [2,3]. However, expanding the extensively studied

XSL•FO
RenderX

Human Factors perspective, technological work design goes beyond the task-specific focus. Human resource-oriented career research, for instance, examines the effects of technological advancements on career intentions, yet typically does not incorporate the task-specific theoretical and methodological approaches established in Human Factors Research. This gap reveals considerable interdisciplinary potential between Human Factors and Career Research and may be illustrated by quotes from preparatory interviews with nurses in this study. These interviews indicated that changes in skill application during surgery influence individual career evaluations and, consequently, the sustainability of career projections. As one participant noted, "I did not choose a career as a theater nurse to be bored by watching robotic arms during surgery," summarizing this perception. Against this background, the present study goes beyond the Human Factors perspective and questions "How do task-specific demands and perceived skill application align with reflection of career sustainability?" and vice versa "How do career-related needs relate to situational evaluations of task-specific demands and perceived skill application?" in order to illustrate the relationship between task-level design of robot-assisted surgeries and nurses' career evaluation (see Questions 2a and 2b in Figure 1).

Overall, this study seeks to empirically capture and conceptually discuss the interdisciplinary potential between Human Factors and Career Research, using the example of RAS. Career Research investigates the changing work tasks and skill requirements within the STARA environment [4-6]. Reflecting the career-related experiences of theater nurses in the case study, we focus on the concept of career sustainability [7]. Thus, we aim to integrate task-level concepts from Human Factors into models of Career Sustainability, emphasizing the potential for an interdisciplinary examination.

Figure 1. Task and career level perspectives of theatre nurses in RAS.

Study Aims

Empirical Human Factors Perspective: Task Design and Skill Application in RAS

Using exploratory data from a case study, we aim to examine, from a Human Factors perspective, how different task-specific demands in surgical workflows of RAS are related to perceived skill application. We explore task-specific concepts from Human Factors Research within a socio-technical environment, highlighting functional task design as essential for ensuring human-centered work systems [8,9]. This focus includes task-related variables such as task variety, perceived workload, and monotony, alongside the perceived application of professional skills during surgical situations (Question 1).

Empirical Transdisciplinary Perspective: Human Factors and Career Evaluation in RAS

Through a case study, we aim to illustrate that STARA-related changes in tasks of theater nurses (eg, surgery execution) go beyond Human Factors' questions and address cross-level effects between task-level related changes and individual perceptions at career level (Question 2). In a field sample, we explore nurses' reflections on career sustainability after RAS with different degrees of task variety and skill application (Question 2a). Vice versa, the influence of individual career-related needs on the Human Factors' variables is explored with respect to interindividual differences in task evaluation (Question 2b).

Interdisciplinary Perspectives: Theoretical, Methodological, and Practical Implications

Following the exploratory case study, theoretical, methodological, and practical implications for Career Research and Human Factors are presented. The data collected contributes to a better understanding of the impact and potential effectiveness of career development and workplace interventions. In 5 implications, we elaborate on the addition of variables at the task-level in existing frameworks for sustainable careers, reflect approaches to human-centered work design, and discuss methodological issues.

XSL•FO
RenderX

The subsequent section briefly introduces the theoretical key concepts from Human Factors and Career Research to elaborate the empirical research questions. It then outlines the study's contribution, followed by a presentation of the empirical study in the method and results sections and, in the discussion, a more in-depth reflection on the interdisciplinary perspectives.

Theoretical Context

STARA and Human Factors Research

Overview

Since the 1980s, the "ironies of automation" have been a central topic in the multidisciplinary field of Human Factors [10]. Instead of simplifying tasks, automation can critically change the demands placed on human operators by reducing active application of skills, leading to more passive tasks such as monitoring [8]. Higher automation levels can diminish valuable hands-on expertise due to limited engagement with manual tasks, which can in turn lead to deterioration of skills required for problem-solving and quick decision-making in high-stakes situations [2,11]. This issue becomes more pronounced with the rise of STARA, where technology interacts interdependently with individual workers or teams–in industry as well as in health care [12]. Subsequently, the need for designing automated work environments which balance technological support with opportunities for skill application and development becomes especially important, as system resilience relies heavily on the operator's situational awareness (SA) adaptability and skill application [13]. In this study, RAS serves as an empirical example for the shift in professional skills due to the introduction of a STARA-technology. Its introduction into surgical practice redefines work and task processes, disrupts established workflows, and necessitates the redistribution of primary and secondary tasks between technology and professional staff [11,14]. But does technology such as RAS adequately represent the broader concept of STARA? In this study, we use the term STARA to refer to the broader category of smart technologies, AI, robotics, and algorithms that are not just automations of manual work but are characterized by different Levels of Autonomy (LoA) [11].

Level of Autonomy in STARA Environments

RAS represents a specific type of STARA, as it mediates human work through a semiautonomous technological system embedded in a complex, multiteam environment [15]. Current generations of da Vinci systems are positioned at lower LoA (eg, level 1) [16,17], functioning in a master-slave configuration and therefore unable to operate autonomously. Nevertheless, underlying AI and algorithms have supportive functions in enabling the system to execute essential secondary tasks, such as image stabilization, motion scaling [15], and augmented reality overlays integrating preoperative imaging data into the live surgical view [18-20]. Following Endsley [11], current RAS systems would be positioned at a relatively low level of executive task support. Determining the level of autonomy at the task level is crucial for comparing the effects of different STARA technologies in health care. Existing frameworks provide useful distinctions between different task types (eg, monitoring, decision-making, and execution) and their respective levels of autonomy, thereby enabling a more nuanced assessment of technological capabilities and human-autonomy interaction [15,21].

The introduction of RAS technology in particular, and STARA technologies more generally, alters the primary tasks of nurses; however, changes in subsequent task characteristics such as variety are driven not only by the LoA of the technology itself but also by the technology-independent design and allocation of secondary tasks. In the present study, surgical teams applied the same RAS system differently, which led to varying task demands for the nurses. The following sections examine how technology-induced changes in task-specific demands affect skill application and broader career-related outcomes in health care settings.

Task-Specific Demands

A central focus of Human-Factor-oriented work design is the work-task itself, with one of its core constructs being task variety. Task variety is defined as the number of distinct tasks an operator must perform within a given job [22]. Research has shown that higher task variety is associated with subjective performance, job satisfaction due to more stimulating and interesting tasks, reduced monotony, increased mental alertness, and greater engagement [8,23]. In STARA environments, technology can take on tasks which were previously performed by humans and thereby reduce task variety [1]. These STARA-related task changes will influence another core construct, namely perceived workload. More specifically, during a RAS with reduced task variety, theater nurses perceive less workload than during non-RAS procedures [24,25]. In practice, however, whether a decrease, invariance, or even increase of task variety and workload will occur after the introduction of RAS depends on unit-specific work design and (secondary and primary) task allocations to the theater nurses [25]. If tasks are delegated to technology without compensatory task design, this subsequently results in decreased involvement of nurses and relates to higher monotony or lower application of professional skills. The latter phenomenon represents the key difference between surgical teams in this study, which was investigated with respect to the effects on professional skill application.

Technical and Nontechnical Professional Skills and System Resilience

In this paper, we use the umbrella term of professional skills and differentiate technical and nontechnical skills [3]. Technical skills often refer to trained knowledge and behaviors required to perform specific tasks. They are present across situations, acquired through training, and form an essential element of an individual's professional competencies [26]. Additionally, Human Factors also considers nontechnical skills, which refer to more generic behavioral, emotional, or cognitive activities shown in a specific situation [27]. Nontechnical skills can further be divided into two subgroups: cognitive (eg, SA) and social (eg, teamwork) nontechnical skills [27].

Nontechnical cognitive skills are significant predictors of safety and resilience in socio-technical work systems [2,3]. In particular, the nontechnical skill of SA is defined as a 3-level hierarchical construct. It consists of the perception of information and stimuli from the environment (I Perceiving),

XSL•FO
RenderX

the understanding of the meaning of this information and stimuli (II Understanding), and the anticipation of their state in the future (III Projecting) [28,29]. With a high level of SA, any changes in a situation can be noticed and, for example, communicated to the team [30], which highlights its importance for team resilience. Regarding the health care sector, maintaining SA or its levels can prevent errors in the work process, for example, by recognizing changes in vital signs, thus ensuring patient safety [29,31]. SA is, therefore, primarily intended to prevent critical situations from arising or escalating [32] and is of utmost importance in maintaining resilient systems [2].

From a Human Factors perspective, the effects of unit-specific task design and its effects during surgeries were of interest. We evaluated how task demands (ie, objective task variety, subjective workload, and perceived monotony) during RAS surgeries influence nurses' application of professional skills (Question 1).

Sustainable Careers: Task Demands, Professional Skills, and Needs

The case of RAS underpins the need for a trans- and interdisciplinary approach: at the task-level, it focuses on Human-Factors questions about optimal and resilient work design. At the career level, it raises pivotal issues of how technologically driven change shapes long-term professional identities and career evaluations. Whilst the former sections examine these interdependencies by analyzing task-specific demands and skill application, the following section focuses on the broader consequences for career sustainability in STARA-mediated health care settings.

Concepts and Models of Sustainable Careers

Most scholars define sustainable careers as "the sequence of an individual's different career experiences, reflected through a variety of patterns of continuity over time, crossing several social spaces, and characterized by individual agency, herewith providing meaning to the individual" [33]. More specifically, the theoretical model of De Vos et al [7] provides three key indicators that distinguish sustainable from unsustainable careers, namely health, happiness, and productivity. Crucial for perceived sustainable careers is a dynamic person-career fit over time, described as the ability to adapt and evolve with changing needs and environmental demands [34]. Chin et al [5] differentiate four dimensions (resourceful, flexible, renewable, and integrative) to capture the dynamic nature of career sustainability in fast-paced environments. The dimension of "renewability" highlights task redesign due to STARA, requiring employees to reorient their role perceptions, knowledge, and skills which also applies to the example of RAS as explained below.

Professional Skills and Task-Specific Design

On a task-level, "renewability" implies that workers evaluate the opportunities to apply, update, or learn role-related professional skills in the light of STARA task-change. In our case study, da Vinci robots fundamentally change the way theater nurses can participate in the workflow. A perceived loss of role-identity creating activities on task-level should therefore influence their evaluations on the career level. If the nurses are hindered in applying their professional skills during the surgery and anticipate this particular task design as a future scenario, they might experience a sense of role incongruence and frustration, leading to the anticipation of a less sustainable career.

However, Chin et al [5] do not elaborate or define specific task-level variables in their model on sustainable careers. Other literature on Career Research has differentiated between tasks within a job [6] or followed a task-based approach to investigate the effects of automation on skill requirements [35]. However, despite the detailed listing of tasks there is a lack of linkage, for example through integration into subsequent processes and analysis of preliminary and secondary tasks. Furthermore, the measurement of skills or competencies tends to be on a much more generic level in studies of Career Research [36,37]. Human Factors, on the other hand, investigates perceived application of professional skills on a "fine-grained" task-level of analysis in specific contexts, which could add to the understanding of career sustainability evaluation and model development.

Complementing the antecedents of sustainable career development in the model by Chin et al [5], a task-level perspective (task variety, workload, or complexity) may contribute to the individual and organizational level of the present theory. To our knowledge, no studies have been conducted on this cross-level mechanism between variations in the task-specific design of a use case and long-term evaluations of career sustainability. Thus, we explore in the case study how task-specific demands and perceived skill application align with reflections on career sustainability (Question 2a).

Career-Related Needs and Situational Perception of Workload and Skill Application

Several researchers elaborate on individual needs or motivation with respect to career evaluation. For example, Chin et al [5] point out that the needs of workers keep changing over their life courses, leading to interindividual differences in desires for sustainable careers. De Vos et al [7] indicate that the fulfillment of personal needs contributes to perceived career satisfaction or success. Especially, the sustainability indicator of happiness relates to how well the career aligns with one's values and needs, for example, the need for personal growth [7,38]. The opportunity to develop and apply new skills contributes to perceived growth and is also considered a facet of subjective career success [39]. In contrast, frustration through a mismatch between personal career needs and developmental opportunities has been linked to higher turnover intentions and job dissatisfaction [40]. However, career-related needs have not yet been connected to evaluations of a specific STARA-related task change. For example, workers with a high need for personal growth would evaluate tasks more critically if STARA hinders the application of skills rather than fostering development. On the other hand, workers with low growth needs would evaluate the objectively similar task less critically and therefore differ from their colleagues within the same unit. Thus, we explore in the case study how career-related needs correspond to situational evaluations of workload and skill application (Question 2b).

XSL•FO
RenderX

Study Contribution

The contribution of this paper is threefold. Firstly, the transdisciplinary multilevel perspective (person, task, and organization) enriches conceptual frameworks for both STARA-related Career Research and Human Factors. Career Research may benefit, for example, if taxonomies or task-level concepts of STARA design from Human Factors are integrated into career-related models to allow differentiated predictions on job threats and career decisions. Conversely, Human Factors will benefit from Career Research if task-designers recognize effects of interindividual differences in career-related variables on the evaluation of STARA design.

Secondly, the paper elaborates on theoretical and methodological perspectives for interdisciplinary STARA research. For example, the variance of task variety, workload, or skill-application between two embedded units raises questions of the appropriate levels of analysis for research models predicting career evaluations.

Thirdly, the paper contributes to applied questions of career development and Human Factors design on multiple levels. Organizations in health care and other STARA-affected fields (macro-level) are urgently looking for highly committed professionals (microlevel) for jobs in a drastically changed task-environment (meso-level). Thus, workplace interventions addressing task design and the consideration of interindividual differences (eg, growth needs) will contribute to retaining specialists in key professions with STARA work tasks that promote both the desired efficiency gains in productivity and personal development goals.

Methods

Background and Setting of the Case Study

In the project underpinning the case study, da Vinci assisted surgery was applied in two units (urological and visceral surgeries) of a hospital. Despite the similar surgical context, the number of tasks (task variety) for theater nurses differed between operating units due to unit-specific task design. Thus, this setting can be classified as embedded (multiple units) single-case design [41] and is illustrated through qualitative and quantitative data.

The underlying project had an application-oriented Human Factors character and aimed to explore qualitatively and quantitatively the effects of different task-specific designs in surgical workflows. A qualitative semistructured focus group interview (n=5) was conducted prior to the quantitative data collection (n=36). The aim of the interviews was to gain a qualitative understanding of the tasks and challenges during RAS and to explain the planned quantitative data collection in the units. Extending beyond a Human Factors focus, career-related experiences were also reported in these interviews. Both perspectives, Human Factors and Career, were subsequently examined empirically and exploratorily in the quantitative phase. This quantitative part of the case study was not designed as a hypothesis-testing study but provides insightful transdisciplinary perspectives.

Methods

Part One: Semistructured Focus Group Interview

The qualitative interview data of the case study derived from a semistructured focus group [42] involving five nurses experienced in the da Vinci X Surgery System (Intuitive Surgical Inc). All had a background in urology, with four also having experience in visceral surgery. The group included two operating department practitioners and three theater nurses. The focus group took place in a room adjacent to the operating theater of the hospital featured in this case study. The Human Factors question (Question 1) prompted was “What changes does the da Vinci robot cause in the different phases of surgery compared to laparoscopic surgery?” During the focus group interview, various aspects were discussed, such as changes in team collaboration (processes), changes in one’s own work and role (tasks, requirements, and skills), occurrence and management of problems, disruptions and critical situations, as well as general concerns, wishes, or ideas for the future design of RAS. Statements from the in-depth focus group interview were documented through field notes and assessed using thematic analysis [43] but without an elaborate coding strategy. Results are reported in a thematic structure later in this paper to illustrate experiences of nurses in terms of Human Factors and career-related perspectives in line with the research questions formulated above. Career-related aspects were not directly elicited but were reported by participants as outcomes of task-related work design and were further explored in the quantitative part.

Part Two: Postsurgery Surveys

The quantitative data of the case study was collected over a period of 12 weeks from June 2024 to September 2024. Theater nurses (including four participants from the interview) were surveyed following each RAS. They responded to task-specific items related to the surgery execution phase and to overarching scales on career sustainability and developmental needs. Variables and measures are displayed in Table 1. Approximately 28 RAS took place during this period, with a total of 44 returned questionnaires after surgery (79% response rate). Four data sets were excluded due to missing data. Four data sets were excluded because task variety was not quantifiable due to role switch or fluctuation during a procedure, resulting in n=36 data sets. Because some nurses had two or more da Vinci surgeries over the course of the study, seven participants completed the survey three times or more, and five participants completed it twice. In the current exploratory correlational analysis, the partially dependent data was treated as independent data points.

XSL•FO
RenderX

Table . Variables and measures of quantitative survey[a].

Variable	Measures
Task variety	Number of specific tasks assigned to theater nurses during the surgery execution phase and was coded by authors following Rau et al [44].
Subjective workload	Three items from NASA-TLX[b] [45] representing mental load, temporal load, and effort on a 15-point rating scale.
Subjective monotony	Two context-specific items on a 6-point rating scale, relating to underchallenge and boredom in DIN EN ISO[c] 10075 - 1 [46].
Perceived application of nontechnical cognitive skills (SA[d] I-III)	Perceived application of nontechnical cognitive skills, measured by behaviorally anchored items adopted from established behavioral observation scales by Schreyer et al [30]. SA I: perceiving, SA II: understanding, SA III: projecting.
Perceived application of technical skills	Single-item, "I was able to apply my skills and abilities to the surgical process" on a 6-point rating scale.
Perceived career sustainability	Participants were asked to reflect: "Imagine that the surgery evaluated here would be a typical day at work for future theatre nurses. In light of this, how do you rate the following career related statements?." Following De Vos et al [7] 3 indicators of sustainable careers were reflected (satisfaction, productivity, and health) using single items.
Growth need	Six items from the JDS[e] originally developed by Hackman and Oldham [47].

[a]All items are accessible in Multimedia Appendix 1.

[c]DIN EN ISO: Deutsches Institut für Normung Europäische Norm International Organization for Standardization.

[d]SA: situational awareness.

[e]JDS: Job Diagnostic Survey.

Ethical Considerations

The study adheres to ethical and legal requirements. Participation was voluntary, and informed consent was collected anonymously prior to participation. Participants received no form of compensation for their partaking in both parts of the study. Both parts of the study received prior ethical approval from the hospital's Clinical Ethics Committee (CEC) and the Staff Representative Council. The study complies with the General Data Protection Regulation (GDPR); participants' privacy and confidentiality of their data were maintained.

Results

Part One: Qualitative Data From the Focus Group Interview

Question 1

Nurses described varied experiences with workload, monotony, and skill application throughout RAS. During the phase of surgery execution (primary task), some reported a notably lower workload, largely due to the assistant surgeon taking over instrument handling. This reduction in engagement led to feelings of monotony and even boredom among theater nurses, who described this phase as repetitive. The reduction of involvement through instrument handling was associated with decreased SA. This can be seen as problematic since in RAS, nontechnical skills such as quick decision-making, cooperation, and quick adaptation to technical difficulties were noted as crucial. One aspect from the interview should be emphasized here and is reflected in the first implication at the end of this paper. It concerns the different evaluation of preparatory and concluding tasks (secondary tasks) in relation to the actual core task of executing the surgery. The monotony reported during surgery execution contrasted with heightened demands in surgery preparation and surgery conclusion. In these phases, staff often faced time pressures, especially in coordinating with anesthesia teams, whose shorter patient preparation times for RAS increase the demand on theater nurses. In response, nurses expressed a desire for additional support personnel. The lack of such support frequently led to overload, especially after undocking the robotic system, when multiple tasks needed immediate attention.

Question 2

Nurses also expressed complex views on how their involvement with RAS influences their job and career projections. The initial enthusiasm for working with advanced technology was reported to fade over time, with some indicating frustration due to the monotony during surgery execution. Additionally, although there was no concern over potential job replacement by the robotic system, questions were raised about future staffing needs: for example, whether two surgical nurses would remain necessary per RAS procedure. The lack of substantial, fulfilling tasks in RAS has led to a sense of diminished responsibility among some staff, with a desire for roles that offer more significant nontechnical skill applications and career development opportunities. While physical demands were not seen as problematic, some participants reported experiencing psychological stress due to workload peaks in phases of surgery

XSL•FO
RenderX

preparation and surgery conclusion. The potential for increased productivity was noted, especially if procedural bottlenecks, such as moving and preparing the robotic system, were addressed. Some staff members mentioned actively trying to reduce their involvement in RAS by transitioning to hospitals with lower frequencies in order to gain enough variety in their schedules to prevent RAS routine monotony.

Part Two: Quantitative Data From Postsurgery Surveys

Table 2 displays the nonparametric correlations (Spearman ρ) between the variables.

Question 1

Correlates indicate a relationship between objective task variety of theater nurses and perceived application of professional skills. The more tasks involved, the lower perceived monotony (ρ=−0.40; *P*=.02), and the higher perceived application of nontechnical (ρ=0.46; *P*=.005) as well as technical skills (ρ=0.39; *P*=.02). A similar pattern emerges for subjectively perceived workload during the surgical task.

Question 2

Results indicate that higher objective task variety and perceived workload during a surgical task are related to more positive evaluation of health-related career prospects (for task variety: ρ=0.37; *P*=.03 and for workload: ρ=0.47; *P*=.004). Similarly, the higher the perceived application of nontechnical and professional skills during a surgery the more positive reported health and productivity related career prospects appear. Moreover, results show a relationship between individual growth need and the individual evaluation of task characteristics and perceived skill application. Participants with high growth need report lower workload during surgery (ρ=−0.48; *P*=.003) and less perceived application of nontechnical (ρ=−0.48; *P*=.003) and technical skills (ρ=−0.30; *P*=.07).

Discussion

This study investigated how task-specific demands shape theater nurses' perceived professional skill application during RAS (Question 1), and how these task-level changes relate to broader evaluations of career sustainability and vice versa (Question 2).

Qualitative results showed that while the surgical execution phase reduced workload, it also heightened monotony and lowered situation awareness, whilst pre- and postoperative preparations led to overload due to time pressure and insufficient staffing. The quantitative data confirmed that in the execution phase higher task variety correlated with higher application of nontechnical and technical skills (Question 1). Moreover, task design and skill application during RAS were linked to nurses' career reflections in the qualitative data. The survey showed higher task variety and skill application during surgeries were correlated with long-term career sustainability evaluations. Moreover, career-related growth needs correlate with

XSL•FO
RenderX

interindividual differences in STARA task evaluations (Question 2).

Limitations of the Case Study

Firstly, it is important to note that the presented correlational data can only be interpreted to a limited extent because of data independence, context-specific unvalidated scales, and small sample size. Repeated observations from the same nurses were included deliberately, as task variety differs situationally across procedures, capturing meaningful within-person variation–, though ensuring fully distinct evaluations remains challenging. Spearman ρ was chosen as it evaluates monotonic relationships regardless of distributional properties [48] with more robust type I error control than Pearson *r* [49,50]. Furthermore, besides task variety and career-related needs, additional contextual factors (eg, duration of the surgery) may affect perceptions of monotony and skill application. However, for exploratory reasons, the data allows for cautious reflections regarding task-specific work design in the field of Human Factors (Question 1). A decrease in task variety during RAS correlates with monotony and reduced application of professional skills. As task variety fluctuates between units, it is the responsibility of surgical team leaders to create conditions which increase task variety through more possibilities to apply nontechnical and technical skills. Task designs with higher applications of nontechnical cognitive skills enable faster and more resilient responses in case of disruptions. Moreover, this contributes to the maintenance and development of individual skills as a requirement of humane work design [8,51].

Examining the relationships between task-level and career evaluations in RAS provides interdisciplinary insights (Question 2). It is evident that both the specific task design of RAS (eg, task variety) and the associated application of professional skills are related to individual evaluations of career prospects. Furthermore, interindividual differences must be considered, as variance in personal growth need covaries with different evaluations of task characteristics and career prospects [1].

The case study gives practical insights with high ecological validity but is empirically limited due to a small sample size, situationally changing context conditions, or changing team compositions. For example, the small number of nurses working with da Vinci in a hospital are surveyed and observed on multiple measurement points. However, depending on the work plan or the motivation to participate, the within measurements vary greatly and range from only one instance of participation to up to 4 sessions per person. This results in a small between sample with varying within measurement points. Moreover, this data is confounded through the complexity and dynamic of the work setting, such as personnel changes during a surgery or “outlier” situations which need to be coded and removed from the statistical evaluation. For this reason, STARA’s interdisciplinary Career Research requires quantitative multilevel methods that are robust against the violation of prerequisites, as well as a broad mix of qualitative and multivariate quantitative methods.

Theoretical, Practical, and Methodological Implications

The following section outlines the implications for Human Factors and interdisciplinary perspectives. These implications extend beyond the specific application of RAS and are discussed more broadly under the framework of STARA.

Human Factors’ Perspectives to Support Skill Application in STARA Environments

From a Human Factors’ perspective, the study’s findings emphasize that skill application in RAS is not determined by technology implementation alone, but rather by how surgical workflows are specifically designed and managed within different units of a hospital. Distinct task configurations across RAS procedures shape task-specific demands and are directly related to theater nurses’ perceived application of their professional skills. This highlights that leadership-driven work design and task allocation decisions, rather than STARA itself, play a critical role in whether skills are maintained, reduced, or expanded. Even within the same technological environment, variations between organizational units can create differences in opportunities for professional skill application. The consequences affect both broader system resilience and individual career projections.

First, professional skill application is closely tied to resilience, particularly through the maintenance of SA. In this case study, preserving nontechnical skills is not limited to perceiving and understanding or monitoring procedural steps (SA levels I and II), but also includes the critical ability to anticipate future disruptions or complications (SA level III). This anticipatory skill is essential for adaptive responses during unexpected events and directly contributes to resilience and safety of work systems. Examples are grounded in both health care and sociotechnical team research. In health care, projecting future states is critical for the early identification of complications and safety threats, thereby strengthening patient safety [52]. Furthermore, within sociotechnical team research, SA extends beyond immediate procedural coordination to encompass risk awareness regarding technological vulnerabilities, system limitations, and potential disruptions introduced by technologies themselves. This broader perspective is particularly relevant in STARA environments, where human actors must continuously perceive, understand, and project technology-related risks across a wide range of tasks [53].

Secondly, ongoing automation of tasks initiates a decrease in middle skilled jobs, such as theater nurses, leading to the individual use of career transition strategies [4]. This very effect became evident in the qualitative part of the case study when nurses mentioned transitioning from high-volume RAS sites to hospitals with lower frequencies. To avoid these negative STARA effects, human-centered design principles should be explicitly considered during the implementation of technologies. For example, Parker and Grote [8] underline the importance of task-variety, as well as human autonomy, skill-use, social interaction, or feedback. These factors can contribute to shaping the workplace and, thus indirectly, the careers of workers in STARA contexts in a way that is sustainable, healthy, productive, and beneficial to personal development. For example, lower task-variety in one subtask may be compensated

XSL•FO
RenderX

with additional primary or secondary tasks so that employees remain involved and can develop personal competencies. In the present case study, lower task-variety during surgery could be complemented by implementing mixed reality technologies in RAS to inform and involve nurses during inactive periods [54,55]. A prospective strategy would focus not only on skill training, but on fostering proactive work as well as task design. Providing competencies and resources for joint optimization of changing workplaces can foster the adaptation to STARA-induced changes [56]. Employees who perceive STARA as an opportunity, rather than a threat, are more likely to engage in job crafting [57], which may also support sustainable careers [5]. Designing human-centered STARA environments therefore requires preserving meaningful opportunities for both technical and nontechnical skill application to promote long-term career sustainability.

Consequently, task design should be understood as a strategic lever for fostering both sustainable careers and system resilience.

Interindividual Differences in Skill Application and Career-Related Needs Are Relevant for Evaluating STARA Work Systems

Human Factors as well as Career Research can benefit from a differential approach focusing on interindividual differences.

Human Factors Research should also consider that there will be interindividual variations in the evaluation of task-characteristics within a given STARA work environment. Evaluations of STARA work systems go beyond task characteristics (see Question 2b). In our case study, we found evidence that interindividual differences in individual growth needs correlate with subjective task evaluations (but not with the objective task variety). Nurses with high growth needs seemed to perceive generally lower workload and skill application than nurses with lower needs. Theoretically, the importance of individual motives on the assessment of work systems is not completely new (Hackman and Oldham [58] for work satisfaction, motivation, and turnover). STARA modifies task characteristics, but individual motives and interindividual differences in task evaluation are often neglected in Human Factors. Numerous motives and personality traits related to STARA work environments can be identified in organizational and Career Research, which may affect the evaluation of the system design in a specific work context (eg, need for autonomy or personal growth [38]). In this context, an interdisciplinary career perspective offers numerous starting points for Human Factors Research and theory development. Differential work design can be used to consider varying development needs based on these findings of interindividual differences in motives and traits.

For Career Research it is important to acknowledge that the perception of skill application in a particular task is highly individual. Beyond that, the interindividual perceptions also relate to the evaluation of indicators for sustainable careers [7]. Question 2a of our case study focused on perceived application of technical and nontechnical skills relevant to system resilience [3] and its link to career reflections. Nurses reporting higher application of role-related nontechnical skills reflected positively on career health, whereas perceived application of technical skills correlated with career productivity. This link between interindividual different perceptions of task-related skills and career evaluations should be considered in future Career Research as theories mention the complexity of objective environmental conditions and subjective evaluations resulting in a wide variety of individual reflections on whether one's career is sustainable or not [7]. For future investigations, Human Factors offers systematic measures of technical and nontechnical skills [30] which can also be applied in practice for resilient task design, personnel development, and career counseling.

Intraindividual Changes Are a Significant Temporal Variable for Theory and Practice

Theories of career sustainability underline the importance of temporal dynamics and intraindividual variation over time from a methodological and conceptual standpoint [5,7,34].

In the short term, research on career sustainability may investigate the effects of time and quality of individual experiences with STARA technology. In this respect, Human Factors Research provides measures and evidence about user experience [59]. User experience does not only have a quantitative temporal focus (ie, the duration of experience with a STARA technology), but also a qualitative one. For example, quality depends on whether STARA experiences fulfill effort and performance expectations [12]. Thus, time and quality of user experience may add technology-related variables to the individual level of models on career sustainability, stimulating future research on STARA implementation.

In the long term, attitudes towards STARA may vary throughout an individual's lifetime. As shown in gerontological research [60], goals related to personal growth and new experiences decrease with age. This variable is related to growth needs and was negatively correlated with perceived career sustainability in our study. Future research may investigate how shifts in personal goals or other motives impact career evaluations, especially in STARA environments.

Human Factors Task Characteristics Expand Models of Career Sustainability

STARA includes an overwhelming variety of technical applications with different implications for workers' career sustainability across diverse contexts. For example, Chin et al [5] focus on manufacturing workers facing full automation of the entire work task correlated with job insecurity and fear of job losses. In contrast, in our case study of RAS, the automation affected one specific subtask regarding SA. The two examples differ essentially in the extent of STARA-induced changes and subsequent career assessments but become comparable on task-level characteristics. Present conceptual frameworks of career sustainability [5] could benefit from expanding the individual and organizational levels to a task-level with different variables such as LoA, task type, or task variety.

First, LoA [61] indicates the degree of autonomy with which STARA technology performs tasks independently from human control. Low degrees of technical autonomy, such as in our RAS example, can have very different effects on career sustainability compared to high degrees of automation, where

XSL•FO
RenderX

machines generate and implement decisions without human involvement. Second, automation through STARA may affect different task types like monitoring, planning, decision-making, or execution [11]. In one context, automation can be related to an executing task in manufacturing [5]. In another context, STARA might automate a monitoring task, leaving decision and execution tasks to humans with different consequences for career evaluations. Third, task-variety can be used to investigate STARA-induced changes between or within contexts. As shown in the case study, nurses' evaluations of career sustainability can even differ when working in the same context with the same technology but in different surgical work units. Nurses with higher objective task variety seemed to reflect generally more positively about anticipated health, one indicator of sustainable careers. Furthermore, task-level analysis also involves the composition of primary and secondary tasks. In the case study, we focused on the variety of tasks nurses performed during the primary task of surgery execution. In addition to this core task, there are preliminary and concluding secondary tasks that might shift in their task characteristics due to STARA and thus influence career evaluations.

The task-level variables mentioned could be further supplemented, for example, by STARA-relevant team-level variables such as team cohesion or team trust [12]. As has been requested in previous studies on sustainable careers [5], task and team-level variables from Human Factors could enrich the framework as relevant predictors, mediators, or moderators, and inspire future studies.

Interdisciplinary Perspectives on STARA Require Conceptual and Methodological Clarity

The former 4 implications display valuable synergies of interdisciplinary research by integrating person, task, and technology characteristics into frameworks of sustainable career as well as Human Factors research. This added value was also highlighted in the case study, which will now be supplemented by conceptual and methodological desiderata for future research.

When interdisciplinary concepts are integrated into models, it must be ensured that variables with the same name do not represent different content or operationalization. In our case study, the perceived application of technical and nontechnical skills was a variable connecting Human Factors with Career Research. Both disciplines have an extensive body of research on skill-related concepts, measures, and models (eg, recruitment diagnostic, and lifelong learning in Career Research; skills for system resilience, and problem solving in Human Factors). However, we were faced with the challenge that even within the discipline of Human Factors, researchers applied terminologies and definitions heterogeneously, which calls urgently for conceptual clarifications. For example, some authors refer to nontechnical skills as skills [27] some as competencies [62]. This issue, referred to as Jingle-Jangle-Fallacy, hinders STARA-related research, because interdisciplinarity increases language diversity [63].

Besides conceptual clarity, our study underlines the careful distinction between objective and subjective evaluations on a measurement level. For example, it is necessary to carefully distinguish between the objective expression of professional skills in a STARA context and the subjective self-evaluations as conceptualized in this study. Consequently, for fruitful interdisciplinary research, it is crucial that concepts, definitions, and operationalization are clearly described and that future work identifies existing inconsistencies (for methods see [63]).

Conclusion

This paper highlights the importance of conceptually and empirically linking task characteristics to career sustainability in health care-related STARA work contexts and beyond. It is the way new technologies are implemented into existing work processes, and not technology itself, that changes task characteristics. This, in turn, affects both short- and long-term employee career experiences in the health-care sector. Research on sustainable careers in particular can benefit from the expansion of existing theories to include highly task- and context-specific variables that can explain inter- and intraindividual differences in career evaluation. Thus, cross-disciplinary insights can and should enrich Career Research's theoretical models, empirical investigations, and practical interventions with constructs and measures.

Acknowledgments

We thank all participants for taking part in this study. The authors would also like to thank the anonymous reviewers and the editor for their constructive comments and valuable suggestions, which substantially improved the quality and clarity of this manuscript.

Abstract

Background: The COVID-19 pandemic highlighted the need for practical digital health tools to support informed decision-making amid rapidly evolving evidence and widespread misinformation.

Objective: We iteratively developed and refined VaxDA-C19, a bilingual (English and French) web-based patient decision aid designed to support informed decision-making in Canada about COVID-19 vaccination. VaxDA-C19 integrates interactive and

XSL•FO
RenderX

personalized features aimed to enhance vaccine confidence, reduce cognitive overload, and respond to diverse informational needs.

Methods: VaxDA-C19 was developed using an iterative, user-centered design approach. Throughout the development process, we involved a citizen panel, health care professionals, user experience designers, and scientific experts to guide refinements. We also conducted usability testing sessions with adults in Canada, using semistructured interviews, comparative testing, and think-aloud protocols with thematic analysis. We ultimately conducted 4 design cycles in total with adults in Canada (users) and expert reviewers (experts). Cycle 1 involved 9 people (9 users), cycle 2 involved 22 people (22 users), cycle 3 involved 9 people (3 users and 6 experts), and cycle 4 involved 9 people (9 experts).

Results: In cycle 1, user feedback guided design decisions about how to present quantitative information and technical vaccine descriptions more simply. In cycle 2, while most users (9/11, 82%) favored in-depth explanations of vaccine development, a few raised concerns about content that could be perceived as politically charged. Cycle 3 identified usability improvements, including more explicit navigation controls, simplified medical terminology, and optimized interactive components (avatars and sliders). Expert reviews in cycle 4 refined linguistic consistency, mobile responsiveness, content transparency, and scientific accuracy, emphasizing explicit instructional guidance and bilingual accessibility.

Conclusions: Our iterative process produced a personalized, bilingual digital decision aid to support evidence-informed, values-congruent decisions about COVID-19 vaccination. A randomized controlled trial will further evaluate VaxDA-C19's impact on vaccination intentions, knowledge retention, emotional responses, decisional conflict, and decisional regret. If it proves effective, the patient decision aid may also be used as a platform to support other vaccine decisions, namely, influenza, measles, shingles, pertussis, and potentially other emerging infectious diseases.

Introduction

The COVID-19 pandemic exposed challenges in public health decision-making driven by rapidly evolving scientific evidence and widespread misinformation [1-8]. People had to make complex choices, such as whether to accept vaccination or adopt preventive behaviors, often under conditions of uncertainty [4,9-13]. These challenges highlighted the need for decision support tools that empower users to make values‐congruent choices informed by the best available evidence [1,10,14-21].

Patient decision aids support shared decision-making by making decisions explicit, providing balanced and evidence-based information about options, and helping individuals clarify their values [22]. Robust evidence from meta-analyses and systematic reviews, including a comprehensive Cochrane review, demonstrates that patient decision aids significantly improve knowledge, accuracy of risk perceptions, and alignment between decisions and personal values, while also reducing decisional conflict [23,24]. In the context of vaccination, a systematic review and meta-analysis of 5 randomized controlled trials (total n=2158) found that patient decision aids for vaccine decisions had significant positive effects on both vaccine intentions (odds ratio 1.89, 95% CI 1.20‐2.97) and uptake (odds ratio 1.77, 95% CI 1.25‐2.52) [25].

Emerging evidence suggests that interactive and personalized digital tools can encourage behavior change among individuals who have not yet engaged in recommended practices, reinforce existing behaviors, and provide reassurance [26-29]. Such multiple purposes may be particularly critical during periods of crisis, when individuals seek validation for their actions and guidance for future decisions [30,31].

As COVID-19 vaccines move toward regular annual or biannual vaccines in Canada, similar to influenza vaccines, there is a need for patient decision aids that can be easily updated to reflect updated vaccines and recommendations. To this end, we created VaxDA-C19, a web-based vaccine (Vax) patient decision aid (DA) designed to support COVID-19 (-C19) vaccination decisions in Canada. VaxDA-C19 is designed to support multiple languages and to provide information in a layered way, meaning that people who want to quickly access basic information can view brief bullet points, while those who want to know more can expand sections, get more details, and access original references. Our goals were to provide clear, evidence-based information on vaccination options, benefits, and risks to oneself and others while reducing cognitive overload. This paper describes VaxDA-C19's design and development process.

Methods

Overview and Theoretical Frameworks

We developed VaxDA-C19 using an iterative, user-centered design approach. Our overall design process followed the International Patient Decision Aids Standards [32]. The patient decision aid was structured according to the Ottawa Decision Support Framework [33]. The web-based design and development approach combined human-centered design principles [34] and a Scrum framework [35]. Human-centered design was implemented via early and ongoing involvement of users and stakeholders, iterative prototyping, and cycle-by-cycle usability feedback to enhance content layout, navigation, and overall user experience (UX) [34]. Scrum served as a structure for delivering small, incremental updates through brief

XSL•FO
RenderX

development cycles, with backlog prioritization and periodic review sessions to ensure that implementation aligned with new evidence and user input [35]. We tailored Scrum for this project by synchronizing review points with usability testing rounds. These rounds included checkpoints to validate content and evidence for modifications to vaccine information or recommendations. We also used streamlined remote meetings to accommodate the team and respond to evolving guidelines.

Throughout the development process, we involved a citizen panel, health care professionals, UX designers, and scientific experts to guide refinements. We also conducted usability testing sessions with adults in Canada, using semistructured interviews, comparative testing, and think-aloud protocols with thematic analysis. We ultimately conducted 4 design cycles in total with adults in Canada and expert reviewers. Cycle 1 involved 9 people (all prospective users), cycle 2 involved 22 people (all prospective users), cycle 3 involved 9 people (3 prospective users and 6 experts), and cycle 4 involved 9 people (9 experts).

Citizen Panel

To help guide the overall project, a citizen panel of 6 individuals, comprising people from a range of age groups, languages, educational backgrounds, health statuses, and geographic regions (Alberta, Saskatchewan, Ontario, and Québec) provided feedback about the design and development of the patient decision aid and other interventions (reported separately) as well as the user testing methods and results. In the context of COVID-19 restrictions in place at the beginning of the project, the citizen panel was assembled from existing contacts with patient and citizen partners across a range of prior projects and life circumstances. This group met by Zoom (Zoom Video Communications) for 2 hours at a time to discuss ongoing project design, development, and study planning. This group served as an advisory panel, distinct from user testing with previously unknown members of the general public, described below [34].

Expert Involvement

Health care professionals and research experts, including infectious disease researchers, epidemiologists, primary care providers, and 2 UX designers (internal and external experts), participated in the iterative process as expert reviewers. The designers' expertise covered interaction design and usability evaluation (UX research and testing) as well as visual and information design. The internal designer was part of the senior author's (HOW) human-centered digital health research team and supported participatory design activities, including planning and conducting user testing in field settings or in a human-computer interaction laboratory. The external designer is a UX lead specializing in design systems, including the development and evolution of interface components. Depending on their exact area of expertise, the designers' roles were to support content presentation, interface coherence, and usability of the web-based patient decision aid [34].

Ethical Considerations

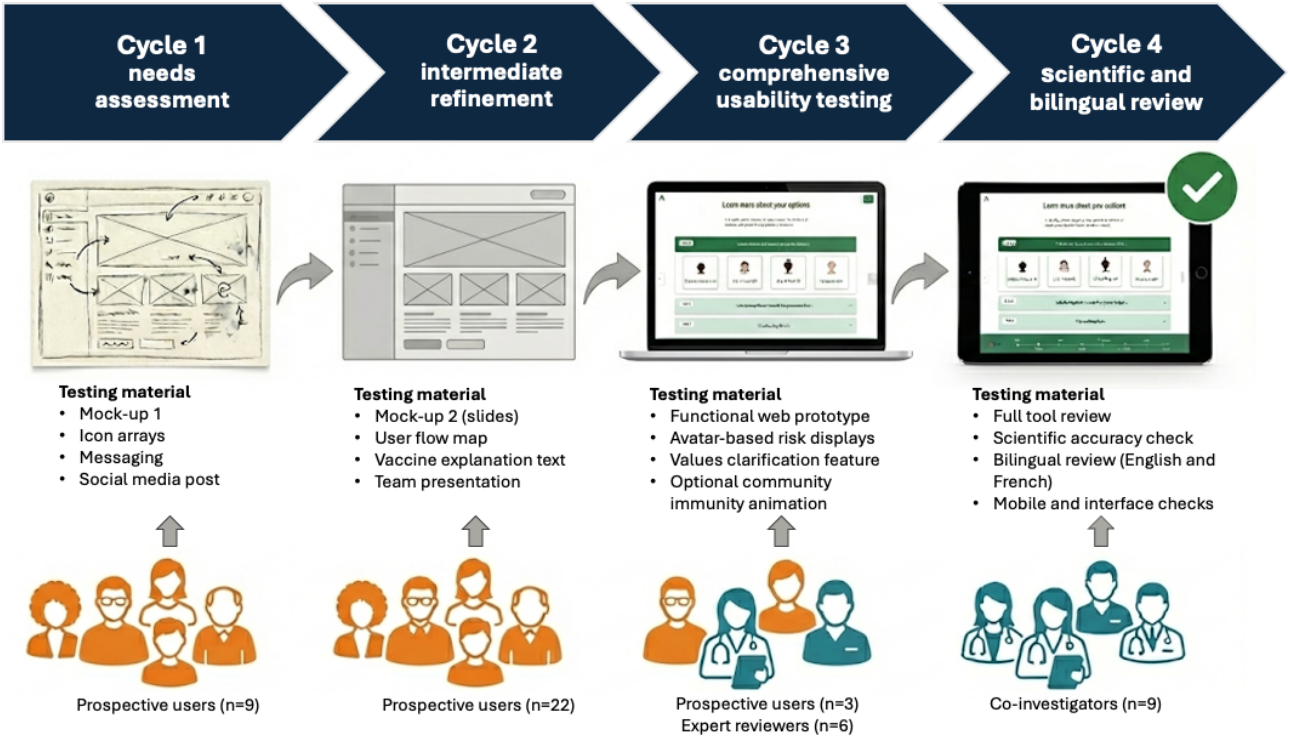
This study received ethics approval from the "Comité d'éthique de la Recherche en Sciences de la Santé" of the Université Laval (approval: 2020 - 222). All participants received detailed study information and provided written informed consent before participation. We offered user testing participants US $28.80 for their time and to help defray internet costs. We removed all identifying details of participants from reports and ensured the confidentiality of data according to institutional policies.

Recruitment for User Testing

In light of COVID-19 restrictions in place during the bulk of this project, we used online tools to conduct our user tests. Specifically, we recruited user testing participants through tailored Facebook advertisements, then conducted user testing sessions using Zoom, with participants sharing their screen with the interviewer. In line with the objectives of human-centered design, the recruitment process involved a nonprobability convenience sample to support rapid, iterative refinement. The findings were intended to inform design improvements rather than statistical generalization [36]. Eligible participants for user testing were adults (≥18 years) residing in Canada, able to communicate in English or French, and possessing basic computer skills. Individuals without internet access or unable to provide informed consent were excluded. We therefore selected Facebook options to advertise to people who were 18 years and older across Canada and who indicated an education level of either an associate degree (eg, 2-year postsecondary diploma), high school graduate, or unspecified. We did not exclude people who had other educational statuses but used tailored recruitment in an effort to include people across a range of backgrounds, as our previous experiences suggested that people who respond to such advertisements are often more highly educated. We stopped recruiting for each cycle after reaching thematic saturation in comments and usability issues identified.

Overall Design of the Intervention

We used Figma design software to iteratively design the overall structure and appearance of VaxDA-C19. As described further in the Results section, the patient decision aid ultimately included an introductory section in which the patient decision aid is presented, and the user selects the age group of the person for whom a decision is required (themself or their child), their province or territory of residence (which determines which vaccines are available), and the decision they are making (whether or not to get a primary series of vaccines, whether or not to get a booster dose, which vaccine to get, or which booster to get). The user is then invited to create an avatar representing themself or their child. This avatar is used in the next section, which describes the individual-level benefits and risks of the vaccine. VaxDA-C19 offers layered, straightforward summaries of evidence tailored to the user's selected age, group, province or territory, and decision, including vaccine availability and eligibility based on current authorizations and guidelines. It presents individual benefits and harms in both text and visual risk formats, with links to public health sources and peer-reviewed evidence. The top of the page provides a summary, and the user can click to view more detailed explanations below the summary. On the next page, the user can choose to create up to 8 more avatars representing people around them or their child or to have additional avatars auto-generated. They may then view or skip a brief (2.5-minute)



XSL•FO
RenderX

animation showing how vaccination may protect those around us [37]. This optional brief animation explains community immunity and can be viewed or skipped. At the same time, core evidence on individual risks and benefits, along with the rest of the patient decision aid, remains accessible at all times. Following this optional component, the user is invited to reflect on what matters to them, relevant to the decision, using a values clarification method previously developed and tested in the context of treatment decisions and influenza vaccination decisions [38]. Finally, the user has the option to read answers to frequently asked questions (FAQs) and to learn more about our team. A short walk-through video is available on YouTube [39].

Design and Development Approach

Our multidisciplinary team followed a human-centered design over 4 iterative cycles, summarized in Figure 1 [34]. We reported our patient decision aid development process using the DEVELOPTOOLS reporting checklist, provided in Checklist 1 [40]. As per the International Patient Decision Aids Standards [32], our design process was structured in multiple testing cycles, each involving small to medium user samples (3 - 31 participants, no overlap between cycles). This aligns with cognitive ergonomics standards [41-43], which state that iterative testing with small samples efficiently identifies approximately 85% of usability issues per cycle. After each cycle, the team met to review findings and make decisions about modifications. The citizen panel met separately throughout the project to offer advice from their viewpoints.

Figure 1. Iterative development cycles of VaxDA-C19, a web-based patient decision aid.

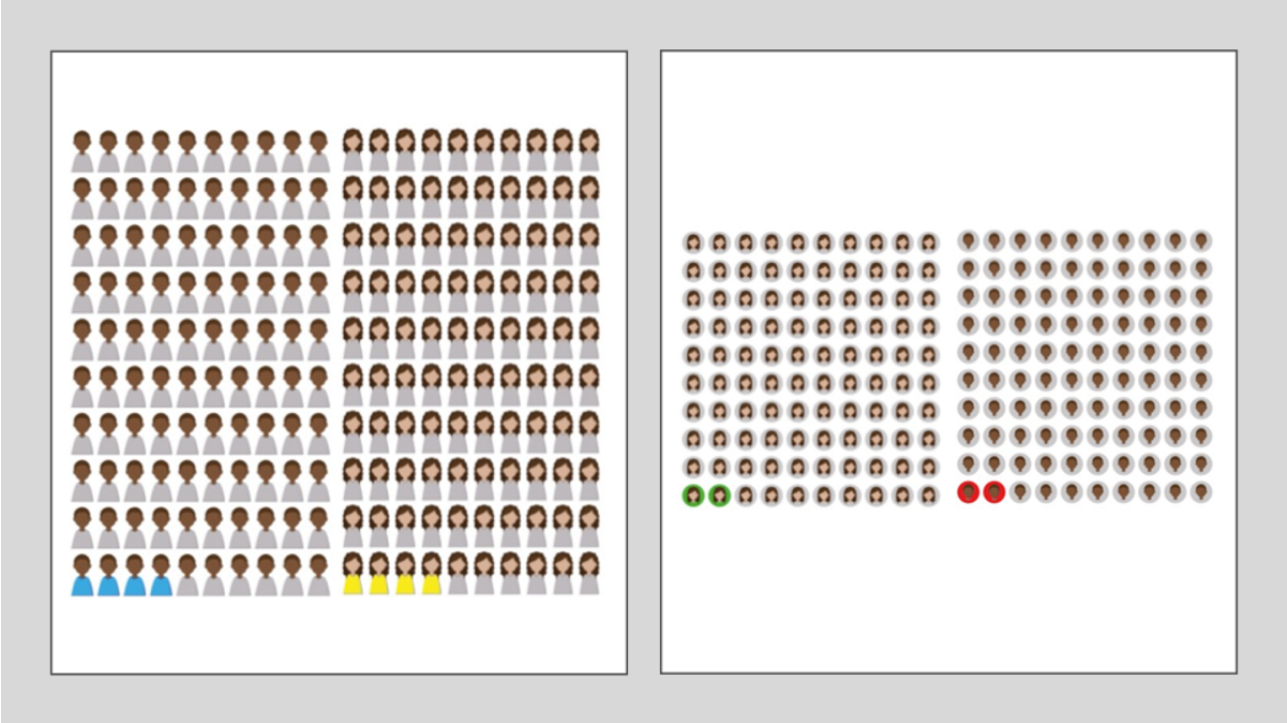
Data Collection and Analysis

We used Zoom to conduct user testing interviews. We evaluated whether VaxDA-C19 met its communication goals, and then applied a rapid thematic analysis [44,45] to qualitative data from interviews, comparative testing, and think-aloud sessions. Two trained research associates (EP and HH) independently coded transcripts, first extracting functional requirements (ie, needed features, content adjustments, and navigation flows), and then flagging any usability issues. We resolved disagreements through discussion with the lead author (DE) and principal investigator (HOW) until we reached a consensus. Finally, DE, EP, and HOW organized the agreed functional requirements and identified bugs into a clear, detailed plan to guide the development team. We reported the qualitative components in line with the SRQR (Standards for Reporting Qualitative Research) and provided the completed checklist in Checklist 2 [46]. We documented cycle-by-cycle decisions and changes to support transparency.

Iterative Cycles

Across all cycles, we presented participants with increasingly higher-fidelity versions of VaxDA-C19 prototypes. We asked participants to summarize the information, identify points of confusion or unanswered questions, and react and respond to wording.

Cycle 1



For the needs assessment, we developed an initial content mock-up of VaxDA-C19 focused on primary COVID-19 vaccination (first-dose decision). We based the mock-up's content on contemporaneous recommendations from the Canadian National Advisory Committee on Immunization, the Institut National de Santé Publique du Québec, and Health Canada authorizations. Feedback from the citizen panel and content experts addressed clarity, scientific accuracy, and relevance. We then recruited participants (n=9) via tailored Facebook advertisements and conducted individual

XSL•FO
RenderX

semistructured Zoom interviews, whose interview guides are shown in full in Multimedia Appendices 1 and 2. In each session, we asked participants to interpret icon arrays, react to hypothetical provider messaging, and consider a social media post.

For the icon arrays, as shown in Figure 2, we offered 2 icon array styles for risk communication: avatars with colored shirts and avatars with circular backdrops, and asked participants to compare these, focusing on how well or poorly these visual aids conveyed risk data.

Figure 2. Icon arrays used during the first cycle.

For the provider messaging, we asked people who were able to receive messages from their primary care provider,

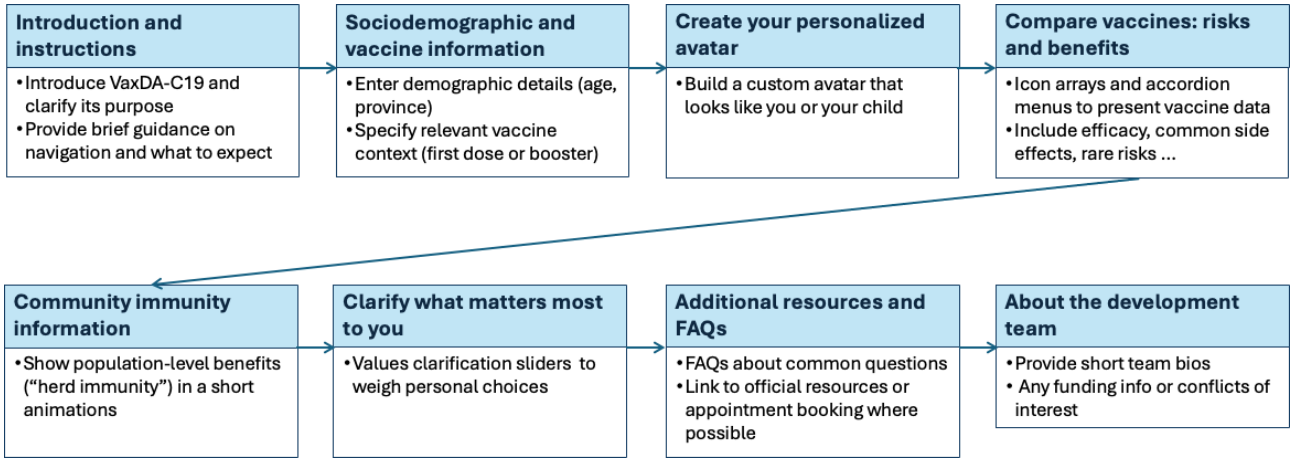
> *Imagine your primary care health professional (e.g., family doctor, nurse practitioner) sends you a message like, "I got my COVID-19 vaccine when I was eligible. Now that you are eligible, I'd like to support you by answering any questions you might have. Here's a link with some information: link. Please send me a message if you have more questions." How would that make you feel? How might you react or respond?*

We asked participants who were unable to receive messages to respond to a similar message, but imagining it was during an in-person visit. Full details are shown in Multimedia Appendix 1.

The proposed social media post aimed to explain why COVID-19 vaccines moved so rapidly through development, for use in a potential image-based post, such as an Instagram carousel. The proposed English text is present in Textbox 1. Full text is available in Multimedia Appendix 2.

XSL•FO
RenderX

Textbox 1. English content for the social media intervention (Instagram carousel) explaining the accelerated development of COVID-19 vaccines.



- 9 women can't make a baby in 1 month, no matter how well they work together!
- But when a bunch of the world's best scientists work together, with enough research funding, motivated by a pandemic that is disrupting lives around the world, vaccine development can happen faster than usual.
- Making a new vaccine usually involves months or years of waiting time. Waiting to get more research funding. Waiting for enough people to sign up for studies that make sure the vaccines are safe and work well. Waiting for approvals from independent regulatory authorities before starting to produce the vaccine for distribution.
- Usually, this waiting happens because the need for the vaccine isn't considered urgent enough for everyone to drop everything else and make the new vaccine everyone's top priority. But COVID-19 has been a different story. It has been a priority around the world.
- To make COVID-19 vaccines, they cut out a lot of the waiting. But they didn't cut corners. All the safety checks are still being done. When COVID-19 vaccines are approved by Health Canada (Canada's independent agency, staffed by top-notch scientists and not affiliated to any political party) you can trust that they are safe and they work.
- We are Canadian scientists, doctors, nurses, and experts in health and vaccines. None of us works for pharmaceutical companies. We don't accept pharmaceutical funds either. We will get the COVID-19 vaccines for ourselves as soon as they are approved by Health Canada and available to us. Once they have been tested and approved for children, our children will get the vaccines, too.
- Still have questions about COVID-19 vaccines and don't know where to ask? We want to use our scientific training to help answer your questions. Send us your question here. We will do our very best to answer as many as we can.

Cycle 2

Based on results from cycle 1, after identifying initial user needs, we developed the first version of content using Google Slides to create mock-ups of a proposed website. These mock-ups served as early prototypes, allowing us to conceptualize the user interface and gather feedback from the citizen panel on design, usability, and information presentation prior to investing substantial time in web development. Figure 3 maps the user flow. It began with a page of welcome text and instructions, then a page in which people indicate the age and province of residence of the person for whom a vaccine is being considered, then a page in which people build an avatar representing that person, then a page showing the individual-level risks and benefits of the vaccine for that person (using the avatar previously created to illustrate statistics), then a section showing the population-level benefits of vaccination, then a values clarification method to help people align their decision with what matters to them, and finally, FAQs, information about where to obtain a vaccine, references supporting the content, and information about our team.

We then recruited new participants (n=22) via tailored Facebook advertisements and conducted a second round of individual semistructured interviews on Zoom, again applying thematic analysis (Multimedia Appendices 3 and 4). In each interview, we asked: "In your own words, what was this text about?," "Why do you think these vaccines arrived so quickly?," and "What important questions about COVID-19 vaccines remain unanswered?" During these sessions, we used A/B testing to compare designs and content presentations of the team working on VaxDA-C19 and related projects. A/B testing, or split testing, involves presenting 2 versions (A and B) of a webpage or app to different user groups to determine which version performs better based on predefined metrics [47]. In this case, participants viewed 2 versions of the team presentation. Version A included only drawings, while version B included photographs and the names of research team members. Full details of the 2 designs are available in Multimedia Appendix 4.

Figure 3. User flow representation of our web-based patient decision aid, VaxDA-C19. FAQ: frequently asked question.

XSL•FO
RenderX

Cycle 3

Cycle 3 moved VaxDA-C19 from static mock-ups into a fully functional web prototype, and then tested it with end users and experts. Based on results from cycle 2, we added 5 interactive features. These included having users create a personalized avatar to promote personalized user engagement [48,49] and to take advantage of the Proteus effect, a documented effect in which people identify with their avatar [50,51]. VaxDA-C19 then uses that personalized avatar in icon arrays to facilitate visual risk comparisons [52-54]. It also offers users the option to view a 2-minute visualization incorporating their avatar, previously developed by our team to illustrate how community immunity (herd immunity) may contribute to protection [48,49]. The visualization makes use of 4 theories or frameworks: the health belief model [55], Gestalt visual principles [56], the cognitive theory of multimedia learning [57,58], and the affect heuristic [59,60]. We also added a values clarification feature, as per International Patient Decision Aid Standards, to help users align their vaccine decision with their values [61,62]. Finally, we used accordion menus (menus that show a brief title and allow people to click to open for full information) to enable users to decide for themselves how much or how little information they wish to read about the available vaccines [63]. We built the prototype in Vue.js (HTML, CSS, and JavaScript) [64] with JSON-templated content. This architecture enabled rapid updates as new vaccine data and guidelines evolved.

Next, we conducted a third round of online user testing, again recruiting new participants (n=3) via tailored Facebook advertisements. Through individual semistructured interviews on Zoom, we used think-aloud protocols focused on multidevice compatibility, navigation, and overall usability (technical details in Multimedia Appendix 5).

Following user testing, the lead author (DE) presented the prototype at the 18th Biennial European Conference of the Society for Medical Decision-Making during the Society for Medical Decision-Making Core Course: Introduction to shared decision-making and patient decision aids. During the session, attendees engaged in a discussion in which attendees shared insights from their respective fields. As part of this discussion, the lead author (DE) had the opportunity to show the attendees the progress of our work and to get their feedback. This additional expert feedback (n=5) addressed some direction on medical content and interface navigation. In addition, an external UX designer (n=1) delivered targeted feedback after testing to complement the internal designer's expertise.

While this cycle was underway, evolving public health guidelines suggested 4 distinct vaccination decisions: initial COVID-19 vaccination for those aged 12 years and older, booster doses for those aged 12 years and older, initial vaccination for children aged 6 months to 11 years, and booster doses for children aged 6 months to 11 years. We therefore restructured VaxDA-C19 accordingly.

Cycle 4

In cycle 4, we finalized VaxDA-C19, such that it might be ready for testing in an online randomized controlled trial. We updated its content to reflect the most recent Health Canada-authorized COVID-19 vaccines and national recommendations from the National Advisory Committee on Immunization. We then invited project coinvestigators to conduct an expert review; 9 experts provided detailed feedback. The expert reviewers were project coinvestigators with multidisciplinary expertise relevant to patient decision aids and COVID-19 vaccination, including digital health, human-centered design, virology, vaccinology, infectious disease epidemiology, primary care, public health, risk communication, health equity, and knowledge translation. Evaluation criteria encompassed scientific accuracy, linguistic clarity, content completeness, and user journey across all 4 vaccination decisions.

Based on this feedback, we prioritized key modifications, including removing irrelevant vaccine selection options for specific age groups, clarifying instructional text to specify required selections more clearly, incorporating contact information and funder logos on the homepage, and resolving layout inconsistencies, notably mobile interface challenges. Textbox 2 presents a synthesis of the key insights and considerations that emerged from our iterative design and development process.

Textbox 2. Key points from the design and development process.

Recruitment strategies: Recruitment through tailored social media advertisements (Facebook), complemented by internal dissemination via research team networks, effectively reached a diverse group of participants, including variations in educational level, age, language, and geographic location. Future studies could potentially benefit from additional strategies, such as direct collaboration with community-based organizations.

Iterative usability testing: Short, iterative usability cycles (4 cycles, sample sizes from 3 to 22 participants each) allowed rapid identification and correction of usability issues. Participants' repeated feedback emphasizes the need to simplify interactive elements (eg, avatar creation, icon arrays, and value clarification sliders), which may have contributed to enhanced clarity and ease of use across testing cycles.

Flexible content management: Implementing JSON-based templates allowed efficient updates to rapidly evolving vaccine guidelines, easing the task of ensuring ongoing scientific accuracy. Early involvement of content experts contributed to the accuracy, clarity, and scientific rigor of the web-based patient decision aid.

Multidisciplinary input: Feedback from diverse interested parties (patients, health care professionals, user experience designers, and researchers) contributed a wide range of perspectives on the clinical relevance, usability, and accuracy of VaxDA-C19.

Table 1 provides an overview of each cycle, along with the major modifications we implemented.

XSL•FO
RenderX

Table . Cycle summaries.

Cycle	Objective	Sample size, n	Procedure used	Main modifications
1	Needs assessment	9 users	• Semistructured interviews • Thematic analysis • Comparative testing	• Clarified initial content
2	Intermediate refinement	22 users	• Google Slides mock-ups • Comparative testing • Thematic analysis	• Added avatar, accordion, icon arrays, visualizations, values clarification feature
3	Comprehensive usability testing	3 users+6 experts	• Think-aloud protocols • Functional prototype testing	• Multidevice optimization • Refined navigation • Specified 4 distinct vaccination decisions
4	Scientific and bilingual review	9 experts	• Expert review • User journey analysis	• Updated content • Included French translation • Improved interface and instructional text

Results

Participant Characteristics

Across the cycles, 45 participants responded to our user testing recruitment efforts, of which 34 completed one iterative user testing phase (cycle 1: n=9, cycle 2: n=22, and cycle 3: n=3). Prospective participants who did not complete the testing did so because they did not wish to finish the study (n=2), were unavailable for any of the times scheduled for testing (n=4), responded after we had already reached saturation in findings (n=2), or for other reasons (n=3). Among the 34 participants, the mean age was 49 (SD 16) years. The majority of our study participants were women, Canadian-born, and English speakers. In total, 11/34, 32% of participants reported an ethnocultural identity other than White. Detailed demographics are shown in Table 2.

Cycle 1

Main Findings

Icon-Array Interpretation

All participants (n=9) correctly identified the icon arrays as representing a "group of people" and understood that the colored icons indicated numerical or probabilistic information. However, some participants struggled initially with the precise probabilistic meaning of each icon. Regarding layout preferences, 5 participants preferred the arrays using circular backgrounds, finding them "easier to count" due to clearer spacing and structure. In total, 3 participants favored the shirt-colored arrays because they appreciated seeing "more character detail," and 1 participant found both layouts equally clear but mentioned that the shirt-colored icons seemed to visually represent more data because of their elongated shape.

Provider-Sent Message Framing

When participants reacted to the hypothetical vaccine recommendation message from their primary care provider (Multimedia Appendix 1), 5 of 9 participants expressed neutral feelings toward the message. In total, 2 of 9 participants indicated that receiving such a message would encourage them to consult their provider with further questions. One participant (1/9) found the message reassuring, whereas another (1/9), who had expressed prior vaccine concerns, felt "pressured and uncomfortable."

Vaccine-Confidence Social Media Text

All participants (9/9) appreciated the explanation provided about the rapid vaccine development process (Multimedia Appendix 2). Nevertheless, several participants raised concerns regarding the text's accessibility and readability. Specifically, 5 of 9 participants thought the text was appropriate mainly for highly educated people or those who already trust the authorities. In total, 3 of 9 participants indicated that the text was too long. Conversely, 3 of 9 participants found this message reassuring. Another 3 of 9 participants (1 English-speaking and 2 French-speaking) reported confusion with the opening sentence, unsure how it related to the subsequent content. Additionally, 1 participant expressed concerns about insufficient transparency regarding potential vaccine side effects.

Citizen Panel Recommendations

The citizen panel (n=6) recommended incorporating relatable real-world data into the patient decision aid, automated vaccine selections based on provincial guidelines, and helped to refine visual branding with a logo.

Changes for the Next Cycle

Following the cycle 1 findings summarized in Table 3, we implemented several targeted modifications to improve the patient decision aid. We explicitly clarified that each icon represented 1 individual in a given population to address confusion around probabilistic visualization. Considering mixed feedback on icon-array layouts, we retained both designs for further testing.

We revised the health care provider message to a more neutral tone, addressing concerns about pressure or discomfort. Finally, to improve the vaccine-confidence content, the structure was reorganized to enhance clarity. We simplified technical language, clarified the opening sentence, and incorporated more transparent information about potential side effects, in line with participants' expectations regarding tone, accessibility, and completeness.

XSL•FO
RenderX

Table . Summary of thematic feedback from cycle 1 user testing (n=9) and changes made following citizen panel recommendations.

Theme and key feedback or issue		Participants, n (%)	Resulting modifications
Avatar arrays			
	Interpreted as a "group of people"; needed a clearer explanation that each icon represents 1 individual in a population	9 (100)	Added explanatory text indicating probabilistic meaning
Icon array design preferences			
	Circular array for better spacing	5 (56)	Refined visual layout, used more spacing
	Shirt-colored array for character detail	3 (33)	None (optional alternate design retained for future testing)
Vaccine question framing			
	Neutral feelings about the question	5 (56)	Adjusted question to more neutral wording
	Would consult a health care provider	2 (22)	None; consistent with decision aid concept
	Increased reassurance	1 (11)	None
	Felt pressured, uncomfortable	1 (11)	Wording revised for less prescriptive tone
Vaccine explanation text			
	Effective explanation of rapid vaccine development	9 (100)	Retained main points; reorganized structure
	Perceived as too technical or lengthy	5 (56)	Simplified text and terminology
	Reassuring	3 (33)	Maintained neutral tone
	Confusion with the first sentence	3 (33)	Clarified opening sentence
	Insufficient details on side effects	1 (11)	Emphasized side-effect transparency in revised draft

Cycle 2

Main Findings

Overview

During this second round of user testing, participants (n=22) reviewed 2 content variants designed to explain the rapid development of COVID-19 vaccines. The objective was to assess the clarity, effectiveness, and comprehensiveness of each version. Version A contained only illustrations, while version B included photographs and researchers' names (Multimedia Appendix 4). We randomly assigned 11 participants to version A and 11 to version B. Participants answered questions on message interpretation and identified important unanswered questions about COVID-19 vaccination missing from the explanations (Multimedia Appendix 3).

Reactions to the VaxDA-C19 Team Presentation

Participants expressed polarized opinions about version B. In total, 2 participants appreciated the inclusion of researchers' names and photos, interpreting it as a sign of credibility and transparency. One participant remarked that it was "good to see a Manitoba doctor" involved, while another said that the real faces "gave some credibility." Others expressed suspicion and discomfort, perceiving the design as overly promotional or politically biased. Participants describe the content using terms like "political PR," "spin," or sarcastic phrases such as "a miracle that will solve everything." Several participants misinterpreted the visuals, believing these scientists developed the vaccines. Some participants perceived the section as an attempt to distance pharmaceutical companies from the vaccine's origins and described this as reassuring or misleading.

Interpretation of Vaccine Explanation Text

In response to the question, "Can you tell me what this text was about?," most participants described an explanation of how vaccines were developed (version A: 7/11 and version B: 9/11). In total, 5 participants in each group thought that the section highlighted the scientists behind the vaccine development. A small number of participants said that the message aimed to counter vaccine skepticism or clarify funding sources. Table S1 in Multimedia Appendix 6 summarizes how participants interpreted the vaccine explanation text.

Reactions to the Vaccine Explanation Text

During this round of testing, participants (n=22) provided varied emotional reactions and interpretations regarding the explanatory text on rapid COVID-19 vaccine development. In total, 2 participants perceived a clear division between the scientists or authorities and the public, illustrated by expressions of suspicion or detachment such as "The people who created it are vouching for it," and referring to authorities as "Them."

XSL•FO
RenderX

Some participants identified important information gaps, particularly the lack of details on vaccine effectiveness, side effects, and characteristics of clinical trial participants. For instance, a participant remarked that the vaccine was presented as "a miracle that will solve everything," while another expressed nuanced skepticism: "I know exactly how it's done, and I take some and leave some [...] I'm a bit perplexed." In total, 2 participants specifically indicated confusion or misunderstanding about the sentence stating, "Other vaccines are still being tested in places with fewer COVID-19 cases." One described needing more time to understand the phrase clearly, while the other explicitly found it ambiguous.

One participant strongly criticized the text as too political and not scientific, disputing claims about vaccine availability and the accuracy of funding statements. Another felt that the text insufficiently emphasized the societal consequences of refusing vaccination, remarking strongly that, "It's basically a crime if people are not taking this seriously."

Finally, one participant noted perceived contradictions within the explanation, particularly regarding how previous coronavirus research aligns with the rapid vaccine development and funding during the pandemic. This participant also highlighted inconsistencies in public health messages from different provincial health authorities. Table S2 in Multimedia Appendix 6 summarizes the main emotional reactions and comprehension issues identified.

Unanswered Questions

Table S3 in Multimedia Appendix 6 summarizes the types of questions participants felt remained unanswered after reading the vaccine explanation text. These focus on vaccine mechanisms, COVID-19–specific information, distribution and eligibility, safety, and research.

Changes for the Next Cycle

Building on participant feedback in cycle 2, we made several targeted changes to the next iteration of the VaxDA-C19 decision aid to enhance its clarity, transparency, and trustworthiness. The photos and names of scientists were moved to a dedicated "About Us" section to reduce perceptions of promotional content and clarified their roles to reduce confusion. While keeping the explanatory text detailed, we simplified complex terms to increase accessibility. In response to recurring concerns and unanswered questions about vaccine technology, safety, variants, and side effects, we also expanded the FAQs section.

Cycle 3

Main Findings

During cycle 3, we conducted a third round of user testing (n=3) and expert consultation (n=6) to assess navigation, usability, and comprehension across devices. Table S4 in Multimedia Appendix 6 presents a thematic summary of participant feedback.

Navigation and Usability Improvements

Participants (users: n=3 and experts: n=6) identified significant navigation issues, notably difficulties finding the "Next" button, which impaired smooth transitions between sections. They also recommended clearer labeling and explicit instructions to clarify interactions with pages involving comparative vaccine selection and slider functionalities.

Information Transparency and Accessibility

Participants emphasized the need for simplified medical terminology and a more transparent presentation of vaccine efficacy and side effects data. They noted that clear, immediate comparative data would be crucial, particularly important for parents evaluating COVID-19 vaccination for children.

Interactive Features Optimization

Interactive elements, such as avatar creation and values clarification sliders, received mixed responses. Participants initially perceived avatar creation positively, but 1 participant found creating multiple avatars to form a community as unnecessary or excessively time-consuming. One participant had a preference for factual information rather than interactive elements or animations. Sliders were occasionally confusing due to unclear functionality interactions, dull colors, and poorly defined medical terms.

Insights From External Experts

Five health care professionals and medical decision-making researchers provided feedback at a medical decision-making conference. This feedback included recommendations for improved mobile navigation, structured vaccine selection menus, refined content spacing, and modal placements. A subsequent external reviewer (n=1) with expertise in UX recommended adding a step-by-step user guide and informative pop-ups to support user interactions.

Changes for the Next Cycle

Following cycle 3, we implemented targeted modifications to improve navigation, content clarity, and overall UX in VaxDA-C19. We enhanced button visibility and repositioned key navigation elements, adding clear user instructions to support a smoother transition. To increase content accessibility and transparency, we simplified medical terminology and added comparative data on vaccine efficacy and side effects directly within relevant sections. To streamline interactivity, we introduced an avatar bypass option and clarified the functionality of values clarification sliders through revised instructions and enhanced visual design. External expert recommendations were also applied to improve mobile navigation, refine spacing, structure vaccine menus more clearly, and integrate contextual guidance through informative pop-ups.

Cycle 4

Main Findings

Cycle 4 consisted of a comprehensive expert review (n=9), focusing on usability, clarity, bilingual implementation, and overall application refinements as shown in Table S5 in Multimedia Appendix 6.

High-Priority Usability Improvements

Experts (n=9) identified several issues affecting clarity and UX. These included irrelevant vaccine comparisons for children younger than 12 years of age, unclear user instructions,

XSL•FO
RenderX

confusing avatar placement, navigation difficulties on the mobile interface, and incomplete French implementation. Experts also suggested clarifying the decision-making context consistently across the web-based application (eg, clearly indicating options such as "I don't know") and recommended optimizations for animations and interactive sliders to reduce confusion and enhance usability.

Moderate-to-Low Priority Feedback

Additional recommendations included improving free navigation across sections, clearly displaying institutional logos and contact information, enhancing visual spacing for provincial selection buttons, and refining icon-array color schemes. Experts also proposed custom speed and pause features for animations, reducing overall text density, and simplifying vaccine comparison visuals. Due to technical and feasibility constraints, we recorded moderate-to-low priority feedback for future updates. Textbox 3 summarizes the key points from the design and development process.

Textbox 3. Key points from usability testing results.

Navigation and interface usability: Participants consistently highlighted the need for clear, intuitive, and easily navigable interfaces. Regular usability checks using small iterative samples allowed the research team to quickly identify critical navigation barriers. Participants recommended explicit labeling of navigation buttons (such as the "Next" button), logical repositioning of interactive elements, and improved visibility of control. These adjustments may improve user satisfaction and reduce cognitive load.

Information transparency and accessibility: Participants frequently emphasized the importance of clear, concise, and transparent information on vaccine efficacy and side effects. The research team anticipated that simplifying medical language and providing immediate comparative information could enhance user engagement, comprehension, and trust. Participants identified addressing transparency around sensitive health decisions, such as pediatric vaccination, as important to increase the usability and credibility of the patient decision aid.

Interactive features optimization: Participants suggested explicitly defining medical terms, clarifying instructions for using interactive elements (avatars and values clarification sliders), optimizing slider functionalities, and offering optional bypass features for less nonessential interactive steps. The research team incorporated these recommendations to reduce perceived cognitive burden and potentially enhance user experience, though further validation remains necessary.

Responsive content adjustments: User feedback identified specific gaps in information (eg, vaccine efficacy, technology, clinical trial, and distribution logistics) and highlighted areas susceptible to misunderstanding or skepticism (eg, funding sources and researchers' roles). Participants recommended expanding and refining frequently asked questions, clearly explaining scientific roles, and transparently communicating funding and clinical processes. The research team implemented these content adjustments to address user skepticism, improve comprehensiveness, and enhance perceived relevance.

Multidisciplinary and expert reviews: Feedback from multidisciplinary perspectives, including health care professionals, user experience specialists, and citizen panels, helped refine the web-based patient decision aid's usability and scientific content. The research team ranked experts' recommendations according to their overall importance and implemented all high and medium priorities, such as improved mobile navigation, a restructured vaccine selection process, and clearer scientific explanations. These refinements aimed to enhance clarity, accessibility, and user acceptance, although further formal validation of their impact is required.

Implementation of the Final Version of VaxDA-C19

VaxDA-C19 evolved from an initial Google Slides mock-up into a fully functional, bilingual web-based application (Figures 4 and 5). Key technical improvements include transitioning to a responsive HTML5 and JavaScript architecture, with real-time content synchronization (Multimedia Appendix 5). Major features include automated visualizations for herd immunity, refining comparative interactive features, and enhanced icon arrays. These refinements ensure that VaxDA-C19 remains human-centered, responsive to evolving vaccination guidelines, while improving usability and user trust.

XSL•FO
RenderX

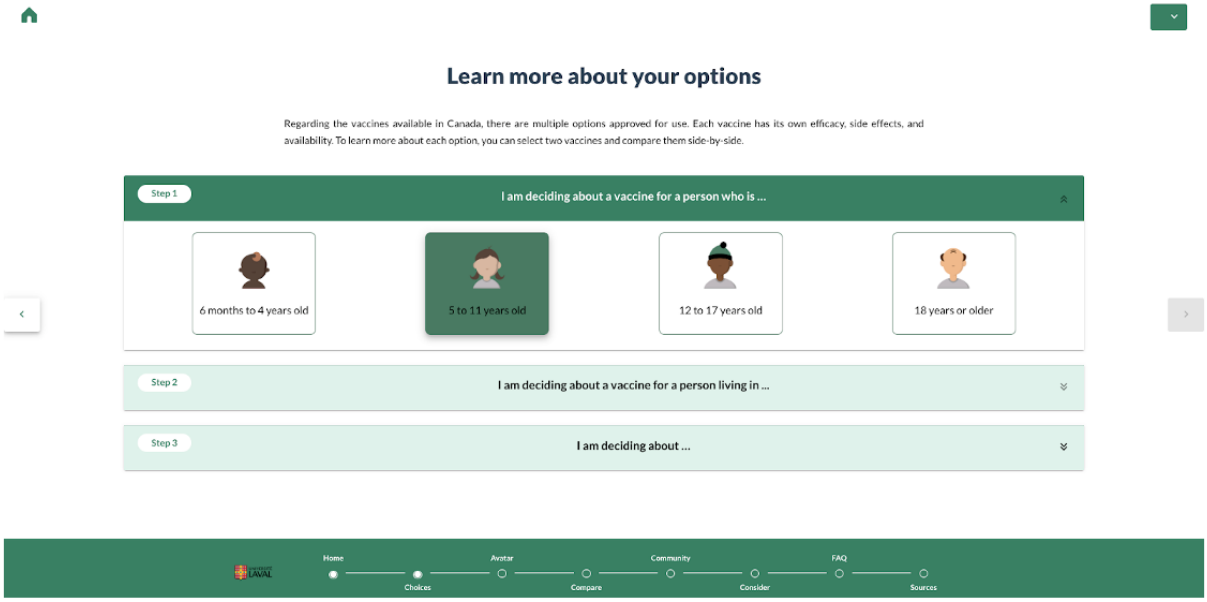

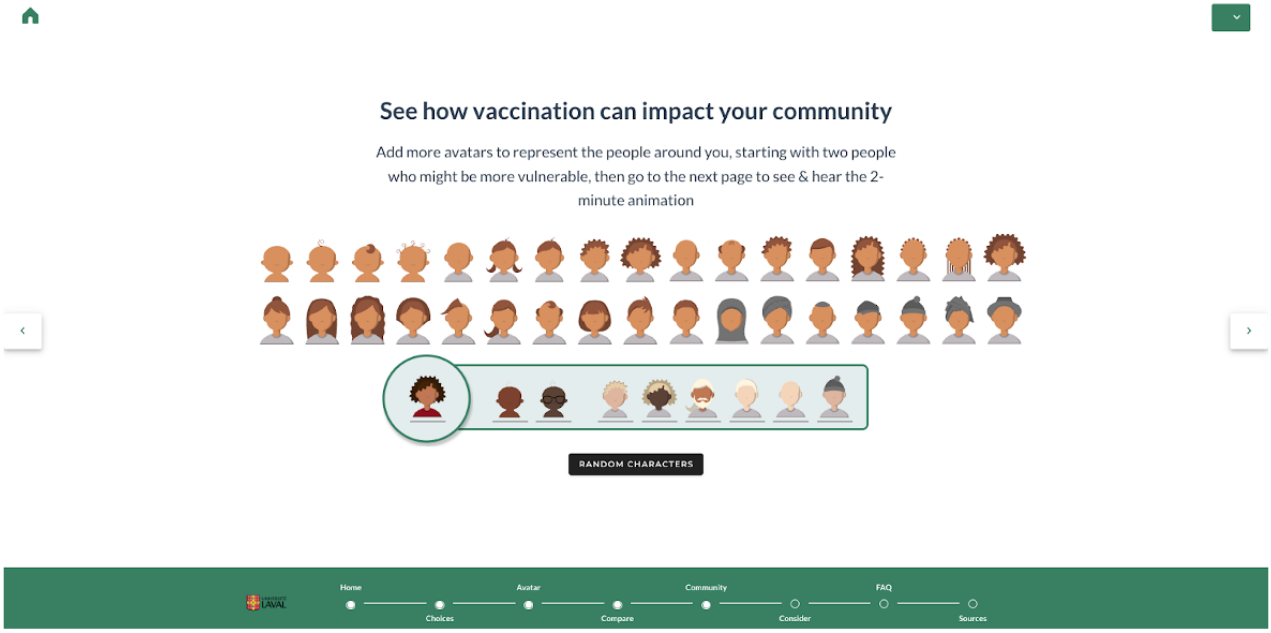

Figure 5. Selected views from the final version of VaxDA-C19.

Discussion

Principal Findings

This study aimed to iteratively develop and refine a bilingual (English and French) web-based patient decision aid (VaxDA-C19) to help people in Canada make evidence-informed, values-congruent decisions about COVID-19 vaccination. VaxDA-C19 includes interactive components such as customizable avatars, personalized icon arrays constructed out of those avatars, an optional, animated, theory-based visualization of community immunity, and a values clarification method. We included these features based on their capacity to facilitate effective communication, optimize cognitive load, enhance empathy, and provide clear, evidence-based information on vaccine options, benefits, and risks [32,48,49,52,61-63]. We present 3 principal findings from this work.

First, a recurrent theme in participant feedback was the need for more detailed and transparent information about vaccine

XSL•FO
RenderX

efficacy, variant coverage, immunity duration, and the inclusivity of clinical trials. To address these concerns, enhance transparency, and hopefully reinforce trust in the information presented, rather than offering a brief list of references in a separate section at the end of the document or website, as is commonly done in patient decision aids, we integrated explicit links to peer-reviewed studies and health authority documents immediately following each statement. We used the word "citation" for each reference and linked directly to open-access resources whenever possible. We also designed visual strategies, such as including images of scientists, to increase credibility [65-67]; however, responses to this approach varied. Some participants found this approach reassuring, while others perceived it as manipulative or politically motivated. To ultimately mitigate these concerns, we removed images and prioritized emotional neutrality and transparent, nonjudgmental communication [1,4,15,68-70]. This approach aligns with the trust determination theory, which emphasizes how credibility, inclusivity, and clarity foster public confidence and reduce skepticism [71]. Similarly, the extended parallel process model highlights how fear, distrust, and perceived governmental or institutional biases influence message reception, potentially diminishing the effectiveness of health communication [72].

Second, rather than seeking an elusive one-size-fits-all information presentation, presenting a simple overview of essential points and allowing people to easily access more detail when they want it may better serve a wider range of information needs. People with lower health literacy, who often express greater vaccine hesitancy, find more transparent explanations of risks and benefits particularly helpful [68,73-75]. Some participants in our study similarly emphasized the importance of clear, simplified explanations, particularly for individuals with varying levels of health literacy and also for people who lack the time or interest to delve deeply into information about vaccines. However, as noted earlier in our first point, other participants wanted far more detail. These tensions between some people's desires for comprehensive information and others' desires for more succinct information highlighted the complexity inherent in balancing simplicity and visual appeal with informational accuracy [76,77]. To address these competing priorities, we revised medical terminology, restructured content for better readability, and ultimately presented a summary of key evidence to all users, followed by accordion menus, which allow users to expand sections to read more about a given topic. By giving people control over the amount of detail they receive, we hope VaxDA-C19 will serve the needs of people who want a summary of essential points as well as people whose questions are not answered by simplified public health messages. Future research should continue to examine optimizing content presentation to provide sufficient detail without overwhelming users [78].

Third and finally, specific challenges associated with developing a patient decision aid for COVID-19 vaccination included a novel pathogen that launched a global pandemic, novel vaccine technology, continuously evolving evidence about vaccine effectiveness and adverse events following immunization, changing vaccine products and authorizations, and evolving recommendations for use. The fast-evolving COVID-19 vaccination landscape required proactive content management. We used flexible structures like JSON templates to enable timely updates aligned with new evidence and public health recommendations. This technical adaptability, combined with sufficient time commitments on the part of team members, should help us ensure that the VaxDA-C19 will remain scientifically accurate, while also facilitating version control, scalability, and potential future reuse for patient decision aids about other vaccine-preventable diseases.

Comparisons With Existing Literature

The COVID-19 pandemic led to the rapid development of digital patient decision aids aimed at addressing vaccine hesitancy, which intensified due to misinformation and information overload (infodemic) [79]. Several countries, including France [80], the Netherlands [81], and Australia [82], introduced digital tools to support informed decision-making. Compared to static informational approaches, these interactive decision aids improved user knowledge, reduced decisional conflict, and increased satisfaction with the decision-making process [79,81]. Despite these benefits, major challenges persist, including potential biases in content presentation, variations in complexity, and inconsistent accessibility, all of which affect usability and effectiveness [79,81].

International evaluations identified key factors that contribute to the success of digital patient decision aids. Co-design approaches that involve health professionals and target populations enhance relevance and usability. Regular updates ensure content accuracy and alignment with evolving public health guidelines. User-friendly interfaces and personalization based on individual risk assessments further support engagement and informed decision-making [79-82]. Certain digital patient decision aids have also integrated practical features, such as direct scheduling links for vaccination appointments, to facilitate action [79,81]. Similarly, in our study, multiple cycles of qualitative usability testing within an iterative, human-centered approach helped identify and address navigation, comprehension, and usability issues early in development. Small-scale usability tests effectively detected key issues, allowing for rapid refinements. Cognitive ergonomics literature supports this strategy, indicating that explanatory texts provide more explicit contextual cues and facilitate information processing, particularly for individuals with lower health literacy [83-85].

Limited linguistic and cultural adaptability restricts the reach of many existing digital patient decision aids, particularly among culturally and linguistically diverse populations [79,81]. VaxDA-C19 aims to address this limitation initially through its bilingual content in English and French, the official languages of Canada. Following evaluation in an online randomized controlled trial, we also plan to translate it into other major languages spoken in Canada.

Although digital patient decision aids may influence vaccine intentions, evidence directly linking these tools to increased vaccine uptake remains incomplete. Ongoing randomized controlled trials, such as SMART-DA in Korea [86], aim to assess their impact on key outcomes, including vaccine intentions, knowledge retention, decisional conflict, and

XSL•FO
RenderX

emotional responses. Findings suggest that patient decision aids improve preventive health behaviors by enhancing decision quality rather than by applying persuasive messaging [87,88].

Our study aligned with previous research, suggesting that effective communication in patient decision aids such as VaxDA-C19 requires careful consideration of emotions, trust, and perceived biases [1,4,10,89]. Emotional responses play an important role in how individuals interpret vaccine-related messages [1,15]. In our study, some participants expressed skepticism, anxiety, or distrust, particularly if they perceived wording as being politically charged, overly promotional, ambiguous, or institutionally biased. This finding aligns with other studies [90], and these reactions overall align with Sandman's risk=hazard + outrage model, which posits that public outrage or mistrust can overshadow objective risk assessments, leading to defensive responses such as rejection or disengagement [4,18,90,91]. Preexisting attitudes toward vaccines may also influence people's reactions to interventions such as VaxDA-C19. Future research should incorporate such considerations into study design.

Our study also confirmed that intuitive navigation, visual clarity, and balanced content presentation played essential roles in usability. These findings align with existing literature, which demonstrates that interactive and personalized elements improve engagement and comprehension in digital health interventions [52,92,93].

Strengths and Limitations

Our study has 2 main limitations. First, while recruiting user testing participants through tailored Facebook advertisements allowed us to reach people living in different parts of Canada with diverse backgrounds and who are online and therefore potential users of a web-based patient decision aid, no recruitment platform can perfectly represent the broader population. We note that our user testing participants were, as a group, slightly older than the broader group of Facebook users in Canada. Specifically, among Facebook users in Canada, the largest age group (around 25%) is between 25 and 34 years, with the next largest group (19%) being 35 to 44 years [94]. We may have recruited more people older than these groups due to increasing interest in COVID-19 vaccines with age. We note that the age group we recruited was approximately representative of the desired population for a patient decision aid about COVID-19 vaccines. Older people in Canada were already receiving strong recommendations to obtain the vaccine, whereas people in the age range of our user testing participants were likely to be both candidates themselves and may also be parents of children who were candidates for COVID-19 vaccination at the time of the study. Our study participants also included more people with higher levels of education than the general population in Canada. People with more education may seek more information about health compared to people with less education. Additionally, we note that, as a group, participants included a substantial proportion of people without a college or university degree. In other words, although there were many people with higher levels of education in our study, there were also many people without such education. No one intervention can be everything to everyone; our goal with this intervention was to provide a middle ground between the simplified information available on public health websites and the detailed information buried in technical documents and academic literature. Because vaccination campaigns are most successful when they reach as many people as possible, an approach with different components for different subpopulations (eg, an online patient decision aid for people with enough motivation to seek more information, community-based education meetings for people who trust community leaders, and simple information for people who have no questions and simply want to know where to get their vaccine) is likely to achieve the best population-level protection. Second, the challenge of balancing comprehensive content with cognitive load remains potentially unresolved, particularly in adapting information for users with varying levels of health literacy. While brief, simple messaging can be most effective in some contexts and for some people, the resulting lack of detail and missing explanations can be a problem for others. Variability in patient decision aid formats, development methodologies, and user preferences suggests that no single approach fits all contexts [25,95]. We therefore chose to prioritize user control over information presentation, trusting that many people will know what they need. Nevertheless, additional research should investigate these aspects further to refine content presentation and improve the effectiveness of digital patient decision aids.

Our study also has 2 main strengths. First, we used a rigorous iterative design based on human-centered methodologies, a multidisciplinary approach, bilingual validation, and structured engagement of a range of interested parties, including user testing, a citizen panel, UX interviews, and expert reviews. The collaboration between a diversity of researchers, UX specialists, members of the public, and health care professionals helped refine the patient decision aid, contributing to its scientific reliability and usability. User testing participants from different backgrounds offered different responses and reactions, providing a range of feedback to which we were able to respond. Complementing the contributions of these members of the public who participated in user testing and saw VaxDA-C19 at a single time point, members of the citizen panel saw VaxDA-C19's evolution over time and were able to comment at a higher level on how well or poorly the design was responding to its original goals as well as the evolving pandemic context. A wide range of experts brought insights from related projects, literature, and guidelines and also lent their expertise to verify VaxDA-C19's content and design. Systematically integrating all these people's feedback on an ongoing basis allowed for continuous adjustments. Second, we believe that VaxDA-C19 fills an unmet need by bridging the gap between highly technical vaccine information and highly simplified public health messaging. As COVID-19 vaccines continue to be offered to people in Canada, we hope to help support high-quality decision-making, thus contributing to the health of people in Canada and to public health more broadly. The platform itself may also be adapted to other vaccines.

We plan to assess the effects of VaxDA-C19 in an online randomized controlled trial (ISRCTN91743566). Specifically, participants who are eligible to receive COVID-19 vaccines will be randomly assigned to 1 of 3 arms: a control group

XSL•FO
RenderX

receiving no additional information, a usual information group directed to the Public Health Agency of Canada's COVID-19 vaccination web pages, or an intervention group receiving access to VaxDA-C19. We will assess effects on the primary outcome of vaccination intentions and secondary outcomes: knowledge, emotions, decisional conflict, vaccine uptake, and decisional regret. We will also examine effects on trust in the information provided, comparing only between the usual information and VaxDA-C19. Finally, we will conduct a follow-up study 3 - 6 months later to ascertain whether or not participants received COVID-19 vaccines.

Conclusions

VaxDA-C19 is an online patient decision aid designed and developed to help people in Canada make evidence-informed, values-congruent decisions about COVID-19 vaccines on an ongoing basis. An iterative, human-centered design approach and a multidisciplinary team bringing diverse perspectives led to a flexible application that we hope will prove useful for years to come.

Acknowledgments

The authors gratefully acknowledge the contributions of all the team members who contributed greatly to this research project as a whole but were unable to accept the invitation to participate on this particular paper as coauthors due to time constraints, including citizen panel members who chose not to accept the invitation to be coauthors: Ross McCreery, Samantha Meyer, Linda Kim, Jean Légaré, and Melissa McLeod. The authors thank Magniol Noubi and Dan Emmanuel Marie Krecoum for programming the web application and Selma Chipenda Dansokho for constructive comments throughout the project. Finally, the authors thank all study participants for helping them identify ways to improve education, communication, and decision-making in health care. The authors declare the use of generative artificial intelligence in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to generative artificial intelligence tools under full human supervision: literature search and systematization, visualization, proofreading and editing, and translation. The generative artificial intelligence tools used were Consensus AI, Perplexity, ChatGPT 4o, Gemini 3, DeepL, and Grammarly. Responsibility for the final manuscript lies entirely with the authors. Generative artificial intelligence tools are not listed as authors and do not bear responsibility for the final outcomes. DE used Consensus AI and Perplexity for literature searches and systematization. ChatGPT 4o and Gemini 3 were used for visualization, while DeepL and Grammarly were used for proofreading, editing, and translation.

Funding

This study was funded by the Canadian Institutes of Health Research and the Canadian Immunization Research Network (VR5-172668; principal investigator: HOW). The funders had no role in determining the study design, the data collection or analysis plans, the decision to publish, or the preparation of this manuscript. DE received doctoral student support from the VITAM Research Centre in Sustainable Health. HOW is funded by a Tier 2 Canada Research Chair in Human-Centred Digital Health.

Data Availability

All data generated or analyzed during this study are included in this published paper and are available on demand.

Authors' Contributions

DE, HOW, and ED contributed to the design of the study. DE, EP, HH, and HOW contributed to data collection. DE conducted data analysis and interpretation. DE and HOW drafted the first version of the paper with an early revision. PMA, IIB, CTC, ADC, JD, SMD, ED, MPG, TG, AG, NG, KG, HH, SJ, JK, AL, SEM, RN, MN, RO, JSP, EP, JSR, BS, MT, DTG, MCT, SV-M, and VAW critically revised the paper and approved the final version for submission for publication. DE and HOW had full access to all the data in the study and had final responsibility for the decision to submit for publication.

Conflicts of Interest

PMA declares research support from AstraZeneca for an unrelated trial of an antiviral agent [96]. IIB consults to the Weapons Threat Reduction Program at Global Affairs Canada. ADC is a paid employee of the Public Health Agency of Canada, in Sexually Transmitted and Blood-Borne Infection Surveillance. KG declares speaker honouria from Apotex, the Candian Society of Hospital Pharmacists and the Ontario Pharmacy Association.

M-PG is Associate Editor of Journal of Medical Internet Research at the time of this publication. HOW is Associate Editor of JMIR Human Factors at the time of this publication.

Other authors declare no conflict of interest.

Abstract

Background: Digital technologies, such as equipment localization systems, can help clinics use mobile devices more efficiently. Their successful implementation, however, depends not only on technical feasibility but also on how staff and patients perceive and understand these systems.

Objective: This research used 2 complementary studies to (1) obtain an initial picture of clinic staff attitudes toward the localization of vacuum-assisted closure (VAC) pumps and related concerns and (2) examine whether a simple layout change in a privacy policy (using guiding questions vs standard text) is associated with greater subjective understanding and acceptance among potential patients.

Methods: In study 1, 38 employees of a German clinic completed a short survey assessing their comfort with and perceived usefulness of VAC pump localization and answered an open-ended question about reservations or concerns. Quantitative responses were analyzed descriptively, and free-text answers were coded using qualitative content analysis. In study 2, 498 participants from an online sample took part in a preregistered experiment. They were randomly assigned to read either a standard privacy policy information sheet or an otherwise identical version supplemented with guiding questions. Subjective understanding of the information and acceptance of the policy were then assessed and analyzed using rank-based regression models controlling for sociodemographic covariates.

Results: Clinic staff in study 1 generally reported high levels of comfort (mean 7.34, SD 2.75) and perceived usefulness (mean 7.29, SD 2.69) regarding localization on 0 - 10 scales. Concerns centered mainly on implementation feasibility, technical reliability, costs, and possible additional workload, rather than on privacy. In study 2, subjective understanding was slightly higher in the guiding-question layout condition than in the standard layout condition (mean 3.37, SD 0.63 [n=248] vs mean 3.24, SD 0.68 [n=250]); this difference was also significant in the rank-based regression model (b=0.13, SE=0.05, t=2.57; P=.01), and better understanding was associated with higher acceptance of the policy, explaining about 13.8% of the variance in acceptance scores.

Conclusions: The exploratory findings suggest that, in the context of VAC pump localization, clinic staff generally view equipment tracking positively while still raising practical concerns that should be addressed during implementation. For potential patients, relatively small changes in the layout of privacy information—such as adding guiding questions—may support subjective understanding and willingness to accept data collection.

KEYWORDS

digital health; informed consent; health care staff; understanding; implementation; patient privacy; real-time location systems

Introduction

In large clinical settings, medical equipment must remain mobile to ensure that resources are available at the right place and time. However, locating mobile assets often requires time-consuming coordination and manual documentation, resulting in inefficiencies. Digital solutions—particularly real-time location systems (RTLSs), which are local infrastructures that identify and track the position of tagged objects or people via beacons distributed throughout the location of interest—offer promising avenues for improving workflows and resource allocation by providing real-time data on equipment use and availability [1-3].

One clinical example in which location-based data collection may be especially valuable involves vacuum-assisted closure (VAC) pumps, which are widely used in wound therapy. Although VAC therapy is well established, the manual process of tracking, cleaning, and redistributing pumps poses logistical challenges. When the stock is low, staff often need to call other units or request short-term rentals. Real-time localization could support more efficient allocation by enabling automated

XSL•FO
RenderX

documentation, identifying device availability, and reducing cost as well as administrative burden [4].

Although the potential benefits of RTLSs include improved workflow, increased safety, and reduced cost [5-7], their successful implementation depends on more than technical infrastructure. On the one hand, health care workers are more likely to adopt new technologies if the benefits are clearly understood and they are actively involved in the implementation process [8]. Conversely, concerns about increased workload, privacy, and surveillance may hinder adoption [9,10].

On the other hand, patients' privacy concerns will be more salient if location data can be linked to individuals. Thus, from a patient perspective, systems that track movement raise critical questions about data security, consent, and control over personal information [11]. Beyond data protection in a narrow sense, RTLS infrastructures can also enable fine-grained monitoring of individuals' movements, which has raised broader concerns about surveillance, autonomy, and potential changes in workplace and care relationships in hospital and long-term care settings [9-11].

Although privacy policies and consent forms are designed to soothe privacy concerns and enable informed decisions, studies have consistently found that these documents are often too complex and that patients struggle to comprehend them—especially when they are presented in dense, text-heavy formats [12,13]. Health communication research has indicated that the layout of consent materials can significantly affect comprehension. Structured documents with headings, bullet points, and guiding questions have been shown to improve readability and facilitate understanding [14,15]. Because document layout directly shapes user trust, informed decision-making, and willingness to give consent, thoughtful designs are pivotal for digital solutions (such as RTLSs) in health contexts.

This research investigated the perspectives of both clinic staff and patients on location-based data collection in health care, using the example of VAC pump localization. In study 1, we administered a survey to assess clinic staff's perceived comfort with and perceived usefulness of device localization and to identify any concerns related to its implementation. In study 2, we used an experimental design to test whether improving the layout of a privacy policy—featuring a guiding-question format as opposed to plain text—could enhance potential patients' subjective understanding and whether a better understanding, in turn, could predict greater acceptance. Together, the 2 studies were designed to inform how digital health tools can be introduced in ways that are transparent, user-centered, and conducive to adoption. Rather than offering a broad theoretical advance, this research provides exploratory, context-specific evidence that links RTLS implementation concerns with consent and privacy-communication design in the concrete case of VAC pump localization.

Methods

Study 1

Participants

In a clinic in southern Germany, 2 wards were selected for recruitment, and volunteers were invited to participate. The final sample consisted of 38 clinic employees. Participants had a mean age of 33.18 (SD 11.92) years and reported working in the clinic for an average of 13.40 (SD 11.66) years. Most participants identified as female (n=27), followed by male (n=7), and a small number of participants preferred not to disclose their gender (n=4). Regarding professional roles, the majority worked in nursing (n=32), while the remaining participants reported working in other roles (n=3), in wound management (n=2), or as a physician (n=1).

Ethical Considerations

This study was conducted in accordance with the ethical principles of the Declaration of Helsinki and was approved by the Ethics Committee of the University of Bamberg, Germany (dossier/review number: 2023-11/23). All participants provided informed consent prior to participation. Participation was voluntary, and participants could discontinue at any time without penalty. Participants were informed about data handling during the consent process. Privacy and confidentiality were protected throughout the study; no directly identifying personal data are reported in this manuscript; study data were analyzed and reported in aggregate form only; and any contact information collected for the raffle was stored separately from the survey responses. As compensation, participants were offered the opportunity to win 1 of 10 gift vouchers worth €10 (US $11.70) each for the city of Bamberg, Germany.

Procedure and Measures

Before data collection, we obtained consent from the clinic's work council. To minimize the disruption of routine clinical workflows, a printed questionnaire was distributed in 2 wards, where staff could complete it whenever their schedules permitted. The completed questionnaires were collected in sealed and nontransparent boxes to ensure anonymization. The survey remained available for a total of 29 days, from March to April 2024.

Attitudes toward the localization of VAC pumps were assessed with 2 self-developed items. Perceived comfort with localization was measured with the item: "How comfortable do you feel about the idea of localizing VAC pumps?" Responses were provided on an 11-point scale ranging from 0 (very uncomfortable) to 10 (very comfortable). Perceived usefulness was assessed with the item: "How helpful do you think the localization of VAC pumps would be?" Participants responded on the same 11-point scale ranging from 0 (not helpful at all) to 10 (very helpful). To minimize the burden during routine clinical work, these brief items were used as exploratory, descriptive indicators (not validated scales).

In addition, participants were asked an open-ended question: "Please describe any doubts or concerns you have about the localization of items or the project as a whole." Responses were

XSL•FO
RenderX

analyzed using qualitative content analysis. Thematic coding was conducted by the research team to group responses on the basis of content similarity.

Because of item-level missing responses, sample sizes vary slightly across study 1 outcomes; we report outcome-specific n values based on available cases for each item.

Study 2

Preregistration

The analysis was preregistered on the Open Science Framework, and an anonymized version can be accessed by following the link in the references under files [16]. Any deviations from the preregistration are transparently reported and justified.

Participants

Participants were recruited online via the following three approaches: (1) snowball sampling, (2) calls posted in the University of Bamberg's student forums, and (3) an announcement distributed through the university's mailing list to individuals from the general population who had signed up to be informed about studies. As an incentive, participants were offered the opportunity to win one of forty €10 (US $11.70) gift vouchers for the city of Bamberg, Germany. Alternatively, psychology students could receive course credit for completing the study. A total of 498 individuals completed the online survey between November 2024 and February 2025. Of these, 308 identified as female, 182 as male, 6 as diverse, and 2 preferred not to disclose their gender. The mean age was 41.12 (SD 18.9) years. Regarding educational background, 38 participants reported basic education, 258 reported intermediate education, and 199 reported higher education, while 3 observations were missing. As this sample size exceeded the originally preregistered sample size of 310, we drew a random subsample of 155 female and 155 male participants for an additional analysis as a robustness check. Participants in the subsample had a mean age of 41.45 (SD 18.64) years. Regarding educational background, 23 participants reported basic education, 150 reported intermediate education, and 136 reported higher education. One participant did not provide information on their education.

Outlier Detection and Exclusion Criteria

To ensure data quality, careless responding was assessed using the relative speed index (RSI), which was calculated as the inverse of each participant's total survey completion time relative to the group average. Participants with an RSI≥3, indicating exceptionally fast completion times, were to be excluded. However, no participants exceeded this threshold; thus, no exclusions were made based on the RSI.

Ethical Considerations

This study was conducted in accordance with the ethical principles of the Declaration of Helsinki and was approved by the Ethics Committee of the University of Bamberg, Germany (dossier/review number: 2025-05/39). All participants provided informed consent prior to participation. Participation was voluntary, and participants could discontinue at any time without penalty. Participants were informed about data handling during the consent process. Privacy and confidentiality were protected throughout the study; no directly identifying personal data are reported in this manuscript; study data were analyzed and reported in aggregate form only; and any contact information collected for the raffle was stored separately from the survey responses. As compensation, participants were offered the opportunity to win 1 of 40 gift vouchers worth €10 (US $11.70) each for the city of Bamberg, Germany. Psychology students could alternatively receive course credit for completing the study.

Measures

Subjective Understanding

Subjective understanding was assessed with 5 self-developed items rated on a 4-point Likert scale (1=strongly disagree, 4=strongly agree), including sample items such as "I feel that I understood the points listed." We deliberately chose a 4-point scale without a neutral midpoint to discourage "safe" or noncommittal responses and to elicit clearly directional judgments about participants' perceived understanding, while also keeping the response format cognitively simple in this applied setting. Responses were aggregated into a single composite score. Internal consistency was high (Cronbach α=0.86, 95% CI 0.837-0.877; McDonald ω=0.86, 95% CI 0.812-0.911). An exploratory factor analysis confirmed unidimensionality, with all factor loadings ranging from 0.68 to 0.81—well above the predefined threshold of 0.40.

Acceptance

Acceptance was measured with a single item: "How likely is it that you would agree to this privacy policy?" Participants responded on a slider scale ranging from 1 (representing 0%) to 101 (representing 100%). For the analyses, the scale was rescaled to range from 0 to 100.

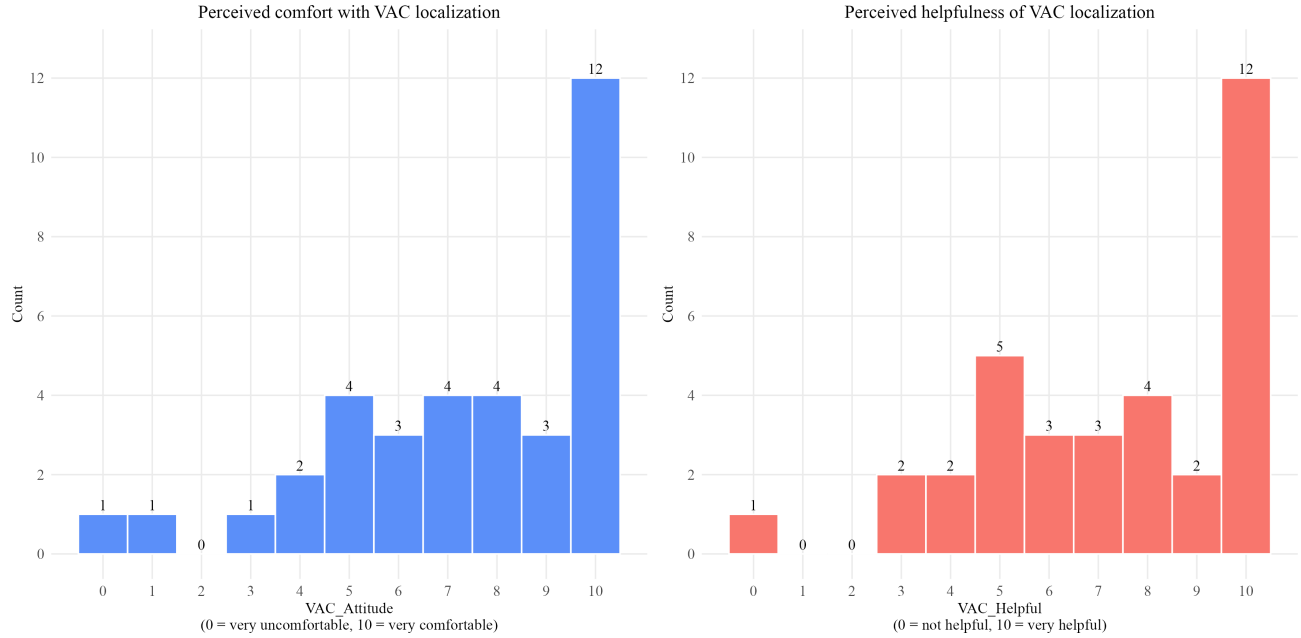
Design

Participants were randomly assigned to one of two types of information sheets. The two versions presented identical content; however, one version included guiding questions for each paragraph (eg, "What data are processed when the vacuum pumps are tracked?" and "Who has access to your data?") to support comprehension. The information sheets (in German) were also uploaded to the Open Science Framework along with this preregistration. Participants were then asked to report their subjective understanding of the information sheet content and their acceptance. To test hypothesis 1—that including guiding questions in the layout of a privacy policy information sheet enhances subjective understanding as compared with a standard layout—we conducted a rank-based regression analysis. The dependent variable was subjective understanding, and the independent variable was the treatment condition (standard vs improved layout). Gender, age, education, and reading time were included as covariates to control for potential confounds.

To test hypothesis 2—that increased subjective understanding would lead to greater acceptance of the privacy policy—we conducted a rank-based regression analysis. Acceptance served as the dependent variable, and subjective understanding was included as the key predictor. Gender, age, and education were entered as covariates to control for potential confounding effects.

XSL•FO
RenderX

To further examine the relationship between layout, subjective understanding, and acceptance, we conducted an exploratory mediation analysis. We tested whether the effect of the layout condition (standard vs guiding questions) on acceptance was mediated by subjective understanding. Subjective understanding was modeled as the mediator and acceptance as the outcome. Both variables were analyzed in their original metric, with acceptance ranging from 0 to 100. We specified two linear regression models. In the mediator model, subjective understanding was regressed on layout condition, controlling for gender, age, education, and reading time. In the outcome model, acceptance was regressed on layout condition and subjective understanding, controlling for gender, age, and education (reading time was not included here to remain consistent with the main regression specification for acceptance). Indirect (average causal mediation effect [ACME]), direct (average direct effect [ADE]), and total effects were estimated using the mediation package in R with nonparametric bootstrap CIs based on 5000 simulations. Because this analysis relies on linear modeling and was not preregistered, we report it as exploratory and interpret it cautiously, using it to complement (but not replace) the rank-based regression analyses.



Results

Study 1

Perceived Comfort and Usefulness of VAC Pump Localization

Participants generally expressed positive attitudes toward the localization of VAC pumps. On a scale ranging from 0 (very uncomfortable) to 10 (very comfortable), the average level of comfort with the idea of localization was 7.34 (SD 2.75; n=35), see Figure 1.

Figure 1. Staff perceptions of vacuum-assisted closure (VAC) pump localization. The histograms show the distributions of responses regarding perceived comfort (left) and perceived helpfulness (right) of localizing VAC pumps. Responses were given on a scale ranging from 0 to 10, with higher values indicating greater comfort or helpfulness.

Similarly, the perceived usefulness of localization was rated positively (mean 7.29, SD 2.69; n=34) on a scale ranging from 0 (not helpful at all) to 10 (very helpful). A visual inspection of the distributions indicated a slight positive skew, with the most frequent response being the highest value (10) for both items.

Staff Concerns Regarding Localization in Clinical Contexts

A total of 18 statements describing concerns about the localization of items in clinical practice were categorized across 5 themes. The most frequently mentioned concern was related to implementation feasibility (n=7), followed by technical doubts (n=3). Other participants questioned whether localization would be helpful, specifically for VAC pumps (n=2). Additional concerns included increased costs (n=2) and added workload for nursing staff (n=2).

Study 2

Layout and Subjective Understanding

We hypothesized that including guiding questions in the layout of a privacy policy information sheet would enhance subjective understanding compared with a standard layout. A rank-based regression analysis was conducted with subjective understanding as the dependent variable; treatment condition (standard vs improved layout) as the predictor; and gender, age, education, and reading time as covariates. The primary analysis was conducted on the full sample, and the preregistered random subset consistent with the preregistered sample size was analyzed as a robustness check.

In the full sample, the analysis revealed a significant effect of treatment (t=2.57; P=.01), indicating higher subjective understanding in the improved layout condition compared with the standard layout (Table 1). Age was a significant positive predictor (t=3.91; P<.001), indicating that older participants

XSL•FO
RenderX

reported a higher subjective understanding. No significant effects were found for gender, education, or reading time. The model explained 3.7% of the variance in subjective understanding (R^2=0.037), and the reduction in dispersion test was significant (P=.006), indicating that the model provided a better fit than an intercept-only model. As a robustness check, the same analysis in the preregistered subset showed a marginal effect of treatment (t=1.93; P=.06) and a significant positive effect of age (t=1.99; P=.048); no significant effects were found for gender, education, or reading time. The model explained 2.5% of the variance in subjective understanding (R^2=0.025), and the reduction in dispersion test was not significant (P=.27).

Table . Rank-based regression predicting subjective understanding[a].

Predictor	Estimate (SE)	t	P value
Full sample (n=498)

Reading time	-9×10^{-6} (7×10^{-6})	−1.25	.21

[a]Subjective understanding was predicted using rank-based regression. Treatment was coded as 0=standard and 1=improved layout. Reading time was measured in seconds. For the treatment comparison, subjective understanding in the full sample was a mean of 3.24 (SD 0.68; n=250) in the standard layout condition and a mean of 3.37 (SD 0.63; n=248) in the improved layout condition. In the preregistered gender-balanced subsample, the corresponding values were mean 3.26 (SD 0.64; n=160) and mean 3.40 (SD 0.61; n=150), respectively. Reported t values are coefficient test statistics from the rank-based regression model.

Subjective Understanding and Acceptance

To examine whether higher subjective understanding would support greater acceptance of the privacy policy (hypothesis 2), we conducted a rank-based regression with acceptance as the dependent variable and subjective understanding as the key predictor. Gender, age, and education were included as covariates. Again, the primary analysis was conducted on the full sample; the preregistered random subset consistent with the preregistered sample size was analyzed as a robustness check.

The full-sample model revealed a significant positive effect of subjective understanding on acceptance (Table 2; t=11.33; P<.001), indicating that participants who reported better understanding of the privacy policy also expressed a greater willingness to accept it. No significant effects were found for gender, age, or education (all Ps>.32). The model explained approximately 13.8% of the variance in acceptance (robust R^2=0.138), and the reduction in dispersion test was significant (P<.001), suggesting that the model provided a better fit than an intercept-only model. As a robustness check, the corresponding analysis in the preregistered subset likewise showed a significant positive effect of subjective understanding on acceptance (t=8.90; P<.001), whereas gender, age, and education were not significant. The model explained approximately 16% of the variance in acceptance (robust R^2=0.16), and the reduction in dispersion test was significant (P<.001).

[a]Acceptance of the privacy policy was predicted using rank-based regression. Subjective understanding was entered as a continuous predictor.

Exploratory Mediation Analysis

In an exploratory step, we examined whether the effect of layout (standard vs guiding questions) on acceptance was mediated by subjective understanding. Using linear regression models with nonparametric bootstrapping, the indirect effect of layout on acceptance via subjective understanding (ACME) was small but statistically significant (ACME=2.26, 95% CI 0.64-4.32; *P*=.006) on a 0 - 100 acceptance scale. The direct effect of layout on acceptance when controlling for subjective understanding (ADE) was not statistically significant (ADE=–1.48, 95% CI –6.68 to 3.66; *P*=.58), and the total effect of layout on acceptance was also nonsignificant (total effect=0.79, 95% CI –4.67 to 6.13; *P*=.78). Overall, this pattern of effects is consistent with an indirect pathway from layout to acceptance via subjective understanding, with no evidence of a remaining direct effect when subjective understanding is included.

Discussion

Study 1

Given the single-site convenience sample, our findings should be interpreted as context-specific and descriptive. The results of study 1 indicate that the staff appeared to be open to the idea of localizing VAC pumps to improve workflows and support them in their daily work. Their concerns were predominantly technical and infrastructural in nature, with no explicit articulation of privacy concerns about the localization of VAC pumps. This finding is encouraging, as privacy concerns have been identified as a potential hindrance to the successful implementation of such systems [9,10]. Nevertheless, it is essential that patients agree to the localization, as it involves their personal data. Ensuring ethical and informed consent necessitates not only patients' acceptance of these systems but also their comprehension of the relevant information provided to them. Consequently, study 2 was designed to gain an understanding of the conditions under which potential patients can subjectively comprehend and accept information about VAC pump localization, with a particular emphasis on the impact of the guiding-question format compared with a plain text format.

Study 2

Our results provide support for the hypothesis that incorporating guiding questions into privacy policy layouts enhances subjective understanding. This aligns with research showing that simplified and well-structured consent materials—using plain language, headings, and clearer layouts—improve comprehension [14,17-19]. While the variance explained in subjective understanding was modest, this is consistent with the fact that we manipulated only a single structural feature of the information sheet and did not account for other plausible determinants of perceived understanding, such as general cognitive ability and health literacy [20].

Interestingly, age emerged as a significant predictor in both analyses, with older participants reporting a greater subjective understanding regardless of condition. Several explanations could account for older participants reporting a greater subjective understanding of privacy policies. One possible explanation could be that older people have had more experience with health care. Older participants may have more extensive experience with health care settings and procedures, making them more confident in their understanding of health care–related documentation, including privacy policies. Another possible explanation could be their familiarity with traditional documentation. Older adults might be more accustomed to reading formal documents, such as consent forms and privacy policies, in their original formats, whereas younger participants might expect more interactive or digital presentations (eg, videos or app-like interfaces) [21]. An additional reason might be a

XSL•FO
RenderX

self-reporting bias. The finding might reflect different calibrations in self-assessments rather than actual differences in understanding. Younger participants may be more critical of their own understanding, whereas older participants may overestimate their understanding in the sense of an illusion of explanatory depth [22]. Finally, the finding may have resulted from greater concerns about privacy among older adults [23]. Older participants might invest more attention in privacy-related content due to heightened privacy concerns, resulting in a better subjective understanding. This counterintuitive finding highlights the importance of testing information design approaches with diverse age groups rather than making assumptions about digital or information literacy based on age alone.

The data also supported our second hypothesis, demonstrating that higher subjective understanding significantly predicted greater acceptance. This relationship explained 13.8% of the variance in acceptance scores (robust R^2=0.138), and the corresponding analysis in the preregistered subset yielded a comparable pattern (robust R^2=0.16). This indicates that subjective understanding is a meaningful predictor of acceptance in this context. Conceptually, this aligns with work on data-intensive technologies—such as crowd-counting systems in smart cities—where better explanations and clearer communication are associated with higher trust and acceptance [24]. In our study, the exploratory mediation analysis yielded a small but statistically significant indirect effect of layout on acceptance via subjective understanding, while the total effect of layout on acceptance was not statistically significant. This pattern is compatible with the interpretation that the layout manipulation primarily affects acceptance via perceived understanding rather than exerting an additional direct influence; however, given the exploratory nature of the mediation analysis and the reliance on self-reported understanding, this inference should be treated cautiously. In general, our results are consistent with broader evidence that design-driven improvements in understanding are only one part of a larger “privacy calculus,” in which perceived benefits, trust, and risk perceptions jointly shape acceptance [25,26].

Building on study 1, which examined health care providers’ perceptions of VAC pump localization systems, in study 2, we shifted our focus to how structural elements of privacy policies affect user comprehension and acceptance. While study 1 highlighted clinical staff concerns, study 2 provided evidence that an improved layout can positively influence how patients perceive privacy information and, via subjective understanding, relate to acceptance judgments. At the same time, study 2 assessed subjective understanding rather than objective comprehension, and acceptance was measured as a single-item willingness judgment; thus, future studies should test whether similar layout manipulations improve performance-based comprehension and decision-relevant outcomes.

General Discussion

Principal Findings

We examined attitudes toward RTLS-based equipment localization in health care, focusing on the example of VAC pump localization in 1 German clinic. Across 2 complementary studies, we explored how clinical staff perceive such technologies and how information sheet layout may influence patient understanding and acceptance.

Study 1 provided initial insights into the perspectives of clinic employees. Overall, participants expressed generally positive attitudes toward the idea of VAC pump localization, reporting high levels of comfort and perceived usefulness. These findings are consistent with prior work on RTLSs, which emphasizes perceived usefulness, workflow support, and safety gains as key drivers of staff acceptance [3,8]. At the same time, some employees voiced concerns about technical feasibility, implementation logistics, and the potential for an increased workload—issues that echo previous evaluations of RTLSs in hospital contexts, where organizational readiness and human-factors considerations often determine whether technically viable systems are used consistently in practice [3,10].

Study 2 experimentally tested whether the layout of a privacy policy influences subjective understanding and its association with acceptance. Controlling for gender, age, education, and reading time, a layout incorporating guiding questions significantly improved subjective understanding compared with a standard format. These results align with health-communication research, demonstrating that structured consent documents with headings, bullet points, and guiding prompts improve readability and comprehension, especially when baseline literacy is heterogeneous [13,14,17,19]. Among the covariates, only age showed a small positive association with subjective understanding, indicating that older participants felt slightly more confident in their understanding (as discussed above). Moreover, higher subjective understanding was associated with greater acceptance of the policy. These findings are consistent with prior evidence showing that structured consent materials—such as those using headings and guiding prompts—can improve comprehension and user engagement [14,15].

Taken together, the findings underscore the dual importance of content and context in the introduction of data-driven technologies in clinical environments. While technical feasibility and staff buy-in are essential for implementation success, the way information is presented also plays a critical role in shaping patients’ perceptions and willingness to engage with such systems. The studies provide complementary perspectives on the implementation of location-tracking technologies in health care settings. Study 1 revealed the nuanced attitudes and operational concerns of frontline staff toward VAC pump localization, and study 2 demonstrated how information sheet layout can impact patients’ understanding and acceptance of such systems. This complementarity is particularly valuable because even though the staff members in study 1 were very positive about the implementation of a localization system, patients might express concerns about their privacy, which study 2 then addressed by testing communication approaches that could mitigate these very concerns. Even though the material that participants in study 2 received was addressed to patients, it might be just as helpful for staff to understand the system. For example, the guiding-question format, which improved subjective comprehension among potential patients, might also

XSL•FO
RenderX

be beneficial for addressing the operational concerns expressed by the clinic staff in study 1. Applying structured communication approaches in training sessions and staff information materials may help mitigate concerns about technical feasibility and implementation logistics. By improving staff members' understanding of how the localization system works and what benefits it offers, their acceptance and willingness to use the system may increase. Greater staff acceptance, in turn, may enable more consistent use in everyday practice and thereby enhance efficiency in clinical workflows—for example, by reducing the time needed to locate equipment. In addition, confident and well-informed staff are likely to convey more trust to patients, thereby positively shaping patients' perceptions and acceptance of the system. Thus, integrating the insights from both studies into a comprehensive communication strategy might simultaneously address staff concerns and patient privacy considerations, thereby facilitating more effective implementation of RTLS technologies in health care settings. Together, the 2 studies provide a more comprehensive picture than either study could have offered in isolation—combining a rich contextual understanding with experimental evidence on how to address key implementation barriers.

Limitations

Several limitations should be noted. The sample size in study 1 was relatively small and limited to a single clinical institution, thereby potentially reducing the generalizability of the findings. Given the voluntary nature of participation, staff who held stronger concerns may have been less likely to respond, which could have biased attitudes in a more positive direction. Moreover, attitudes toward VAC pump localization were assessed with 2 single self-developed items (comfort and perceived usefulness), which precludes an assessment of internal consistency and may have reduced measurement reliability. Because these items were not validated and we did not estimate a measurement model, the study 1 quantitative results should be interpreted as descriptive indicators in this specific setting rather than as precise or generalizable estimates of staff acceptance. We chose this brief format to keep the survey feasible in a busy clinical environment and obtain an initial indication of staff attitudes, but future studies should use multi-item scales and larger, multisite samples to provide more robust and generalizable evidence. Furthermore, the acceptance of object localization may depend on the specific type of item that is being tracked. While VAC pumps were seen as unproblematic, other objects—particularly those more closely associated with staff or patient movement—may raise greater concerns, including fears of increased surveillance or performance monitoring, which our data do not capture [9-11]. Generalization to other use cases should therefore be approached with caution.

In study 2, the measures relied on self-reported understanding and a single-item acceptance judgment rather than behavioral outcomes. Additionally, while the layout manipulation in study 2 targeted structural design, other features, such as language complexity and institutional trust, were not varied and may also influence understanding [13]. Moreover, participants' subjective understanding was the sole focus of the assessment. Consequently, the study lacks the necessary data to determine whether participants' comprehension was genuinely enhanced by the improved explanation or whether they merely perceived an improvement in understanding. Recent work in the context of location tracking in a different setting has shown that objective understanding, assessed with comprehension questions, can be more strongly related to acceptance—via increased project-specific trust—than subjective understanding alone [24]. Against this background, our reliance on subjective understanding may have attenuated the observed associations and could partly explain why the estimated indirect effect of layout on acceptance via understanding was small but statistically significant. Future studies should therefore combine subjective ratings with performance-based comprehension measures and, where possible, behavioral indicators of information use and technology acceptance.

Practical Implications

The results point to several actionable recommendations. First, incorporating clear, question-based formatting into privacy communications can support perceived understanding, as evidenced by study 2. Such formatting could be implemented by redesigning consent forms, digital interfaces, and educational materials throughout the health care facility.

Second, early engagement with clinic personnel—especially those responsible for operational logistics—is essential to address concerns and increase buy-in. This engagement should include structured opportunities for staff to provide feedback during all implementation phases, from initial planning to postdeployment evaluation. Implementation could include comprehensive training programs that not only focus on technical operation but also provide context about how the technology integrates with existing workflows and benefits patient care. Such information is especially important given that staff voiced concerns about potential increases in workload in study 1.

Future Directions

Future research could build on these findings in several ways. Longitudinal studies may help assess whether improved understanding leads to sustained trust and actual use over time. In addition, experimental variations in communication elements—such as video-based or interactive explanations—could shed more light on how to optimize privacy-related materials for clinical audiences [5]. Critically, future studies should directly compare subjective understanding with objective comprehension to determine whether layout- or format-driven changes translate into demonstrable knowledge gains. Building on these initial directions, future research should examine whether the age-related differences we observed in subjective understanding translate into actual differences in comprehension. Studies incorporating brief knowledge assessments (eg, multiple-choice or true or false items targeting key policy elements such as what data are collected, who can access them, and retention periods) alongside self-reported measures would provide valuable insights into this question, as earlier research found differences between objective and subjective understanding and their relationships with acceptance [24]. Where feasible, such work should also incorporate

XSL•FO
RenderX

decision-relevant outcomes (eg, consent decisions or information-seeking behavior) rather than relying solely on self-report.

Additionally, comparative research across different health care institutions could help identify how contextual variables, such as organizational culture and existing technology infrastructure, influence staff attitudes toward location-tracking technologies. Such research would expand upon our single-institution findings and provide a more generalizable understanding of implementation factors.

Conclusion

As health care systems continue to adopt digital technologies, understanding how such innovations are communicated and perceived is becoming increasingly important. Within the specific context of VAC pump localization in one clinic and a hypothetical patient scenario, this research highlights 2 practical dimensions of successful implementation: the design of communication materials and the perspectives of clinical staff who are expected to engage with new systems. We showed that simple layout adjustments can significantly improve subjective understanding and are indirectly related to acceptance via perceived understanding. In our clinic sample, staff respondents generally welcome innovations such as equipment localization when they are presented transparently and aligned with clinical needs. At the same time, implementation must account for practical concerns on the ground. Together, these findings underscore the value of integrating human-centered design principles—in both communication and system planning—to ensure that digital innovations are not only functional but are also trusted and embraced by those who use them.

Abstract

Background: Computerized clinical decision support (CDS) has the potential to improve patient outcomes by offering evidence-based guidance at the point of care—enhancing guideline adherence and diagnostic accuracy—and supporting system-level outcomes by enabling predictive analytics for more efficient resource planning. Prior work has identified factors that affect adoption, such as clinicians' expectations of usefulness, ease of use, alignment with workflows, and resources to support utilization. However, CDS adoption is not static and changes according to dynamic systems of behaviors and workflows, requiring a deeper understanding of how evolving conditions affect implementation and outcomes.

Objective: To explore the dynamic factors influencing CDS adoption, we examined the implementation of the "Unplanned readmission model version 1," developed by Epic Medical Records System, at Duke University Health System, using group model building and system dynamics modeling.

Methods: We first conducted group model-building workshops with staff (case managers, physical and occupational therapists, hospitalist faculty physicians, and resident physicians) who participate in decisions about discharging patients. Study team members guided participants to identify and connect variables in causal loop diagrams. We coded workshop transcripts in software designed for system dynamics analysis to identify themes, aggregated them into a causal loop diagram, and reviewed them with participants to converge on a common model. A team member applied equations to the pathways and tested data to simulate conditions leading to full, limited, or no adoption of a tool.

Results: We identified key balancing loops driven by external pressure (eg, Centers for Medicare & Medicaid Services penalties) that motivated initial adoption and reinforcing loops based on perceived internal benefits to sustain use. While institutional incentives led to early training and tool use, efforts declined due to staff turnover, competing priorities (eg, COVID-19), and workflow changes. Reinforcing loops emerged when staff described clinical utility, such as improved discharge planning and team communication. However, staff also suggested that these loops were often weak due to difficulty linking the use of the tool to outcomes in real time. Simulation modeling showed that while strong external pressure and rapid training led to initial success, interest in using the tool waned as workflows improved and readmission rates approached Centers for Medicare & Medicaid Services goals. When conflicting priorities were introduced, adoption stalled earlier, and fewer staff were trained. In contrast, when internal motivation was strengthened by reducing the amount of evidence needed to perceive success, individual interest remained high even as institutional attention declined, sustaining tool use and further reducing readmissions.

Conclusions: External pressure to improve can be a strong motivator for initial adoption, but in the face of conflicting demands for attention, it may fall short of sustained long-term tool use. Tools are more likely to have extensive and sustained use when those using the tools can perceive internal benefits.

Introduction

Computerized clinical decision support (CDS) tools, health IT systems that deliver patient-specific recommendations during clinical workflows, have the potential to transform health care delivery. By delivering evidence-based guidance at the point of care, these tools enhance clinical decision-making, improve patient outcomes, and enable health care organizations to anticipate future resource needs through predictive analytics, leading to more efficient planning and resource allocation [1-4]. A targeted literature review published in the *Interactive Journal of Medical Research* found that CDS systems positively impacted quality assurance in 69% of the studies analyzed and provided clinical benefits in 41% compared to usual care [5]. Quality assurance was supported through improved adherence to clinical guidelines, better diagnostic support, monitoring practices, and improved screening and treatments. Clinical benefits included improved diagnostic accuracy, clinical decision-making, and treatment selection. The effectiveness of CDS tools is closely linked to their successful adoption at the bedside.

Understanding the factors that influence clinicians' adoption of CDS tools is essential for designing effective implementation strategies. The Unified Theory of Acceptance and Use of Technology, developed in 2003, has identified 4 key concepts that could influence new information technology adoption: performance expectancy (belief that using the system will help one improve job performance), effort expectancy (ease associated with the system including individual perceptions and design features), social influence (perceived social pressure to use the system), and facilitating conditions (perceived organizational and technical support for system use) [6]. Lui et al [7] found that performance expectancy and effort expectancy were significant predictors of CDS adoption and that these beliefs depended on individuals having autonomy and agency. A meta-analysis that examined predictors of health care practitioners' intention to use artificial intelligence–enabled CDS through the lens of the Unified Theory of Acceptance and Use of Technology found that facilitating conditions influenced performance and effort expectancy and, in turn, intention to use artificial intelligence–enabled CDS [8]. A recent study by Wang et al [9] additionally demonstrated the importance of top management support, in which senior administrators recognize the importance of the information system and are actively engaged in its implementation, for adoption by positively shaping not only performance and effort expectancies but also social influence. Other work has shown that clinicians are more likely to adopt tools that they view as accurate and useful when these tools integrate with existing workflows and have resources available to act on the risk scores [10,11]. Conversely, tools perceived as irrelevant and interruptive to workflows have led to "alert fatigue" and low utilization rates [12,13]. While this work sheds light on how multilevel factors affect CDS adoption, there is additionally a need to understand the dynamics of the systems within which CDS functions, with behaviors and workflows that change over time; this information is important for developing strategies to sustain adoption [14].

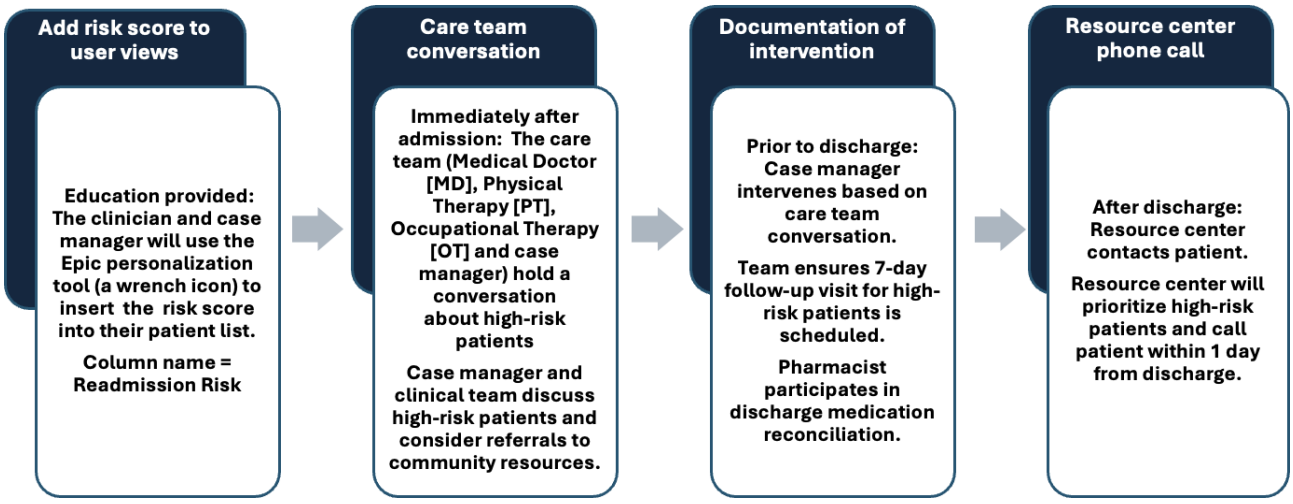
Systems-aligned precision medicine describes CDS strategies that account for complex and dynamic systems of care, not only for the patient but also for the clinician engaged in decision-making [15]. To understand the dynamic complexity of factors that affect adoption, we developed a study to explore facilitators and barriers in the adoption of a single use case, the implementation of "Unplanned readmission model version 1," developed by Epic Medical Records System, at Duke University Health System using system dynamics modeling [16]. Readmissions have been identified as an essential quality indicator and linked to institutional financial incentives through the Centers for Medicare & Medicaid Services (CMS) Hospital Readmission Reduction Program [17,18]. Due to the significant impact on patients and institutional stakeholders, many readmission risk scores have been developed to target high-risk patients with an improved discharge process [19,20]. We engaged interest holders in developing a system dynamics model by conducting group-based modeling sessions with health system staff actively involved in the discharge process. Through these sessions, we aimed to uncover factors that inhibit or promote the use of the readmission risk score and identify potential solutions to enhance its adoption and effectiveness. After completing the workshops, we built a mathematical version of the model to explore the logic captured in the causal loop diagram. This type of model, known as a simulation model, provides an opportunity to determine if the loops can create the behaviors reported in the workshops and under what conditions they may create other, not yet observed, behaviors.

Methods

Ethical Considerations

The protocol was reviewed by the Duke Health institutional review board and determined to be exempt from further institutional review board review (Pro00118266). The exemption was granted under category 2, covering minimal-risk research involving survey or interview procedures, and was consistent with institutional policy and applicable federal regulations. Because the study was deemed exempt, written informed consent was not required; participants were provided with study information and informed that participation was voluntary. No direct identifiers were collected, and the data were managed in accordance with Duke Health policies on privacy and confidentiality. Participants did not receive compensation for participation.

Setting



In 2017, Duke Health implemented Epic's "Unplanned readmission model version 1" (hereafter referred to as the Epic readmission risk score) in response to the need to reduce unplanned readmissions. CMS considers readmissions a key quality indicator and thus implemented the Hospital Readmissions Reduction Program to incentivize institutions to

XSL•FO
RenderX

reduce their readmission rates [18]. Duke University Hospital (DUH) is a quaternary academic hospital located in Durham, North Carolina, providing high-acuity care across specialties. The hospital serves a diverse patient population from Durham County, Wake County, and surrounding areas in North Carolina.

At a hospital like DUH, with almost 1200 beds and an average of more than 100 discharges a day, it would be impossible and unnecessary to apply all discharge resources to every patient. Hospitals like DUH need to stratify their time and resources based on patients who have the highest risk of being readmitted. The Epic readmission risk score was introduced at DUH in November 2017 to proactively identify patients at high risk of readmission and implement targeted interventions to reduce readmission rates [16]. This CDS tool analyzes Epic's electronic health record data to generate a readmission risk score, ranging from 0 to 100, along with corresponding color codes: red for high risk, yellow for medium risk, and green for low risk. Predictors such as patient age, laboratory variables, clinical diagnosis variables, medication numbers and classes, order types, and utilization variables are used to populate the score. This score and color code are then displayed within the patient's electronic health record, allowing clinicians to make informed decisions about postdischarge care and follow-up. Figure 1 shows the proposed integration into clinical workflows with multidisciplinary review at discharge and the implementation of close follow-up and additional services upon discharge.

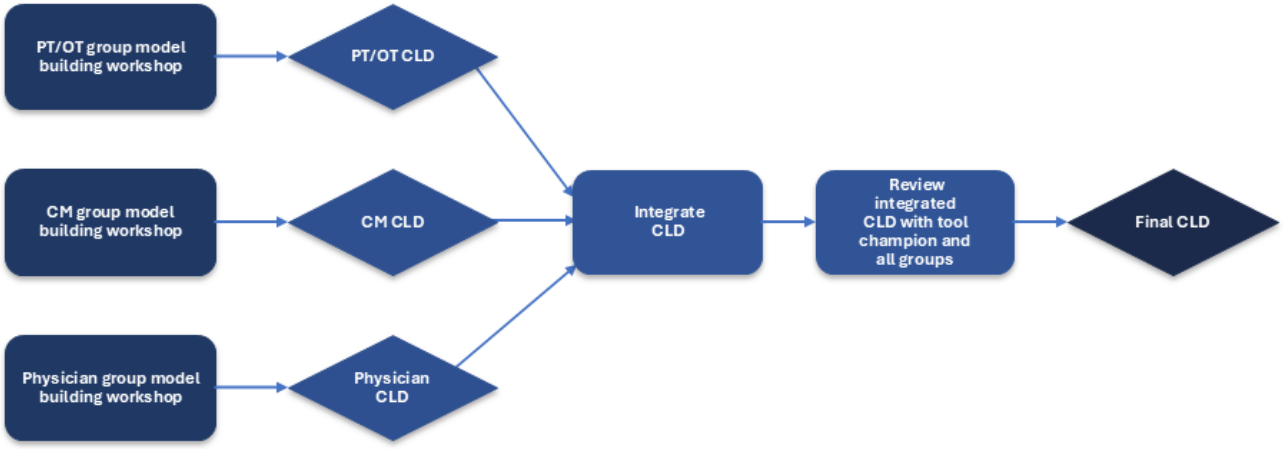


Figure 1. Integration of the Epic readmission risk score into clinical workflows used during training and the initial implementation.

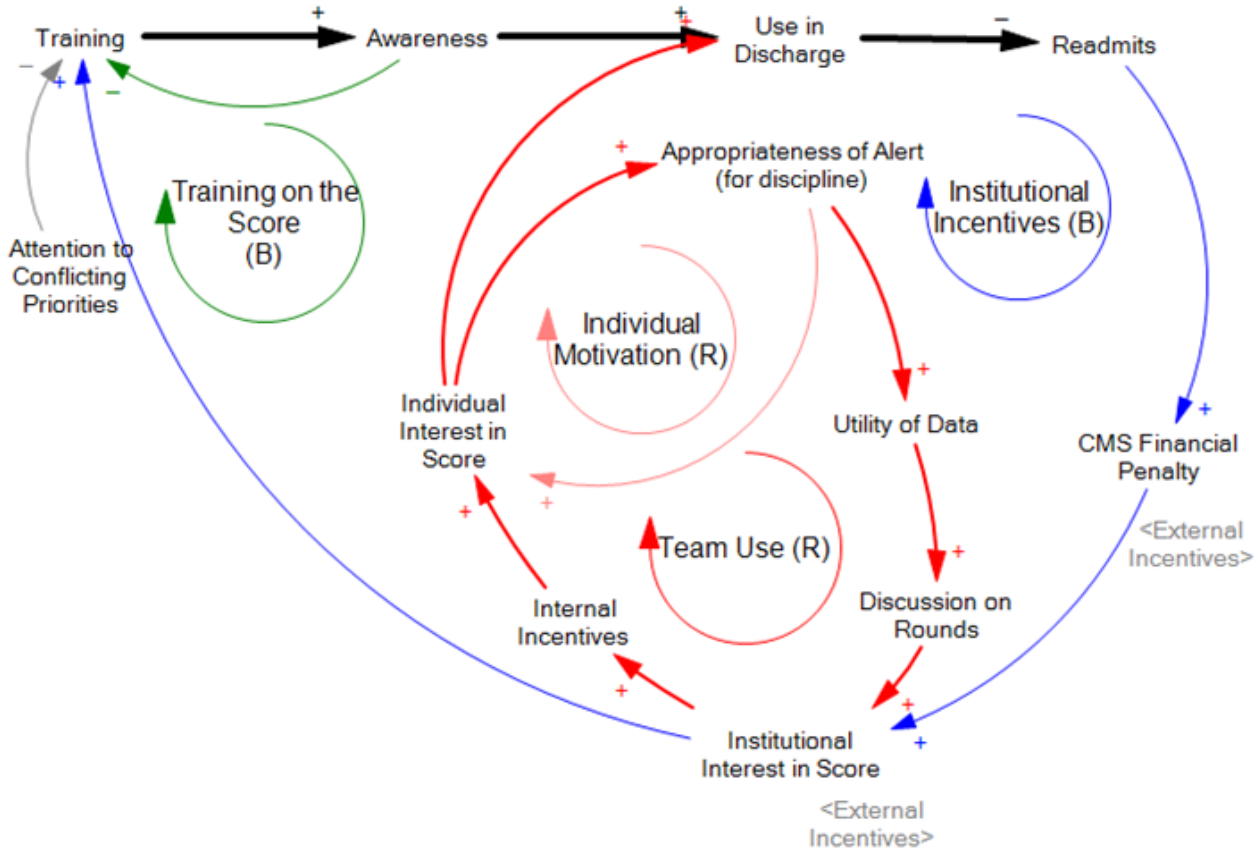
Project Design

To explore adoption in this setting, we used group model building, a process that engages stakeholders in developing a system dynamics model. We performed 3 group model-building workshops with small groups of staff involved in the discharge process at DUH. These staff included case managers, physical and occupational therapists, and internal medicine and general surgery resident physicians. The workshops aimed to understand the factors influencing the uptake and sustained use of the Epic readmission risk score. In each session, the team facilitated the production of a causal loop diagram meant to represent the utilization of the Epic readmission risk score at the hospital, from the participants' perspectives. A final review session was held with members from all groups, as well as the chief medical officer, who initially led the implementation of the tool, and faculty hospitalist physicians. Figure 2 provides a visual representation of how our causal loop diagram was developed by the workshop participants and facilitators.

Figure 2. Study diagram. PT/OT: physical therapy/occupational therapy, CM: case manager, CLD: causal loop diagram.

Before the sessions, a script was created detailing the intended agenda of the workshops. The team adopted a process for variable elicitation and causal loop diagramming from *Scriptapedia*, a handbook of scripts for developing structured

XSL•FO
RenderX



group model-building sessions [21]. In this structure of group modeling, there is a core modeling team that includes facilitators who lead the discussion, a recorder who monitors the audio recording while documenting important themes, and a "wall builder" who draws content on a whiteboard [22]. In these workshops, the facilitators (primary and secondary) first introduced themselves, the problem of declining use of the risk score, and the objective of constructing a causal loop diagram. The facilitators then prompted participants to describe their roles in the discharge process and discuss their experiences, or lack thereof, with the tool. The facilitators invited participants to contribute, by speaking or writing, suggestions about conditions that have affected tool use and worked with the group to identify variables and feedback loops. While the "wall builder" recorded the variables and diagram on a whiteboard, participants additionally had the opportunity to "take the pen" and contribute to the diagram directly. These workshops were transcribed, and the transcriptions were then coded in the DynamicVu (DynamicVu) software for key variables and causal links to match quotes from participants to parts of the causal loop diagram [23]. The study team worked together to integrate data from the 3 workshops into a single causal loop diagram, which was subsequently converted into a mathematical simulation model to assess internal validity, utilizing Vensim PLE (Ventana Systems, Inc). A final review session was conducted with a few members of each group, along with the chief medical officer at DUH, who led the initial implementation of the tool in 2017.

Results

Overview

We successfully completed the 3 interest holder workshops with the active participation of 5 to 10 clinicians per workshop. We then held a final group workshop with representatives from each group with active participation. As we explored one tool, we developed a set of dynamic hypotheses based on workshop participants' insights. The analysis revealed 3 key themes that explain the dynamics observed in the organization's efforts to lower the readmission rate. The three themes included institutional-level learning and reinforcement, individual-level learning and reinforcement, and the training and support of a champion (Figure 3).

Figure 3. Simplified causal loop diagram developed from the workshops directly. CMS: Centers for Medicare & Medicaid Services.

Organizational Response to Lower Readmission Rates

The first feedback loop identified was the organization's response to the external desire to lower the readmission rate ("Institutional Incentives" loop). This initiative to implement the Epic unplanned readmission score, driven by the institution's general concern for reducing readmissions, began prior to these modeling workshops. The tool was initially implemented through a pilot project that included an evaluation component led by a multidisciplinary team comprising members from hospital medicine, case management, clinical operations, biostatistics, and informatics, who encouraged training programs on the tool [16]. The hope was that this training would lead to increased use and thus better discharge plans for patients with a high risk of 30-day readmission. The initial push for tool use led to more training and awareness.

XSL•FO
RenderX

Our workshops led us to believe that while some staff still use the tool, many are unaware of its presence or capabilities, with usage generally declining over time rather than becoming widespread. We explored with staff potential explanations for the lack of widespread awareness and use of the tool, resulting in a balancing feedback loop, in which initial training that aimed at equipping staff with the necessary skills to achieve the desired outcomes dropped off, and other circumstances distracted attention away from continued training and use. We identified several reasons why training may have declined. These included normal turnover and events such as the COVID-19 pandemic, which placed other constraints on training. Additional changes, including arguably positive ones, changed the workflow by incorporating alternative practices and tools that may have been inspired by and substituted for the tool. The case managers described how the pilot program to introduce the score had changed their behavior by providing a visual cue to collect more information for specific patients indicated as "high risk" for readmission with a red alert. Some participants suggested there would be increased adoption if factors included in the algorithm aligned with their conceptual model of risk in these patients. Over time, however, they internalized the criteria associated with the alert, and those characteristics themselves became the cues. For example, one case manager said:

> *I think that the … [alert] started out like great in the beginning because it was the startup of a new system. So, it was like, hey, this is your visual to know that we have to do something. And maybe now we lost part of that visual because now we know what we're looking for. Practice had changed since the introduction of the score to collect additional information for patients flagged as "high risk" for readmission. … it just became part of our workflow of knowing in our assessment, like of room to assess more in depth, right, if that makes sense. It gave us the tools to then ask more in-depth questions, but then that became part of our assessment process.*

This organizational-level balancing loop indicates that, over time, as the readmission rate reaches a certain threshold, the institutional interest, driven by external pressure from the CMS penalty, will eventually drop [18]. The level of institutional interest, in turn, would affect individual staff members' interest in using the score. As one resident said, "… if the institution is saying we need to reduce readmissions at the end, I'm going to do everything I can to reduce readmissions ..."

Reinforcement Through Perceived Benefits

Over the long term, however, as the initiative transitions from the initial training phase to broader institutionalization, the efforts of these champions may be partly or wholly replaced by individual or organizational learning processes that reinforce tool use (see "Individual Motivation" and "Team Use" loops, which are reinforcing). These feedback loops emerged from the hope that staff would recognize the benefits of the training and the resulting improvements in readmission rates.

At both the individual and team levels, reinforcement can come from staff using the tools, observing the tool's appropriateness for their work, and becoming more committed to its use. Clinicians discussed how evidence of the effectiveness of the tool for their practice is an important driver for adoption. They indicated that they encounter many scores in their field and said that those they want to use "have been shown to be effective" and "provide obvious, clear direct value." In this case, they want to know what contributes to the score and "if any of that relates back to discharge." One resident explained:

> *It's on par with a new risk score where we don't actually know- like you're telling us that this is going to work or this is going to do this, but we have no backing or no evidence of that. So, I think that's another aspect to consider is like, yeah, we could look at it, but we don't actually know how much this makes a difference, how impactful this truly is.*

Staff said that they would value the data generated from the score if they contained information that would affect their decisions in real time. One physician said:

> *The only scores that we have time to spend on in medicine when we're running around 8000 times a day are the ones that directly affect our decision-making in that exact moment.*

They would then incorporate the information into the discussion during multidisciplinary rounds, which aligns with institutional interests. One case manager described a push for bringing multidisciplinary teams together at the same time as the introduction of the readmission risk tool:

> *There's been a push for pulling the multidisciplinary team together to improve communication. So, there's been lots of work all happening at the same time, and then we've got the hospital care hub ... part of the interdisciplinary ... case reviews and rounds.*

These reinforcing loops were based on the expectation that visible positive outcomes would motivate continued engagement and institutionalization of the practices introduced during the training. A medical doctor said:

> *If the institution is saying we need to reduce readmissions at the end, I'm going to do everything I can to reduce readmissions if I'm incentivized to do so … If using this helps, then I will keep using. So then that gets into clinical utility.*

A physical therapist suggested a similar sentiment, saying that their use would depend on evidence that the score had clinical utility for the kinds of factors that they assess to prevent discharge. For example, "I think it would be helpful if we knew a little bit more about … what's contributing to the score and if there's any … factors … that relate back to discharge ..."

Risk for Reinforcement

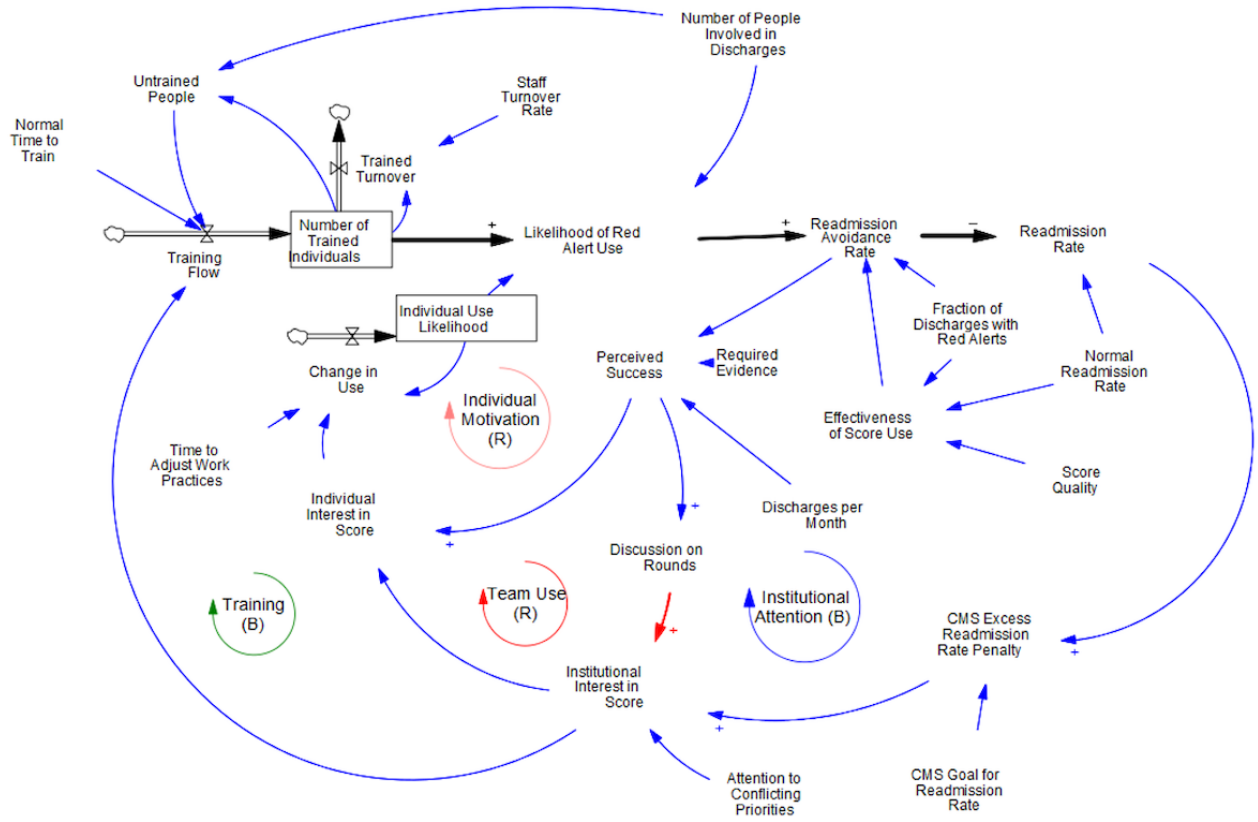
We additionally recognized areas of risk that could prevent this reinforcement from taking over. In our setting, the reinforcing loops could be weak and thus unable to sustain the program at a high level. The "Individual Motivation" loop may be weak because readmission is a rare event and often not directly managed by the discharging team, so team members are unlikely to see the immediate impact of their actions by observing fewer readmissions. In addition, the clear causal connection between

XSL•FO
RenderX

the recommended interventions and the intended outcome may be difficult to observe in real time. On the other hand, length of stay was much more directly observed by discharging clinicians, and efforts to reduce length of stay may come into conflict with efforts to reduce readmission, which can at times increase length of stay. Therefore, the natural reinforcing loops are weak, and external reinforcement through training and awareness campaigns is required. However, the ongoing work of champions and reinforcement can be disrupted in various ways, leading to a decline in tool awareness and use over time. As people change roles and take on new tasks, the ongoing active support of champions is likely to diminish, leading to a drop in training and awareness, especially as other changes crowd out efforts to support the use of the tool. Reinforcement relies on individuals being able to observe the tool's value in their work or, at higher administrative levels, recognizing the value of the tool and creating incentives. One medical doctor described how awareness of a tool would decline over time if it was perceived as inappropriate for their workflow and not easily integrated into the work of new team members:

> *... that institutional knowledge you have to maintain over those cycles. And that means that it has to be, like directly applicable, because I'm helping set up my interns who will then help set up someone for another four years, right. So, if like, if I don't know about it now, then no one... [will] four years from now.*

Additionally, participants expressed difficulty in observing the tool's value at an individual level for low-probability events (readmission is a relatively low probability event, making it harder to see the tool's signal). Resistance to broader changes in the workflow for how decisions are made could also impede the use of the tool. For example, participants observed barriers as the institution encouraged moving to a more consultative, multidisciplinary group process. As one medical doctor said:



> *I think one thing is hierarchical decision-making is a barrier in the sense that like if the case managers or the residents are the target utilizers for the tool, but we're not the primary stakeholders in decision-making, then it's … kind of futile like I, I guess to make it very concrete. It may be difficult for individuals or organizations to recognize the value of the tools, and it may be challenging to find ways to ensure continued use.*

Internal Validity Test With Simulation Modeling

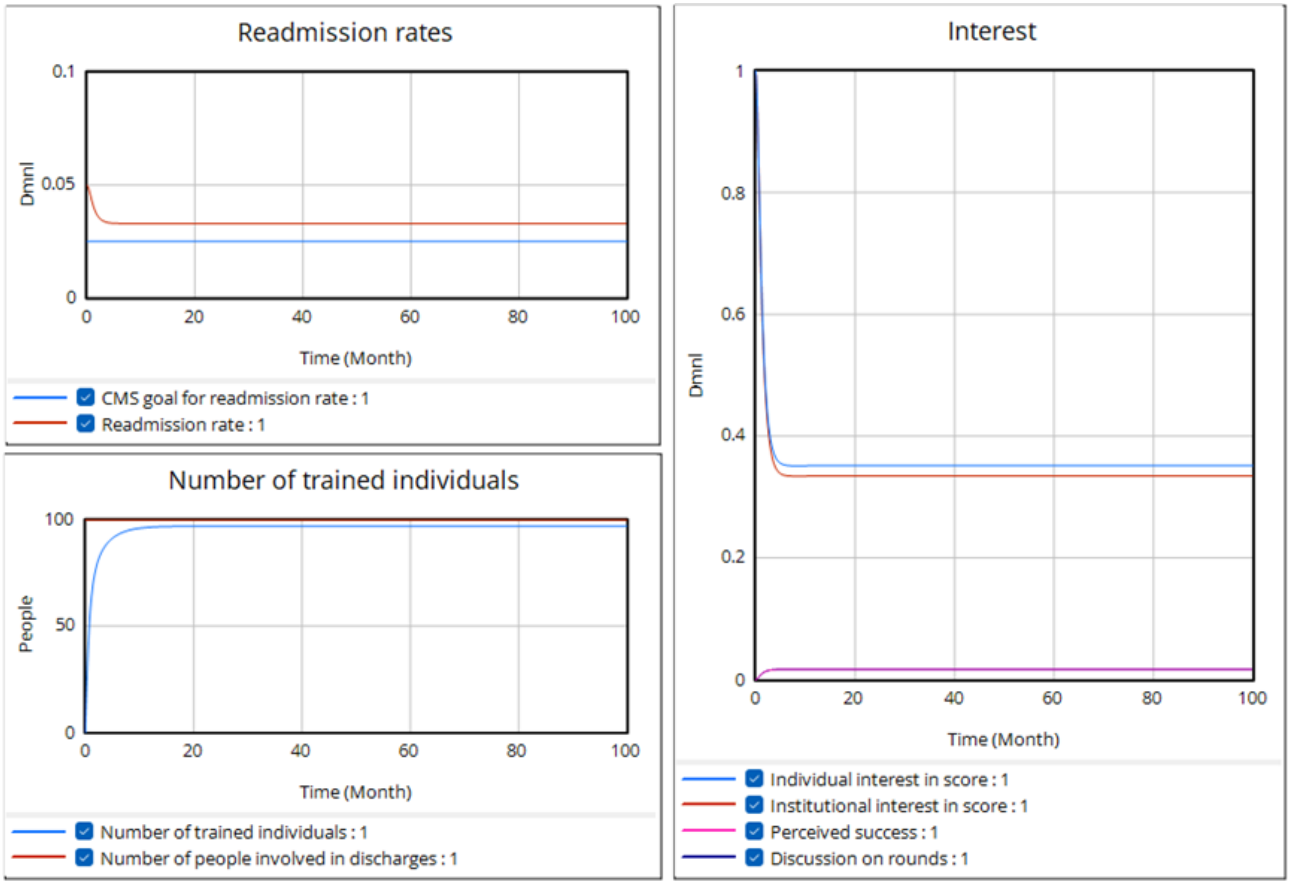
A mathematical simulation model was developed from the initial causal relationships (Figure 4; see Multimedia Appendix 1 for equations). The primary objective in building the mathematical model was to adhere as closely as possible to the causal-loop diagram. To that end, the equations leverage the simplest possible "accounting" or probabilistic logic wherever feasible. As an example of an "accounting" logic, "Awareness" is modeled as the "Number of Trained Individuals," with that number increasing when people are trained and decreasing when trained staff depart. As an example of probabilistic logic, the "Likelihood of Red Alert Use" is modeled as the fraction of people involved in discharges who are trained (the Number of Trained Individuals divided by the Number of People Involved in Discharges), multiplied by the fraction of discharges during which trained individuals pay attention to the score. The product of these 2 variables should capture the fraction of people involved in each discharge who are both trained to use the score and are actively looking at the score.

XSL•FO
RenderX

Figure 4. Simulation model derived from the causal loop diagram. CMS: Centers for Medicare & Medicaid Services.

The “Readmission Avoidance Rate” is central to the model, which captures the reduction in readmissions. This equation leverages probabilistic logic. The “Readmission Avoidance Rate” is the product of 3 parameters: the “Likelihood of Red Alert Use,” the “Fraction of Discharges with Red Alerts,” and the “Effectiveness of Score Use.” In the best possible case, 3 factors are true. First, every red alert is given full attention (the Likelihood of Red Alert Use equals 1). Second, everyone and only those who would later be readmitted are given a red alert (the Fraction of Discharges with Red Alerts equals the Normal Discharge Rate with no false positives). Third, attention to the score leads to interventions that are entirely effective in avoiding readmission (the Effectiveness of Score Use equals 1). If these conditions are true, the “Readmission Avoidance Rate” will equal the “Normal Readmission Rate,” and readmissions will drop to zero.

Understanding this logic around avoiding readmissions takes us most of the way to understanding how the model captures workshop themes of balancing institutional incentives and training on the score loops and the 2 reinforcing loops of individual interest and team use. As derived from the workshop discussions, the 2 institutional level loops are strong initially, when readmissions are high enough to drive institutional interest in the score, leading to training and individual attention to the score. In the simulation model, the training loop is a balancing loop because if training is successful, the use of the tool will lead to lower readmissions and thus the penalty to fall, resulting in a drop in institutional interest and, with it, training. The simulation model similarly recognizes that a reduction in the financial penalty reduces institutional interest in and attention to the score with a similar logic, except that, rather than the reduced readmission rate leading to a fall in training, it leads to a fall in individual interest in the score.



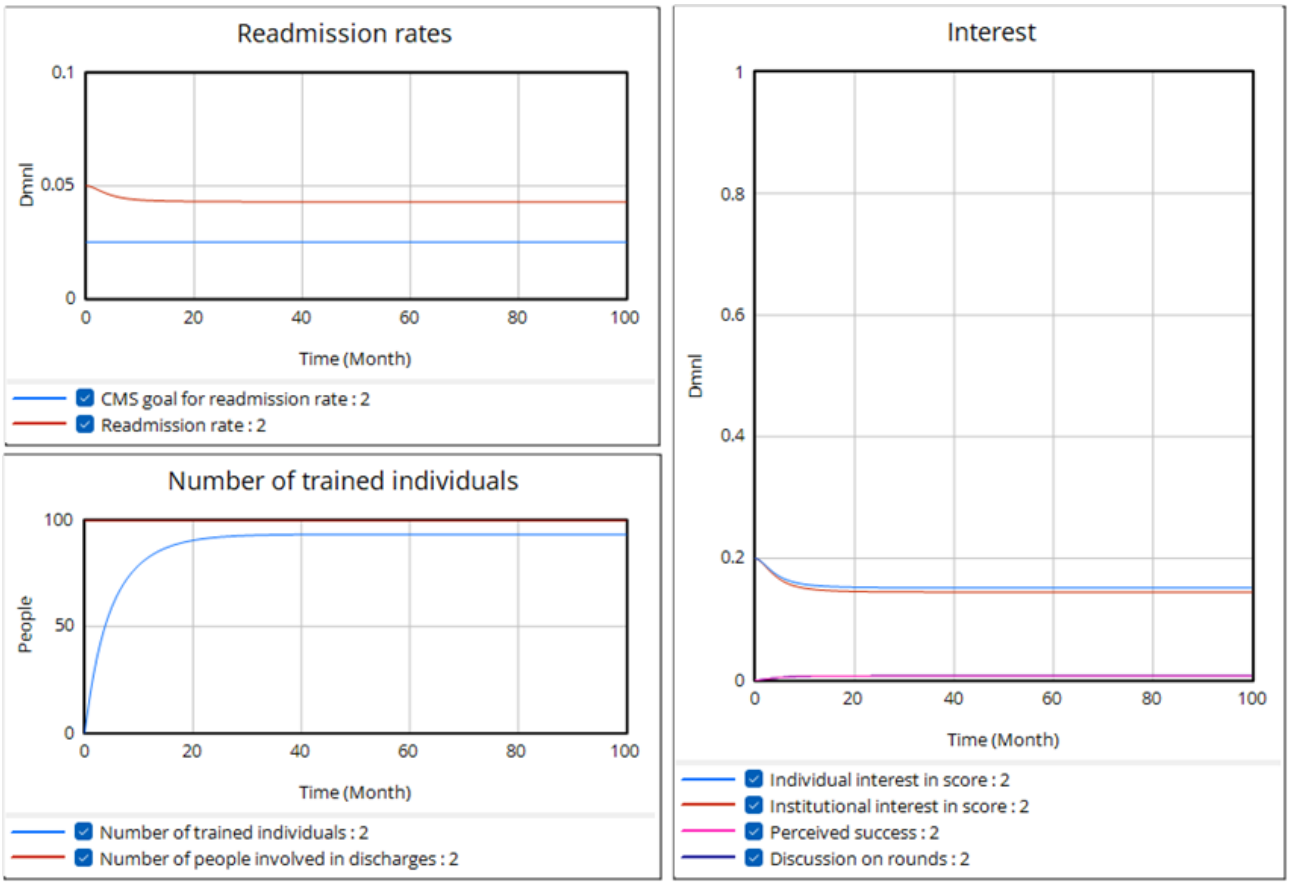
We grounded the connection between the readmission rate and institutional interest in the score using the CMS “Excess Readmission Rate Penalty.” When institutional readmission rates exceed the CMS goal, CMS payments to institutions decrease, driving institutional interest in tools (in this case the score) that can lower the rate to below the CMS goal for the Readmission Rate. For simplicity, we have assumed that this penalty depends on the fractional amount by which the institution’s readmission rate exceeds the CMS goal (This is both a simplified calculation of the CMS penalty and a change in wording from the CMS original word “score” to “penalty” to avoid using the word “score” for multiple different ideas in the model.).

We can see the behavior of these 2 balancing loops in a run of the model (Figure 5) set, so that these are strong loops, and the other (reinforcing) loops are weak. Here, training is quick (all untrained people are trained within 1 month), and turnover is low (only 1% per month), so the number of qualified individuals can rise quickly and, if so, stay high. Red alerts are set to match the regular readmission rate with no false positives, so attention to the score always leads to avoiding readmission. In addition, we have assumed that the institution has little need to address conflicting priorities. With this favorable set of parameters, the

XSL•FO
RenderX

high initial readmission rate relative to the CMS goal leads to high institutional interest that drives training and individual interest in the score. With trained people using the score regularly, the readmission rate falls rapidly. The number of qualified individuals never quite rises to equal the number of individuals involved in discharges because of the delay in training as staff depart.

Figure 5. Simulation run with strong balancing loops. The equations and parameters for this run are given in Multimedia Appendix 1. CMS: Centers for Medicare & Medicaid Services.



Additionally, institutional and individual interest in the score decreases as the readmission rate approaches the CMS goal. While we see a highly successful introduction of the tools with widespread and effective use, external pressure can only drive the effort so far. As the institution gets better, we can expect balancing loops to stop short of complete success because the organization relies on some continued external pressure (provided by high readmission rates) to sustain interest.

As is likely apparent from the discussion above, many factors could limit the effectiveness of these 2 balancing loops. A second run (Figure 6) shows one of these factors affecting both loops. Imagine a scenario where, as hospital staff discussed, the institution faces substantially higher conflicting priorities such as a pandemic or a stronger focus on reducing length of stay. These alternative priorities, which may have a more proximal impact than hospital readmissions, could reasonably divert attention and resources from training on the readmission risk score, thereby increasing the gap between the number of trained individuals and the number of people involved in discharge. While the readmission rate decreases as a result of the initial push for training and education, institutional interest will drop sooner with conflicting priorities, leading to reduced training and diminished individual interest in the score. Although still successful, the program results in fewer people being trained and a smaller reduction in readmissions. The shortfall is even more significant because the organization relies on continued pressure (provided by even higher readmission rates) to maintain interest.

XSL•FO
RenderX

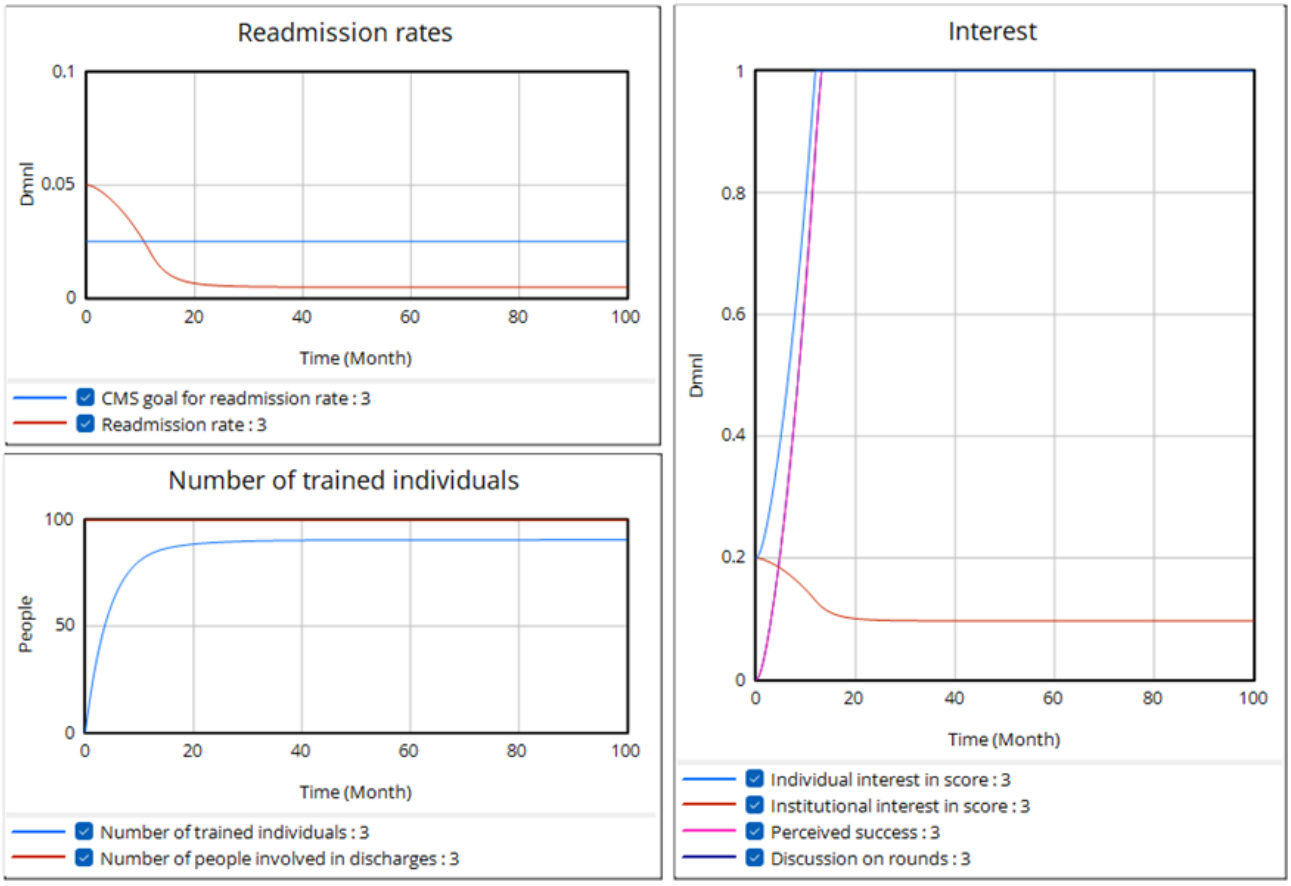


Figure 6. Simulation run with greater attention to conflicting priorities weakening the balancing loops. In this run, the Attention to Conflicting Priorities has been raised from 1 to 5 with no other changes to the model equations or parameters from the previous run. CMS: Centers for Medicare & Medicaid Services.

Having set the parameters (notably raising attention to conflicting priorities) so that the balancing loops alone lead to limited success, we then explore conditions under which the reinforcing loops could take over and drive more significant use of the tool and improvement in the readmission rate (Figure 7). The main change in this run is to reduce the Required Evidence, which refers to how many discharged patients each month must avoid readmission for individuals and groups involved in discharges to perceive tool success. We were mainly trying to capture how evident it is that unplanned readmissions were avoided, as we heard in the group model building (GMB) sessions. In this case, the readmission rate falls below the CMS goal, causing a drop in institutional interest. Despite the loss of external pressure from the CMS, the program continues to be driven by the excitement generated internally from perceived tool success. Institutional interest is even lower than before, and thus so is training, though it is buoyed by internal pressure from use on rounds. Still, individual interest is far higher, which offsets the drop in training.

XSL•FO
RenderX

Figure 7. Run with reduced required evidence strengthening the reinforcing loops. In this run, the Required Evidence has been reduced from 100 persons/month to 3.5 persons/month with no other changes to the model equations or parameters from the previous run. CMS: Centers for Medicare & Medicaid Services.

Discussion

Principal Findings

The causal loop diagram represents hypotheses that emerged from workshops regarding the adoption of a readmission risk prediction tool. The analysis of these feedback loops provided insights into the organizational dynamics influencing the success and sustainability of the initiative to reduce readmission rates. The findings inspired the development of a mathematical model to explore the logic of these loops in greater depth.

The balancing loops identified during the workshops highlighted challenges in maintaining the momentum of training and the need for ongoing reinforcement, both "facilitating conditions," to achieve the desired reduction in readmission rates [6]. Eagerness to reduce readmission rates to meet an external goal can only take adoption so far. Although feedback loops tied to external goals are intended to close the gap between current readmission rates and benchmark targets, the narrowing of that gap can paradoxically reduce effort. This effort refers to the ongoing commitment of time, training, and behavioral adaptation required for successful tool integration into clinical workflows. Depending on how quickly the effort to close the gap diminishes, as it might do rapidly in the face of strong external pressure for attention elsewhere, effort may fall too low before the gap is closed, and the tool may be used far less than its potential.

For sustained success, we believe the implementation of the readmission risk score requires additional input. The workshops provided indications that these additional inputs, in the form of reinforcing loops, would likely come from individuals across several disciplines perceiving internal benefits from the tool. Similarly, Venkatesh et al [6] suggested that while institutional influence, such as the perception that management wants staff to use the tool, tends to motivate new technology use in the early stages of implementation, over time, employees will rely less on these external drivers as they gain experience and integrate it with their workflow. If these internal reinforcing loops are strong, the process is likely to sustain itself without additional training or input from the tool developer. However, there is a risk of relying too heavily on the education of clinical team members and getting them to incorporate it into their own workflow. If the reinforcing loops are not strong, there are implementation strategies that could provide additional input. For example, a monitoring and evaluation system could function as an integral control mechanism for the Institutional Attention balancing loop that maintains tool use even when performance improves by reminding people of the improvements that could be lost without continued efforts [24,25]. Interventions might include a champion who could respond to feedback by adjusting support, such as by reinforcing the Training loop, to reduce long-term drift from desired tool use or an electronic health record–integrated dashboard that provides immediate feedback on key metrics to address the need for evidence about the CDS within the Individual Motivation and Team Use loops [26,27]. The key lesson then is that widespread and sustained adoption is far more likely if those who use the tool are able to see a

XSL•FO
RenderX

positive impact in daily practice on patient care decisions and outcomes.

By using a group model-building approach, we uncovered how these constructs interact over time through feedback loops at our institution. Our simulation model showed that while external pressure can drive initial adoption, it often leads to balancing loops that limit long-term success. Competing priorities that arise only magnify the effect of these balancing loops by directing attention away from initiatives to promote use. In contrast, reinforcing loops—driven by perceived internal benefits and team-level learning—can sustain tool use even after institutional interest declines. However, these reinforcing loops are fragile and require conditions such as visible tool impact, low required evidence thresholds, and integration into daily workflows to take hold. This dynamic systems perspective highlights the importance of designing implementation strategies that not only address user perceptions but also anticipate and support the evolving organizational and social conditions in which CDS tools are used. Modeling system behavior with different types of CDS tools and across diverse institutional contexts will help build a more generalizable theory of how system structure shapes adoption. For example, tools that provide more immediate feedback, such as real-time alerts for clinical deterioration, may be less vulnerable to competing priorities than tools with delayed feedback. To advance this work, it will also be important to build protocols to measure the effectiveness of the GMB and derived solutions: this could include measuring changes in staff understanding of the problem as a result of participating in the GMB and changes in implementation outcomes as a result of solutions implemented based on GMB insights. While this model explores the dynamics of implementing one type of CDS in one institutional setting, it provides a foundation for future research to extend toward a broader systems-aligned precision medicine framework.

Conclusions

We have developed a system dynamics model to approximate the driving and impeding forces related to the adoption of a readmission risk tool at a quaternary academic hospital through group model-building approaches. While we examined one specific outcome of CDS tool use, where there remains uncertainty about the widespread adoption of the tool into clinical workflow, the workshops and modeling point to the potential for a range of different outcomes in different settings. The decline in adoption of this specific score likely relates to the rare nature of the event, as there is limited real-world experience of the impact of the risk model on day-to-day experiences, combined with a decrease in active training and promotion due to competing priorities with the COVID-19 pandemic and an additional focus on length of stay. Understanding the implementation of these risk algorithms in a dynamic system will help developers iterate and improve implementation moving forward. Further research is planned to test the model predictions against a wider range of cases and settings, calibrate the model to test for external validity of the arguments, and refine the lessons.

Abstract

Background: Exposure to patients and clinical diagnoses drives learning in graduate medical education (GME). Measuring practice data, how each trainee experiences that exposure, is critical to planned learning processes including the assessment of trainee needs. We previously developed and validated an automated system to accurately identify resident provider-patient interactions.

Objective: In this follow-up study, we use human-centered design methods to meet two objectives: (1) to understand trainees' planned learning needs and (2) to design, build, and validate the usability and use of a tool based on our automated resident provider-patient interaction system to meet these needs.

Methods: We collected data from 2 institutions new to the American Medical Association's "Advancing Change" initiative, using a mixed methods approach with purposive sampling. First, interviews and formative prototype testing yielded qualitative data that we analyzed in several coding cycles. We built interview guides to collect data required for a work domain assessment, learning use case elicitation, and ultimately design requirement identification. We structured coding efforts within 2 existing theoretical models. Feature prioritization matrix analysis then transformed qualitative analysis outputs into actionable prototype elements that were refined through formative usability methods. Finally, qualitative data from a summative usability test validated the final prototype with measures of usefulness, usability, and intent to use. We used quantitative methods (eg, time on task and task completion rate in summative testing).

Results: We represented the GME work domain assessment through process-map-design artifacts that provide target opportunities for intervention. Of the identified decision-making opportunities, trainee-mentor meetings stood out as optimal for delivering reliable practice-area information. We designed a "midpoint" report for the use case of such meetings. We arrived at a final prototype through formative testing and design iteration. This final version showed 5 essential visualizations. Summative usability testing resulted in high performance in subjective and objective metrics. Insufficient baseline data were captured to draw comparative conclusions in a formal evaluation against existing tools or workarounds to support planned learning. However, the prevailing reported absence of tools and the ad hoc nature of approaches that do exist strongly imply an unmet need for the type of usable summary method delivered in our tool. We collected data from June 2021 through September 2023. Eight resident physicians composed the validation sample, including 4 (50%) residents from the Children's Hospital of Philadelphia and 4 (50%) residents from the University of Rochester Medical Center.

Conclusions: We describe the multisite development of a tool providing visualizations of log-level electronic health record data, using human-centered design methods. Delivered at an identified point in GME, the tool is ideal for fostering the development of master adaptive learners. The resulting prototype is validated with high performance on a summative usability test. Additionally, the design, development, and assessment process may be applied to other tools and topics within clinical informatics.

Introduction

Experiential learning through direct patient care is an important paradigm in graduate medical education (GME) [1]. Readily available measures of patient exposure are necessary to quantify gaps in trainee experience [2]. Such objective tools can provide data to guide a trainee's individualized education plan and enhance future learning [3,4]. The reflective practice and precision education (PE) conceptual models build on the Master Adaptive Learner (MAL) model, pointing to patient exposure data powerfully informing the planning phases of trainee education [5-7]. Planned learning in this context amounts to educational experiences that are structured by the institution, but also extends to intentional, goal-directed behavior arising organically from metacognition surrounding practice. Planned learning is integrated into the residency or fellowship curriculum either by program directors or the learners themselves. It can be the decision to take one elective over another, but it can also be the decision to look out for and seize opportunities to get exposure to a certain patient population or procedure. It is distinct from informal, spontaneous learning that might occur during daily patient care without specific predefined objectives or evaluation methods. This intentionality is anchored in the MAL model, which holds that material learning occurs by cycling through states of planning, learning, assessing, and adjusting.

Using practice data, trainees may situate their experience within their cohorts, identifying targeted opportunities for learning [6]. Although manually tracked case logs by trainees themselves show promise in providing such data, those methods are labor-intensive and limited in their ability to scale [8,9]. Several technology-based systems have been developed to identify trainees' patient experiences automatically and accurately across rotations [10-12]. PE of this kind in GME has recently been advanced as a data-driven approach for improving personalization and efficiency of learning, assessment, and feedback by using longitudinal learner data and analytics. In this framing, programs move beyond aggregate case logs or episodic evaluations toward fruitful cycles of the MAL [13,14]. And while reliable characterization of each trainee's clinical experiences at deep granularity has emerged as a key PE enabler, it remains unknown how to optimally deliver this information to trainees [15,16].

GME trainees need targeted delivery of specific information and knowledge to enhance their educational experience. *Educational* decision support (EDS) deals with such information [17]. We posit that EDS systems are as necessary as clinical decision support (CDS) systems that support clinical duties. To this end, authors initially developed and validated TRAILS (Trainee Individualized Learning System), an automated software platform that uses electronic health record (EHR) metadata—particularly audit logs, note authorship, order placement, and care team assignments—to identify clinically meaningful resident provider-patient interactions across multiple care settings for medical education tracking and assessment [11,18]. We used EHR audit log time stamps and algorithmically calculated interaction intervals by summing time gaps between consecutive events to derive total time-in-chart, a computed metric with strong predictive power to add to raw metadata features. Data cleaning steps like exclusion of data when total time-in-chart is less than 1 hour ensured the models accurately distinguished genuine clinical interactions from incidental chart access. We then applied logistic regression classifiers trained on resident-validated resident provider-patient interactions.

To be useful and usable, EDS output like that of TRAILS must deliver the right information to the right subset of users, at the right time, through the right information channels, and in the most usable format [19]. Traditional technology-centered design (TCD) approaches are insufficient, with outcomes of increased complexity for users, elevated error rates, poor intention to use, and abandoned adoption [20,21]. TCD approaches fit an interface to work-as-imagined and engage users late in the process, if at all. The alternative, human-centered design (HCD), begins by assessing user goals, tasks, abilities, and cognition prior to design ideation. By first identifying contextual needs through requirements elicitation with end users, followed by iterative prototyping and formative evaluation, HCD interface creation instead fits work-as-done, and better results follow: simplified use, low error rates, high affinity, and eventually, high adoption [22,23].

The objective of this study was to follow an HCD approach to design and develop a user interface overlaying an existing automated EDS system, and to measure the summative usability of the design product. Specifically, we sought to: assess the trainee learning work domain and overall context for system implementation; use this knowledge to inform initial designs; apply formative and summative evaluation techniques to the tool; use mixed methods for data collection consistent with HCD standards. We hypothesized that this approach would generate a prototype, meeting acceptable benchmarks for technological acceptance, predicting eventual adoption. The endorsement of such a prototype, assessed to have good usability, would support that our approach could be generalized to other medical applications. The HCD approach we targeted was synthesized across diverse health innovations and health IT including CDS [24-26]. It is also supported by systematic reviews in broader human-computer interaction or software-engineering contexts [27,28]. These suggest that any one viable HCD method is transferable beyond a single specialty or use case.

Methods

Study Design

We performed a prospective mixed methods study within 3 distinct phases of data collection (Table 1) and analysis. Participants were physicians from 2 large academic institutions: the Children's Hospital of Philadelphia (CHOP) and the University of Rochester Medical Center (URMC). Annual trainee cohort sizes are over 500 and over 900, respectively [29,30]. These programs cultivate cultures of planned learning by embedding residents in mentored research projects and data-driven quality improvement teams where they critically reflect on performance metrics, identify specific gaps in outcomes, and develop targeted interventions that close those gaps through iterative, supervised cycles of implementation and

XSL•FO
RenderX

assessment [31,32]. We conducted the study over a 2-year period, from June 2021 to September 2023.

Table . Data collection methods.

Principal data collection method	Participant recruitment[a]	Moderation[b] and setup	Data
Semistructured interview	Trainees and individuals responsible for trainee coaching and program-level planned learning.	Participant was asked questions from role-appropriate interview guide	• Recorded and transcribed session • Moderator notes
Prototype walkthrough interview	Trainees and faculty mentors	Participant was given most recent prototype iteration of planned learning tool and asked to share screen during walkthrough	• Recorded and transcribed session • Moderator notes
Summative usability test	Residents	Participant was given final prototype of planned learning support tool, the "MV[c] midpoint report" and directed to complete test on REDCap[d] (Vanderbilt University) using the report	• Time-stamped, REDCap-collected answers to task questions • Responses to TAM[e]-based Likert psychometrics assessing PU[f], PEOU[g], and scenario realism.

[a]All samples purposive; interview phase saturation was reached succeeding first session when no new data could be synthesized in analysis; repeat participation in or across phases was disallowed.

[b]Each session in all methods was conducted with 1 participant at a time with 1 moderator over Teams (Microsoft) or Zoom (Zoom Communications, Inc) over 1 hour.

[c]MV: minimum viable.

[d]REDCap: Research Electronic Data Capture.

[e]TAM: technology acceptance model.

[f]PU: perceived usability.

[g]PEUO: perceived ease of use.

For coding paradigms in all qualitative research, a 4-member coding team reached cooperative consensus. All had full access to the complete qualitative datasets. Each team member independently reviewed first-cycle coding of all raw data prior to weekly consensus sessions. In these meetings, the team interrogated discrepant interpretations and pursued dialogical intersubjectivity until group consensus was reached. We also refined codebooks in this way, revising, collapsing, or generating new codes, categories, and themes as warranted.

Work Domain Assessment

The first phase of an HCD process, work domain assessment, identifies individuals' roles and details the overall context or work system in which a prototype tool would be used [33,34]. We conducted semistructured interviews with a purposive sample of stakeholders involved in trainee-planned learning. Collecting data from all roles involved is essential to characterize a sociotechnical system of clinical work accurately [35]. Role-specific interview guides covered 2 subjects: trainee sensemaking and decision-making in practice-area learning; mentor or program perspectives on entrustment ladders and how practice-area gaps are identified, discussed, and closed (Multimedia Appendix 1).

We coded the corpus of qualitative data (Table 2). Notably, we borrowed constructs in the Systems Engineering Initiative for Patient Safety to create early cycle topic codes [35,36]. From early cycle coding analysis, we created process maps visually representing dynamics of planned learning.

XSL•FO
RenderX

Table . Qualitative analysis methods used in the study.

Coding type	Purpose	Output
Descriptive coding [37]	Identify topics in the interview corpus.	Table of quotes from interviews and their labels
Provisional coding [36]	Deductively organize topics into categories using a "start list" code book from SEIPS[a] [35]. Improve the design team's grasp of users [38,39].	Expanded table with labels fit to topics and categories
Process coding and causation coding [40,41]	Abstract dynamism or change in topics or categories into graphical representations: SEIPS topics acting as barriers or facilitators to learning; mental models acting on decisions; evolving intentions, choices, objectives, values, perspectives, needs, desires, and agency.	Process maps explaining contexts, conditions, interactions, and consequences of planned learning
Inductive coding [42]	Abstract process map and code table data into questions our users ask, answerable with trainee EHR[b] metadata filtered on clinically meaningful rPPIs[c] and encounter context fields required by that question (eg, care setting or elective label).	Column in feature prioritization matrix
Magnitude coding [43]	Assigns each user question an impact score: numerical value (from 1 to 5 where 5="high impact") showing impact an informed answer would have to planned learning weighing use of the described learnings and degree of relevance to scenarios described in interviews.	Column in feature prioritization matrix

[a]SEIPS: Systems Engineering Initiative for Patient Safety.

[b]EHR: electronic health record.

[c]rPPI: resident provider patient interaction.

Formative Usability Test

To begin formative testing, we required an initial prototype. We initiated further coding processes (Table 1), first inferring key user questions, such as "Will I see important diagnoses if I choose elective X?" These questions formed the basis of an important design artifact in HCD, the feature prioritization matrix (FPM; Figure 1).

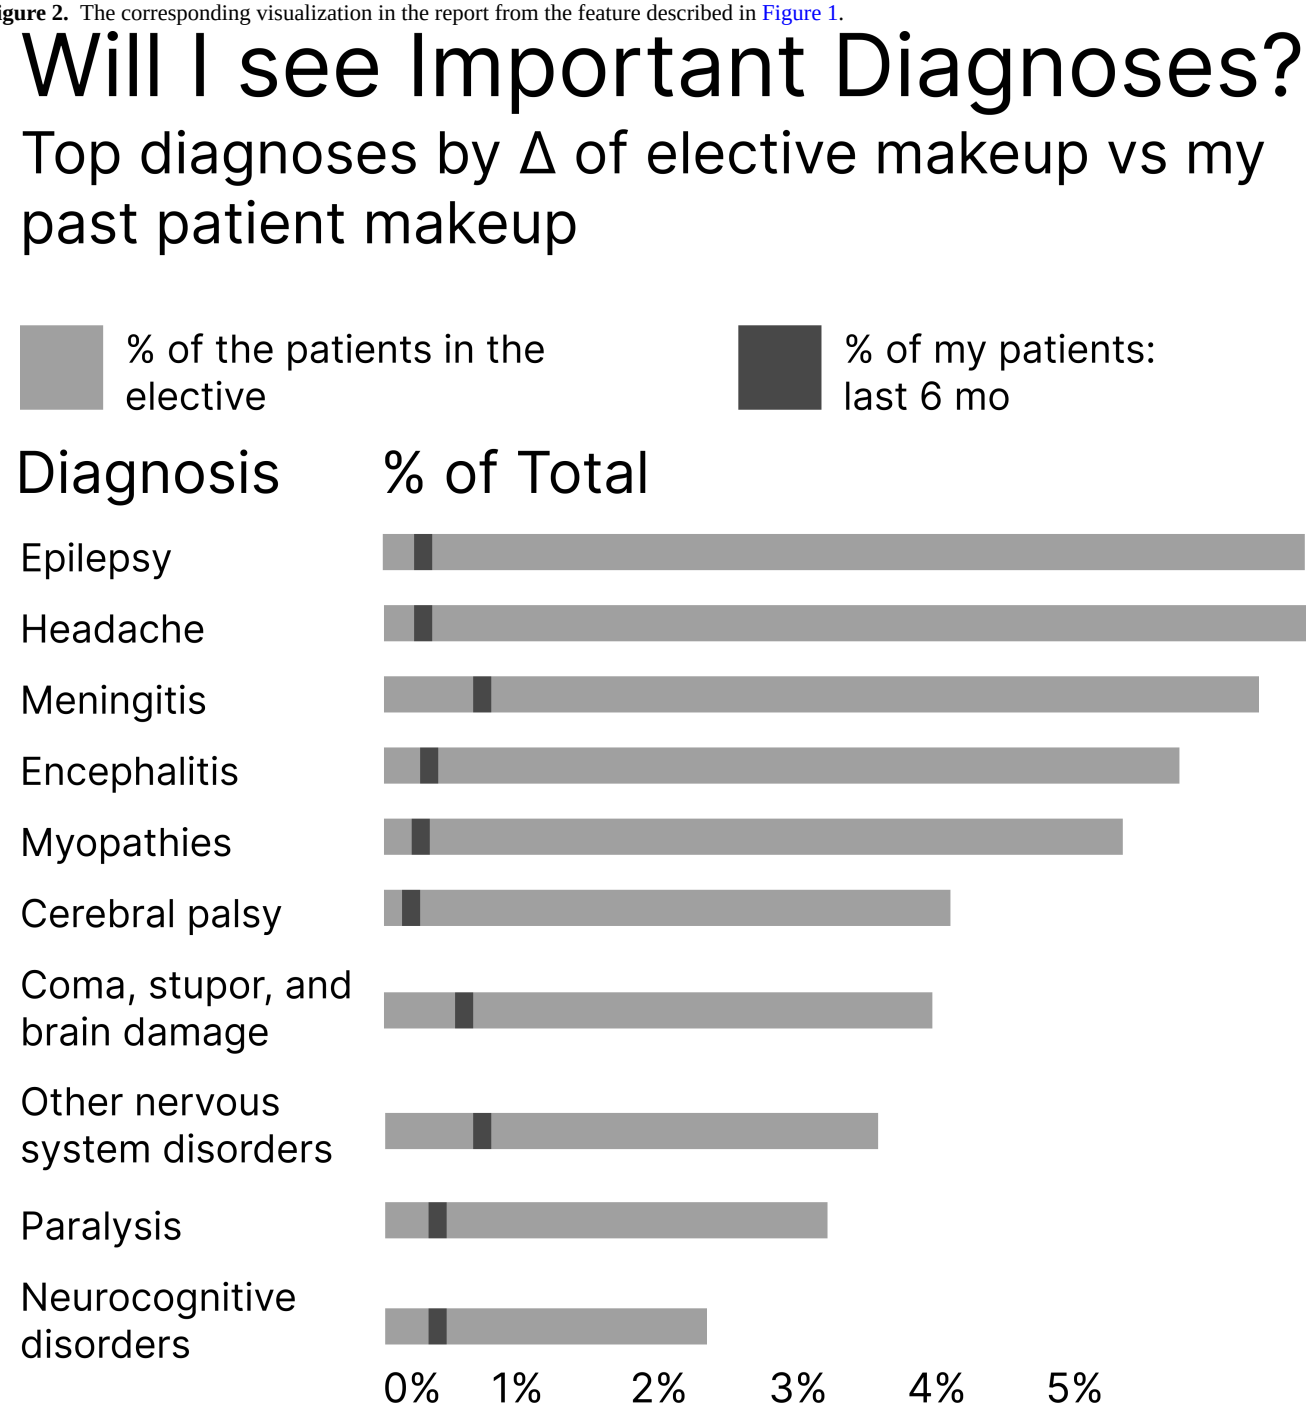

Figure 1. An example of a single record from the feature prioritization matrix.

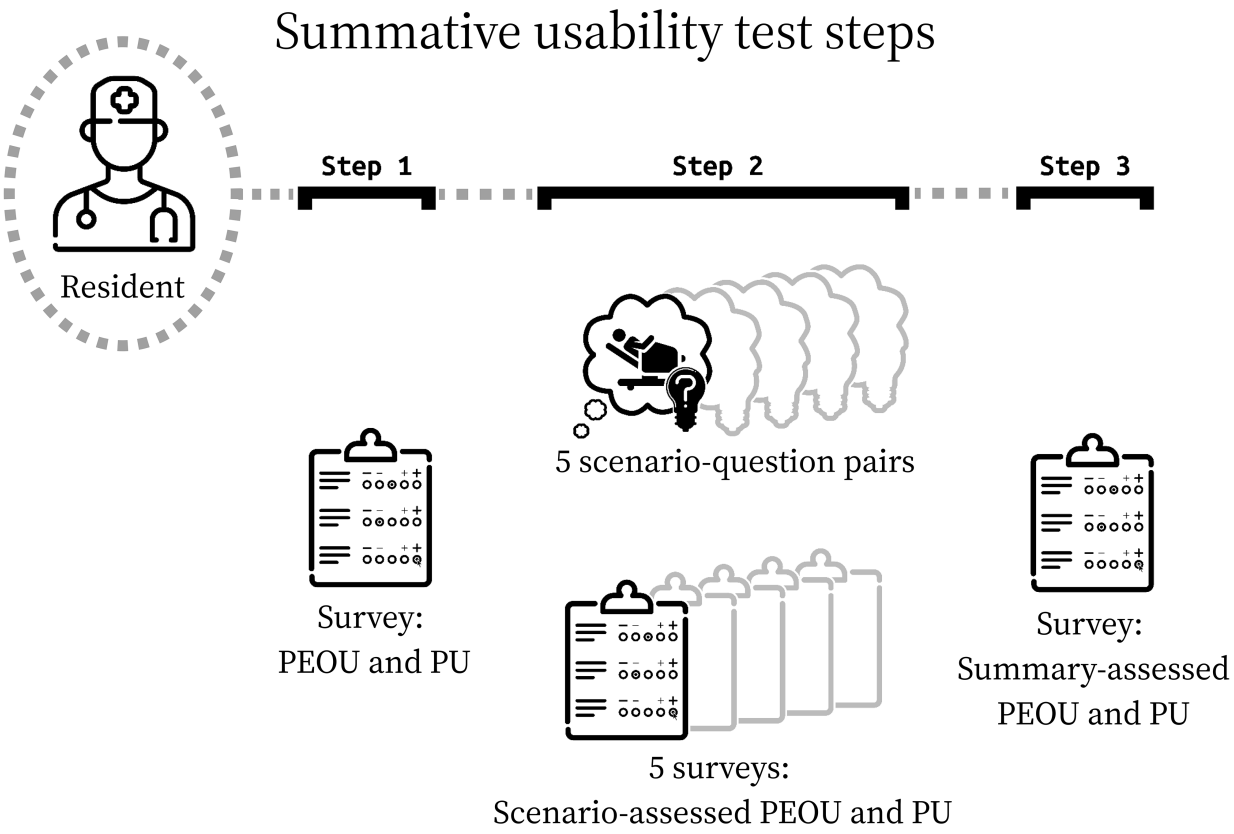
Visualization Title	Report Section (question answered by graph)	What is displayed? (Metadata displayed and analytic logic)	Date Range for Data Pull	Impact Score (1=low; 5= high)
Top diagnoses by Δ of elective makeup vs my past patient makeup	Will I see important diagnoses (if I choose this elective)?	Count of all diags seen by same-year-as-user trainees. Group by diags. Show as a % of total. Show count of diags seen by the user-trainee as a comparison.	Last 6 Months	4

We produced an initial prototype of a planned learning support tool using the FPM from a collaborative unmoderated design session informed by reviewing recently completed process maps. We reached consensus on data visualizations that would allow trainees to identify or close gaps in experience (Figure 2). This action is the core of planned learning, and we formed the first report with visualizations supporting it.

XSL•FO
RenderX

Figure 2. The corresponding visualization in the report from the feature described in Figure 1.

We then iterated on the design in interview walkthroughs with users. With each walkthrough, newly elicited features and corresponding visualizations were added to the FPM and report. Using an impact metric from the completed FPM (Multimedia Appendix 2) and descriptions of required data for each visualization, we determined which features the current system architecture could feasibly support. We then produced a final version of our planned learning tool, the "minimum viable (MV) midpoint report," including only the most impactful, feasible visualizations (Multimedia Appendix 3).



Summative Usability Test

Whereas formative usability testing is meant to expose design flaws and drive prototype iteration forward, summative usability testing is meant to validate a prototype that designers theorize is ready for deployment. We developed a summative usability test to assess usability and use of the "MV midpoint report" and measure performance on MAL planning-related tasks using the report (Multimedia Appendix 4). Participants completed 5 tasks (Figure 3). For each task, participants used the report to answer one of the following key user questions:

1. What are the diagnoses to which I have received the most exposure?
2. In what clinical environments am I seeing them?
3. What gaps in diagnosis exposure could I be filling?
4. What is my exposure to acuity and complex care?
5. In each elective available to me, will I see important diagnoses?

XSL•FO
RenderX

Figure 3. Summative usability test procedure for a single session, where a resident participant moves through the 3 steps, guided by a moderator. PEOU: perceived ease of use; PU: perceived usability.

In this way, the final cycle of analysis and design in the HCD process would be complete (Multimedia Appendix 5).

For each task, we developed a scenario with realistic clinical data and a single complementary test question to which an MV report feature offered an answer. The purpose of each scenario-question pair was to assess usability and use. Four of the 5 scenarios were paired with a multiple-choice question. A fifth scenario was paired with a free-text response. Participants in this usability test were thus assessed with these 5 scenario-question pairs.

Participants were given the MV report in advance of the test for optional review. Participants were told to suspend disbelief and answer questions in the test as though the report were their own, aggregating their own practice area data and encountering the described scenarios during residency.

Participants completed a pretest questionnaire that asked postgraduate year of the participant, whether and how they kept records of their practice areas, and if so, perceived usability (PU) and perceived ease of use (PEOU) of that system. This quantified the usability of participants' baseline approaches to tracking practice-area exposure (if any) for comparison against our tool. PU and PEOU questions were adapted from the development of another successfully implemented CDS tool (Table 3) [44].

XSL•FO
RenderX

Table . Measures within the summative test and the group of user beliefs which they assess.

Measure[a]	Score group
This scenario is important in finding learning or entrustment gaps and resolving them.	Test realism
This scenario is realistic in the search for learning or entrustment gaps and resolving them.	Test realism
In this scenario, the system was easy to use.	PEOU[b]
In this scenario, the system allowed me to perform tasks efficiently.	PEOU
Overall, I am satisfied with how the system is designed in this scenario.	PEOU
In this scenario, the system provided useful features.	PU[c]
In this scenario, the system provided useful information.	PU
In this scenario, the system is an improvement over what I would have used before.	PU

[a]Measures were assessed on a Likert scale from 1 (strongly disagree) to 9 (strongly agree). Participants were assessed after each scenario and then once more in a summary assessment at the end of the test.

[b]PEUO: perceived ease of use.

[c]PU: perceived usability.

We report these descriptive statistics for the groups of measures that assessed PU and PEOU immediately after scenarios, PU and PEOU summarily at the very end of the test, and for the group assessing the realism of the scenarios. Scenario-question pairs were scored for correctness and used to calculate the task completion rate (TCR) by dividing correct answers by total answered questions. We also report average task completion time as the amount of time spent from a scenario-question load page to the submission of a *correct* response.

Ethical Considerations

This study protocol was reviewed by the institutional review boards (IRBs) of both CHOP (IRB 18-014866) and URMC (study 00006717) and determined to meet exemption criteria. We obtained a waiver of written informed consent from both IRBs. Participant data were deidentified and stored by random identifier to protect subject privacy. The participants were not compensated for their participation.

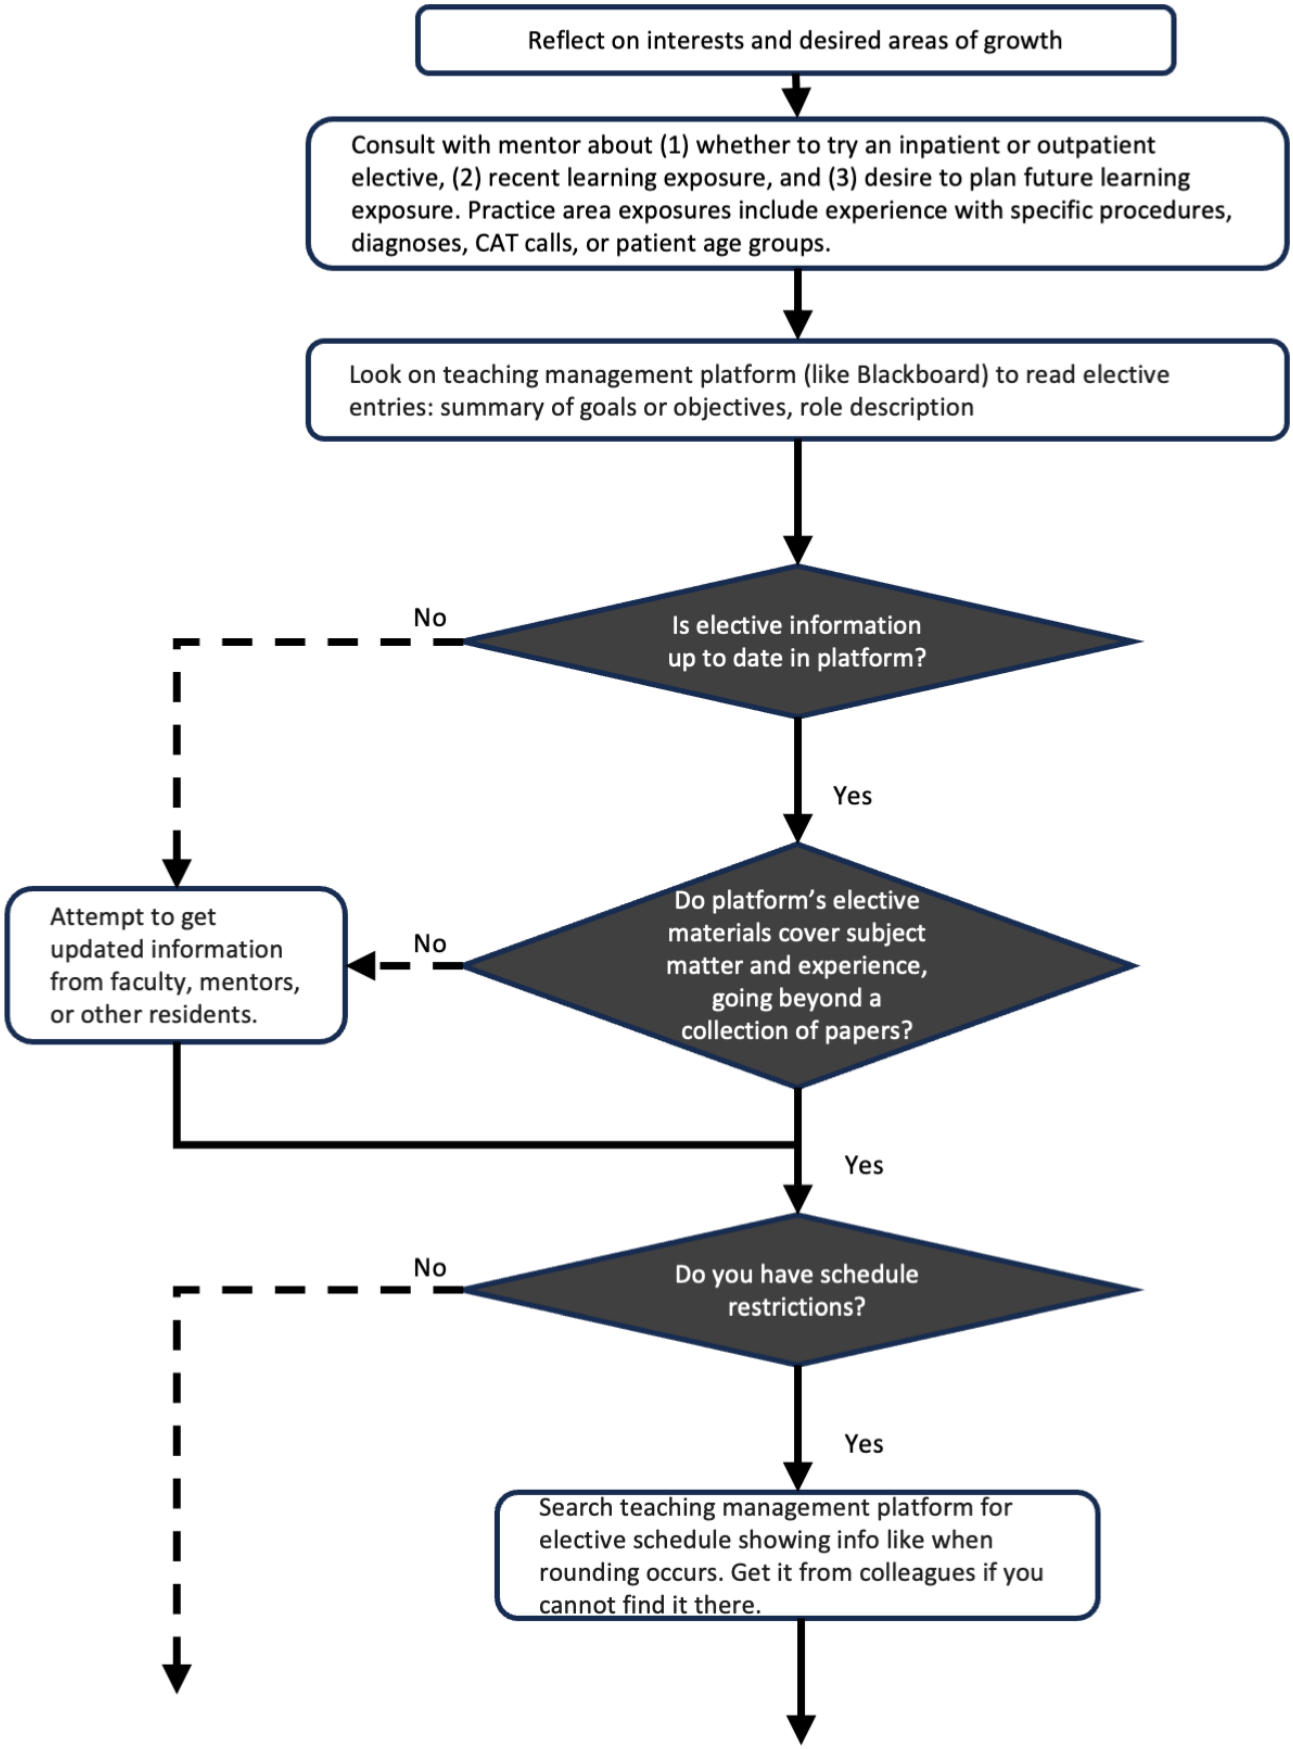
Results

Work Domain Assessment Results

We interviewed 8 participants (Table 4). We deployed initial descriptive and provisional coding efforts. Starting from the top of the codebook, 4 People, Environment, Tools, and Tasks scan categories were decomposed into 34 topics which yet further broke down into 57 subtopics. Multimedia Appendix 5 links key quotations from the interviews for each of the People, Environment, Tools, and Tasks categories and traces their impact forward through all study phases.

Table . Participants for all study phases.

Phase	Purpose	Sample
Work domain assessment (interview)	Understand work system or planned learning decisions	2 trainees, 5 program directors, and 1 administrator
Formative usability testing (prototype walk-through)	Iterate report design	6 mentors and 1 resident
Summative usability testing	Validate EDS[a] tool (MV[b] midpoint report) with end users	8 residents



[a]EDS: educational decision support.

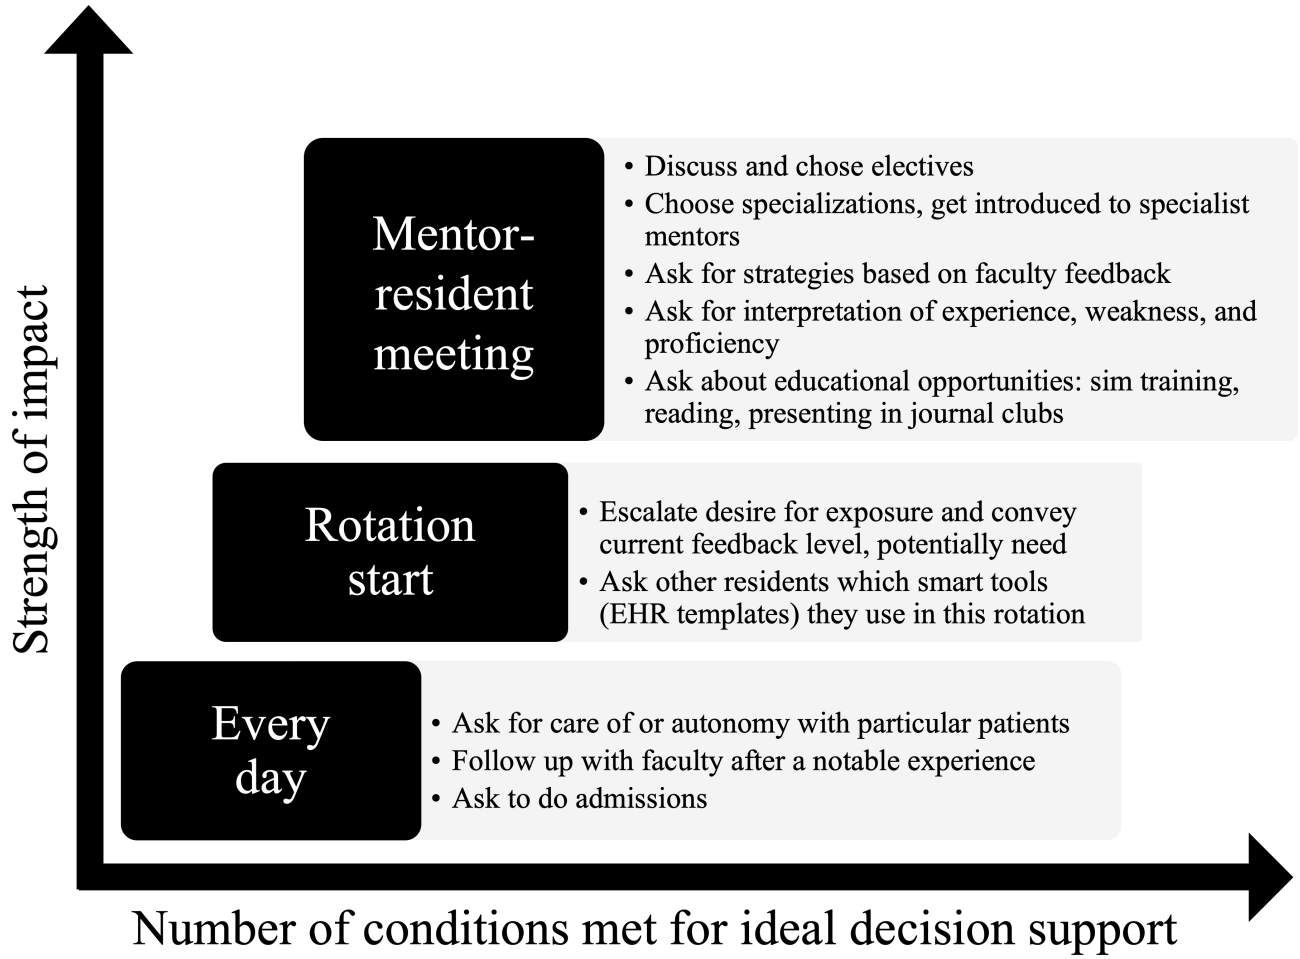
[b]MV: minimum viable.

Through our process or causation coding and process map analysis, we produced 7 maps describing processes across 3 roles: trainees (Figure 4), trainee mentors or program directors, and program administrators. The documents mapped 52 decisions or forks in the processes with 128 other steps, actions, or changes in the mental model (Multimedia Appendix 6).

XSL•FO
RenderX

Figure 4. A segment of 1 of the 7 process maps. Diamonds denote decisions and rectangles stand for events, actions, or changes in mental model. CAT: Critical Activation Team.

We first established that mentors and program directors had fewer existing assessment workflows than trainees. While their leadership and expertise amplified potential impact they could achieve with better practice data, trainees had a far greater



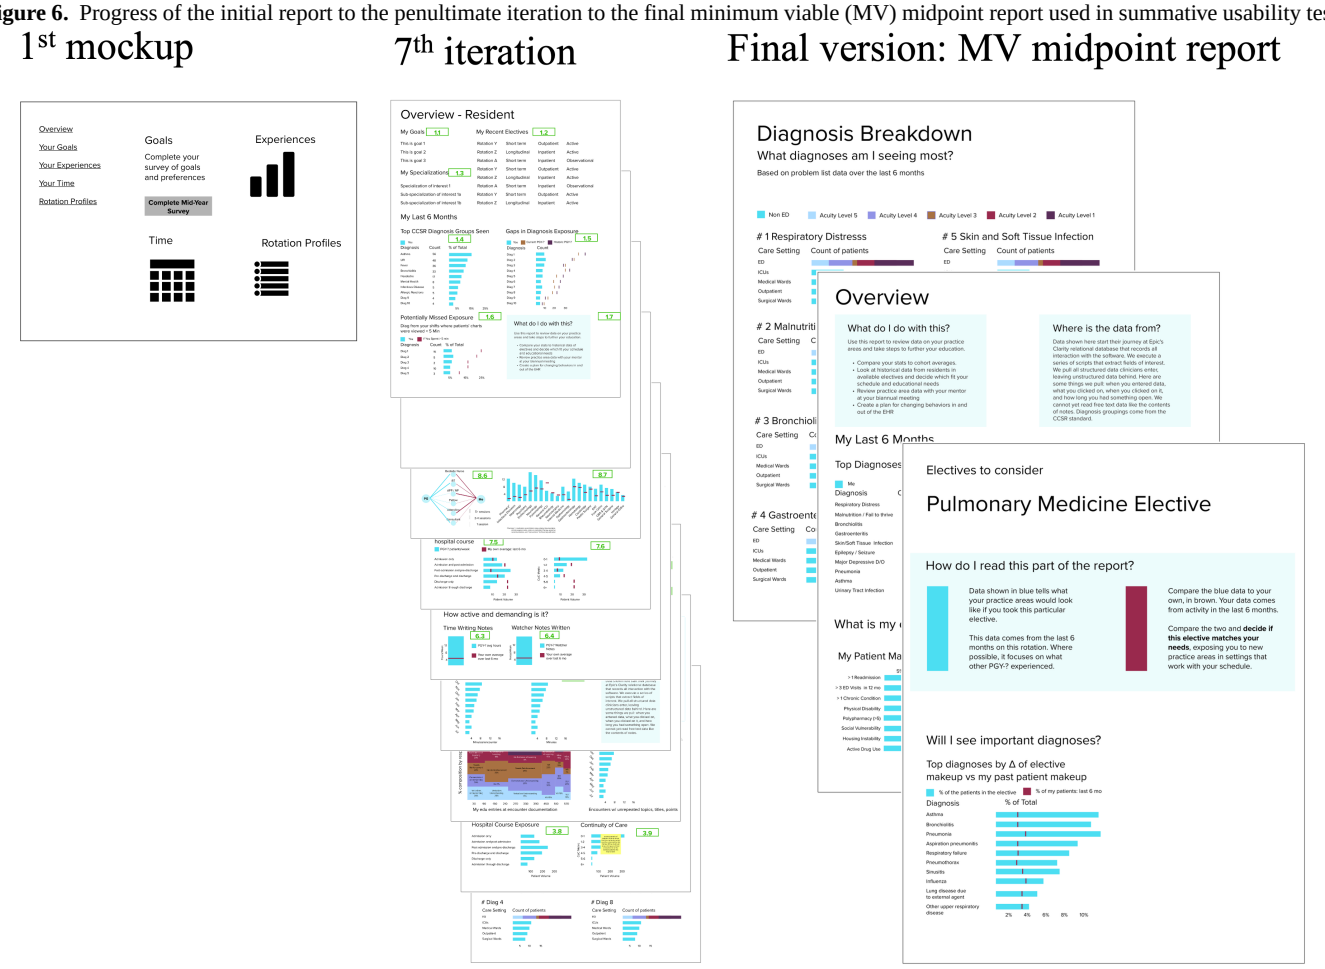
XSL•FO
RenderX

volume of opportunity to identify gaps and close them for themselves. Residents, in particular, had the highest number of planning and assessment opportunities. While other populations could still be influential secondary users of an EDS, residents emerged as optimal primary users of a decision support tool targeting planned learning.

Reviewing the process maps, we determined that clinic and rotations were high-inertia settings with high mental stimulation for our trainee users. The heavy demands on cognitive resources meant that planning in these situations would be secondary to a primary use case that also emerged from the data.

Alternatively, trainee-mentor meetings, conducted much less frequently, stood out as a key target experience. By the time trainees meet with their mentors, they have usually formed some idea of a learning state gap but lack the expert system knowledge required for planning its closure. The MAL model holds that planned learning occurs by cycling through states of planning, learning, assessing, and adjusting. These meetings offered a calm moment when trainees and mentors cooperatively identify gaps, make plans to close them, or assess those efforts. This is the critical work of the planning and assessing phases. This trainee-mentor meeting environment had other benefits. It also allowed for contingency plans and provided a structure for replanning in future meetings, both of which are optimal planning practices from the standpoint of human factors engineering and cognitive science (Figure 5).

Figure 5. Settings where a report of practice area data could be leveraged and planned learning opportunities for each. These are plotted against qualities the research team used to select the target setting of the report. EHR: electronic health record.



Formative Usability Test Results

Based on the results of our workflow assessment, we designed an initial report containing a single page of placeholder visualizations. Seven participants (6 program directors and 1 resident) completed the formative usability test, iterating from this initial version. Iterations to the midpoint report were made following each test, adding new and altering extant features. The seventh version of the report following the final formative interview contained 51 distinct visualizations of trainee past and potential future data, spanning nine pages (Figure 6). The complete FPM contained a corresponding 51 records (Multimedia Appendix 6). Following feature reduction, the MV midpoint report contained 5 visualizations over 3 pages, assuming one elective under consideration where an additional page would be added for each elective.

XSL•FO
RenderX

Figure 6. Progress of the initial report to the penultimate iteration to the final minimum viable (MV) midpoint report used in summative usability test.

Summative Usability Test Results

Eight resident physician participants in total completed the summative test; 4 each from CHOP and the URMC (n=4, 50%). The TCR across all 5 scenario-question pairs, defined by the selection of the correct answer to a scenario's accompanying multiple-choice question, was 78%. Mean task completion time was 2 minutes and 39 seconds (SD 2 minutes and 30 seconds). Results broken out by each of the 5 scenario-question pair tasks (Table 5) show that completion-time variance was primarily driven by task 1 which showed a much longer mean time and wider range than the other tasks. This may have included orientation time with the structure of the test as well as the MV midpoint report. Tasks 3 and 4 most negatively impacted overall TCR. This may be attributed to more salient, earlier visualizations in the report being used in favor of more setting-specific data breakdowns required for these questions. The summative usability test data and capture plan did not allow for more thorough error type analysis.

Table . Summative test results by task (N=8).

Task	Completion time (min:s), mean (SD)	Task completion rate (%)
1	04:31 (4:18)	88
2	01:40 (0:36)	88
3	03:28 (1:24)	63
4	02:43 (1:00)	50
5	01:19 (0:48)	100

The pretest questionnaire provided baseline findings. Seven of the 8 participants reported no systematic method for tracking their practice-area exposure. Only 1 participant reported using an EHR-based workaround (described in a free text survey field as "saving patient reports on Epic"), and rated this approach 5/9 for both PU and PEOU (scores 6 - 9 considered positive). PU and PEOU scores for the MV midpoint report were high (Table 6). The median scores for scenario-assessed PU and scenario-assessed PEOU were 8 (IQR 5-9) and 8 (IQR 6-9), respectively. Scenario realism received a median score of 8 (IQR 6-9). Distinct from the scenario-assessed PU and PEOU that followed each of the 5 scenarios, a single summary questionnaire assessed the same measures at the end of the test.

XSL•FO
RenderX

The median summaries for PU and PEOU were 8 (IQR 8-9) and 7.5 (IQR 7-8.25), respectively.

Table . Performance of the education decision support tool in terms of usability and scenarios in terms of task fidelity in summative usability testing (N=8).

Score group	Median[a] (IQR)
Scenario-assessed (per-task) measures	
Perceived usefulness	8 (5-9)
Perceived ease of use	8 (6-9)
Summary (holistic post-test) measures	
Perceived usefulness	8 (8-9)
Perceived ease of use	7.5 (7-8.25)
Test realism	8 (6-9)

[a]Scale from 1 (nonperformant) to 9 (performant).

Discussion

Principal Findings

In this study, we describe the HCD process used to develop and assess a user interface to an EDS system that we find likely to be adopted. Like many designs for complex sociotechnical systems, an initial phase to better understand the implementation context led to substantial changes in our design goal. We shifted from a tool that trainees might use regularly to a tool for longer-term planning in the context of trainee-mentor meetings and potential choice of future elective rotations. We subsequently followed a typical iterative design and formative testing process. Upon achieving a stable "MV" design, we conducted our summative testing. Given that our goal in summative testing is to predict future adoption of the tool by trainees, we supplement typical usability measures of task completion, efficiency, and perceived satisfaction with an assessment of perceived usefulness and intent to use, consistent with the technology acceptance model (TAM) [45].

Systems have been judged above average in their usability when TAM-based questionnaires reach 80% [46]. High TAM usability scores signify intent to use a tool, and intent is the highest predictor of adoption [45]. This predictive factor is strengthened by high TCR [47]. Unfortunately, it is known in usability research that meta-analysis has not set completion rate benchmarks [48]. Deference, however, to TCR of similar tools at testing is standard practice in their place [49]. In comparable analytics software from education or clinical data analysis in sensemaking, reflective contexts (as opposed to CDS for real-time use preceding immediate, nonreversible patient action), we find similar TCR [46,50,51]. Matching this standard, we may draw the conclusion that our scores suggest the likely adoption of the tool.

The Accreditation Council for Graduate Medical Education requires trainees to experience a range of diagnoses during graduate medical training [1]. Using an EDS system, we can facilitate appropriate diversity of patient experiences and better quantify outcomes in GME using informatics tools [52-54]. Previous efforts to attribute trainee patient experiences have been limited in scope and dissemination. Several automated systems rely solely on EHR data to link clinical practice directly with education to personalized, timely outcomes [10,16,53]. However, these systems do not attribute patient experiences across clinical contexts or institutions. Dashboards to facilitate the feedback of clinical data to both GME and to continuous professional development have had mixed effectiveness, citing development without proper learning system stakeholder involvement and the absence of facilitated precepting to understand their learning gaps [55,56]. Our tool follows established HCD methods to include those users in interaction conception and make precepting intuitive.

With the usability and PU demonstrated in the summative test, we will implement the MV report to assist trainees with a number of tasks: visualizations of their top diagnosis types seen; their gaps in exposure compared to their peers and historical comparisons; their exposure to complex care patients; and most importantly, diagnosis makeup of electives or clinics that trainees could choose to further their exposure in weak areas of knowledge. The report will be delivered to trainees and their mentors before scheduled meetings biannually and will be discussed by the pair. Among other decisions that the report may inform, it will simplify the critical choice of electives or clinics that trainees can choose to better close their training gaps.

Limitations

The formative testing sample over-represented mentors or program leaders relative to trainees; however, the final MV report was evaluated with resident end users in summative usability testing.

The study is limited by the sample size at 2 institutions, which may not represent the breadth of GME experience. Because of this, projected adoption based on high scores on PU and PEOU assessments may not be generalizable, and ongoing measurement will be necessary during implementation.

The level of realism achieved in the simulations required participants to suspend disbelief. All participants had experience and context to create clear mental settings from experience in the medical education system, though the fidelity achieved by descriptive text in immersing participants in that reality is low. In addition, the level of realism was tempered by technological limitations. We could not use actual trainee data from each

XSL•FO
RenderX

specific participant or generalized trainee data from each site. Reports were populated by data that did not map to participants' clinical experience, instead showing a generalized portrait of an "average" resident validated by clinical experts, requiring further suspension of disbelief.

Future work will improve validity deficiencies by using trainee-specific data in usability testing in a multicenter study with a greater sample drawn from more institutions, additionally including error type analysis of failed tasks. Exploration should also attempt to draw insights from beyond the EHR to triangulate them from multiple datasets including those from sources like training management systems, health care workforce management platforms, and other self-reported data. Similar efforts are already underway to support professional development [57,58]. A follow-up longitudinal study should examine click-stream engagement metrics, long-term post-deployment satisfaction via psychometrics, and downstream effects, such as changes in elective selection patterns, increased exposure in previously underrepresented diagnoses, and improvements in competency-based assessments.

Conclusions

We iteratively developed and performed usability testing on a 5-visualization report displaying trainees' aggregate practice area data from the EHR. Our results indicate a high likelihood of the report's adoption as an effective tool in graduate medical education, aligning with the MAL planning phase tasks and allowing them to be completed in a timely manner. We assessed use and usability with instruments and results that predict significant future adoption. Evolving research will examine downstream effects on entrustment following implementation. This study provides a successful user interface for functions executed from an educational decision support system and offers a foundation for further research of clinical and educational applications of this system.

Acknowledgments

The authors would like to acknowledge the program leadership, administration, chief residents, and trainees in the pediatrics residency programs at the Children's Hospital of Philadelphia and the University of Rochester Medical Center.

Funding

This study was partially funded through the American Medical Association's "Accelerating Change in Medical Education" program (ACD and MVM). The funder did not have a role in the conceptualization, design, data collection, analysis, or publication preparation. The authors have no other funding sources to declare.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available due to data privacy restrictions established by our institutional review boards but are available from the corresponding author upon reasonable request.

Authors' Contributions

ACD and MVM conceptualized the study and designed the protocol along with NM and AF. AF, MVM, and ACD recruited participants and conducted interviews. All authors participated in the human-centered design process and analyzed the interview results. AF conducted summative usability testing and prepared the draft manuscript. All authors read, edited, and approved the final manuscript.

Conflicts of Interest

NM reports equity ownership in Phrase Health, a clinical workflow analytics company. The other authors declare no conflicts of interest.
